Publication information: *Journal of Hepatology* (ISSN 0168-8278). For 2020, volumes 72 and 73 are scheduled for publication. Subscription prices are available upon request from the Publisher or from the Elsevier Customer Service Department nearest you or from this journal's website (http://www.elsevier.com/locate/jhep). Further information is available on this journal and other Elsevier products through Elsevier's website: (http://www.elsevier.com). Subscriptions are accepted on a prepaid basis only and are entered on a calendar year basis. Issues are sent by standard mail (surface within Europe, air delivery outside Europe). Priority rates are available upon request. Claims for missing issues should be made within six months of the date of dispatch.

Orders, claims, and journal enquiries: Please visit our Support Hub page https://service.elsevier.com for assistance.

Advertising information: Advertising orders and enquiries can be sent to: **USA, Canada and South America:** Elsevier Inc., 360 Park Avenue, Suite 800, New York, NY 10169-0901, USA; phone: (+1) (212) 989 5800. **Europe and ROW:** Robert Bayliss, Pharma Solutions, Elsevier Ltd., 125 London Wall, London EC2Y 5AS, UK; phone: (+44) 207 424 4454; e-mail: r.bayliss@elsevier.com.

Author enquiries: You can track your submitted article at http://www.elsevier.com/track-submission. You can track your accepted article at http://www.elsevier.com/trackarticle. You are also welcome to contact Customer Support via http://service.elsevier.com.

Funding body agreements and policies: Elsevier has established agreements and developed policies to allow authors whose articles appear in journals published by Elsevier, to comply with potential manuscript archiving requirements as specified as conditions of their grant awards. To learn more about existing agreements and policies please visit http://www.elsevier.com/fundingbodies.

ALIVER

The ALIVER Consortium has developed and optimized a novel ‘liver dialysis device’ – DIALIVE

Overview of ALIVER:

+ Consortium comprised of experts in liver failure, hospitals, SMEs, not-for-profit organisations

+ Funded from EU Horizon 2020 research and innovation programme

+ Benefits from 25 years of experimental research and data collection on extracorporeal perfusion as a therapy option in liver failure

For more info, visit www.aliver.info

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 733057.

The objective of the DECISION project is to enhance the understanding of the pathophysiology of decompensation of cirrhosis leading to acute-on-chronic liver failure (ACLF) or death. This consortium will take advantage of already existing large and clinically well characterized cohorts to ultimately develop prognostic and response tests and combinatorial therapies tailored to the needs of individual patients to decrease the risk of short-term death.

- Systems level elucidation of the pathophysiology of acute decompensation of cirrhosis at multiple levels (genetic, epigenetic, transcriptomic, metabolomics, lipidomics, miR, and extracellular vesicles)
- Integration of existing clinical data and new multi-omics data from 2,200 patients with more than 8,600 measurements
- Development of new combinatorial therapies
- Optimization of therapies using existing and newly developed animal models
- Development of new tests for prediction of outcome and response to new therapies
- Phase II clinical trial to test new combination therapies
- Creation of new guidelines for prediction and treatment of acute decompensation of cirrhosis to prevent ACLF and death

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 847949.

Registration of Clinical Trials
The *Journal of Hepatology* endorses the policy of the WHO and the International Committee of Medical Journal Editors (ICMJE) on the registration of clinical trials. Therefore, any trial that starts recruiting on or after July 1, 2005 should be registered in a publicly owned, publicly accessible registry and should satisfy a minimal standard dataset. Trials that started recruiting before that date will be considered for publication if registered before September 13, 2005.
More detailed information regarding clinical trials and registration can be found in New Engl J Med 2004; 351:1250–1251 and New Engl J Med 2005; 352:2437–2438.

LITMUS

The overarching aim of LITMUS is to develop, robustly validate and advance towards regulatory qualification biomarkers that diagnose, risk stratify and/or monitor NAFLD/NASH progression and fibrosis stage.

Bezafibrate add-on therapy improves liver transplantation-free survival in patients with primary biliary cholangitis: a Japanese nationwide cohort study

Atsushi Tanaka[1], Junko Hirohara[2], Toshinari Nakano[2], Kosuke Matsumoto[1], Olivier Chazouillères[3], Hajime Takikawa[4], Bettina Hansen[5], Fabrice Carrat[6], Christophe Corpechot[3]. [1]*Teikyo University School of Medicine, Medicine, Tokyo, Japan;* [2]*Kansai Medical University, The Third Department of Internal Medicine, Hirakata, Japan;* [3]*Sorbonne University, Reference Center for Inflammatory Biliary Diseases and Autoimmune Hepatitis, Saint-Antoine Hospital, APHP, Paris, France;* [4]*Teikyo University School of Medicine, Medical Technology, Tokyo, Japan;* [5]*University Health Network & IHPME, University of Toronto, Toronto Centre for Liver Disease, Toronto General Hospital, Toronto, Canada;* [6]*Sorbonne University, Pierre Louis Institute of Epidemiology and Public Health, Paris, France*
Email: a-tanaka@med.teikyo-u.ac.jp

Background and Aims: Bezafibrate (BZF) is a dual PPARs/PXR agonist with potent anti-cholestatic efficacy. Beneficial effect of BZF on symptoms and biochemical features of primary biliary cholangitis (PBC) has been reported but its long-term efficacy on survival remains to be determined. In Japan BZF (400 mg/d) has been used as *de facto* second-line treatment for PBC patients with incomplete response to ursodeoxycholic acid (UDCA, 13–15 mg/d) since 2000's. Herein, we retrospectively investigated long-term efficacy of bezafibrate, taking advantage of a large-scale nationwide cohort of PBC patients in Japan.
Method: The Japanese PBC cohort is established by the nation-wide surveys, initiated in 1980 and updated every 3 years by the Intractable Hepato-Biliary Diseases Study Group (Japan PBC Study Group). To date, 9,919 patients with PBC have been registered. Primary and secondary outcomes (all-cause death or liver transplantation (LT); liver-related death or LT) were assessed using multivariable- or IPTW-adjusted Cox models with UDCA and BZF as time-varying covariates. Baseline covariates included age, sex, diagnosis year (by 10 years), presence of symptoms, serum levels of bilirubin, alkaline phosphatase, and albumin, and histological stage (early vs. advanced stage). Multiple imputation method was used for missing starting data of UDCA or BZF, and Cox models excluding missing data were used as sensitivity analysis.
Results: 1,739 patients were excluded from the analysis due to missing data in terms of outcome and final follow-up date. The remaining 8,180 patients were included: mean age at diagnosis 56.9yrs, 1,104 males (14%). Treatment protocol included UDCA monotherapy (6,087; 74%), a combination of UDCA and BZF (943; 12%), and no treatment (1,133; 14%). Exposure to BZF add-on therapy was associated with a significant improvement in long-term outcome as compared to UDCA alone or no treatment; Compared to no treatment, adjusted hazard ratio (aHR) for all-cause death or LT was 0.55 (95% CI 0.47–0.65, $p < 0.0001$) in patients treated with UDCA monotherapy, while BZF therapy conferred a further risk reduction of 0.23 (95% CI 0.15–0.35, $p < 0.0001$) when added to UDCA (Figure). Related HRs for liver-related death or LT were 0.52 (95% CI 0.43–0.63, $p < 0.0001$) and 0.21 (95% CI 0.12–0.37, $p < 0.0001$), respectively. Sensitivity analysis indicated similar significant improvement of survivals with BZF and UDCA combined therapy.

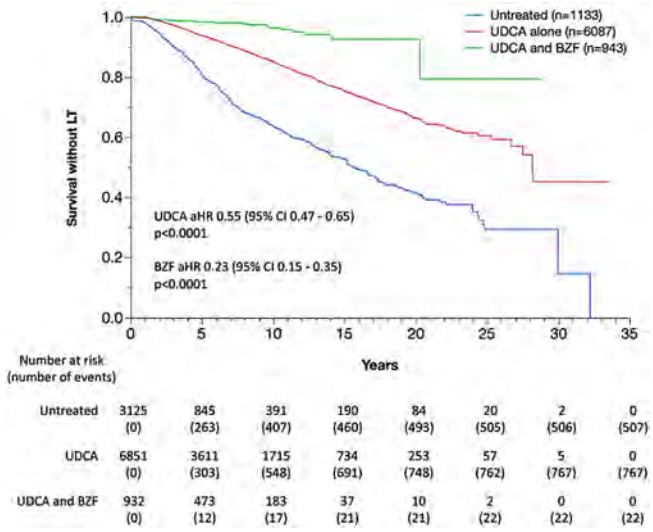

Figure: LT-free survival rates of Japanese patients with PBC according to time and treatment groups.

Conclusion: Combined treatment with BZF and UDCA in patients with PBC is associated with reduced risk for mortality or needs for LT as compared to UDCA alone.

GS02

Virulence-related genes in fecal metagenomes associated with mortality in patients with alcoholic hepatitis

Sonja Lang[1], Yi Duan[1,2], Yan Shao[3], Kevin Vervier[3], Peter Stärkel[4], Trevor Lawley[3], Bernd Schnabl[1,2]. Email: slang@ucsd.edu

Background and Aims: Intestinal dysbiosis is associated with the development and progression of alcohol-related liver disease (ALD), but most studies have focused on diversity, relative abundance and metabolic profiles of specific microorganisms. Bacterial virulence factors are proteins or peptides encoded by bacterial genes that help the organisms colonize the intestine or mediate disease. The aim of this study was to study the presence of virulence factors of the commensal gut microbiota in ALD and to correlate virulence factors with outcome in alcoholic hepatitis patients.
Method: Alcoholic hepatitis patients were enrolled at 9 centers in Europe, the United States, and Mexico in a multi-center observational

ELSEVIER

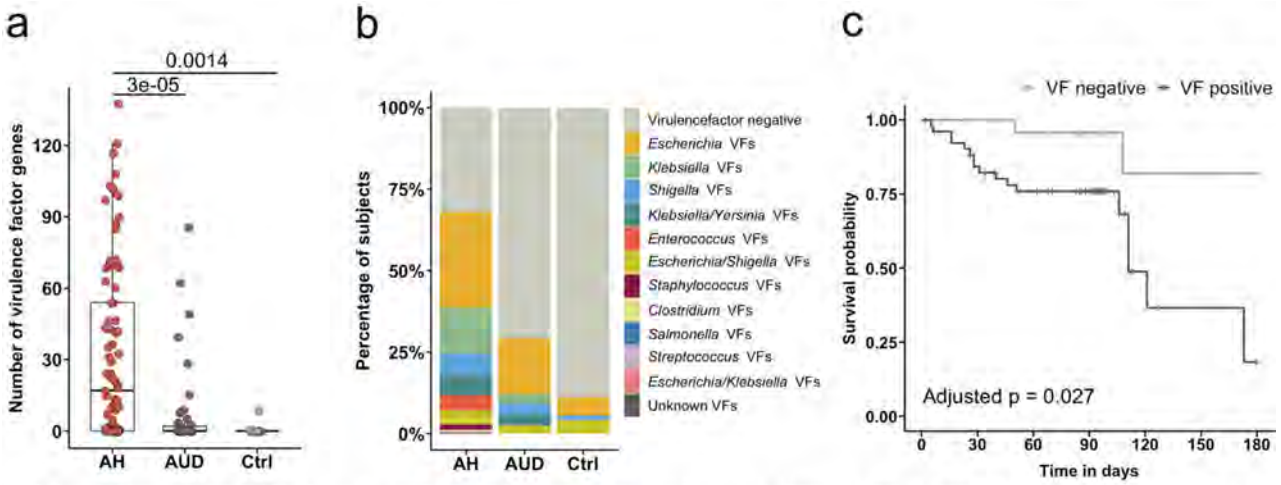

Figure legend: (a) Presence of 350 different virulence-related core genes in fecal samples from 81 patients with alcoholic hepatitis (AH), 41 patients with alcohol use disorder (AUD), and 9 controls (Ctrl). (b) Relative abundance of virulence factors found in fecal samples from 81 patients with alcoholic hepatitis, 41 patients with alcohol use disorder, and 9 non-alcoholic controls; factors are color-coded by genus of bacteria that produce them. (c) Kaplan-Meier curve of survival of patients with alcoholic hepatitis whose fecal samples were virulence factor (VF)-positive (n=55) or VF-negative (n=26). For the only patient who underwent liver transplantation, the transplantation date was considered as date of death. Patients were censored at the time point they were last seen alive.

Figure: (abstract: GS02)

study. We analyzed intestinal bacterial metagenomes and genes that encode virulence factors by using shotgun sequencing in fecal samples from 81 patients with alcoholic hepatitis, 41 patients with alcohol use disorder, and 9 non-alcoholic controls. The sequences were aligned with those in the virulence factor gene database (VFDB). Virulence factor associated genes were compared among the three groups. We further used multivariate Cox regression analysis to assess associations of virulence factors with 180-day mortality.

Results: The core virulence factor genes of the VFDB included 350 different, experimentally verified genes that encode virulence factors. Significantly more virulence factors were found in fecal metagenomes from patients with alcoholic hepatitis than patients with alcohol use disorder or controls (Fig. 1a). Overall, fecal samples from 68% of patients with alcoholic hepatitis expressed at least one virulence factor gene, compared with 29% of patients with alcohol use disorder and 11% of controls ($p < 0.001$). The most frequently observed virulence factors were derived from *Escherichia*, followed by *Klebsiella*, *Shigella, Klebsiella* or *Yersinia,* and then *Enterococcus* (Fig. 1b). 82% of virulence factor-negative alcoholic hepatitis patients were alive after 180 days following enrolment, compared with 18% of virulence factor-positive patients (hazard ratio adjusted for antibiotic and steroid treatment 5.32 (95% CI 1.20–23.50), $p = 0.027$, Fig. 1c).

Conclusion: The presence of virulence factors in the commensal gut microbiota determines mortality on patients with alcoholic hepatitis. Assessing the abundance of specific virulence factors might lead to new diagnostic biomarkers and treatment targets in patients with alcoholic hepatitis.

GS03

Liver involvement in patients with telomere-related genes mutations: prevalence, clinical, radiological, pathological features, outcome and risk factors

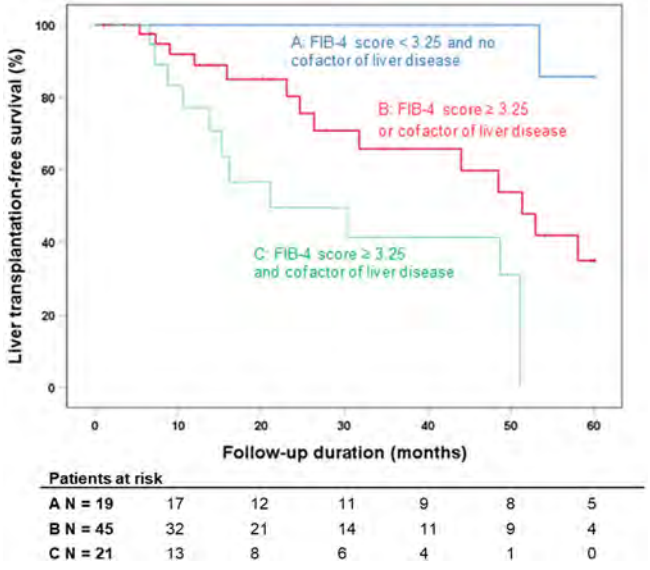
Background and Aims: Germline mutations of telomere-related genes (TRG) induce excessive shortening of telomeres, genetic instability and early cell aging. The aim of this study was to provide a detailed characterization of liver involvement (LI) associated with these rare mutations.
Method: Retrospective analysis of all patients in whom a pathogenic germline mutation of one or more TRG has been identified between 2004 and 2019, in 25 pneumology, haematology and hepatology French tertiary centers. LI was defined as serum transaminases (AST and/or ALT) >30 IU/L and/or abnormal liver morphology. Survival analysis (Kaplan-Meier method) was performed only in patients who had both diagnosis of LI and genetic mutation after 2004.
Results: 132 patients were included: 95 with LI; 94 men; median age 57 years (35–63); 77 with *TERT* mutation, 26 with *TERC* mutation, and 29 mutations in other genes; telomere length <1st percentile in 95% of the patients. Patients with LI had pulmonary, blood, skin, bone, ocular involvement in 82%, 77%, 55%, 39% and 30% respectively. At LI diagnosis, liver characteristics were: AST 36 (28–50) IU/L, ALT 35 (25–48) IU/L, MELD 8 (7–10), Child-Pugh 5 (5–5), FIB-4 2.3 (1.4–4.7), liver stiffness (FibroScan®) 8 (6–15) kPa and hepatic venous pressure gradient 6 (4–11) mmHg. Liver biopsy (n = 52) identified vascular porto-sinusoidal disease, advanced fibrosis/cirrhosis, and NASH in respectively 35%, 19%, and 13% of the patients. After a median follow-up of 21 (12–54) months after LI diagnosis, ascites, variceal bleeding, portal vein thrombosis, hepatic encephalopathy and hepatocellular carcinoma occurred in 14%, 13%, 5%, 4% and 2% of the patients respectively. Twelve patients underwent liver transplantation (LT), 5 hematopoietic stem cell graft and 13 lung transplantation. Five-year overall survival rate and LT-free survival rate of patients with LI were 79% and 70% respectively. In multivariate analysis, a FIB-4 score ≥ 3.25 and cofactor of liver disease (alcohol consumption >100 g/week, HBsAg +, metabolic syndrome, BMI >25 kg/m², ferritin >1000 μg/L) independently predicted LT or death (Figure 1).



Conclusion: Liver involvement is frequent but paucisymptomatic. Histological lesions are heterogeneous, including vascular porto-sinusoidal disease and advanced fibrosis/cirrhosis. A FIB-4 score ≥ 3.25 and/or association with excessive alcohol consumption, overweight and iron overload are risk factors for LT or death.

GS04

Gut microbiota drives hepatocarcinogenesis by promoting TLR4-dependent expansion of monocytic myeloid-derived suppressor cells

Kai Markus Schneider[1], Antje Mohs[1], Lena Susanna Candels[1], Carsten Elfers[1], Konrad Kilic[1], Liao Lijun[1,2], Mick Frissen[1], Hanns-Ulrich Marschall[3], Stefanie Rosenhain[4], Johannes Haybäck[5], Felix Gremse[4], Eicke Latz[6], Anika Nier[7], Ina Bergheim[7], Galvez Eric[8], Till Strowig[8], Christian Trautwein[1]. [1]University Hospital RWTH Aachen, Department of Medicine III, Aachen, Germany; [2]Department of Anesthesiology and Pain Management, Tongji University, Shanghai, China; [3]Institute of Medicine, Sahlgrenska Academy, Department of Molecular and Clinical Medicine, Gothenburg, Sweden; [4]University Hospital RWTH Aachen, Institute for Experimental Molecular Imaging; [5]Otto von Guericke University of Magdeburg, Department of Pathology, Magdeburg, Germany; [6]University of Bonn, Institute of Innate Immunity, Bonn, Germany; [7]University of Vienna, Molecular Nutritional Science Division, Department of Nutritional Sciences, Vienna, Austria; [8]Helmholtz Centre for Infection Research, Department of Microbial Immune Regulation, Braunschweig, Germany
Email: kai.markus.schneider@gmail.com

Background: Today, the link between intestinal dysbiosis and chronic liver disease is well established. However, molecular mechanisms by which intestinal microbiota affect HCC development and direct antitumor immune surveillance need to be defined. Here, we investigated how NLRP6-mediated intestinal dysbiosis and dynamic microbiota modulation control hepatocarcinogenesis.
Methods: Hepatocyte-specific NEMO/IKKγ knockout mice ($NEMO^{\Delta hepa}$) were used as a model of experimental steatohepatitis. To investigate the impact of NLRP6-mediated intestinal dysbiosis on the inflammatory microenvironment, $NEMO^{\Delta hepa}$ mice were crossed with constitutive *Tlr4* and *Nlrp6* knockout mice. Microbiota of $NEMO^{\Delta hepa}$, $NEMO^{\Delta hepa}$/$Tlr4^{-/-}$ and $NEMO^{\Delta hepa}$/$Nlrp6^{-/-}$ mice were modulated by broad-spectrum antibiotics (ABx) or fecal microbiota transfer (FMT), respectively. Suppressive capacity of myeloid derived suppressor cells (MDSCs) on T-cells was studied in-vitro. Finally, targeted microbiota reconstitution experiments with *Akkermansia muciniphila* were performed.
Results: Intestinal dysbiosis in $NEMO^{\Delta hepa}$/$Nlrp6^{-/-}$ was associated with more pronounced steatohepatitis encompassing elevated liver transaminase levels, leukocyte infiltration and apoptotic cell death, ultimately leading to aberrant hepatocyte proliferation and increased tumor burden in 52 weeks old mice. Interestingly, intestinal barrier function measured by in-vivo FITC permeability was highly correlated with tumor burden and followed by a significantly increased infiltration of $Ly6C^{hi}$ monocytic myeloid derived suppressor cells (mMDSC) and suppression of CD4+ and CD8+ T cells in $NEMO^{\Delta hepa}$/$Nlrp6^{-/-}$. This immune phenotype was transmissible via FMT of dysbiotic $Nlrp6^{-/-}$ microbiota, reversible upon microbiota depletion with ABx and dependent on functional TLR4 signaling. Strikingly, the dysbiotic $Nlrp6^{-/-}$ gut microbiota community of 13 and 52 weeks old mice was characterized by a loss of *Akkermansia muc.*, which correlated with steatohepatitis activity. Targeted reconstitution with *Akkermansia muc.* ameliorated steatohepatitis and dampened mMDSC infiltration.
Conclusion: NLRP6-mediated intestinal dysbiosis drives steatohepatitis progression towards HCC by shaping the hepatic inflammatory microenvironment. Short-term microbiota modulation or targeted microbiota reconstitution closely reshapes the hepatic tumor microenvironment ultimately opening new therapeutic windows for future cancer prevention and therapy.

GS05

Validation of the Model for End-stage Liver Disease sodium score for the Eurotransplant region

Ben Goudsmit[1,2], Hein Putter[3], Bart Van Hoek[4], Andries Braat[1].
[1]*Leiden University Medical Center (LUMC), Transplantation Surgery, Leiden, Netherlands;* [2]*Eurotransplant International Foundation, Leiden, Netherlands;* [3]*Leiden University Medical Center (LUMC), Medical Statistics and Bioinformatics, Leiden, Netherlands;* [4]*Leiden University Medical Center (LUMC), Gastroenterology and Hepatology, Leiden, Netherlands*
Email: ben_goudsmit@hotmail.com

Background and Aims: The shortage of liver grafts results in the prioritization of the sickest patients on the waiting list for liver transplantation. Since 2006, the degree of disease severity in transplant candidates is estimated with the Model for End-stage Liver Disease (MELD) score. However, MELD does not account for the worse prognosis associated with hyponatremia. Since the prevalence of cirrhosis is on the rise, better prediction of mortality and improved allocation for liver transplantation are becoming increasingly important. This study researches the potential impact of using MELD-Na instead of MELD for the allocation of livers in the Eurotransplant region.
Method: All candidates allocated through MELD with chronic liver disease on the Eurotransplant (ET) liver transplant waiting list between 2007–2018 were included. They were followed from first listing to delisting or until 90 days. The relation between MELD and Na values at listing and 90-day mortality was assessed through a multivariate Cox proportional hazard regression. A reclassification table was constructed of the relevant changes in MELD to MELD-Na score. This allowed an estimation of the lives saved if MELD-Na-based allocation would have been used.
Results: 5223 patients were included. After 90 days, 21.3% were transplanted, 24.2% were removed and 2.8% had died. Hyponatremia of <135, <130 and <125 mmol/L was found in respectively 28.5%, 8.8% and 2.6% of the listed patients. Between 140 to 125 mmol/L, the MELD-corrected risk of 90-day death increased by threefold (2.9; 95% CI 2.30–3.53; $p < 0.001$). The hazard ratio for death was 1.16 (95%CI 1.15–1.17; $p < 0.001$) per gained MELD point and 1.08 (95%CI 1.06–1.09; $p < 0.001$) per 1-unit Na decrease. The MELD-Na had a c-index of 0.847 (SE 0.007, $p < 0.001$). Of the deceased patients, 26.3% would have had a significantly higher chance of transplantation with MELD-Na, which equals to a 4.9% decrease in 90-day waiting list mortality.
Conclusion: The ET waiting list population has a relatively high prevalence of hyponatremia. For transplant candidates, a low Na increases the risk of 90-day mortality by threefold. If MELD-Na would have been used, 26.3% of the deceased patients would have had a significantly higher chance of transplantation. The 90-day waiting list mortality would have been lowered by 4.9%. Thus, MELD-Na-based allocation could reduce waiting list mortality for the ET region.

Background and Aims: Covert hepatic encephalopathy (CHE) leads to poor quality of life (QOL) in liver cirrhosis (LC) patients. We aimed to evaluate the impact of L-carnitine on the QOL evaluated by the 36-Item Short Form Survey (SF-36) in CHE patients following 24 weeks of treatment. Secondary endpoints were the effects of L-carnitine on the improvement of cognitive dysfunction.
Method: We performed a prospective, randomized, double-blinded, placebo-controlled study administering L-carnitine for 24 weeks to LC patients with CHE. Thirteen centers from Korea were engaged. CHE was defined as either West-Haven grade 1 or grade 0 with the Psychometric hepatic encephalopathy score (PHES) below –4. Patients who had previously experienced overt HE were excluded.
Results: A total of 230 LC patients were screened. 150 CHE patients underwent randomization. The mean age was 53 years and 65% were male. Mostly they were chronic hepatitis B and 82% were Child-Pugh A. Seventy two and 70 patients were randomly assigned to the placebo group and the L-carnitine group. Baseline characteristics including results of PHES scores were similar between the groups. Although SF-36 levels were not different between the groups, the differences of SF-36 between the baseline and at 24 weeks of treatment were 2.42 ± 12.86 in the placebo vs. 4.60 ± 11.73 in the L-carnitine groups ($P = 0.001$). Trend analysis for PHES showed significant improvement in the L-carnitine group ($P = 0.023$). The rate correct score of inhibition test among the Korean Stroop Test at 24 weeks of treatment was significantly higher in the L-carnitine group ($P = 0.038$). Additionally, the gap of total carnitine level between the baseline and week 24 were positively correlated with the improvement of rate correct scores of all four components in the Korean Stroop Test ($r = 0.3$ for Color Test; $r = 0.4$ for Word Test; $r = 0.5$ for Inhibition Test; $r = 0.3$ for Inhibition/Switching Test; all P values <0.05) in the L-carnitine group.
Conclusion: Administration of L-carnitine for 24 weeks in the LC patients with CHE were related to improvement of QOL as well as cognitive function.

GS07

Nidufexor, a non-bile acid FXR agonist, decreases ALT and hepatic fat fraction in patients with NASH after 12 weeks dosing

Richard Aspinall[1], Mustafa Shennak[2], George Stocia[3], Dean Quinn[4], Lali Javashvili[5], Valentina Molteni[6], Chinweike Ukomadu[7], Bindi Sohal[7], Yiming Zhang[7], Miljen Martic[7], Alexandre Avrameas[7], Sheena Kao[7], Jacques Herve[7], Rachel Soon[7], Michael Badman[7]. Email: michael.badman@novartis.com

Background and Aims: Non-bile acid farnesoid X receptor (FXR) agonists have significant therapeutic potential for treatment of non-alcoholic steatohepatitis (NASH). FXR has pleiotropic metabolic effects and agonists with different chemical and pharmacological properties may exert diverse effects. Nidufexor (LMB763) is a FXR partial agonist being evaluated in NASH and renal disorders.
Method: We performed a randomized, double blind, placebo-controlled, study to assess safety, tolerability and biomarker efficacy of nidufexor at 50 mg and 100 mg over 12 weeks of treatment. The study population included those diagnosed with NASH (historical liver biopsy, elevated ALT) or phenotypic NASH (elevated ALT, BMI and Type 2 DM). Primary endpoints were safety and reduction in ALT. Secondary endpoints included hepatic fat (MRI PDFF), pharmacokinetics, lipid profiles and anthropometry.
Results: 121 patients were randomized to placebo (N = 40) or nidufexor at 50 mg (N = 44) or 100 mg (N = 37) and 94 patients (77.7%) completed the study. Following oral administration of nidufexor the mean Tmax was 2 hours; systemic exposure was approximately dose proportional (Cmax on Day 42; 1.29 μM and 2.23 μM) with little accumulation (AUC accumulation ratio 1.3 and 0.9) at 50 mg and 100 mg nidufexor respectively. At Week 12, ALT decreased by 8% (2.5 U/L), 31% (14.3 U/L; p = 0.038) and 33% (18.8 U/L; p = 0.0031) in patients receiving placebo, 50 mg or 100 mg nidufexor. Placebo adjusted geometric mean hepatic fat reduction was 29% and 32% for 50 mg or 100 mg nidufexor (p < 0.0001 Vs placebo). Body weight decreased by 0.31 kg, 1.94 kg (p = 0.012) and 2.1 kg (p = 0.013) in patients receiving placebo, 50 mg or 100 mg nidufexor. Most patients (86.8%) experienced at least one AE, the most common being pruritus, reported in 15%, 29.5%, and 54.1% of placebo, 50 mg and 100 mg nidufexor respectively. There was no significant change in total cholesterol, LDL-C or triglycerides; HDL-C decreased by 12% and 16% in patients receiving 50 mg or 100 mg nidufexor.
Conclusion: In patients with NASH, both dosages of nidufexor appeared safe and were associated with significant reductions in ALT levels, hepatic fat fraction and body weight. The most frequent AE was pruritus, which was more common at 100 mg nidufexor. There were no meaningful changes in total cholesterol, LDL–C or triglycerides, although HDL–C decreased in both active groups. This study reinforces the likely utility of FXR agonism in NASH pharmacotherapy and further defines the range of potential class effects.

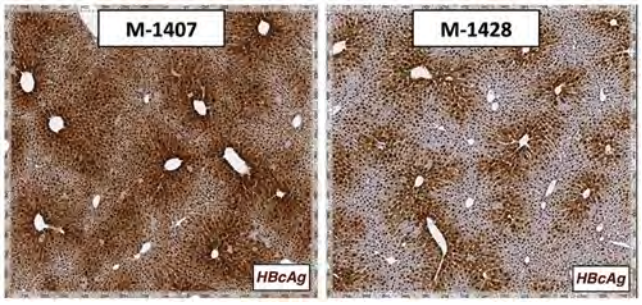
Hepatitis B – Translational

AS001

Preclinical assessment of capsid assembly modulators (CAMs) of varying potency revealed a novel class of picomolar-acting CAMs inducing neither significant HBcAg cytoplasmic retention nor adverse interactions with HBcAg-specific adaptive immunity

Romano Di Fabio[1], Leda Bencheva[1], Raffaele De Francesco[2,3], Lorena Donnici[2], Vincenzo Summa[4,5], Edith Monteagudo[4], Matteo Iannacone[6,7], Luca Guidotti[6,7]. *[1]Promidis, Milan, Italy; [2]National Institute of Molecular Genetics "Romeo ed Enrica Invernizzi", Virology, Milan, Italy; [3]University of Milan, Department of Pharmacological and Biomolecular Sciences, Milano, Italy; [4]IRBM Science Park S.p.A., Pomezia, Italy; [5]University of Naples Federico II, Napoli, Italy; [6]San Raffaele Hospital, Immunology & Infectious Diseases, Milano, Italy; [7]Vita-Salute San Raffaele University, Milano, Italy*
Email: guidotti.luca@hsr.it

Background and Aims: Capsid assembly modulators (CAMs) that induce the formation of empty/aberrant HBV capsids in the hepatocyte are currently under development. Whether CAMs of different potency in vitro varyingly alter the normal intracellular distribution of the particulate and nonparticulate forms of the HBV core protein (HBcAg) in vivo, and whether such supposed alteration has toxic and/or immunoregulatory/immunopathological consequences is ill defined. The aim of this study was to evaluate these issues, exploiting immunocompetent transgenic mice that - being immune tolerant to HBV - indefinitely replicate the virus at high levels in the liver and display stable and lifelong viremia of ~10^8 HBV genomes/ml.
Method: Three proprietary CAMs (termed M-1103, M-1407 and M-1428) and a first-in-class CAM (termed NVR3-778) endowed with diverse potency profiles in vitro were evaluated in HBV-replicating transgenic mice (transferred or not with HBcAg-specific mouse naïve or effector CD8 T cells) as per i) relative antiviral potency, ii) capsid/core protein distribution, iii) direct or immune-mediated hepatocellular toxicity and iv) immunoregulatory potential.
Results: EC50/EC90 evaluation in HepAD38 cells and HBV-infected HepG2-NTCP cells indicated that M-1103 and M-1407 are ~30 and ~100-fold more potent in vitro than NVR3-778, respectively; potency increased to ~ 500 folds in the case of the picomolar-active M-1428. Similar potency ratios over NVR3-778 were observed in vivo, with M-1428 quantitively eliminating HBV replicative intermediates from the liver of transgenic mice after only 3 days of dosing at 50 mg/kg QD (with commensurate reductions in serum HBV DNA, HBV RNA and HBeAg). Time- and dose-dependent experiments revealed that none of the tested CAMs caused direct liver injury. Surprisingly, however, NVR3-778, M-1103 and M-1407 induced significant cytoplasmic retention of HBcAg, whereas the more potent M-1428 and structurally related analogues with increased potency did not. Of note, the latter compounds did not sensitize hepatocytes to HBcAg-specific effector CD8 T cell-mediated killing and did not interfere with a recently described IL-2-based therapeutic strategy (*Nature* 574:200, 2019) capable of reverting T cell tolerance in this same animal model.



Conclusion: This study revealed that CAMs endowed with highly diverse antiviral potency in vitro behave in vivo quite unpredictably as per their intrinsic capacity to retain cytoplasmic HBcAg and, secondarily, influence the interaction of CAM-exposed HBV-expressing hepatocytes with adaptive immune responses.

AS002

Targeting inhibitor of apoptosis proteins (IAPs) enhances intrahepatic antiviral immunity to clear hepatitis B virus infection in vivo

Xiaoyong Zhang[1], Kuiyuan Huang[1], Wei Zhu[1], Geng Zhang[1], Jiehua Chen[1], Xuan Huang[1], Hongyan Liu[1], Yifan Zhai[2,3], Dajun Yang[3], Jinlin Hou[1]. *[1]Nanfang Hospital, Southern Medical University, Department of Infectious Diseases, Guangzhou, China; [2]HealthQuest Pharma Inc., Guangzhou, China; [3]Ascentage Pharma Group Corp. Limited, Suzhou, China*
Email: xiaoyzhang@smu.edu.cn

Background and Aims: The chronic infection caused by hepatitis B virus (HBV) remains hard to cure by current antiviral therapies. Previous studies had shown that the inhibitor of apoptosis proteins (IAPs) prevented TNFα-mediated killing of infected hepatocytes and

resulted in HBV persistence. APG-1387 is a novel bivalent antagonist of IAPs targeting IAPs and is well tolerated in clinical trials of cancer therapy. Here, we evaluated the anti-HBV function of APG-1387 and explored the underlying mechanisms in *vivo*.
Method: Three immunocompetent HBV carrier mouse models were established by infection with recombinant rAAV8-HBV1.3 in C57BL/6j mice or hydrodynamically injected with pAAV-HBV1.2 plasmid to C57BL/6j and C3H/HeN mice strains. 20 mg/kg of APG-1387 was injected by i.v. or i.p. once weekly. Quantification of viral DNA, antigens and transaminases in serum and liver samples were examined. Cell apoptosis were determined by TUNEL or cleaved-caspase-3 immunofluorescence staining. Intrahepatic T cell responses were analyzed by flow cytometry. Transcriptomic analysis of liver tissues after therapy was performed by RNA-seq.
Results: Compared to vehicle injection, APG-1387 treatment for 4–20 weeks in different models led to completely clearance of HBsAg, HBeAg and HBV DNA in serum, as well as HBcAg and HBV replicative intermediates in infected livers, and no relapse after stop therapy. After APG-1387 injection, cleaved-caspase-3 expression in HBcAg-positive hepatocytes was detected, and serum transaminase levels were transiently elevated and its peak levels were associated with the baseline HBsAg levels. However, pan-caspase inhibitor Emricasan or Z-VAD-FMK treatment could not block the antiviral effect of APG-1387. Furthermore, clearance of HBV by APG-1387 was found to be associated with upregulation of intrahepatic HBV-specific CD4+ and CD8+ T cells frequency and function. As expected, APG-1387 was unable to clear HBV in TNFα, CD4 or CD8 deficiency mice. Finally, Gene Set Enrichment Analysis of RNA-seq data showed that multiple immune-related genes were upregulated by APG-1387, similar to the genes induced in the liver during HBV clearance in chimpanzees.
Conclusion: These findings indicated that APG-1387 was able to clear chronic HBV infection in various mouse models with a unique induction of apoptosis and immunoregulation mechanism. Application of IAP antagonist might represent a novel immunotherapeutic strategy for HBV functional cure.

Serum and intrahepatic HBV markers and HBV-specific CD8 T cell responses after nucleos(t)ide analog therapy discontinuation in HBeAg-negative chronic hepatitis B patients
Mireia García-López[1], Sabela Lens[1], Laura J. Pallett[2], Barbara Testoni[3], Zoe Mariño[1], Sergio Rodriguez-Tajes[1], Concepció Bartres[1], Ester García-Pras[1], Thais Leonel[1], Elena Perpiñan[1], Juanjo Lozano[4], Francisco Rodríguez-Frías[5], George Koutsoudakis[1], Fabien Zoulim[3], Mala Maini[2], Xavier Forns[1], Sofía Pérez-del-Pulgar[1]. *[1]Liver Unit, Hospital Clínic, University of Barcelona, IDIBAPS, CIBERehd, Barcelona, Spain; [2]Division of Infection and Immunity, Institute of Immunity and Transplantation, University College London, London, United Kingdom; [3]Cancer Research Center of Lyon (CRCL), University of Lyon, UMR_S1052, UCBL, INSERM, U1052, Lyon, France; [4]Bioinformatics Platform, CIBERehd, Barcelona, Spain; [5]Liver Pathology Unit, Department of Biochemistry and Microbiology, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, CIBERehd, Barcelona, Spain*
Email: sofiapp@clinic.cat

Background and Aims: Previous studies have reported that up to 20% of patients with chronic hepatitis B (CHB) may achieve functional cure (HBsAg loss) after nucleos(t)ide analog (NA) treatment withdrawal. CD8 T cells play an important role in the immune control of HBV infection. The objective of this study was to analyze HBV-specific CD8 responses in parallel with peripheral and intrahepatic virological markers after NUC discontinuation in patients with HBeAg-negative (HBeAg-) CHB.
Method: Twenty-seven HBeAg- CHB patients with complete viral suppression (>3 years) and without cirrhosis were prospectively studied. A liver biopsy was taken at the time of treatment withdrawal (baseline). PBMC and serum samples were collected at baseline and various time-points during follow-up. Intrahepatic HBV-DNA (iHBV-DNA), covalently closed circular DNA (cccDNA) and serum HBV-DNA, HBsAg, core-related antigen (HBcrAg) and pregenomic RNA (pgRNA) levels were determined. HBV-specific T cell responses (IFNγ, TNF and CD107a) were analyzed by multiparametric flow cytometry after in vitro expansion in the presence of overlapping peptides (OLP) spanning core, envelope and polymerase.
Results: After a median follow-up of 34 months (IQR 26–37), 22 (81%) patients remain off-therapy, with 8 (30% of the total cohort) losing HBsAg; whilst 5 (19%) required NA reintroduction due to relapse. Although all patients were iHBV-DNA and cccDNA positive at baseline, only 41% and 48% had detectable serum pgRNA and HBcrAg, respectively. Baseline HBsAg levels correlated significantly with iHBV-DNA ($r = 0.7$, $p < 0.0001$) and both markers were lower in patients who lost HBsAg ($p < 0.001$). Baseline intrahepatic (iHBV-DNA, cccDNA) or serum (HBsAg, HBcrAg or pgRNA) viral markers did not show any association with peripheral CD8 T cell responses. Importantly, degranulating CD8 T cells (CD107a+) or those co-producing IFNγ and TNF in response to stimulation with core OLP were significantly higher ($p = 0.05$ and $p = 0.039$, respectively) at baseline in patients remaining off-therapy compared to those requiring NA reintroduction. Interestingly, the enhanced frequency of CD8 T cells co-producing IFNγ and TNF persisted up to 1 year of follow-up ($p = 0.009$). Notably, CD8 T cell responses to polymerase or envelope failed to associate with outcome as robustly as those against core.
Conclusion: NA discontinuation is feasible in a high proportion of HBeAg- patients, particularly in those with low HBsAg levels. Higher frequencies of CD8 T cells with cytotoxic and non-cytolytic anti-HBV (core) reactivity are detectable at baseline in those patients who maintain viral control after therapy withdrawal. These data support HBsAg levels and HBV-specific CD8 T cell frequencies as correlates of HBV control off-therapy, requiring validation in larger studies.

AS004
Targeted long read sequencing reveals the comprehensive architecture and expression patterns of integrated HBV DNA in CHB liver biopsies
Ricardo Ramirez[1], Nicholas Van Buuren[1], Vithika Suri[1], Henry Chan[1,2], Maria Buti[1,3], Patrick Marcellin[1,4], Hongmei Mo[1], Anuj Gaggar[1], Li Li[1], Becket Feierbach[1]. *[1]Gilead Sciences, Inc., Foster City, United States; [2]Chinese University Of Hong Kong, Hong Kong; [3]Vall d'Hebron University Hospital, Barcelona, Spain; [4]Hospital Beaujon AP-HP, Clichy, France*
Email: ricardo.ramirez@gilead.com

Background and Aims: Hepatitis B virus (HBV) integration into the host genome has been implicated in the development of hepatocellular carcinoma and has been observed with PCR-based assays or short read sequencing, but limitations of these methods have prevented the full characterization of integration events. Here, we use an HBV-targeted sequencing strategy to determine the full architecture of HBV integrations in the liver of chronically-infected HBV (CHB) patients. We define the full sequences of integrated HBV DNA and compare these sequences with data from RNA-Seq to determine productive vs non-productive integrations.
Method: 28 liver biopsies were obtained from CHB patients enrolled in Gilead Clinical Trial GS-US-174-0149 with an even distribution of HBeAg positive and negative samples, including five samples taken 96 weeks post-baseline. Genomic DNA was sheared to 7 kb fragments, barcoded for multiplexing, and enriched for HBV using the IDT xGen platform with a custom panel of biotinylated 120 bp probes targeted to HBV genotypes A through H. Enriched DNA libraries were sequenced using a Pacific Biosciences Sequel II (PacBio) and compared to corresponding RNA-Seq.
Results: Target enrichment increased detection of HBV sequences, and the PacBio platform produced high quality reads that were several kilobases long, many of which contained the entire viral integration sequence and thousands of base pairs of adjacent host sequences within a single read. In contrast, short read whole genome

sequencing data only detected virus-host junctions. We also observed transcripts resulting from non-integrated HBV as identified by the presence of 3.2 kb reads exclusive of host sequences. Host/HBV chimeric reads were compared to RNA-Seq data from the same biopsies to match transcripts with specific integration events. Several partial integration events, not associated with HBV direct repeats (DR1 and DR2), were identified and appeared transcriptionally silent despite being inserted in or near host gene loci. Most transcribed integrations contained HBV promoter sequences driving S transcript expression and are associated with the HBV DR1 region.
Conclusion: Targeted long-read sequencing provides better accuracy and deeper coverage, compared to whole genome sequencing. This assay can elucidate full primary sequence of integrated HBV, and, when paired with RNA-Seq data, can show the differences between transcriptionally active and inactive events.

AS005

Transcriptome analysis of paired liver biopsies identifies correlates of HBsAg response in placebo and TDF treated CHB patients

Yao-Chun Hsu[1], Diana Chen[2], Vithika Suri[2], Jeffrey Wallin[2], Jing Zhu Zhou[2], Cheng-Hao Tseng[3], Yen-Tsung Huang[4], Mani Subramanian[2], Anuj Gaggar[2], Ondrej Podlaha[2]. [1]*Center for Liver Diseases;* [2]*Gilead Sciences, Inc., Foster City, United States;* [3]*Division of Gastroenterology and Hepatology;* [4]*Institute of Statistical Science*
Email: ondrej.podlaha@gilead.com

Background and Aims: Intrahepatic evaluation of host immunity can provide insight into events leading to important clinical events in patients with chronic hepatitis B (CHB) infection. Here we investigate baseline and year 3 liver biopsies from a randomized placebo-controlled trial of Tenofovir Disoproxil Fumarate (TDF) in CHB patients (IN-US-174-0178) with minimally elevated aminotransferase for gene expression signatures associated with clinical response.
Method: CHB patients (N = 130) with serum ALT 1-2x upper limit of normal (ULN) with no clinical liver cirrhosis or decompensation were randomized into TDF and Placebo 3-year treatment arms. Liver biopsies were taken at baseline and year 3. Gene expression from liver biopsies was quantified with salmon software and gene set enrichment was interrogated using GSEA software package (Broad Institute) and pathway gene signatures from MSigDB database.
Results: Overall, at year 3 patients treated with TDF displayed significantly reduced inflammatory response (False Discovery Rate, FDR = 0.001), while gene signatures for fatty and bile acid metabolism and adipogenesis were significantly upregulated (FDR < 0.001), suggesting improved liver function. Nine and 16 patients in the placebo and TDF arms, respectively, experienced HBsAg reduction greater than 0.5 Log10 IU at year 3. Compared to HBsAg non-responders, these HBsAg responders at baseline demonstrated upregulation of B cell activation (FDR = 0.006) as well as IFN alpha (FDR = 0.008) and IFN gamma response (FDR = 0.081). In addition, placebo responders exhibited elevation of innate immune response (FDR = 0.022) and TNF alpha signaling (FDR < 0.001) compared to placebo non-responders, whereas TDF responders demonstrated enrichment B cell activation signatures (FDR = 0.021) and B cell proliferation (FDR = 0.061) compared to TDF non-responders. Comparison between placebo and TDF HBsAg responders revealed that placebo responders (NPlacebo = 9; NTDF = 16) again exhibited stronger upregulated IFN-alpha (FDR < 0.001) and IFN-gamma (FDR < 0.001) signaling pathways at baseline (Figure 1), suggesting different pathways for HBsAg reduction by natural history and antiviral treatment.
Conclusion: Our results demonstrate that HBV control is linked to interferon and humoral immune response and suggest that immunotherapies aimed to boost these immune responses may act synergistically with nucleotide analogue therapy to achieve sustained control of HBV.

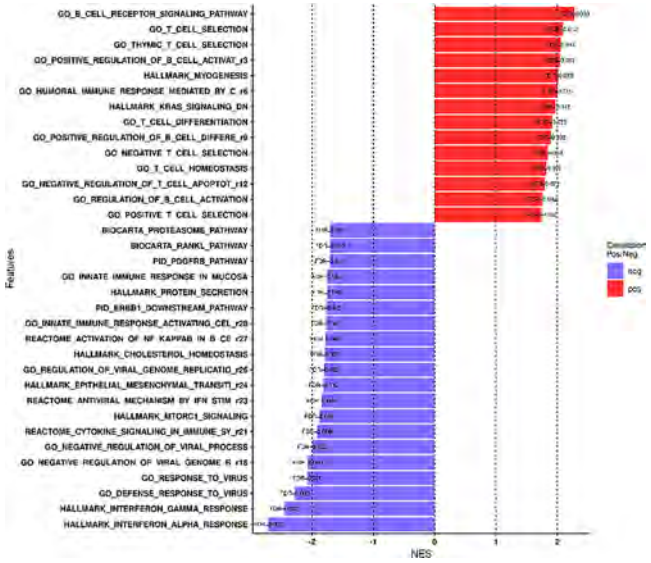

Figure: Gene Signature Enrichment Analysis comparing TDF and Placebo HBsAg responders (>0.5 Log10 HBsAg reduction at year 3) at baseline. Negative NES (Normalized Enrichment Score) represents feature upregulation in the Placebo arm, whereas positive NES identifies upregulated features in the TDF arm.

Email: francois.villeret@gmail.com

Background and Aims: Combined Nucleoside Analogues (NAs) and hepatitis B immunoglobulins (HBIG) therapy accounts for the low risk of HBV recurrence after liver transplantation (LT). The duration of the double prophylaxis remains a matter of debate and the lack of non-invasive biomarkers for intrahepatic HBV replication prevents the implementation of personalized duration of treatment.
Method: Blood samples from 34 patients transplanted for HBV-related disease were collected at LT registration, the day of the LT, 3 and 12 months after LT. A tissue sample from the native liver, after liver reperfusion and at 12 months after LT were collected and snap frozen at −80°C. Intrahepatic HBV cccDNA, DNA replicative intermediates (tHBV DNA) and 3.5Kb-RNA were quantified by digital-droplet PCR. Serum HBcrAg and quantitative HBsAg were analysed using the Lumipulse platform (Fujirebio - LLOQ of 3 logU/ml and 5 mIU/ml, respectively).
Results: At the time of LT, serum HBV DNA was undetectable in 86.2% of patients. The median age was 54.3 years, 24 had hepatocellular

carcinoma, 28 were HBeAg-negative and 2 were co-infected with HDV. HBV DNA was detectable in 97% of the native livers with a median value of 0.036 copies/cell for tHBV DNA and 0.0012 copies/cell for cccDNA. 3.5 Kb RNA was found in 20 patients with a median of 0.0029 copies/cell. All recipients received NA and 1-year HBIG treatment after LT and had undetectable serum HBV DNA 1 year post-LT. 14/29 reperfusion biopsies were positive for HBV DNA and 3 were positive for 3.5 Kb RNA. 13/20 liver biopsies available 1 year post-LT were positive for HBV DNA and 7 for 3.5 Kb-RNA with a mean of 0.006 copies/cell for tHBV DNA, 0.0006 copies/cell for cccDNA and 0.0012 copies/cell for 3.5Kb RNA. Pre-LT serum HBcrAg was significantly correlated with native liver tHBV DNA ($r = 0.67$, $p < 0.0001$), cccDNA ($r = 0.56$; $p = 0.0004$) and 3.5 Kb-RNA ($r = 0.71$; $p < 0.0001$). Pre-LT qHBsAg correlated with native liver tHBV DNA ($r = 0.63$; $p = 0.0003$) and 3.5 Kb-RNA ($r = 0.62$; $p = 0.0005$) but not with cccDNA levels. At 3 months and 1 year post-LT, 7 and 5 patients, respectively, were still positive for serum HBcrAg. Albeit negative with classic techniques, 5 patients scored positive for HBsAg 1 year post-LT by highly sensitive Lumipulse test.

Conclusion: Our study shows a rapid HBV infection of the graft despite NA + HBIG prophylaxis. One year post-LT, a majority of patients had detectable intrahepatic HBV markers. No direct correlation between pre-LT serum HBcrAg and HBsAg with HBV recurrence was identified. Correlation of intrahepatic HBV markers with serum circulating HBV RNAs is under investigation.

This work was funded in part by French National Research Agency (ANR) as part of the second "Investissements d'Avenir" program (reference: ANR-17-RHUS-0003 "cirB-RNA" program) and Gilead; we thank Fujirebio for providing the Lumipulse kits for HBsAg and HBcrAg quantification.

Email: helena.degroote@ugent.be

Background and Aims: After downstaging of patients with hepatocellular carcinoma (HCC) beyond the conventional criteria, a similar outcome for liver transplant has been shown compared to patients initially meeting the Milan criteria. We aimed to evaluate the effect of locoregional therapy during waiting time on the outcome after liver transplant by comparing patients within the Milan criteria with the group meeting the University of California San Francisco downstaging protocol (UCSF-DS) and the "All-comers" beyond these inclusion criteria. We also assessed the role of alpha-fetoprotein (AFP) in predicting HCC recurrence in the downstaging groups.

Method: This international, multicenter cohort study included 2,444 consecutive adult patients with liver transplantation for non-metastatic HCC in 47 centers from France, Italy, Belgium and Latin America (2000–2018). Pre-transplant tumor characteristics and serum AFP levels were obtained at diagnosis, listing, last imaging evaluation prior to liver transplant and explant pathology analysis. Survival and cumulative recurrence were compared at listing and last evaluation prior transplantation according to the Milan criteria and UCSF-DS protocol. Multivariate Cox regression models, with hazard ratios (HR) and 95% confidence intervals (CI) were conducted. Further competing risk regression analysis was carried out for HCC recurrence (competing event was considered any death without prior recurrence).

Results: At listing, 1978 patients were within Milan criteria (80.9%), 295 met the UCSF-DS protocol (12.1%) and 168 (6.9%) were All-comers. Median time on waiting list was 5.5 months. Similar post-transplant survival and higher recurrence cumulative incidence rates were observed for the UCSF-DS group [SHR 1.64 (CI 1.15–2.35); $p = 0.007$] and All-comers [SHR 3.69 (CI 2.65–5.14); $p < .0001$] compared to Milan criteria at listing. After locoregional bridging therapies, effective downstaging to Milan criteria at last evaluation prior to transplant was achieved in 47% (CI 37–57%) of the UCSF-DS group and in 38% (CI 26–52%) of All-comers. After effective downstaging, similar recurrence and survival rates were observed between the Milan and UCSF-DS group, whereas a higher recurrence [SHR 6.1 (CI 3.10–11.9); $p < 0.0001$] was observed in the All-comers. An AFP value at listing more than 20 ng/ml was associated with a higher risk for recurrence [SHR 1.75 (CI 1.05–2.9); $p = 0.015$] and lower survival [HR 2.20 (CI 1.34–3.59); $p = 0.002$] among patients in the UCSF-DS group.

Conclusion: Although the efficacy of downstaging to Milan criteria was lower than fifty percent, survival and recurrence rates were similar in patients within UCSF-DS criteria successfully downstaged when compared to patients initially within the Milan criteria at listing. An AFP value below 20 ng/ml might be an additional clinical tool to select better candidates in the UCSF-DS group.

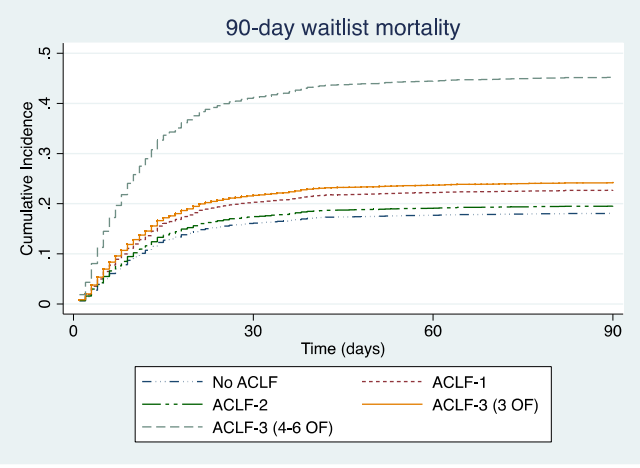
AS008

Share MELD-35 does not fully address the high waiting list mortality of patients with acute on chronic liver failure grade 3

Vinay Sundaram[1], Parth Shah[1], Constantine Karvellas[2], Sumeet Asrani[3], Robert Wong[4], Rajiv Jalan[5]. *[1]Cedars-Sinai Medical Center, Los Angeles, United States; [2]University of Alberta, Edmonton, Canada; [3]Baylor Scott & White Medical Center - Grapevine, Grapevine, United States; [4]Alameda Health Systems, Oakland, United States; [5]University College London Hospital, United Kingdom*
Email: vinaysundaram@yahoo.com

Background and Aims: Patients with acute on chronic liver failure grade 3 (ACLF-3) have the highest risk for waitlist mortality. The share

MELD-35 rule was introduced in the USA in 2013 to allow regional sharing of organs, to reduce the high mortality rates of patients with MELD ≥ 35. Although this change has reduced mortality for patients with high MELD-Na scores, by enabling regional sharing, its impact on patients with ACLF-3 is unknown. Our aims were to determine whether share MELD-35 addresses the high mortality on the waiting list of patients with acute on chronic liver failure grade 3 (ACLF-3).
Method: We studied the UNOS database, years 2010–2017. ACLF was identified using the EASL-CLIF definition. We assessed the effect of the share 35 rule according to year of LT, specifically years 2010–2012 considered pre-share 35 and years 2014–2016 designated post-share 35. We evaluated outcomes of 90-day waitlist mortality using competing risks regression analysis.
Results: We identified 6,342 candidates at listing with a MELD-Na score > = 35, of which 3,122 patients had ACLF-3. Among those with ACLF-3, extra-hepatic organ failures were significantly more prevalent in patients with 4–6 organ failures. Competing risks regression, adjusting for age, etiology of liver disease, and MELD-Na score, revealed that candidates listed with ACLF-3 had a significant risk for 90-day waitlist mortality (SHR = 1.76; 95% CI 1.27–2.44), particularly those with four or more organ failures (SHR = 3.01; 95% CI 2.15–4.24). (Figure) ACLF-1 and ACLF-2 were not associated with greater mortality relative to no ACLF. Organ failures with the strongest association for waitlist mortality included mechanical ventilation (SHR = 1.89; 95% CI 1.67–2.15), circulatory failure (SHR = 1.64; 95% CI 1.45–1.86) and brain failure (SHR = 1.16; 95% CI 1.03–1.33). LT occurring post-share 35 was associated with reduced 90-day waitlist mortality among patients listed with ACLF-3 and MELD-Na score ≥ 35 (SHR = 0.58; 95% CI 0.49–0.69). However, among patients with 4–6 organ failures, LT after share 35 implementation was not significantly associated with reduced waitlist mortality (SHR = 0.79; 95% CI 0.60–1.05).



Conclusion: Although regional sharing of organs for patients with MELD ≥ 35 is associated with a significant reduction in waitlist mortality, patients with ACLF-3, particularly those with extra-hepatic organ failures are not fully addressed by this scheme. Incorporation of ACLF grading into organ allocation schemes may allow more equitable distribution of organs.

AS009

Pretransplant rifaximin administration reduces posttransplant liver injury and early allograft dysfunction in mouse and human liver transplantation

Takahiro Ito[1], Shoichi Kageyama[1], Kojiro Nakamura[1,2,3], Hirofumi Hirao[1], Kentaro Kadono[1], Hidenobu Kojima[1], Ronald Busuttil[1], Fady M. Kaldas[1], Jerzy Kupiec-Weglinski[1]. *[1]The Dumont-UCLA Transplant Center, Department of Surgery, Los Angeles, United States; [2]Kyoto University, Department of Surgery, Kyoto, Japan; [3]Nishi-Kobe Medical Center, Department of Surgery*
Email: jkupiec@mednet.ucla.edu

Background and Aims: Rifaximin commonly used to treat hepatic encephalopathy is a minimally absorbed antibiotic. Gut-liver axis is considered to play an important role in hepatic injury, and its microbiota is receiving increased attention in the field of organ transplantation. We examined the effectiveness of rifaximin treatment in mice and human liver transplant (LT) recipients on hepatocellular graft injury.
Methods: In the experimental arm, livers from C57BL/6 mice were transplanted to allogeneic BALB/c mice after 18 h of cold-storage. To examine the impact of gut microbiota, fecal microbiota transplant (FMT) was performed prior to LT in three major groups (n = 4/grp): Gr. I - control (naïve untreated); Gr. II - rifaximin (7d rifaximin treatment prior to LT); Gr. III - rifaximin + FMT (7d rifaximin treatment + FMT from naïve mice). In the clinical arm, 447 adult primary LT recipients were retrospectively reviewed and classified based on the duration of pre-LT rifaximin therapy: Gr. I - rifaximin (≥ 7d); and Gr. II - control (<7d).
Results: In mouse LT recipients, rifaximin treatment prevented hepatocellular damage, evidenced by lower serum transaminase levels as compared to control or rifaximin + FMT groups (control vs rifaximin vs rifaximin + FMT vs control, mean ALT (IU/L): 8132 vs 3197 vs 8897, resp., $p < 0.05$). In addition, LT in rifaximin group showed significantly lower Suzuki's histological score of hepatocellular injury; and lower CD68 (macrophage)/Ly6G (neutrophil) infiltration as compared to control or rifaximin + FMT group ($p < 0.05$). In the clinical arm, 260 LT patients who underwent ≥7d rifaximin treatment were characterized by significantly lower maximum postoperative serum ALT levels within 7 POD (409 vs 571 IU/L, $p < 0.001$) and depressed occurrence of early allograft dysfunction (EAD; 22.7 vs 31.0%, $p = 0.048$) as compared with controls. Notably, multivariate analysis identified pre-LT rifaximin treatment of <7d as an independent risk factors for development of EAD (Odds ratio: 1.917, $p = 0.008$), along extended cold ischemia time ($p = 0.003$), higher donor age ($p = 0.003$), and larger amount of blood transfusions ($p = 0.019$).
Conclusion: We demonstrated the effectiveness of rifaximin therapy prior to LT in mice and humans, assessed by graft hepatocellular damage and EAD. As rifaximin-mediated benefits were negated by concomitant FMT from normal mice, targeting gut microbiota has a therapeutic potential to prevent post-LT injury and improve clinical outcomes.

Background and Aims: Patients with hepatocellular carcinoma (HCC) are selected for liver transplantation (LT) based on pre-LT imaging ± AFP level but discrepancies between pre-LT imaging and explanted liver findings are frequent. Our aim was to design an explant-based Recurrence Risk Reassessment (R3) model in patients transplanted for HCC to reassess the risk of recurrence after LT.
Method: A multicenter multinational cohort study of consecutive adult patients with HCC and a first LT in 47 centers from France, Italy, Belgium and Latin America was included (2000–2018). In a TEST cohort from Europe (n = 1359), an explant-based model was design and further evaluated in an external VALIDATION cohort from Latin America (n = 1085). Explant liver findings included macroscopic and microscopic evaluation of each nodule, number and diameter (cm) of each, presence of microvascular invasion (mvi) and degree of tumor differentiation. Multivariate Cox regression models, with hazard ratios (HR) and 95% confidence intervals (CI) were conducted. Further competing risk regression analysis was performed for HCC recurrence (competing event was considered any death without prior recurrence) with sub-HR calculated. We estimated Harrell's C and Somers' D predictive power for HCC recurrence for comparison of different explant based predictive models including: Milan criteria, the Up-to 7, RETREAT score.

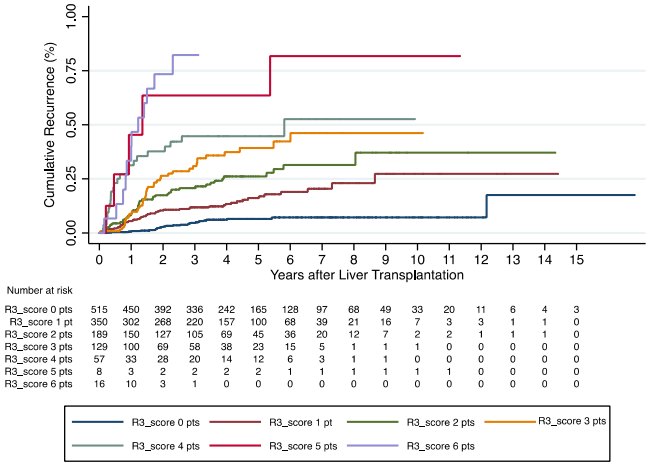

Figure: R3 score as continuous variable SHR 1.97 (CI 1.80–2.16).

Results: In the TEST cohort, variables at explant pathology independently associated with recurrence were number of nodules [1–3 nodules vs ≥4 nodules SHR 1.77 (CI 1.30–2.40)], major nodule diameter [3 cm vs 3–6 cm SHR 2.0 (CI 1.50–2.77) vs >6 cm SHR 6.0

(CI 3.87–9.3)] and presence of microvascular invasion [SHR 2.81 (CI 2.09–3.79)]. Based on this multivariable model, a R3 score ranging from 0 to 5 points was developed. The R3 score was associated with recurrence with a 2 fold increasing cumulative incidence of recurrence for every increasing point (Figure). A cut-off of 1 point was selected as highly associated with HCC recurrence [SHR 0.20 (CI 0.15–0.27); P < 0.0001]. Harrells' c-statistic was higher for the R3 score either as continuous or dichotomous cut-off [0.75 (CI 0.71–0.78)] when compared to Milan, RETREAT and the Up-to 7 models in the TEST cohort. In the external VALIDATION cohort, again the R3 score could stratify two recurrence risk populations with a SHR of 0.22 (CI 0.15–0.32).

Conclusion: A new simple R3 model improves prediction of recurrence compared with other explant-based and composed models for HCC recurrence. The R3 score may be useful to adjust HCC surveillance strategies after LT and may provide a framework for risk stratification in the design of adjuvant therapy clinical trials.

Email: sebastien.dharancy@chru-lille.fr

Background and Aims: Severe alcoholic hepatitis (AH) refractory to medical therapy is associated with a 6-month mortality of more than 70%. We reported in 2011 that early liver transplantation (eLT), in extremely carefully selected patients with corticosteroid-resistant AH, could been performed with promising short-term results. After this initial experience, several studies from the United States on similar outcomes in these patients have been published. The aim of the present study is to report the long-term results in the cohort of patients initially reported in 2011, with the addition of more recent transplanted patients in the same centers and according to the same inclusion criteria.

Method: The seven transplant centers who participated to the initial pilot study published in 2011 selected patients with severe AH who were considered to be candidates for eLT, according to the following criteria: nonresponse to medical therapy, severe AH as the first liver-decompensating event, presence of close supportive family members, absence of severe coexisting or psychiatric disorders, and agreement by patients to adhere to lifelong alcohol abstinence. Patients were included between November 2005 and December 2012. End-points of the present retrospective analysis were patients' survival and rate of (severe) alcohol relapse. Alcohol use was assessed at short intervals during informal interviews of patients and their families as previously described. The final follow-up was on May 31, 2019.

Results: Sixty eight patients (69% of male; median age of 51 years; 95% CI 46–54 yrs) with severe AH that had failed to respond to medical therapy underwent eLT in the seven participating centers. Median discriminant function on the first day of therapy was 72 (95% CI 58–87) and median MELD score was of 31 (95% CI 28–35). Sepsis and hepatorenal syndrome rates before eLT were 47 and 54%, respectively. AH was confirmed in all cases by histological analysis of explanted livers. 84% of patients were treated with steroids for a median duration of 7 days (95% CI 7–8); median Lille score after 7 days of medical therapy was of 0.87 (95% CI 0.33–0.99). After a mean length of follow up after eLT of 59.6 months, severe alcohol relapse reached 10.3% (7/68). Among them, two developed recurrent alcoholic cirrhosis and died. After eLT, overall patients' survival was 82.6 ± 5% at 1 year, 70 ± 6% at 5 years and 56 ± 7% at 10 years. Twenty four patients (35%) deceased from sepsis (n = 7), head-neck cancer (n = 6), major cardiovascular event (n = 4), recurrent alcoholic cirrhosis (n = 2), and others causes (n = 5).

Conclusion: Our results on a large cohort with long follow-up confirm that AH could be a good indication for LT in selected patients; survival is impaired by early death related to severity of liver failure and later because of alcohol-related co-morbidities, especially de novo malignancies.

AS012

Non-alcoholic steatohepatitis (NASH)-related cirrhosis is not associated with lower patient eligibility for liver transplantation compared to other liver disease aetiologies

Evangelia Koutli[1], Anna Mantovani[2], Aileen Marshall[1], Jennifer Ryan[1], Rachel Westbrook[1], Emmanuel Tsochatzis[1]. *[1]UCL Institute for Liver and Digestive Health, Royal Free Hospital and UCL, London, United Kingdom; [2]UCL Institute for Liver and Digestive Health, Royal Free Hospital and UCL, London, United Kingdom*
Email: evangelia.koutli@nhs.net

Background and Aims: NASH is a growing indication for liver transplantation, however there are concerns regarding transplant eligibility of patients because of the high prevalence of metabolic comorbidities. We compared transplant listing rates of NASH-related cirrhosis to other aetiologies in consecutive patients referred for transplant assessment.

Method: We retrospectively evaluated patients with end-stage liver disease at their first contact in the Transplant Assessment Clinic, Royal Free Hospital, London, United Kingdom. From September 2011 to February 2019, 444 patients (66.7% male, mean age 53.7 ± 10.9 years) underwent assessment which consisted of a first clinic appointment followed by a dedicated cardiac, respiratory, psychiatric, anaesthetic and surgical assessment, in selected patients. Final decision on eligibility status for Orthotopic Liver Transplant (OLT) was obtained in multi-disciplinary meetings.

Results: Alcoholic liver disease (ALD) was the most common indication for referral (35.4%), followed by NASH (20.7%), viral hepatitis (17.1%), autoimmune-related disease (14.9%) and other aetiologies (12%). Patients with NASH cirrhosis (n = 92) had a mean age of 60 ± 7 years, 71.7% of them had diabetes, 23.9% of them had hypertension and 5.4% of them had positive history of cardiovascular disease. Overall, 52.1% of patients were listed for OLT. Patients with NASH showed the highest eligibility for OLT (67%), followed by the autoimmune (65.2%) and the viral group (55.3%) (p < 0.001). Patients with ALD presented the lowest eligibility (34.9%). Among patients not adjudicated as candidates for transplantation, liver improvement was the leading reason for exclusion in all groups (ranging from 19.2% to 34.8%). Frailty was also common in most groups, but its prevalence was lower in NAFLD patients (6.7%). As expected, alcohol misuse was high in ALD patients who were deemed ineligible for OLT (Table).

Table: Counts and percentages of patients that were not listed for OLT according to different aetiology

	NAFLD		ALD		VIRAL		AUTOIMMUNE	
	N	(%)	N	(%)	N	(%)	N	(%)
Liver improvement	10	33.3	19	19.2	11	32.4	8	34.8
Frailty	2	6.7	10	10.1	5	14.7	5	21.7
Co-morbidities	2	6.7	6	6.1	3	8.8	5	21.7
Alcohol abuse	–	–	16	16.2	2	5.9	–	–
HCC out of Milan criteria	2	6.7	7	7.1	3	8.8	–	–

Conclusion: In a tertiary high-volume centre, half of end-stage liver patients fulfilled the criteria for OLT. Contrary to common belief, patients with NASH presented the most favourable listing profile (despite older age and higher prevalence of metabolic comorbidities). Spontaneous liver improvement abrogated the need for transplantation in almost one third of evaluated subjects. Importantly, frailty

and alcohol history/misuse were adverse predictors of successful transplantation listing.

NAFLD – Target identification and drug pipeline

AS013

MBOAT7, HSD17B13 and metabolic risk factors in the progression of PNPLA3-associated steatohepatitis

Marie Schulte[1], Arslanow Anita[1], Susanne N. Weber[1], Marcin Krawczyk[1], Frank Lammert[1]. [1]*Saarland University, Department of Medicine II, Homburg, Germany*
Email: frank.lammert@uks.eu

Background and Aims: Carriers of the adiponutrin (*PNPLA3*) p.I148M variant have an increased risk of (non-)alcoholic fatty liver disease (NAFLD) and fibrosis (Krawczyk et al. *J Lipid Res* 2017). Furthermore, mutations in the *MBOAT7* gene worsen hepatic fibrosis and hepatocellular damage, whereas a splice variant of *HSD17B13* reduces the general risk of chronic liver disease (CLD) and fatty liver progression (Abul-Husn et al. *N Engl J Med* 2018). Here, we aim to investigate how the *MBOAT7* and *HSD17B13* variants affect steatosis and fibrosis in *homozygous* carriers of the *PNPLA3* risk variant p.I148M.
Methods: In total, 2,278 patients with CLD were screened for the *PNPLA3* variant. Clinical, laboratory and imaging data were collected, including non-invasive liver stiffness measurements (LSM) and controlled attenuation parameter (CAP) by transient elastography. *MBOAT7* rs641738 and *HSD17B13* rs72613567 were genotyped by PCR-based allelic discrimination assays, and genotype-to-phenotype correlations were analysed.
Results: Overall, 144 patients (6.3%) were carriers of the homozygous *PNPLA3* p.148MM genotype (59.7% men, age 18–83 years, 19.7% diabetes). Median CAP was 279 dB/m and median LSM was 12.0 kPa, consistent with advanced fibrosis and steatosis in these patients. The fibrosis stages in NAFLD patients were associated with metabolic risk factors (diabetes, BMI, age), but not *MBOAT7* genotypes. The incidence of cirrhosis and hepatocellular carcinoma was not influenced by *MBOAT7* alleles either. However, a decrease of hepatic steatosis, as measured by CAP, per additionally mutated *MBOAT7* allele was found (−23 dB/m, p = 0.019). Of note, the maximum LSM and CAP in patients with the protective *HSD17B13* genotype were on average 41 kPa and 58 dB/m lower than in carriers of the common allele.
Conclusions: Since a decrease of steatosis in patients with end-stage CLD represents an unfavorable prognostic marker, patients with both homozygous mutated *PNPLA3* and *MBOAT7* allele could represent a vulnerable group of NAFLD patients in whom exogenous factors confer significant risk. The *HSD17B13* splice variant mitigates in part the harmful effects conferred by *PNPLA3* homozygosity.

The combination of elafibranor and semaglutide drastically improves fibrosing steatohepatitis and distinctly modulates liver inflammatory signature

Vanessa Legry[1], Philippe Poulain[1], Nicolas Stankovic Valentin[1], Peggy Parroche[1], Emeline Descamps[1], Carole Belanger[1], Dean Hum[2], Bart Staels[3,4,5,6], Stephen Harrison[7], Rohit Loomba[8], Arun Sanyal[9], Vlad Ratziu[10], Robert Walczak[1]. [1]*GENFIT SA, Loos, France;* [2]*GENFIT CORP, Cambridge, United States;* [3]*Inserm U1011, Lille, France;* [4]*Institut Pasteur de Lille, Lille, France;* [5]*CHU Lille, Lille, France;* [6]*Egid Université Lille, Lille, France;* [7]*Pinnacle Clinical Research Center, San Antonio, United States;* [8]*NAFLD Research Center, UCSD, Division of Gastroenterology, La Jolla, United States;* [9]*Virginia Commonwealth University, Richmond, United States;* [10]*Hopital Pitié-Salpêtrière, Paris, France*
Email: robert.walczak@genfit.com

Background and Aims: High prevalence of diabetes among patients with NASH prompted us to investigate the combination of elafibranor (ELA) with the anti-diabetic drug semaglutide (SEMA). The aim of this study is to explore the complementary actions of ELA and SEMA in NASH reversal.
Method: Male C57BL/6J mice were fed with the AMLN diet for 35 weeks. Mice with biopsy-confirmed significant steatosis and fibrosis were randomized into treatment groups (n = 12–14). Mice received vehicle, ELA (10 mg/kg/day, PO), SEMA (0.3 nmol/kg, SC) or combination of both drugs for 12 weeks. Submaximal drug doses were used in this study.
Results: At inclusion, mice were obese (41 g), had a severe NASH phenotype (NAFLD activity score (NAS) between 5 and 7, and fibrosis stage of at least 2). Following 12 weeks of treatment with the ELA/SEMA combo, NAS decreased by 3 stages in 14% of mice, and by 2 stages in 44% of mice. This drop was accounted for by a decrease in both steatosis and activity index. None of the mice that received either a low dose of ELA or a low dose of SEMA showed NAS reduction beyond 1 stage. A strong decrease in liver triglycerides (−56%), in the number of inflammatory foci (−59%) and in plasma ALT (−60%), was also observed in the ELA/SEMA arm, corroborating the effect on liver histology. Fibrosis improvement was observed in 29% of animals that received a low dose of ELA. SEMA showed no effect on fibrosis and did not enhance the ELA-induced change when used in combination.
A profound liver transcriptome remodeling was documented. A set of 2194 genes was differentially modulated in the ELA/SEMA combo arm vs 1140 and 55 genes in ELA and SEMA monotherapy arms, respectively. Surprisingly, SEMA treatment only modestly affected the expression of lipid-metabolism-related genes. However, numerous inflammatory genes and especially myeloid cell markers were selectively reduced in animals that received the combination. Further analyses to better characterize ELA/SEMA combo-induced changes in inflammatory infiltrate signature will be presented. In vitro studies to evaluate the direct signaling of both drugs on different myeloid cell populations will be also reported.
Conclusion: Combination of low doses of elafibranor and semaglutide alleviates severe NASH phenotype and liver injury markers in AMLN diet-induced disease model. Transcriptomic studies reveal that ELA and SEMA synergize to specifically reduce the inflammatory infiltration in the liver.

AS015

Therapeutic effect of a novel long-acting GLP-1/GIP/glucagon triple agonist (HM15211) in animal models of NASH and fibrosis

Background and Aims: Nonalcoholic steatohepatitis (NASH) and fibrosis remains a major cause of liver-related mortality. However, no pharmacologic treatment has been approved despite accelerated drug development. Since multiple biological pathways are involved in disease progression, therapeutic approaches simultaneously targeting multiple pathways might be required to effectively treat NASH and fibrosis. To address this, we developed a novel long-acting GLP-1/GIP/Glucagon triple agonist, HM15211. Previously, HM15211 significantly improved steatosis, hepatic inflammation, and fibrosis in diet-induced NASH mouse models of NASH. Here, we further evaluated the anti-inflammation and anti-fibrotic effects in additional animal models of NASH and fibrosis.
Method: NASH and fibrosis mouse model was established by AMLN diet and thioacetamide treatment (AMLN/TAA mice) for 16 weeks, and HM15211 was subcutaneously administered during last 8 weeks. For direct anti-fibrotic effect evaluation, bile duct ligation (BDL)-induced fibrosis mouse model was established, and HM15211 was

administered for 2 weeks. At the end of treatment, the degree of fibrosis was evaluated by hydroxyproline (HP) contents and sirius red staining. Liver tissue samples were subjected to qPCR to determine the expression of relevant markers for inflammation and fibrosis, and blood levels of fibrosis surrogate markers were measured by ELISA.
Results: In AMLN/TAA mice, HM15211 treatment significantly reduced HP content (−53.1% *vs.* Veh.). In addition, the expression of markers for hepatic inflammation (−92.8, −34.7 and −32.7% *vs.* Veh. for F4/80, MCP-1, and IL-6) and fibrosis (−53.9, −41.4, and −51.9% *vs.* Veh. for alpha-SMA, TIMP-1, and collagen1a1) was significantly reduced in HM15211 treated group. Similar reduction in blood levels of TIMP-1, PIIINP and hyaluronic acid (HA) (−49.3, −48.0, and −49.1% *vs.* Veh., respectively) was also observed. In BDL model, HM15211 treatment showed greater reduction in HP content (−33.4 ~ −43.7% and −21.9% *vs.* Veh for HM15211 and OCA), and fibrosis score (1.0, 1.75, and 1.7 for HM15211, OCA and vehicle) compared to obeticholic acid (OCA). Consistently, blood levels of TGF-beta, HA, and TIMP-1 were also significantly reduced by HM15211 treatment.
Conclusion: Based on the beneficial effects in AMLN/TAA and BDL mice, HM15211 may provide therapeutic effects on fibrosis as well as NASH. Human efficacy studies are ongoing to assess the clinical relevance of these findings.

AS016
Combination therapy with a dual CCR2/CCR5 antagonist and a FGF21 analogue synergizes in ameliorating steatohepatitis and fibrosis

Tobias Puengel[1], Sander Lefere[1,2], Jana Hundertmark[3], Christian Penners[1], Frederique Van de Velde[4], Bruno Lapauw[4], Lindsey Devisscher[5], Anja Geerts[2], Stephanie Boehm[6], Zhao Qihong[6], John Krupinski[6], Edgar Charles[6], Bradley Zinker[6], Frank Tacke[3].

Email: tobias.puengel@rwth-aachen.de

Background and Aims: With new drug targets emerging, combination therapies appear attractive to treat NASH and fibrosis. Dual chemokine receptor types 2 and 5 (CCR2/5) antagonists can improve fibrosis by reducing monocyte infiltration and altering macrophage subsets in the liver. Fibroblast growth factor 21 (FGF21) is a non-mitogenic hormone that is a key regulator of lipid and glucose metabolism. A PEGylated FGF21 analogue has been shown to improve steatosis, liver injury and fibrosis markers in NASH patients. We compared effects of combined therapy to single drug treatment in mouse models of acute and chronic liver injury.
Method: We measured serum CCL2 in 85 patients with biopsy-proven NAFLD. We tested a CCR2/5 antagonist (BMS-687681, 45 mpk bid PO or 15 mpk bid in combination) and/or a PEG-FGF21 variant (PEG-FGF21v, BMS-986171, 0.6 mpk biw SC) in male C57BL/6J mice, subjected to either acute liver injury (single carbon tetrachloride injection, CCl_4) or chronic steatohepatitis and fibrosis (choline-deficient, L-amino acid-defined high-fat diet (CDAHFD) for up to 12 weeks).
Results: In NAFLD patients, CCL2 levels correlated with fibrosis severity. In acute liver injury, CCR2/5 antagonist treated mice had significantly lower numbers of circulating and hepatic $Ly6C^+$ inflammatory monocytes and monocyte-derived macrophages (MoMFs). Upon PEG-FGF21v treatment, hepatic MoMF numbers remained unaffected, but ALT and hepatocellular necrosis were reduced. In chronic steatohepatitis, compound dosing was initiated after 6w of CDAHFD, and effects were assessed after either short- (2w) or long-term (6w) treatment. In both regimens, CCR2/5 antagonism reduced MoMF, inflammatory markers and hepatic fibrosis, whereas PEG-FGF21v reduced body weight, liver triglycerides, steatosis, and NASH activity. Combination treatment demonstrated additive benefits of both therapies regarding weight gain, hepatic fat, ALT levels and fibrosis, while combination showed even synergistic effects on NAFLD activity score.
Conclusion: CCR2/5 antagonism blocks inflammatory monocytes infiltration, and treatment with an FGF21 analogue has beneficial effects on metabolism and pathogenic drivers of NASH and fibrosis. Combined therapy ameliorates progressive steatohepatitis and fibrosis more effectively than single drug treatment, corroborating the therapeutic potential of combining these two approaches in patients with advanced NASH.

Background and Aims: Noninvasive identification of patients with dysmetabolism at risk of nonalcoholic fatty liver disease (NAFLD), severe fibrosis and hepatocellular carcinoma (HCC) is a major unmet clinical need. Genetic predisposition plays a major role in determining progressive NAFLD. We previously developed a genetic risk score (GRS) estimating the inherited predisposition to accumulate liver fat based on common variants in *PNPLA3*, *TM6SF2*, *MBOAT7* and *GCKR*. The aim of this study was to examine the accuracy of GRS to stratify the risk of NAFLD, severe fibrosis, and HCC in a multicenter cross-sectional cohort.
Method: We considered 2021 individuals: 464 without liver disease, 1034 with histological NAFLD without severe fibrosis, 275 with NAFLD and severe fibrosis without HCC, and 248 with NAFLD-HCC. All were genotyped for the rs738409 (*PNPLA3* I148M), rs58542926 (*TM6SF2* E167 K), rs641738 C > T at *MBOAT7* and rs1260326 (*GCKR* P446L). Genetic data were combined in the GRS, and association with disease risk was tested by multivariate logistic regression models, adjusted for age, sex, BMI, presence of diabetes (and fibrosis).
Results: In the overall cohort, GRS predicted NAFLD independently of confounders ($p < 10^{-11}$, OR for the upper quartile: 4.22, 95%CI 2.72–6.54), more robustly than the single variants. In patients with

NAFLD, GRS predicted severe fibrosis independently of confounders (p < 10^ −14, OR for the upper quartile 2.96, 95%CI 1.55–5.65), more robustly than the single variants, and the association was also independent of histological NASH. In NAFLD, GRS was also independently associated with HCC (p = 10^ −6, OR for the upper quartile 2.41, 95%CI 1.28–4.54). The AUROC was 0.604 for the GRS, better than the single variants alone. The association between GRS and HCC was independent of NASH, but it was lost after correction for fibrosis severity.

Conclusion: The polygenic GRS improved the accuracy to detect NAFLD, severe fibrosis and HCC compared to single variants. Genetically determined hepatic fat accumulation causes liver fibrosis. Although we could not rule out an independent contribution due to pleiotropic effects of specific variants, predisposition to HCC development seems mainly dependent on the induction of fibrosis. We are currently evaluating whether the GRS can improve the diagnostic accuracy of classical risk factors for NAFLD, severe fibrosis, and HCC.

AS018

Carbohydrate restriction reverses NAFLD by altering hepatic mitochondrial fluxes in humans

Panu Luukkonen[1,2,3], Sylvie Dufour[1,4], Kun Lyu[5], Xian-Man Zhang[1,4], Antti Hakkarainen[6,7], Tiina E. Lehtimäki[6], Gary W. Cline[1,4], Kitt Falk Petersen[1,4], Gerald I. Shulman[1,4,5], Hannele Yki-Järvinen[2,3].

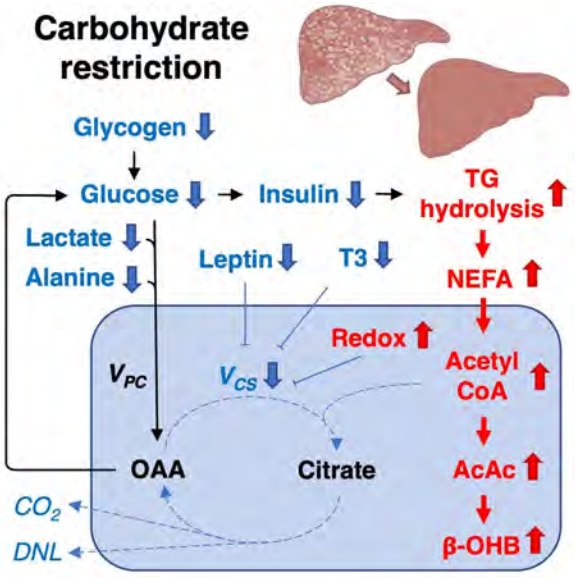
Email: hannele.yki-jarvinen@helsinki.fi

Background and Aims: Carbohydrate restriction (CR) has emerged as an effective dietary regimen in the management of non-alcoholic fatty liver disease (NAFLD), but the underlying intrahepatic mechanisms have remained poorly understood. We examined the mechanisms by which CR improves liver metabolism *in vivo* in humans before and after a 6-day CR diet using Positional Isotopomer NMR Tracer Analysis (PINTA) by infusing of [D_7]-glucose, [$^{13}C_4$]-hydroxybutyrate and [3-^{13}C]-lactate for quantification of rates of endogenous glucose production, ketogenesis and hepatic citrate synthase (V_{CS}) and pyruvate carboxylase (V_{PC}) fluxes.

Method: We performed PINTA in ten overweight/obese participants (mean age 58 ± 2 yrs, BMI 32 ± 2 kg/m^2, 50% men) before and after 6-day CR diet. Compliance was assessed by measuring plasma β-hydroxybutyrate and acetoacetate concentrations and by 3-day food records. Liver fat and stiffness were measured using magnetic resonance spectroscopy and magnetic resonance elastography. Potential regulators of V_{CS}, *i.e.* hepatic mitochondrial redox state (ratio of plasma β-hydroxybutyrate and acetoacetate) and plasma concentrations of leptin and triiodothyronine were also measured.

Results: The CR diet was very low in carbohydrates (183 ± 20 vs. 23 ± 1 g/day, before vs. during the diet, $p < 0.000001$) while intakes of other macronutrients were unchanged, which resulted in decreased energy intake (2019 ± 177 vs. 1444 kcal/day, $p < 0.01$). Plasma β-hydroxybutyrate and acetoacetate concentrations increased by 10-fold and 6-fold, and body weight decreased by 3% during the diet (all $p < 0.001$). The CR diet markedly decreased rates of endogenous glucose production (−22%), serum insulin concentrations (−53%) and liver fat content (−31%, all p < 0.001). The latter was attributed to increased mobilization of fatty acids (+35%), increased rates of ketogenesis (+232%), and decreased rates of V_{CS} (−38%, all p < 0.001) which together with reduced serum insulin concentrations limits hepatic lipogenesis. Reduced hepatic V_{CS} was associated with increased mitochondrial redox state as determined by ratio of plasma β-hydroxybutyrate and acetoacetate (+167%) and decreased plasma leptin (−45%) and triiodothyronine (−21%) concentrations.



Conclusion: We demonstrate heretofore undescribed mechanisms by which carbohydrate restriction reverses NAFLD in humans, *i.e.* by altering hepatic mitochondrial fluxes to promote hepatic fatty acid disposal.

Liver tumour – Basic

AS019

TREM2 protects the liver against hepatocellular carcinoma through multifactorial protective mechanisms

Background and Aims: Hepatocellular carcinoma (HCC) represents the 6th most common cancer world-wide and the 3rd cause of cancer-related mortality. HCCs arise in a background of chronic liver diseases where chronic inflammation and regeneration play a pivotal role. We have previously shown that the triggering receptor expressed on myeloid cells 2 (TREM2) protects the liver from hepatotoxic injury, via its negative regulation of toll-like receptor (TLR)-derived signalling in non-parenchymal liver cells. However, its role in liver cancer is still far from clear. Here, the role of TREM2 in hepatocarcinogenesis and liver regeneration was investigated.
Method: TREM2 expression was analysed in liver tissue of patients with HCC from 2 independent cohorts compared to control individuals. Wild type (WT) and *Trem2*$^{-/-}$ mice were subjected to experimental models of HCC and liver regeneration. *In vitro* studies with hepatic stellate cells (HSCs) and HCC spheroids were conducted.
Results: *TREM2* expression is increased in liver tissue of patients with HCC compared to normal liver tissue. Interestingly, TREM2 expression positively correlates with immune cell infiltration (macrophages, NKT cells, dendritic cells and B cells, among others) and activated HSC markers in human HCC tumours. In addition, *Trem2* expression was induced in the livers of mice subjected to DEN-induced carcinogenesis (a mouse model of HCC) and to partial hepatectomy (mouse model of liver regeneration). *Trem2*$^{-/-}$ mice developed more liver tumours after diethylnitrosamine (DEN) administration, which was associated with exacerbated liver damage, inflammation, oxidative stress and hepatocyte proliferation. Moreover, *Trem2*$^{-/-}$ livers showed increased hepatocyte proliferation and inflammation after partial hepatectomy. *Trem2*$^{-/-}$ mice also exhibited enhanced carcinogenesis in fibrosis-associated HCC models. Specifically, *Trem2*$^{-/-}$ mice displayed more small tumours after DEN + CCl4 injections and increased tumour volume after 40 weeks of TAA treatment. Administration of an anti-inflammatory diet blocked DEN-induced hepatocarcinogenesis in *Trem2*$^{-/-}$ mice. The supernatant of human hepatic stellate cells overexpressing TREM2 inhibits human HCC spheroid growth *in vitro*.
Conclusion: *TREM2* in non-parenchymal cells protects the liver from hepatocarcinogenesis, representing a novel promising therapeutic target.

Email: myojin@gh.med.osaka-u.ac.jp

Background and Aims: Autophagy in hepatoma cells is supposed to promote the progression of cancer. However, the effect of autophagy in hepatic stellate cells (HSCs) on hepatocellular carcinoma (HCC) has not yet been clarified.
Method: HepG2 cells and HuH7 cells were used as human hepatoma cells and LX-2 cells as human HSCs. Autophagy was examined from the ratio of the fluorescence intensities of GFP and RFP using LX-2 cells overexpressing GFP-LC3-RFP-LC3ΔG probe. Atg7 knockout or GDF15 knockout LX-2 cells were generated by CRISPR Cas9. HSC-specific Atg7 knockout (G-Atg7 KO mice) mice were generated by crossing GFAP-Cre mice and Atg7 fl/fl mice. These mice were administered streptozotocin at the age of 2 days, followed by a high-fat diet feeding. Human HCC samples were analyzed by single-cell RNA sequence (scRNAseq).
Results: When co-culturing LX-2 cells with hepatoma cells, autophagy in LX-2 cells was promoted, and cell viability in hepatoma cells was increased. Atg7 knockout in LX-2 cells attenuated the proliferation effect on hepatoma cells when co-culturing. HepG2 cells, but not LX2 cells, were successfully engrafted into NOG mice. The growth of xenograft tumor of HepG2 cells in NOG mice was accelerated by co-transplantation with LX-2 cells. The acceleration was suppressed by Atg7 KO in LX-2 cells. Wild-type (WT) mice or G-Atg7 KO mice were administrated with streptozotocin and fed a high-fat diet. Atg7 was efficiently inhibited in stellate cells isolated from G-Atg7 KO mice. At 20 weeks of age, there was no significant difference in body weight, adipose tissue weight, blood glucose level, serum ALT and insulin levels between them. The macroscopic tumor formation rate was lower in G-Atg7 KO mice than WT mice. The maximum size of liver tumors was significantly suppressed in G-Atg7 KO mice (2.0 ± 2.1 mm v.s. 10.0 ± 5.8 mm (p = 0.002)) with decrease in ASMA positive cells in tumor lesions. The number of liver tumors was also significantly suppressed in G-Atg7 KO mice. To examine the mechanism by which HSC autophagy promotes HCC growth, RNA expression was analyzed by RNA sequence after co-culturing. It revealed several genes expression levels significantly elevated in LX-2 cells co-cultured with HepG2 cells. Among them, GDF15 changed most drastically, and that was attenuated by Atg7 knockout in LX-2 cells. The concentration of GDF15 in supernatant of co-culturing cells was higher than that of mono-culturing LX-2 cells or HepG2 cells. GDF15 knockout in LX-2 cells attenuated the proliferation effect on HepG2 cells in co-culturing and xenograft model. In clinical specimens, serum GDF15 concentration correlated with the prognosis of HCC patients and scRNAseq showed that HSCs existed in HCCs and HSCs in tumorous lesion expressed GDF15 more than HSCs in non-tumorous lesion.
Conclusion: HCC promotes autophagy in HSCs, which modulates secreted proteins such as GDF15, leading to progression of HCCs.

AS021
Phospholipid metabolism rewiring in liver regeneration and hepatocellular carcinoma

Zoe Hall[1], Jack Leslie[2], Emma Scott[2], Davide Chiarugi[3], Evelina Charidemou[3], Luca Pelligrinet[3], Gerard Evan[3], Michael Allison[4], Antonio Vidal-Puig[3], Quentin Anstee[2], Matthew Hoare[5], Fiona Oakley[2], Julian Griffin[1], Michele Vacca[3]. [1]*Imperial College London;* [2]*Newcastle University;* [3]*University of Cambridge;* [4]*Addenbrooke's Hospital, Cambridge Biomedical Research Centre;* [5]*CRUK Cambridge Institute*
Email: mv400@medschl.cam.ac.uk

Background and Aims: Hepatocytes undergo profound metabolic rewiring when primed to proliferate during compensatory regeneration. Aberrant hepatocyte proliferation in chronic liver disease is also a driving cause of hepatocellular carcinoma (HCC), one of the leading causes of cancer-related deaths world-wide. Characterising the metabolic remodelling occurring in hepatocytes undergoing compensatory regeneration and in HCC is a crucial step to identify metabolic pathways that relate to cell proliferation in general and, more specifically, to hepatocellular carcinogenesis.
Method: In order to capture the metabolic signature of proliferating hepatocytes, we applied state-of-the-art systems biology approaches to models of liver regeneration (partial hepatectomy and acute carbon tetrachloride models), pharmacologically-(phenobarbital) and genetically (c-Myc inducible)-activated cell proliferation, and both mouse (DEN) and human HCC (on a fatty liver background). We integrated metabolomics, lipidomics and transcriptomics data, performed metabolic flux analysis and used mass spectrometry imaging (MSI) to study metabolic remodelling.
Results: An increase in monounsaturated fatty acid (MUFA)-containing phosphatidylcholine (PC) was measured by lipidomics in all the models (Fig. 1A), and confirmed by MSI in HCC (Fig. 1B). We integrated data from lipidomics, metabolomics and transcriptomics to link these changes in lipid content to lipid metabolism pathways. These included increased lipogenesis, fatty acyl desaturation and de novo synthesis of PC, as well as decreased beta-oxidation. We confirm this altered lipid signature in human HCC and show a strong positive correlation of MUFA-PC with key genes involved in proliferation and

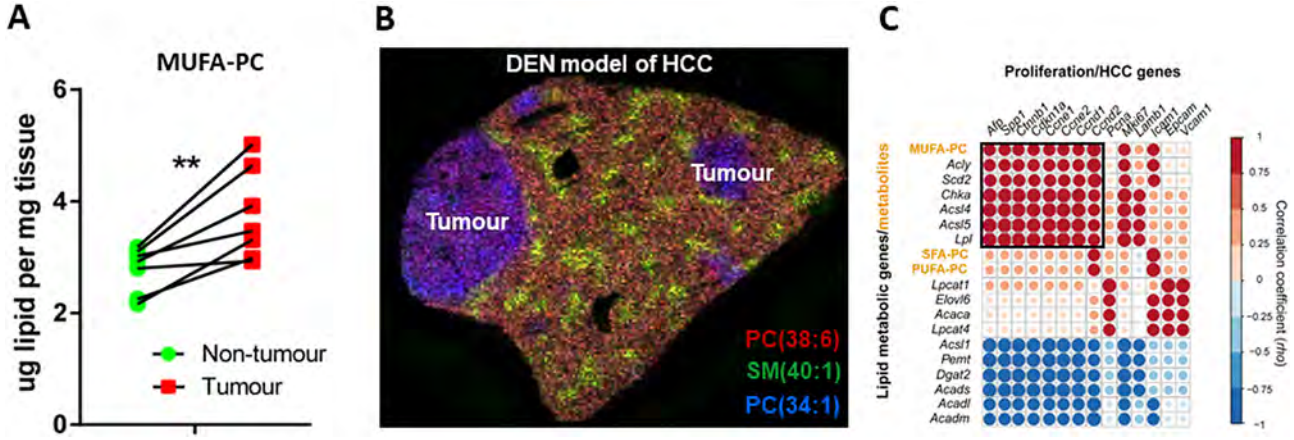

Figure: (abstract: AS021)

cell cycle control, as well as with other known genetic markers of hepatocellular carcinogenesis (Fig. 1C).
Conclusion: Overall, we demonstrate that lipid metabolic pathways are coherently altered, when hepatocytes switch to proliferation in murine and human models of compensatory regeneration and HCC. Hepatic MUFA-PC content closely correlates with markers of proliferation and hepatocellular carcinogenesis. We thus speculate that MUFA-PC and lipid imaging have the potential to offer new diagnostic and prognostic strategies for HCC. Our results also represent a source of targets for the development of new therapeutic strategies.

Email: maavila@unav.es

Background and Aims: Hepatoblastoma (HB) is the most frequent pediatric tumor affecting the liver and albeit a rare tumor its incidence has increased four-fold in the past few decades. Surgical resection forms the mainstay treatment which frequently is preceded by neoadjuvant chemotherapy (cisplatin or doxorubicin). There is a significant proportion of patients (30%) presenting with advanced disease or more aggressive and chemoresistant variants with very poor prognosis. Molecularly, HB presents a surprisingly low mutation rate and very few genetic alterations, suggesting that epigenetic dysregulation plays a key role in HB development and progression. In the present work we have evaluated the functional relevance of the epigenetic complex constituted by DNA methyltransferase 1 (DNMT1), the histone methyltransferase G9a and the adapter molecule UHRF1 in HB and evaluated the *in vitro* therapeutic efficacy of a first-in-class substrate-competitive dual G9a-DNMT1 inhibitor.
Method: G9a, DNMT1 and UHRF1 mRNA levels were examined in a molecularly well-characterized set of HB samples (n = 32) and non-tumor tissues (n = 18) by qPCR. Anti-HB efficacy of our G9a/DNMT1 inhibitor lead compound, CM272, was tested in HepG2 and HuH6 cells, and in a unique collection of patient-derived HB cell lines, alone and in combination with cisplatin. Transcriptomic studies and epigenetic analyses of DNA and H3K9 methylation on selected genes were performed.
Results: A significant and correlative overexpression of G9a, DNMT1 and UHRF1 was observed in HB samples in association with poor prognosis. All cell lines showed very high sensitivity to CM272 (GI_{50}: 100–300nM). Mechanistically, there was a robust reinduction of tumor suppressor genes silenced in HB, such as HHIP, SFRP1, IGFBP3 or RASSF1A as well as a drastic decrease in the expression of genes involved in key metabolic pathways for tumor progression, such as HK-II, PKM2, LDHA or PHGDH. DNA hypermethylation and H3K9me2 levels at RASFF1A promoter were reduced upon CM272 treatment. CM272 significantly sensitized HB cells to cisplatin.
Conclusion: The epigenetic complex G9a-DNMT1-UHRF1 plays an important role in HB. Its pharmacological targeting with a dual inhibitor like CM272 can be promising antitumor strategy alone or in combination with current chemotherapeutic agents.

AS023
Analysis and prediction of cholangiocarcinoma from transcriptomic profile of patients

Harpreet Kaur[1,2], Sherry Bhalla[2], Divya Garg[2], Nikhil Mehta[2], Gajendra P. S. Raghava[2]. *[1]CSIR-Institute of Microbial Technology, Bioinformatics Center, Chandigarh, India; [2]Indraprastha Institute of Information Technology, Department of Computational Biology, New Delhi, India*
Email: raghava@iiitd.ac.in

Background and Aims: Cholangiocarcinoma (CCA) is the second most common type of primary malignancies of the liver after Hepatocellular carcinoma (HCC), accounts for 15–20% of liver cancer cases. Earlier, numerous studies mainly focussed on the identification of signatures and drug-targets for HCC; while only limited attempts made to scrutinize signatures for CCA. Previously, it has been shown that CCA and HCC have different carcinogenic mechanisms using metabolomic and transcriptomic profiles of ten HCC and six CCA patients. Thus, HCC biomarkers cannot be employed for CCA diagnosis. Thus, the recognition of CCA-specific transcriptomic signatures is vital for accurate CCA diagnosis. Hence, the current study is an attempt to fill this lacuna.
Method: Eight datasets containing a total of 350 CCA, 133 adjacent-non-tumorous and 90 HCC samples, were downloaded from GEO. Six

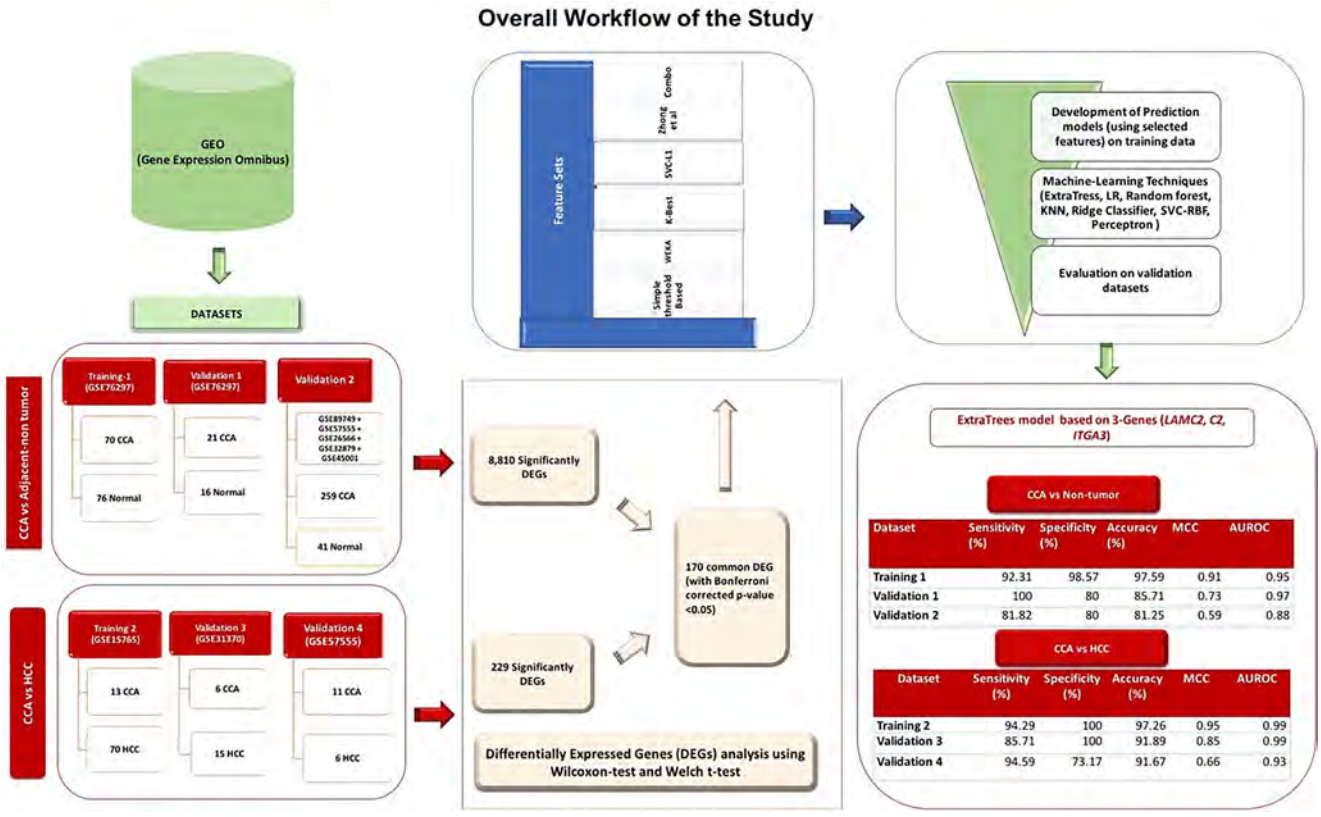

Figure: (abstract: AS023)

and three datasets used for CCA vs. non-tumorous and CCA vs. HCC analysis, respectively. Datasets partitioned into training and validation datasets, subsequently, pre-processed to apply statistical and bioinformatics analysis. Differentially Expressed Genes (DEGs) with Bonferroni-corrected p-value<0.05, identified by applying Wilcoxon and Welch t-test. Further, a Simple threshold-based approach, SVC-L1, *etc*. were used to select a signature-set with the minimum number of genes. Thereafter, several prediction models developed employing training dataset based on selected signature sets using different machine-learning techniques. Eventually, the performance is evaluated on validation datasets.

Results: Firstly, 170 common significantly DEG identified between CCA vs. non-tumorous and CCA vs. HCC samples. Subsequently, various machine-learning prediction models developed using different combinations of selected genes. ExtraTrees model based on three genes (*LAMC2, C2, ITGA3*) classified CCA from non-tumorous samples of the training dataset with accuracy 97.26% and AUROC 0.99, while, predicted samples of validation datasets with the accuracy of ~ 91% and AUROC 0.93–0.99. In addition, ExtraTrees model based on these three-genes categorized CCA from HCC samples of training dataset with an accuracy of 97.59% and AUROC 0.95, and of validation datasets with an accuracy of 81.25–85.71% and AUROC 0.88–0.97, respectively.

Conclusion: Prediction models developed based on three genes categorized CCA with high precision. Thus, they can be further explored for their diagnostic and therapeutic potential for CCA.

AS024

Single cell RNA sequencing and functional in vivo genetic manipulation reveal heterogeneity and tumor-promoting roles of cancer-associated fibroblasts in intrahepatic cholangiocarcinoma

Background and Aims: Intrahepatic cholangiocarcinoma (ICC) is a desmoplastic tumor with abundant cancer-associated fibroblasts (CAF). With limited therapeutic options, there is growing interest in targeting CAF in ICC. Studies in other tumors have shown that CAF may promote or restrict tumor growth, possibly related to tumor or CAF heterogeneity. In ICC, CAF functions and heterogeneity remain largely unknown. Here, we aimed to dissect cellular origin, diversity and functions of CAF in ICC by single cell RNA-sequencing (scRNA-seq), and by *in vivo* CAF depletion or Cre-lox-based genetic CAF tracing and manipulation.

Method: ICC was induced by sleeping beauty-mediated expression of pT3-myrAKT-HA and pT3-YAP127SA or pT3-KrasG12D and Crisp/Cas sg-p19 by hydrodynamic injection. CAF origin and heterogeneity were analyzed in mice expressing Col1a1-GFP (labeling all CAF); LratCre and TdTom reporter (labeling hepatic stellate cells = HSC), and

by scRNA-seq using 10x Genomics. CAF functions were studied by CAF depletion in LratCre x iDTR or aSMA-TK mice, and by HSC-selective knockout of several ECM members including Col1a1, Wnts, RelA and growth factors via LratCre. Ki67, cleaved caspase 3 and CD3 were analyzed by IHC.

Results: LratCre tracing as well as scRNA-seq in 2 ICC models with different mutation profiles, showed that HSC contribute >85% of CAF. scRNAseq revealed multiple CAF subpopulations, including inflammatory (iCAF, 43%), myofibroblastic (myCAF, 36%), antigen-presenting CAF (apCAF, 2%) and mixed-marker CAF (19%). HSC markers segregated with iCAF and myCAF populations, whereas portal fibroblasts markers segregated with apCAF. Genetic CAF depletion strongly reduced ICC growth, mediated by reduced proliferation and increased apoptosis but not by CD3+ T cell infiltration. Deleting Col1a1 by LratCre (constitutive) or MxCre (inducible) reduced liver stiffness but did not reduce tumor growth. scRNA-seq revealed distinct candidates in myCAF and iCAF, suggesting a tumor-promoting role of specific ECM components in myCAF and growth factors in iCAF, which was functionally confirmed by *in vivo* studies.

Conclusion: Our data unveil CAF heterogeneity in ICC and show a tumor-promoting role of HSC-derived-CAF. Tumor promotion is mediated by iCAF and myCAF through distinct mediators. Surprisingly, type I collagen and stiffness do not contribute to the growth of this highly desmoplastic tumor. In summary, our studies point towards CAF as a novel therapeutic target in ICC.

Introduction of "reflex" AST testing in primary care increases detection of advanced liver disease: the Gwent AST project (GAP)

Andrew Yeoman[1], David Samuel[1], Dr. Fidan Yousuf[1], Marek A. Czajkowski[2], Sally Venn[3], Jane Salmon[4], Nadia El-Farhan[2], Moises Hernandez[5]. [1]*Aneurin Bevan University Health Board, Hepatology, Newport, United Kingdom;* [2]*Aneurin Bevan University Health Board, Clinical Biochemistry, Newport, United Kingdom;* [3]*Aneurin Bevan University Health Board, Primary Care Division, Caerleon, United Kingdom;* [4]*Public Health Wales, Health Protection Division, Cardiff, United Kingdom;* [5]*Aneurin Bevan University Health Board, Clinical Biochemistry*
Email: yeoman_andrew@hotmail.com

Background and Aims: The incidence and mortality from chronic liver disease in the general population continues to increase. Previous studies have suggested that abnormal liver blood tests are frequently not followed up in primary care and historical clinical practice based on societal has not routinely incorporated assertive fibrosis testing although the recent BSG abnormal liver blood test guidance from 2017 aims to address this.
Method: In 2016 we set out to improve the recognition of significant liver disease through the reflex use of AST testing in the context of an elevated ALT. This work was commissioned by the Wales Liver Plan as a pilot, proof of concept service development pathway. This pathway Figure: facilitated automatic calculation of the AST:ALT ratio and advice to refer for further assessment (predominantly via Fibroscan) if the ratio was >1. We report here the 2 year experience of this pathway on the diagnosis of advanced fibrosis and cirrhosis.

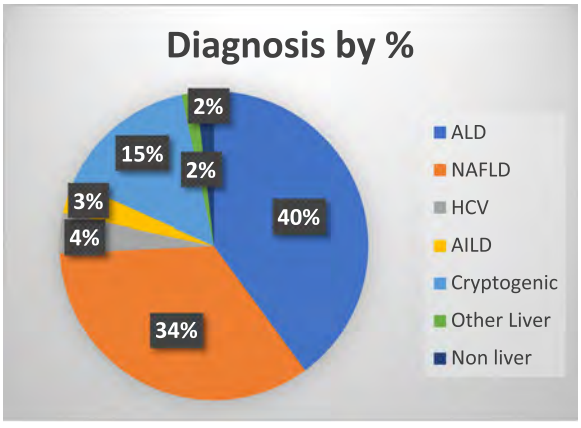

Figure: Clinical Diagnosis in Patients Undergoing Fibroscan.

Results: 17,770 individuals had an elevated ALT. Of these, 2,117 (12%) had an AST:ALT ratio >1. Of these patients, 750 were referred from primary care. 348 underwent Fibroscan. A significant number of patients (approximately 40%) did not attend (DNA) a Fibroscan appointment. In patients undergoing Fibroscan 43% had a reading <8 kPa, 28% were 8–15 kPa and 29% >15 kPa. The commonest cause of liver disease was NAFLD in 49% and Alcohol in 40% In total, 192 cases of advanced fibrosis were identified through this pathway and there has been an 81% increase in coded diagnoses of cirrhosis since its introduction. Furthermore, a further 33 patients who were not originally referred have subsequently received a liver diagnosis (28 with cirrhosis or HCC).
A FIB 4 score was calculable in 13,626 individuals and was >1.3 in 47% which would potentially lead to a 4 fold increase in secondary testing compared with an AST:ALT ratio >1.
Conclusion: Introduction of reflex AST testing and calculation of the AST:ALT ratio in primary care has led to a significant increase in new diagnoses of cirrhosis. However, GP compliance with the pathway was low and further work is required to improve this as well as providing better community access to Fibroscan testing to reduce the DNA rate. Future work will also explore the utility of reducing the AST: ALT threshold to 0.8 as some cases of advanced fibrosis may have been missed by utilising the higher threshold.

GS09

Monoacylglycerol lipase reprograms lipid metabolism in macrophages and hepatocytes to promote liver regeneration

Manon Allaire[1,2], Matthieu Siebert[1], Rola Al-Sayegh[1], Morgane Mabire[1], JingHong Wan[1], Benjamin Morin[1], Maude Le Gall[1], Sophie Lotersztajn[1], Hélène Gilgenkrantz[1]. [1]*UMR 1149, centre de recherche sur l'inflammation, Paris, France;* [2]*AP-HP, Groupe Hospitalier Pitié-Salpêtrière-Charles Foix, Service d'Hépatologie, Paris, France*
Email: allama5@hotmail.fr

Background and Aims: Monoacylglycerol lipase (MAGL) is a proinflammatory enzyme that reprograms lipid metabolism by converting monoacylglycerols into free fatty acids, in particular arachidonic acid. We have previously shown that MAGL displays pro-inflammatory and profibrogenic functions in the liver. Since a delicate balance exists between regeneration and fibrosis, and because both parenchymal and non-parenchymal cells participate to tissue repair, in the present study we studied the impact of MAGL on liver regeneration, and investigated the respective contribution of hepatocytes and immune cells.
Method: Liver regeneration was induced by 2/3 partial hepatectomy (PH) or acute intraperitoneal injection of carbon tetrachloride (CCl_4). Mice with genetic ($MAGL^{-/-}$) or pharmacological (using MJN110) invalidation of MAGL were used, as well as mice bearing MAGL invalidation in myeloid cells ($MAGL^{Mye-/-}$), lymphocytes ($MAGL^{Lympho-/-}$) or hepatocytes ($MAGL^{Hep-/-}$), and their control counterparts (WT). *In vitro* studies were conducted on bone marrow derived macrophages (BMDM) and primary hepatocytes.
Results: Mice with global invalidation of MAGL, or exposed to the pharmacological MAGL inhibitor MJN 110 showed impaired liver regeneration following PH or acute injection of CCl_4, reflected by a lower number of BrdU+ hepatocytes and reduced Cyclin A expression. MAGL global inhibition was associated with a lower production of PGE2 and reduced mRNA expression of TGF-α, IL-17 and HGF after injury. A similar impairment of liver regeneration was also observed in mice bearing a specific MAGL deletion in hepatocytes or in myeloid cells. In $MAGL^{Mye-/-}$ mice, liver regeneration defect was associated

ELSEVIER

with a decrease in hepatic TNF production. Mice with MAGL deletion in lymphocytes showed similar hepatocyte proliferation than WT counterparts.
In vitro studies further confirmed that primary hepatocytes exposed to MJN110 or isolated from $MAGL^{-/-}$ mice displayed lower proliferative index compared to control hepatocytes, and decreased PGE2 production. Finally, LPS-stimulated BMDM isolated from $MAGL^{Mye-/-}$ mice or from wild type mice but exposed to MJN110 displayed reduced TNF secretion compared to their respective control.
Conclusion: Inhibition of MAGL is associated with compromised liver regeneration, that results both from a direct effect on hepatocytes and an indirect effect on macrophages Thus, while being profibrogenic, MAGL displays pro-regenerative capacities in the liver.

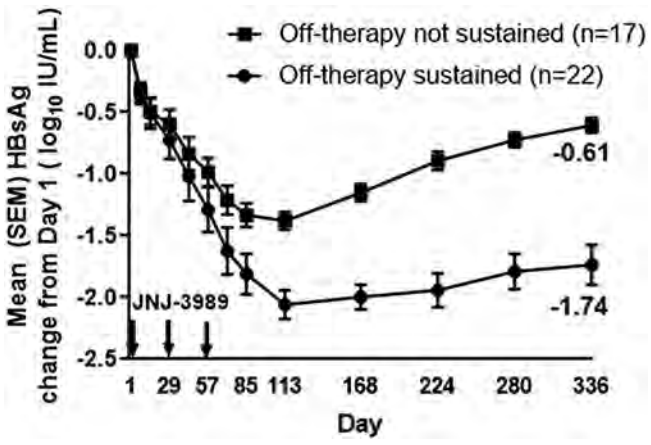
Email: tschluep@arrowheadpharma.com

Background and Aims: RNA interference (RNAi) therapy with JNJ-3989 silences HBV RNA transcripts from episomal cccDNA and integrated HBV DNA. In AROHBV1001 (phase 2a), JNJ-3989 (3 monthly doses 25–400 mg) + a nucleos(t)ide analogue (NA) demonstrated antiviral activity in patients (pts) with chronic hepatitis B (CHB) by reducing serum viral parameters (AASLD 2019). 9-month follow-up data for pts on ≥100 mg are presented.
Method: 8 CHB pts/cohort (NA experienced or naïve; HBeAg +ve or –ve) received 3 subcutaneous JNJ-3989 doses (days 1, 27, 57) of 100, 200, 300 (n = 16) or 400 mg. Pts started/continued with an NA on day 1 and continued throughout the study. Safety and viral parameters (HBsAg, HBeAg, HBV DNA, HBV RNA, HBcrAg) were assessed. For all parameters, sustained suppression was defined as a ≥1.0 $\log_{10}$ reduction from day 1 or a value <lower limit of quantification at day 336.
Results: 40 pts were enrolled: 73% males; 85% Asian; median age 45 (26–66) yrs; HBeAg: 14 +ve, 26 –ve; 80% NA experienced. No deaths, treatment discontinuations or drug-related serious adverse events (AEs) were seen; 1 pt was lost to follow up. The most common drug-related AEs were mild injection site AEs (7 pts). One AE of elevated ALT (peak 136 U/L) was reported. HBsAg levels rapidly declined during treatment. At the HBsAg nadir, 39/40 pts had a ≥1.0 $\log_{10}$ HBsAg reduction from day 1; range 1.11–3.77; for 1 pt the maximum decline was 0.77 $\log_{10}$. Mean nadir for HBsAg (SE) $\log_{10}$ reduction from day 1 was 1.72 (0.18; 100 mg), 1.79 (0.14; 200 mg), 2.04 (0.20; 300 mg; 11/16 HBeAg +ve) and 1.90 (0.18; 400 mg). 22/39 (56%) pts had sustained HBsAg reductions (≥1.0 $\log_{10}$ reduction at day 336, ~9 months after last JNJ-3989 dose, Fig); mean (SE; range) HBsAg reductions in pts with sustained suppression were: 1.74 (0.77; 1.00–3.38) vs 0.61 (0.06; 0.15–0.96) for non-sustained suppression. For pts with quantifiable parameters on day 1 and available data at day 336, a sustained suppression was observed for HBV RNA in 15/26, HBeAg in 9/14 and HBcrAg in 10/24 pts.



Conclusion: JNJ-3989 (100–400 mg) with an NA was well tolerated in CHB pts. A ≥1.0 $\log_{10}$ reduction in HBsAg at nadir was achieved in 98% of pts. A subset of pts had sustained suppression of HBsAg ~9 months after the last RNAi dose (mean 1.74); sustained suppression of other viral parameters was also seen. Studies with longer term dual therapy (48 weeks) and triple therapy including a capsid assembly modulator are underway.

Email: olivier.govaere@newcastle.ac.uk

Background and Aims: Although low-grade chronic hepatic inflammation (steatohepatitis) plays a key role in the pathogenesis of NAFLD, there is substantial inter-patient variation in its occurrence and the molecular regulators controlling obesity-associated

inflammation and consequent disease progression remain incompletely defined. Recent data showed that pro-inflammatory activation of macrophages by saturated fatty acids is independent of Toll-like receptor 4, yet the receptor that is responsible is still not known. In this study we aim to investigate the role of the phagocytic receptor, macrophage scavenger receptor 1 (MSR1, also known as SR-A or CD204), in NAFLD by combing human transcriptomic and genetic data with transgenic mouse models and *in vitro* assays.

Method: For the histopathological and transcriptomics nanoString® study, 214 liver and adipose tissue samples from Caucasian patients were included. For the Genome Wide Association Study, 1,483 patients with histological proven NAFLD were included recruited at different European centres. Quantitative trait analysis was done using the UKBiobank cohort. *Msr1*$^{-/-}$ and Wt mice were fed or high-fat and high-cholesterol diet. Tissue-specific macrophages were isolated using magnetic beads or FACS; bone marrow-derived macrophages (BMDMs) were co-cultured with or adipocyte-like or hepatoma cells in the presence of lipids. Read-out was based on histological and biochemical results, Seahorse and mass-spectrometry.

Results: We show that MSR1 expression in the liver of human NAFLD patients is associated with a greater disease activity and the occurrence of hepatic lipid-laden foamy macrophages. Mice lacking Msr1 are protected against diet-induced metabolic disorder, showing less hepatic inflammation and fibrosis, reduced circulating fatty acids, hepatic triglycerides levels and more lipid storage in the adipocytes. Moreover, MSR1 triggers the inflammatory activation of liver macrophages *in vivo* and *in vitro* in the presence of lipids in a JNK-dependent manner. We further demonstrate that MSR1 induces lipid-induced inflammation independent of lipopolysaccharide. Using a cohort of 1,483 European Caucasian patients with histologically-proven NAFLD and 17,781 European general-population controls, we identified 4 SNPs at the *MSR1* locus with a p-value<5*10^{-4}, with rs41505344 as the most significant. Quantitative trait analysis for rs41505344 in 430,101 patients enrolled in the UKBiobank showed a significant correlation with serum triglycerides and ALT levels.

Conclusion: Our data suggest a critical role for MSR1 as a sensor for lipid homeostasis and a potential therapeutic target for the treatment of NAFLD.

Long-term patient and graft survival after liver transplantation for autoimmune hepatitis

Melina Heinemann[1], René Adam[2], Marina Berenguer Haym[3], Darius F. Mirza[4], Seyed Ali Malek-Hosseini[5], John G. O'Grady[6], Ernest Hidalgo[7], Johann Pratschke[8], Karim Boudjema[9], Andreas Paul[10], Krzysztof Zieniewicz[11], Jiri Fronek[12], Karl Heinz Weiss[13], Vincent Karam[2], Christophe Duvoux[14], Ansgar Lohse[15,16], Christoph Schramm[15,16]. *[1] University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]AP-HP Paul Brousse Hospital, University of Paris-Sud, Villejuif, France; [3]La Fe University Hospital and Ciberehd, University of Valencia, Valencia, Spain; [4]Queen Elizabeth Hospital, Birmingham, United Kingdom; [5]Shiraz University of Medical Sciences, Shiraz, Iran; [6]King's College Hospital NHS Foundation Trust, London, United Kingdom; [7]The Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [8]Charité - Universitätsmedizin Berlin, Berlin, Germany; [9]Pontchaillou University Hospital, Rennes, France; [10]University Hospital Essen, Essen, Germany; [11]Medical University of Warsaw, Warsaw, Poland; [12]Institute for Clinical and Experimental Medicine, Prague, Czech Republic; [13]University Hospital Heidelberg, Heidelberg, Germany; [14]University Hospital of Henri-Mondor, Creteil, France; [15]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [16]European Reference Network for Hepatological Diseases (ERN-RARE-LIVER)*
Email: c.schramm@uke.de

Background and Aims: Autoimmune hepatitis (AIH) is an autoimmune liver disease requiring liver transplantation (LT) in a subgroup of patients (AIH-LT). In these patients, data on long-term outcomes is scarce. The aim of this study was to assess long-term patient and graft survival after AIH-LT from the prospective multicentric European Liver Transplant Registry (ELTR).

Method: The ELTR database was screened for patients who received AIH-LT between 1998 and 2017. In total, n = 2,515 patients were identified and included in the analysis. As controls, patients were included who underwent LT during the same time as a consequence of the other autoimmune liver diseases primary biliary cholangitis (PBC-LT, n = 3,733) and primary sclerosing cholangitis (PSC-LT, n = 5,155), and for alcoholic liver cirrhosis (ALC-LT, n = 19,567). Survival was analyzed using the Kaplan-Meyer method and Cox proportional hazards regression.

Results: AIH-LT resulted in an actuarial patient survival of 79.4%, 70.9% and 60.6% and an actuarial graft survival of 73.2%, 63.4% and

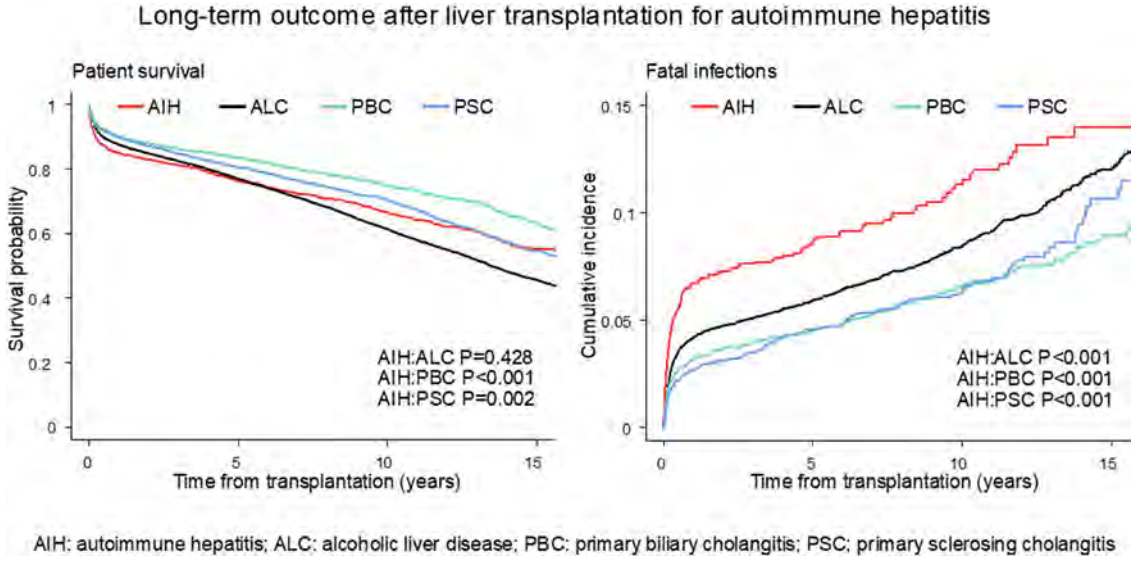

Figure: (abstract: GS12)

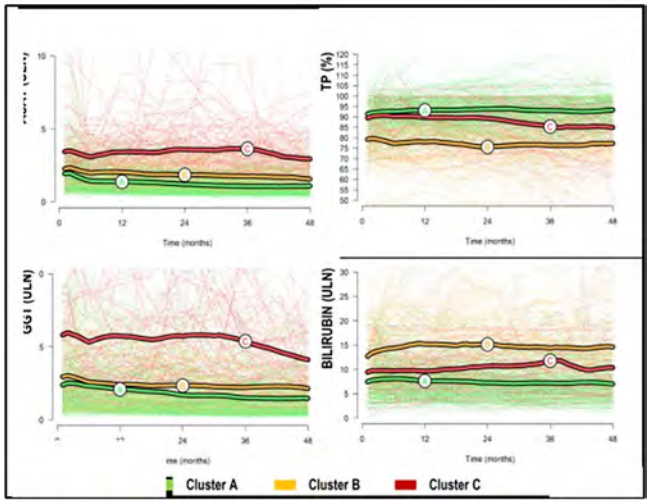
50.9% after 5, 10 and 15 years of follow-up, respectively. Overall survival of patients after AIH-LT was comparable to patients after ALC-LT ($p = 0.428$), but inferior compared to patients after PBC-LT (hazard ratio [HR] = 1.48, $p < 0.001$) and PSC-LT (HR = 1.18, $p = 0.002$). Patients after AIH-LT showed an increased risk of death within 5 years of follow-up compared to all other groups (HR = 1.13–1.56, $p \leq 0.031$). AIH-LT patients had an increased hazard of death (HR = 1.37–1.84, $p < 0.001$) and graft loss (HR = 1.38–1.88, $p \leq 0.002$) as a consequence of infections. In particular, patients after AIH-LT showed a greatly increased risk for lethal fungal infections (HR = 3.24–4.02, $p < 0.01$). All deaths from fungal infections affecting AIH-LT patients occurred during the first year of follow-up. Patients with AIH receiving a living donor LT showed a decreased survival compared to AIH-LT patients who received donation after brain death (HR = 1.93, $p = 0.001$).
Conclusion: Survival of patients after AIH-LT was inferior compared to all other patient groups within the first 5 years after LT. This was mainly explained by an increased incidence of early lethal infections, including fungal infections. After 5 years of follow-up the prognosis of patients after AIH-LT improved considerably compared to the control groups.

GS13
Profiling of routine serum parameters and AFP evolution in cirrhosis following HCV eradication for stratification of HCC risk: a trajectory clustering analysis from the ANRS CO12 CirVir cohort
Pierre Nahon[1], Layese Richard[2], Carole Cagnot[3], Stanislas Pol[4], Tarik Asselah[4], Etienne Audureau[2]. [1]*Hepatology, APHP, Bondy, France;* [2]*APHP, Santé Publique, Créteil, France;* [3]*ANRS, Paris, France;* [4]*APHP, Paris, France*
Email: pierre.nahon@aphp.fr

Background and Aims: HCC surveillance following HCV eradication in patients with cirrhosis needs to be refined to tailor personalized management and increase cost-effectiveness. Our study aimed to identify specific longitudinal profiles of routine serum parameters (RSP) and AFP evolution before and after HCV eradication in patients with cirrhosis which could be associated with higher risk of HCC occurrence.
Method: Data were driven from the French ANRS CirVir multicenter prospective cohort of patients with biopsy-proven viral compensated cirrhosis included in semi-annual HCC surveillance programs. Serum AFP and RSP (ALT, AST, GGT, PT, albumin, bilirubin, platelets) were assessed every 6 months. For the present analysis, only patients with at least 3 available AFP and RSP repeated measurements per trajectory analysis (i) no/before SVR, (ii) after SVR achievement) were included. Trajectory analysis was based on a k-means approach for clustering individuals with similar trajectories of AFP and RSP over time.
Results: After a median follow-up of 74.2 months, 717 patients with active HCV replication at baseline and 413 achieving SVR during follow-up were included, of whom 142 and 47 patients developed HCC, respectively. Before SVR achievement, trajectory analysis identified 3 clusters of patients with common AFP and RSP evolution, with profiles characterized by increasing AFP and the highest GGT/ALT/AST levels (cluster A, n = 190; HCC incidence during follow-up 25.3%), a globally worsening liver function (cluster B, n = 198; HCC 26.8%), or overall more favorable and stable levels over time (Cluster C, n = 329; HCC 12.5%, $p < 0.0001$). In the 413 patients who achieved SVR, trajectory analysis then revealed 3 post-SVR patients clusters (Figure), all demonstrating a global trend towards AST, ALT, GGT and AFP normalization, particularly in Cluster A (n = 228; HCC 7.5%). Of note, the two other clusters were associated with higher HCC incidence rates despite SVR achievement, being characterized either by persisting impaired liver function (cluster B, n = 109; HCC 15.6%) or elevated biochemical parameters (Cluster C, n = 95; HCC 13.7%).



Conclusion: Liver function impairment ("liver failure cluster") or persistent elevated biochemical parameters ("inflammatory cluster") despite SVR achievement in cirrhosis define two different profiles of patients in whom the residual risk of HCC following HCV eradication is increased. These analyses based on novel statistical approaches suggest that HCC surveillance in these patients could be refined and improved according to the longitudinal evolution of these parameters over time.

Nurses and AHP: Oral presentation

N01
Home based care pathway for the stratified treatment of HCV infection
Jasmina Khaldi[1], Samantha Bird[2], Elizabeth Blackwell[1], Edward Nicholson[2], Sherrelle Smith[1], Kathryn Jack[3], Breanne Dilks[1], Stephen Ryder[3], Brian Thomson[3]. [1]*Nottingham University Hospitals, Hepatology, Nottingham, United Kingdom;* [2]*Nottingham University Hospitals, Trust Pharmacy, Nottingham, United Kingdom;* [3]*University of Nottingham, Nottingham Digestive Diseases Centre, Nottingham, United Kingdom*
Email: brian.thomson@nottingham.ac.uk

Background and Aims: Directly acting anti-viral agents (DAAs) for HCV infection have an excellent safety record and are suited for use in community environments which better meet patient needs. We present a novel home treatment pathway, delivered by a partnership between specialist hepatitis nurses and pharmacists in the Nottingham regional Hepatitis C Operational Delivery Network (ODN).
Method: Patients eligible for DAAs are assessed for suitability for homecare on the basis of: competence to adhere to therapy without direct supervision; no current or previous evidence of hepatic decompensation; contactable by telephone. Following signed consent, patients receive: one month medication; a schedule for community blood testing; information leaflets; hospital contacts. DAAs and blood forms are then delivered to the patient's home each month by pharmacy until completion. A dedicated pharmacy technician works with specialist hepatitis nurses and ODN Management to co-ordinate the service. 12 week post-treatment blood tests are organised by the technician and reviewed by specialist nurses.
Results: Since inception of the service in 2016, 261 patients have been treated at home. 85% of those offered the choice of home or

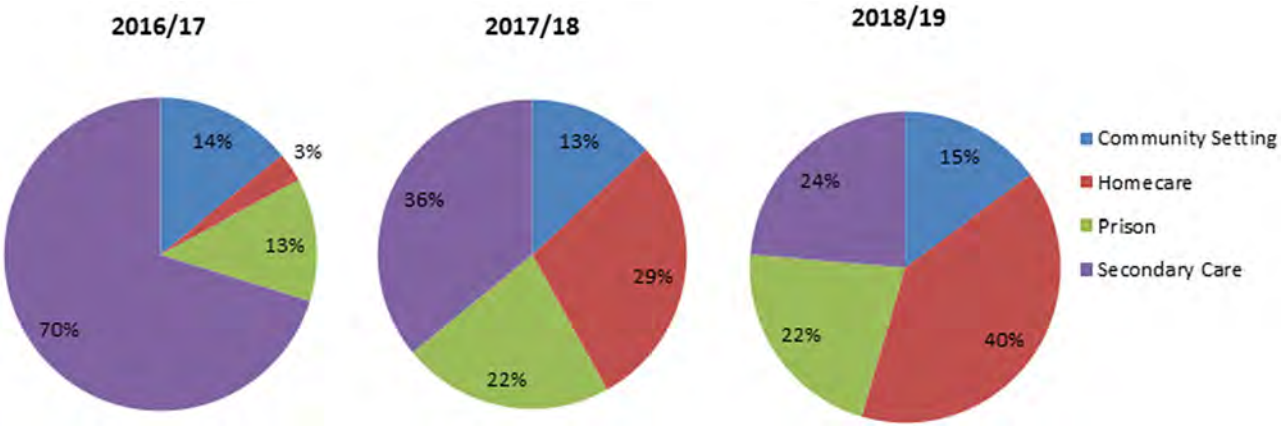


Figure: (abstract: N01): Percentages of patients treated in different healthcare settings in Nottingham annually between April 2016 and September 2019.

hospital based care during this period elected to receive treatment at home. Of those commenced on treatment, 234 have completed. Of the 179 with a 12 week post treatment test result, 177 achieved sustained viral response (SVR). The remainder have either not completed treatment or had a 12 weeks post treatment test. Six patients defaulted from treatment and four returned to hospital based care. Two patients died for reasons unrelated to treatment. 61 feedback forms have been returned with very positive feedback. The Homecare pathway was particularly valued by patients living distant from the hospital.

Conclusion: Homecare provides a safe and scaleable option preferred by patients. The strategy of pharmacy based implementation and economies of staff time intrinsic to the model has relieved pressure on specialised hepatitis services. Homecare has led a major and ongoing reduction in proportions of patients treated in secondary care (Figure 1). This has allowed the hospital to focus on patients with severe co-morbidities and the ODN to shift resources onto the community to promote case finding and community care for harder to reach groups with HCV infection.

N02

Oral health and the impact of oral diseases on the clinical course of cirrhosis

Lea Ladegaard Grønkjær[1,2], Hendrik Vilstrup[1]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark;* [2]*Hospital of South West Jutland, Department of Gastroenterology, Esbjerg, Denmark*
Email: lea.ladegaard.gronkjaer@rsyd.dk

Background and Aims: Poor oral health is prevalent in patients with cirrhosis, but the clinical significance is largely unknown. The aim of the study was to describe oral health and the prevalence of oral diseases in a cohort of cirrhosis patients, and to examine the association of oral diseases on the clinical course of cirrhosis.

Method: 184 consecutive cirrhosis patients were enrolled. They underwent a standardized oral clinical and radiographic examination. One-way anova was used to examine the association between single and multiple oral diseases and patients cirrhosis-related complications, inflammation- and nutritional status at baseline. Cox regression adjusted for confounding by age, male gender, smoker status, alcohol use, alcoholic cirrhosis, comorbidity, and MELD score was used to examine the associations between single and multiple oral diseases and the incidence of mortality.

Results: At baseline, the median number of teeth was 22 and 18% of the patients were edentulous. Twenty-seven percent had gross caries, 46% periapical lesions, 27% oral mucosal lesions, and 45% severe periodontitis. Sixty-one percent of the patients had one or more oral diseases. Having multiple oral diseases were associated with a gradual increase in cirrhosis-related complications (from 50.0% to 82.3%, p = 0.05), C-reactive protein (from 11.1 to 41.2 mg/L, p = 0.02), and nutritional risk score (from 3 to 4, p = 0.08). The total follow-up time was 427 years with a median of 2 years per patient and 66% of the patients died during follow-up. Multiple oral diseases were associated with higher cirrhosis-related mortality (HR 1.56, 95% CI 1.02–3.14, HR 1.91, 95% CI 1.12–3.24, and HR 4.51, 95% CI 1.30–15.62) in both the crude and adjusted analysis (Table 1).

Conclusion: The cirrhosis patients had poor oral health. The presence of multiple oral diseases was associated with a worsened clinical course of cirrhosis. The finding seems to necessitate closer attention to oral health in the clinic for patients with cirrhosis.

Table 1: (abstract: N02): Oral diseases and risk of all-cause and cirrhosis-related mortality

	All-cause mortality		Cirrhosis-related mortality

Email: nllarch@clinic.cat

Background and Aims: Chemoembolization (TACE) is the recommended treatment for hepatocellular carcinoma in the BCLC intermediate stage classification. The most frequent adverse events are fever, pain, nausea and fatigue known as "post-embolization syndrome (PES)." PES can cause anxiety and prompt consultations, unscheduled outpatient visits and emergency room attendance. The study evaluates how the BCLC Nurses Educational Program (BCLC-NEP) encourages patient autonomy after TACE to optimally manage PES.
Method: We retrospectively analyzed prospective data of all BCLC TACE-treated patients from Feb/2014 to Feb/2017. The program includes three key nurse visits: an outpatient visit before treatment, an inpatient visit post-procedure, and a 1-week-postTACE outpatient visit and phone consultations on request. This study analyzed symptoms reported after hospital discharge for the first two TACE sessions, and registered who resolved the first PES complaint reported by each patient.
Results: We reviewed 104 TACE-candidates: 92 TACE-treated patients who received at least the first TACE [median age 69 (range; 43–85), 85% male, (BCLC-A 46.7%, BCLC-B 53.3% and Child Pugh A (92.4%)]; 63 patients who received a 2nd TACE.
Seventy-nine patients (75.9%) reported PES after the first TACE, 52 (65.8%) were able to manage symptoms autonomously, 17 (21.5%) received nurse intervention and 8 (10.1%) required physician intervention. Patient interventions followed the BCLC-NEP recommendations regarding self-monitoring (50%), medication use (38.5) and other issues (7.6%). Only two patients (3.9%) attended the emergency department due to fever and pain. The main nurse intervention after TACE involved education and empowerment (88.2%).
After the second TACE, 50 patients (79.3%) reported PES, 39 (78%) were able to resolve the first sign/symptoms autonomously, 9 (18%) needed nurse intervention and 2 (4%) required physician intervention. Resolution of patient issues was achieved by following instructions regarding self-monitoring 46.2% and drug intake 53.8%. The main role of nurses after the second TACE was education (88.9%).
Conclusion: The BCLC-NEP for TACE patients promotes patient autonomy in PES management. The impact of the program proved more noticeable after the second TACE when patients had more experience with treatment and PES management (78%). This study reflects the extent to which the professional skills of nurses has an impact on the management of patients with liver cancer.

N04

Addition of palliative care nurse on the liver care team

Renee Pozza[1], Leslie Kennedy[2], Bonita Huiskes[3], Anna Marie Hefner[1], Tarek Hassanein[1]. [1]*Southern California GI & Liver Centers, Coronado, United States;* [2]*Sharp Coronado Hospital, Coronado, United States;* [3]*Azusa Pacific University, Azusa, United States*
Email: rpozza@livercenters.com

Background and Aims: Management of decompensated end stage liver disease (ESLD) individuals is a complex practice issue requiring collaboration between patients, caregivers, and a multidisciplinary team. Hospitalization is often required. Due to the uncertainty of prognosis and disease trajectory the role of palliative care in this population is not clearly understood. Providers often associate palliative care as "giving up" with removal of treatment modalities leading to a low rate of referrals to palliative care for these patients. Palliative care is an approach which is very distinct from end-of-life hospice programs. The goal of palliative care is to alleviate physical, psychosocial and spiritual suffering regardless of end-of-life. This provides complementary supportive services for seriously ill patients while pursuing aggressive, life-prolonging and curative care of chronic illness.
Method: In February 2018 a Palliative Care Nurse (PCN) was added to a specialized liver care team in a single center acute care hospital. The PCN joined daily rounds on all hospitalized ESLD patients and received referrals for one-on-one consultation. Consultation focused on supporting the care of these patients and their families in goal of care discussions, advance directives, and referrals for services as appropriate. Rates of referral for consultation as well as patient outcomes were captured. The EASL-CLIF scores were utilized to determine prognosis and trajectory of disease in these hospitalized patients.
Results: Between 02/2018 and 10/2019 there were 615 admissions with a diagnosis of ESLD with decompensation. Complication of portal hypertension such as ascites, variceal hemorrhage and hepatic encephalopathy was the most common reason for admission. The PCN provided 169 unique care consults to 89 ESLD patients during their acute care admissions. Patients determined to have ACLF Type 2 who were not transplant candidates were referred for palliative care, while the ACLF Type 3 patients were referred to a hospice program. All patients received Goals of Care discussion that included patient and family discussions of desired outcomes, advanced directives and/or care planning upon discharge. 29 patients (33%) were referred to Palliative Care; and 39 patients (43%) were referred to Hospice.
Conclusion: The need for palliative care in ESLD is increasing; although there are many barriers to the utilization of these services. The addition of a dedicated palliative care nurse to the acute care team caring for ESLD patients provides a mechanism to increase awareness of palliative care concepts, increase utilization of the concepts and overall improve patient and family quality of life, improve communication and goal setting, reduce suffering and impact appropriate referrals for needed services in a timely manner.

Acute liver failure

AS026

The VWF/ADAMTS13 unbalance, but not global coagulation or fibrinolytic status, is associated with outcome and bleeding in patients with acute liver failure

Ellen Driever[1], Richard Todd Stravitz[2], Jingwen Zhang[3], Jelle Adelmeijer[1], Valerie Durkalski-Mauldin[3], William M. Lee[4], Ton Lisman[1]. [1]*University Medical Center Groningen, Groningen, Netherlands;* [2]*VCU Health Hume-Lee Transplant Center, Richmond, United States;* [3]*Medical University of South Carolina, Charleston, United States;* [4]*UT Southwestern Medical Center, Dallas, United States*
Email: e.g.driever@umcg.nl

Background and Aims: Patients with acute liver failure (ALF) rarely bleed, although historically they were considered to have a bleeding tendency. In fact, ALF is characterized by rebalanced hemostasis with hypercoagulable features, including an unbalance between the platelet adhesive protein Von Willebrand Factor (VWF) and its

cleaving protease, ADAMTS13, and a hypofibrinolytic status. Rodent models have shown a link between VWF, hepatic platelet accumulation, and progression of ALF. Here, we evaluated the hemostatic state of ALF patients in relation to bleeding and clinical outcome.
Method: Patients with ALF (INR (international normalized ratio) ≥1.5) or severe acute liver injury (ALI; INR ≥ 2.0) were recruited from the US ALF Study Group Registry between 2011 and 2018. Citrated plasma samples were taken on admission and levels of VWF, ADAMTS13 activity, thrombomodulin-modified thrombin generation, and clot lysis time were determined, and compared to levels in 40 healthy controls.
Results: We studied 676 patients, of whom 308 patients (45.6%) had acetaminophen-induced ALF. Bleeding occurred in 50 patients (7.4%), and 483 patients (71.4%) survived without liver transplantation (LT). ALF patients had 5-fold increased VWF levels, 5-fold decreased ADAMTS13 activity, similar thrombin generation, and 2.4-fold increased clot lysis time, compared to controls. Patients with bleeding complications had higher VWF levels (523% vs. 441%; p = 0.0122), and lower ADAMTS13 activity (15% vs. 22%; p = 0.005) compared to patients without bleeding. Thrombin generation and clot lysis time did not differ significantly between bleeding and non-bleeding patients. Patients who died or underwent LT within 21 days of admission had higher VWF levels (559% vs. 404%; p < 0.0001), lower ADAMTS13 activity (18% vs. 22%; p = 0.0111), similar total thrombin generation, and shorter clot lysis time (136 min vs. 146 min; p = 0.04), compared to transplant-free survivors.
Conclusion: Hemostasis in a large cohort of patients with ALF is characterized by VWF/ADAMTS13 unbalance, normocoagulability, and hypofibrinolysis, features which do not suggest a bleeding diathesis. The VWF/ADAMTS13 unbalance is associated with poor outcome, consistent with our recent studies suggesting a detrimental effect of VWF in ALF in mice. The association between VWF/ADAMTS13 unbalance and bleeding complications suggest that bleeding in ALF reflects the effects of systemic inflammation rather than coagulopathy.

AS027
Bicyclol mitigates acute liver injury via inhibition of ferroptosis by modulating GPx4/Xc- system activity

Tianming Zhao[1,2], Xiaofei Fan[1,2], You Deng[1,2], Lijun Hou[1,2], Lihong Mao[1,2], Junjie Hou[1,2], Bangmao Wang[1,2], Xiaocang Cao[1,2], Chao Sun[2]. *[1]Tianjin Medical University General Hospital, Tianjin Institute of Digestive Disease, Tianjin, China; [2]Tianjin Medical University General Hospital, Department of Gastroenterology and Hepatology, Tianjin, China*
Email: chaosun@tmu.edu.cn

Background and Aims: Acute liver injury (ALI) relates to high mortality rates globally, which is compromised with several patterns of programmed cell death (PCD) including necrosis, apoptosis as well as autophagic-dependent cell death. Ferroptosis is a recently discovered form of PCD characterized by iron-dependent accumulation of reactive oxygen species. Bicyclol, a novel synthetic anti-hepatitis drug, has been shown to protect against liver damage via various pharmacological activities. Our previous study has showed that bicyclol could enhance autophagy and suppress oxidative stress for alleviating carbon tetrachloride (CCl_4)-induced acute liver injury (ALI). However, the potential role of ferroptosis in ALI and the modulatory mechanism of bicyclol remains elusive and warrants further investigation.
Method: ALI was induced by CCl_4 treatment *in vivo* and *in vitro*. Hepatic damage was assessed via measuring serum concentration of ALT, and liver tissue was subjected to H&E staining for histological scoring. Expression of protein with respect to ferroptotic machinery was assessed by WB. Transmission electron microscopy was applied to investigate morphological change of mitochondria. The production of several damage-associated molecular pattern molecules (DAMPs) was determined by ELISA and qRT-PCR. The production of ferroptosis-related proteins was compared by WB in CCl_4-challenged HepG2 cells. The underlying molecular paradigms that regulate ferroptosis was confirmed by disruption of Gpx4 *in vitro*.
Results: Our *in vivo* model showed enhanced lipid peroxidation and labile iron accumulation with concomitant cell-death during CCl_4 exposure. Mice treated with bicyclol exhibited marked liver protection which was positively regulated by Gpx4 and system xc-, and these hepatoprotective impact were similar to administration of ferrostatin-1 (a specific inhibitor of ferroptosis). Meanwhile, NCOA4-mediated ferritin selective autophagy (ferritinophagy) was initiated during ferritin degradation in response to CCl_4 treatment, which was reversed by bicyclol pretreatment. Additionally, bicyclol could attenuate the increased expression of level of PTGS2 and its gene product cyclooxygenase-2 *ex vivo*.
Conclusion: These results implicate that ferroptosis may contribute to hepatic cytotoxicity during CCl_4 exposure, that bicyclol has protective potential via inhibition of ferroptosis and subsequent DAMPs release. The insight achieved from this result advances our knowledge of ALI relevant cell death cascade and be critical for future preclinical studies.

AS028
Safe and effective treatment of acute liver failure by allogeneic transplantation of stem cell-derived encapsulated liver tissue without immunosuppression

Claudia Raggi[1], Marie-Agnès M'Callum[1], Quang Toan Pham[1], Silvia Selleri[1], Basma Benabdallah[2], Christian Beauséjour[2], Elie Haddad[3], Massimiliano Paganelli[1]. *[1]CHU Sainte-Justine, Université de Montréal, Liver Tissue Engineering and Cell Therapy & Pediatric Hepatology, Montréal, Canada; [2]CHU Sainte-Justine, Université de Montréal, Cancer Immunology & Pharmacology, Montréal, Canada; [3]CHU Sainte-Justine, Université de Montréal, Pediatric Immunology, Montréal, Canada*
Email: massimiliano.paganelli@gmail.com

Background and Aims: There is an urgent need for new therapies capable of replacing liver functions in patients with acute liver failure (ALF). We developed a human induced pluripotent stem cell (iPSC)-derived Encapsulated Liver Tissue (ELT) capable of consistently performing mature liver functions *in vitro* and *in vivo*. Thanks to the combination of complex iPSC-derived liver organoids and tailored biomaterials, the ELT performs liver-specific synthetic and metabolic functions at least as effectively as primary human hepatocytes, with the added advantages of being stable over time and upon cryopreservation, lot-to-lot consistency and sustainability (lower costs and unlimited availability). Here we assessed the efficacy and safety of the human ELT to treat ALF.
Methods: We generated human ELT using our patented, GMP-ready protocols, and transplanted them into immunocompetent mice with

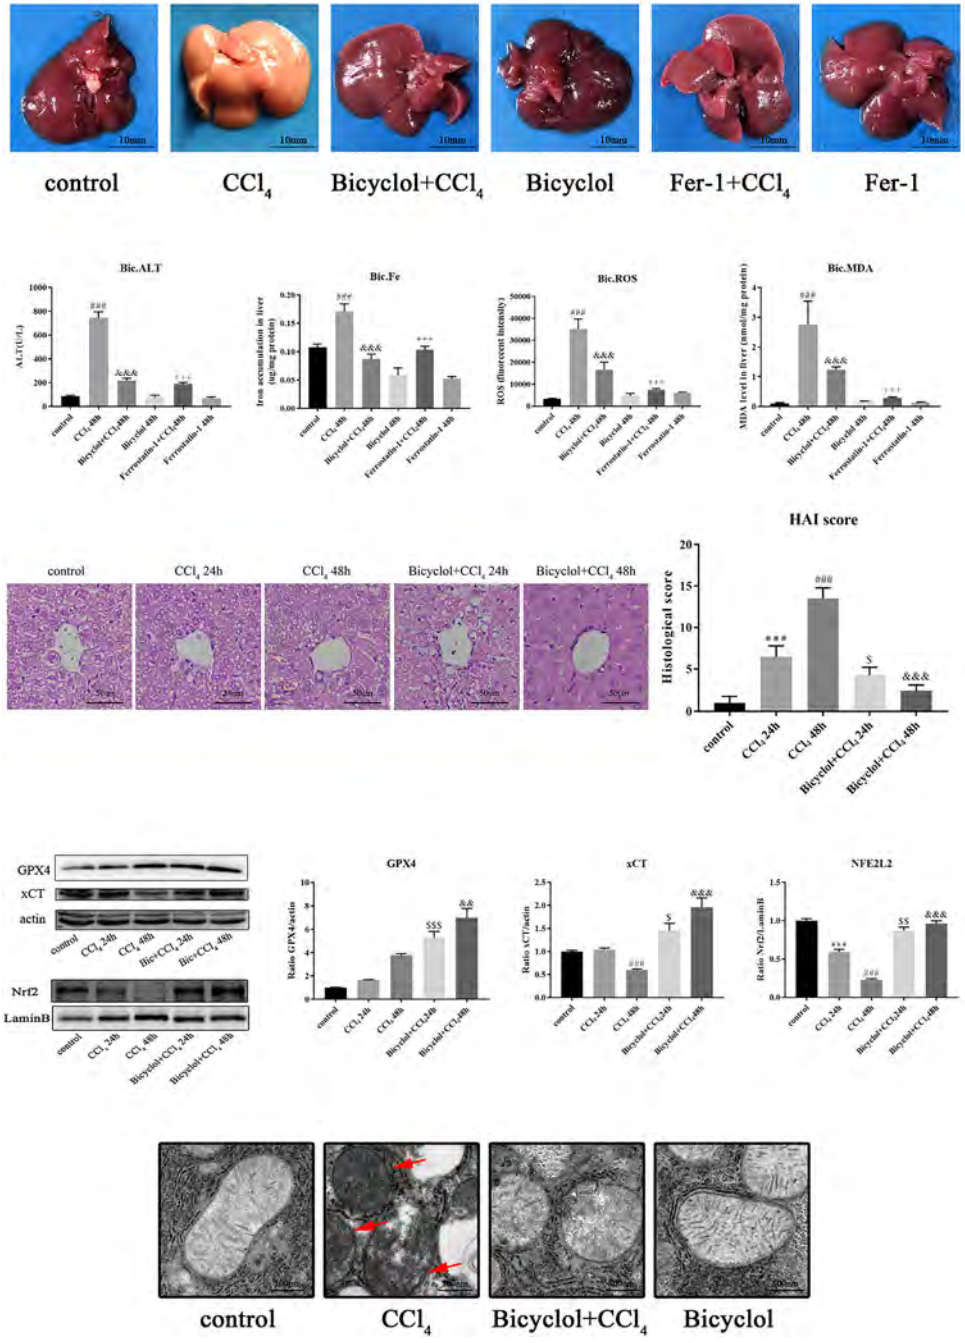

Figure: (abstract: AS027)

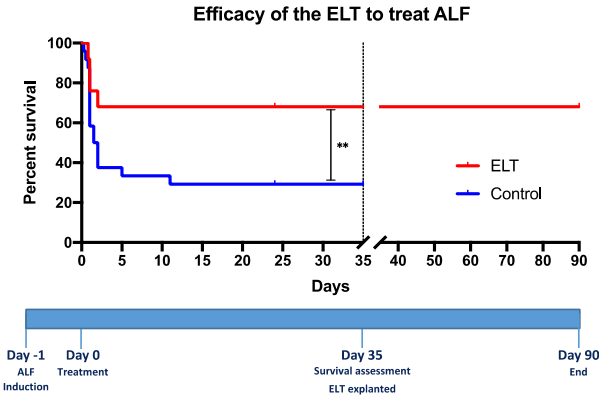
CCl4-induced fulminant liver failure, without immunosuppression, to assess survival in comparison to controls receiving the empty biomaterial (25 mice/group). We then assessed the biocompatibility, immunogenicity and tumorigenicity of our product both in vitro and in vivo.

Results: The human ELT effectively replaced liver functions and prevented death (68% survival at 5 weeks vs. 28% in controls, HR 0.3, $p < 0.01$) in immunocompetent mice with CCl_4-induced ALF, with no rejection or tumor formation (see Figure). Mice receiving the ELT showed less severe hepatic encephalopathy and an accelerated liver regeneration. The ELT was explanted from surviving mice at day 35, once their own liver had regenerated: all the animals survived long term with normal liver function. The immune-isolating capacity of the biomaterial was tested in vitro by mixed lymphocyte reaction: the biomaterial completely isolated embedded organoids (as well as activated dendritic cells used as positive control) from allogeneic T cells. Upon implantation into immunocompetent healthy mice, the human ELT did not trigger any inflammatory reaction, with no adhesions or foreign body reaction. At explant, after 4 weeks, the organoids within the ELT were alive and functional, without signs of rejection. No tumor or teratoma was observed after 16 weeks when encapsulated highly tumorigenic cells or undifferentiated iPSCs were transplanted into NSG mice, confirming the protective capacity of the biomaterial towards tumor formation.



Conclusion: Overall, we illustrate here the first stem cell-derived liver tissue capable of immediate, effective allogeneic replacement of liver functions in immunocompetent subjects with ALF, without the risk of rejection or tumor formation. The ELT has the potential of being developed into an off-the-shelf, allogeneic cell therapy to replace liver functions in patients with ALF without the need of immunosuppression.

Restricted protein intake in acute liver failure neither reduces ammonia nor improves cerebral edema but may increase risk of infection

Harshita Tripathi[1], Jaya Benjamin[2], Puja Bhatia Kapoor[2], Rakhi Maiwall[3], Vandana Saluja[4], Dr. Prashant Mohan Agarwal[4], Guresh Kumar[5], Yogendrakumar Joshi[2,3], Shiv Kumar Sarin[3]. *[1]Institute of Liver and Biliary Sciences, Clinical Nutrition, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Clinical Nutrition, New Delhi, India; [3]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India; [4]Institute of Liver and Biliary Sciences, Critical Care, New Delhi, India; [5]Institute of Liver and Biliary Sciences, Biostatistics, New Delhi, India*
Email: harshtrip.tripathi02@gmail.com

Background and Aims: Prevention or reversal of cerebral edema (CE) and hepatic encephalopathy (HE) is the cornerstone of management in acute liver failure (ALF). Since ammonia (NH_3) originates from breakdown of dietary proteins and hyperammonemia has been implicated in promoting CE; zero to low intake of dietary protein with slow increments in delivery is recommended. However, adequate protein is vital for preventing infection and maintaining eumetabolism. We studied the association of protein delivery with CE as measured by optic nerve sheath diameter (ONSD), arterial NH_3 levels and clinical outcomes in patients with ALF.
Method: In this prospective study, consecutive patients with ALF admitted to the Liver ICU (LICU) between December 2018 and September 2019 were enrolled. Information pertaining to clinical [HE status, requirement of continuous renal replacement therapy (CRRT), incidence of new-onset infections and ONSD] biochemical (arterial NH3) and nutritional (calorie and protein intake) parameters were recorded daily. Enteral nutrition (EN) was initiated within two hours of LICU admission using a standard EN formula. Individual EN provided 35–40 kcal and protein ranging from 0–2 g per kg ideal body weight (IBW) depending upon the clinical status and requirement for CRRT. The average protein intake of 7 days was categorized as low protein (LP: 0–1 gm/d) or high protein (HP: 1.1–2 g/d) and resolution of HE and incidence of new-onset infection was compared between LP and HP groups. The response of daily protein delivery (from baseline to day7) on ONSD and NH_3 was assessed using generalized linear model (GLM).
Results: In 40 patients with ALF [M-52%, age 32 ± 14.7 yrs; etiology-viral-30 (75%): DILLI-4 (10%): others-6 (15%); subtype-hyper acute-38 (95%): sub acute- 2 (5%); HE grade 2:3:4–2(5%): 4 (10%): 34 (85%); BMI- 25.54 ± 3.5 kg/m^2; ONSD- 4.6 (2.7–5.7); NH_3 -257 (89–839); lactate-4 (2–15)] enrolled, HE resolved in 15 (37.5%) and CRRT was done in 11 (27.5%). GLM assessment suggested no interaction of HP or LP with ONSD (beta = 1.095; p = 0.238) and NH_3 levels (beta = 198.11; p = 0.391). 24 (60%) patients received LP and 16 (40%) HP. There was no difference in the resolution of HE [LP 6(%) vs. HP 9(%); p = 0.738], though a trend to higher incidence of new infections was seen with LP diet [LP vs. HP = 10(25%) vs. 3(7.5%); p = 0.45].
Conclusion: Protein restriction practiced in patients with ALF admitted to an ICU is not helpful in preventing cerebral edema or lowering ammonia levels. However, zero or low protein intake may predispose the patients to an increased risk of infection.

AS030

Improved clinical and neurological outcomes in acetaminophen-induced acute liver failure: a twenty-one year, prospective multicenter study

Andrew MacDonald[1], Jaime Speiser[2], Daniel Ganger[3], Kathleen Nilles[4], Babak Orandi[5], Anne Larson[6], William M. Lee[7], Constantine Karvellas[1]. *[1]University of Alberta, Critical Care Medicine, Edmonton, Canada; [2]Wake Forest University, Department of Biostatistics and Data Science, Winston-Salem, United States; [3]Northwestern University, Hepatology, Chicago, United States; [4]Georgetown University, Medicine/Hepatology, Washington DC, United States; [5]University of Alabama, Transplant Surgery, Birmingham, United States; [6]University of Washington, Hepatology, Seattle, United States; [7]University of Texas Southwestern, Hepatology, Dallas, United States*
Email: dean.karvellas@ualberta.ca

Background and Aims: Acetaminophen (APAP)-induced acute liver failure (ALF) is associated with significant mortality. Liver transplant (LT) in APAP-ALF presents challenges due to the rapidity and severity of illness, the potential for recovery without LT, and the presence of concomitant complex psychosocial issues. We aimed to evaluate trends in clinical interventions and important clinical outcomes over a 21-year period.
Method: We analyzed data from a multicentre retrospective cohort study of all APAP-ALF patients enrolled in the *United States ALF Study Group* prospective registry (1998–2018). Primary outcomes evaluated were 21-day transplant-free survival (TFS) and neurological complications. Covariates evaluated included enrollment cohort (early: 1998–2007, recent: 2008–2018), psychiatric comorbidity and the use of organ support including continuous renal replacement therapy (CRRT).

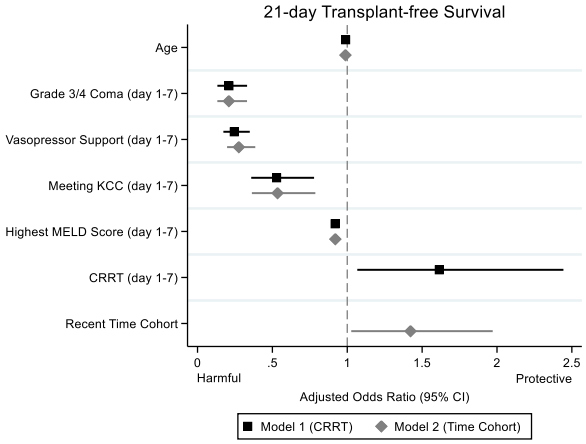

Figure: Independent associations with 21-day transplant free survival in 1190 APAP-ALF patients.

Results: There were 1190 APAP-ALF patients (early: n = 582; recent: n = 608). In comparing the recent and early cohorts, TFS was significantly lower in the recent (69.8 vs.61.7%, p = 0.005), with similar use of N-acetylcysteine. Recent cohort patients were more likely to receive CRRT (22.2% vs. 7.6), less likely to develop cerebral

edema (CE) (29.9% vs. 51.5%) or die to CE by day 21 (4.5%,vs. 11.6%; p < 0.001 for all). Stratifying by TFS status (non-TFS: n = 365 (273 died/100 transplanted) vs. TFS: n = 704), there were no differences in existing psychiatric comorbidity (51.5% vs. 55.0%; p = 0.3) or overdose intention (intentional: 39.7% vs. 41.6%; p = 0.6). During the first 7 days of study, TFS patients were less likely to develop grade 3/4 hepatic encephalopathy (HE; 52.7% vs. 91.5%), required less organ support (mechanical ventilation: 51.3% vs. 90.7%; vasopressors:19.5% vs. 65.8%; CRRT: 13.6% vs. 21.4%), and were less likely to develop cerebral edema by day 21 (CE; 22.1% vs. 61.4%; p < 0.002 for all). On multivariable logistic regression adjusting for vasopressor support (OR 0.25; 95% CI: 0.17–0.35; p < 0.001), development of grade 3/4 HE (OR 0.21; 0.13–0.33; p < 0.001), King's College Criteria (OR 0.53; 0.36–0.78; p = 0.001), and highest MELD score (per unit increase: OR 0.92; 0.90–0.94; p < 0.001), the use of CRRT (OR 1.61; 1.07–2.44; p = 0.02) was associated with TFS (c-statistic 0.86). In a second model substituting enrolment cohort for CRRT, recent enrolment was associated with improved TFS (OR 1.42; 95% CI: 1.03–1.97; p = 0.03; c-statistic 0.86).

Conclusion: Transplant-free survival in APAP ALF has improved over time while the incidence of CE/CE-related death has declined with improved intensive care support possibly related to increased CRRT use.

Cirrhosis – Experimental aspects

AS031

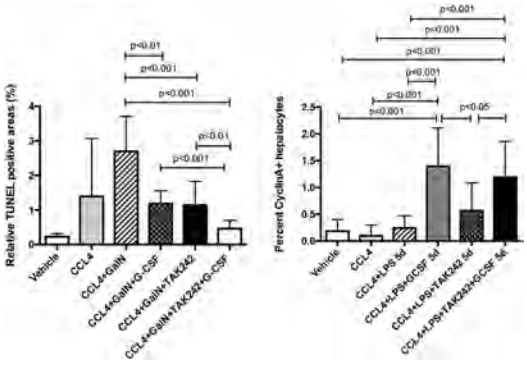
Toll-like receptor 4 inhibition acts synergistically with G-CSF to prevent organ injury and induce liver regeneration in acute-on-chronic liver failure

Cornelius Engelmann[1,2], Fausto Andreola[1], Abeba Habtesion[1], Simone Novelli[1], Annarein Kerbert[1], Nathan Davies[1], Sofia Ferreira-Gonzalez[3], Stuart Forbes[3], Thomas Berg[2], Rajiv Jalan[1].
[1]*University College London, Institute for Liver and Digestive Health, London, United Kingdom;* [2]*University Hospital Leipzig, Section Hepatology, Clinic for Gastroenterology and Rheumatology, Leipzig, Germany;* [3]*MRC Centre for Regenerative Medicine, SCRM Building, Edinburgh, United Kingdom*
Email: cornelius.engelmann@medizin.uni-leipzig.de

Background and Aims: Acute-on-chronic liver failure (ACLF) is characterised by lack of regeneration. Granulocyte colony stimulating factor (G-CSF) carries pro-regenerative properties and has been shown to be of benefit in ACLF. However, the large trial of G-CSF (GRAFT study) in patients with ACLF showed no benefit and in certain groups mortality tended to be higher. This study was performed to define the mechanisms underlying the negative effect of G-CSF and determine whether its beneficial effect could be harnessed using a toll-like receptor 4 (TLR4) antagonist.

Method: Two mouse models of ACLF were used: CCl4 (0.5 mg/ml,6w) to induce chronic liver injury followed by LPS i.p. (Klebsiella, 4 mg/kg) (n = 4–10) or Galactosamine (GalN) i.p. (1000 mg/kg) as a second hit (n = 8). 1 h after, G-CSF 250 μg/kg s.c. and/or TLR4-inhibitor TAK-242 10 mg/kg i.p. were injected and continued every 24 h. The treatment duration was 24 h and 5 d in the LPS model and 48 h in the GalN model. Samples were stored and analysed for liver injury, inflammation, senescence and regeneration.

Results: 6w CCl4 led to bridging fibrosis, TLR4 up-regulation and infiltration of G-CSFr expressing cells. LPS increased ALT levels, cell death (TUNEL+), enhanced hepatic infiltration of neutrophils (Ly6G+), macrophages (F4/80+) and TNFa. G-CSF increased the 48 h mortality from 0% to 66%, aggravated liver inflammation with macrophage and NK cell (CD45+,CD49b+,CD3-,CD19-) infiltration and IL6 expression. G-CSF+TAK-242 reduced the mortality to 0%, abrogated the liver injury (TUNEL) and liver inflammation (macrophages, neutrophils, TNFa, IL6) significantly. In the second model, GalN also induced a significant liver injury. Treatment with G-CSF+TAK-242 was significantly more effective than the individual therapies (figure). G-CSF +TAK-242 was associated with increased liver regeneration evidenced by increased tissue expression of pSTAT3 and BCL2. CCL4+LPS induced a p53 and p16-dependent cell cycle arrest and lack of proliferation (CyclinA) in hepatocytes. G-CSF+TAK-242 mitigated senescence and significantly increased the rate of CyclinA expressing hepatocytes (figure) suggesting enhanced liver regeneration.



Conclusion: The present study shows that G-CSF is deleterious in LPS-associated ACLF through further activation of inflammatory pathways and immune cell infiltration. TLR4 inhibition with TAK-242 prevented G-CSF driven tissue injury and induced liver regeneration showing evidence of synergy between the two molecules thereby providing a novel therapeutic strategy for ACLF patients.

Background and Aims: Chronic liver disease and hepatocellular carcinoma (HCC) are life-threatening diseases with limited treatment options. Previously, we have identified a pan-etiology 186-gene prognostic liver signature (PLS) in diseased liver tissues robustly predicting liver disease progression and HCC risk in patients with advanced liver disease (Hoshida *et al.*, N. Engl. J. Med. 2008; Nakagawa *et al.* Cancer Cell 2016). Efficient and high-throughput identification of candidate compounds for treatment of advanced liver disease and HCC has been hampered by the absence of tractable model systems.
Method: Here we developed a simple and robust human liver cell-based system modeling the clinical PLS of long-term liver disease progression and HCC risk for the major liver disease etiologies. Using the clinical PLS as a readout, we screened computationally enriched small molecules in the cell-based model (cPLS), followed by validation in NASH-HCC animal models and patient-derived tumor-spheroids. Using a recently developed single cell RNASeq pipeline (Aizarani et al. Nature 2019), we performed perturbation studies for mechanistic analyses.
Results: Our cPLS system robustly models the clinical PLS of long-term HCC risk within two weeks of cell culture, which takes two decades in patients. The clinical relevance of the cPLS was confirmed by similar transcriptomic dysregulation in the cell culture models and the diseased liver of clinical cohorts with corresponding liver disease etiologies. Using the cPLS model we identified a panel of previously undiscovered small molecules for treatment of advanced liver disease and HCC prevention. The two compounds scoring highest in reverting the poor-prognosis starts of the PLS were validated in two complementary NASH-HCC rodent models. Both compounds effectively inhibited liver fibrosis, inflammation and hepatocarcinogenesis *in vivo* confirming the validity of the approach. Using perturbation studies combined with single-cell RNA-Seq analyses of patient liver tissues, we unravelled previously undiscovered mechanistic roles of liver nonparenchymal cells in disease biology.
Conclusion: The cPLS model combined with single cell RNASeq analyses enables fast-track discovery of novel liver disease targets and therapeutics – a major global unmet medical need.

Neprilysin-neuropeptide Y axis as a target for treatment of liver fibrosis and portal hypertension

Cristina Ortiz[1], Sabine Klein[1], Winfried Reul[2], Fernando Magdaleno[2], Stefanie Gröschl[2], Peter Dietrich[3,4], Robert Schierwagen[1], Frank Uschner[1], Olaf Tyc[1], Stefan Zeuzem[1], Christoph Welsch[1], Marko Poglitsch[5], Claus Hellerbrand[3], Mercedes Alfonso-Prieto[6,7], Thomas Walther[8,9,10], Jonel Trebicka[1,11,12,13]. *[1]Hospital of the Goethe University Frankfurt, Department of Internal Medicine I, Frankfurt am Main, Germany; [2]University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany; [3]Friedrich-Alexander-University Erlangen-Nürnberg, Institute of Biochemistry, Emil-Fischer-Zentrum, Erlangen, Germany; [4] Friedrich-Alexander-University Erlangen-Nürnberg, University Hospital Erlangen, Department of Medicine 1, Erlangen, Germany; [5]Attoquant Diagnostics GmbH, Vienna, Austria; [6]Institute for Advanced Simulations IAS-5, Institute for Neuroscience and Medicine INM-9, Jülich, Germany; [7]Cécile and Oskar Vogt Institute for Brain Research, Medical Faculty, Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [8]University College Cork, Department of Pharmacology and Therapeutics, Cork, Ireland; [9]University of Leipzig, Department of Pediatric Surgery, Centre for Fetal Medicine, Division of Women and Child Health, Leipzig, Germany; [10]University of Leipzig, Department of Obstetrics, Centre for Fetal Medicine, Division of Women and Child Health, Leipzig, Germany; [11]University of Southern Denmark, Institute of Clinical Research, Odense University Hospital, Odense, Denmark; [12]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain; [13]Institute for Bioengineering of Catalonia, Barcelona, Spain*
Email: cristina.ortiz@kgu.de

Background and Aims: Chronic liver injury induces fibrosis and contraction of hepatic stellate cells (HSC) leading to fibrosis and portal hypertension (PHT). Importantly, the angiotensin converting enzyme (ACE) and angiotensin-II levels are involved in these processes. Neprilysin (NEP) is a neutral endopeptidase that cleaves neuropeptide Y (NPY), a 36 amino acid peptide described as a co-transmiter for contraction mediated by angiotensin II type 1 receptor (AT1R). Our aim is to study the effects of NPY and its cleavage mediated by NEP on fibrosis and PHT.
Method: Portal, hepatic, central and peripheral venous blood was collected from patients receiving transjugular intrahepatic portosystemic stent (TIPS) and analyzed for circulating levels of NPY. NEP expression was correlated with collagen1a1 expression in human fibrotic liver. *In silico* docking experiments reveals the effect of full-length NPY or the short NPY fragments cleaved by NEP on NPY type 1 receptor (Y1R). Liver fibrosis and PHT was induced in wild type (WT) and $Nep^{-/-}$ mice using bile duct ligation (BDL) (2 weeks) and carbon tetrachloride (CCl_4) (4 weeks) and hemodynamic changes were measured *in vivo*. Hepatic protein and mRNA expression were analyzed in these animals. *In vitro* analysis of primary HSC from WT and $Nep^{-/-}$ mice were incubated with NPY. In addition, fibrotic $Nep^{-/-}$ mice (BDL/CCl_4) were treated with AT1R blocker (losartan) or ACE inhibitor (captopril) for 2 weeks/4 weeks respectively.
Results: NPY levels increased in cirrhosis in humans and originates largely from portal vein. Hepatic NEP increases also with the severity of the disease but only in HSC. NEP deficiency in mice showed less fibrosis but higher hepatic NPY levels which induced PHT. *In vitro,* full-length NPY induces contraction of HSC by activation of Y1R but its fragments derived from NEP proteolysis, blocked Y1R and increased fibrosis in HSC. Molecular docking of NPY fragments to the receptor confirmed that NPY short peptides act as antagonist of the Y1R and act profibrotic. AT1R blockage (losartan) or ACE inhibition (captopril) in NEP deficiency mice, decreased fibrosis and portal pressure.
Conclusion: The link between fibrosis and contraction relay on the NEP/NPY axis. Dual NEP inhibition with AT1R blockade should be evaluated as a treatment to decrease fibrosis and portal hypertension in humans.

AS034

Endothelial portal venous damage is associated with alterations in local TM and EPCR expression in patients with cirrhosis and portal hypertension

Sarah Shalaby[1], Paolo Simioni[2], Elena Campello[2], Sabrina Gavasso[2], Debora Bizzaro[1], Romilda Cardin[1], Enrico Gringeri[3], Francesco D'Amico[3], Umberto Cillo[3], Giulio Barbiero[4], Michele Battistel[4], Alberto Zanetto[1], Alessandro Ruzzarin[1], Patrizia Burra[1], Marco Senzolo[1]. *[1]Multivisceral Transplant Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy; [2]Hemorrhagic and Thrombotic Diseases Unit, Department of Medicine DIMED, Padua, Italy; [3]Hepatobiliary Surgery and Liver Transplantation Unit, Department of Surgery, Oncology and Gastroenterology, Padua University Hospital, Padua, Italy; [4]University Radiology, Department of Medicine, Padua University Hospital, Padua, Italy*
Email: sarahshalaby18@gmail.com

Background and Aims: Portal vein thrombosis is the most common thrombotic complication in cirrhosis, however its pathogenesis is still not fully understood. Endotoxemia, shear stress and inflammation secondary to portal hypertension, may lead to portal endothelial damage and disruption of its glycocalyx. Data regarding global haemocoagulative state in the portal vein are still scarce.
Method: We consecutively enrolled adult cirrhotic patients undergoing liver transplantation or transjugular-intrahepatic-portosystemic-shunt. Rotational-thrombelastometry (ROTEM), dosage of total circulating glycosaminoglycans (GAGs) and endotoxemia levels (LPS), along with evaluation of endothelial dysfunction by quantification of circulating endothelial-microparticles, were performed on citrated peripheral and portal venous blood samples of all enrolled patients.
Results: Forty-five cirrhotic patients were enrolled. ROTEM-analysis showed the presence of a heparin-like effect in portal blood by heparinase addition to the native test (median α angle NATEM® 50° vs HEPTEM® 55°, p = .027; median CT NATEM® 665 sec vs HEPTEM® 585 sec, p = .006), which was not detected in peripheral blood. This effect was consistent with the higher GAGs levels in the portal district compared to peripheral blood (median 4176 vs 2565 ng/ml, p < .001). The proportion MPs of endothelial origin, with respect to total Annessin V-MP, was significantly increased in the portal district (p = .036), highlighting a higher grade of endothelial damage in this site, which is in keeping with the higher concentrations of LPS (median portal 197 vs peripheral 165 pg/mL, p = <.001). Additionally, between endothelial MPs a decreased concentration in portal blood of those carrying thrombomodulin (median 232 vs 377MP/μL p = .002) and endothelial protein C receptor (median 16 vs 37MP/μL, p < 0.001), showed a specific impairment in the physiological anticoagulant properties of the endothelium of the portal vein.
Conclusion: In cirrhosis, portal vein is characterized by higher grade of endothelial dysfunction, glycocalyx damage and decerase in its anticoagulation function, associated with a higher concentration of LPS. These alterations may represent an important local risk factor in the pathogenesis of PVT.

AS035

The albumin-functionality-test (AFT) as a new valuable tool to assess human albumin function and predict ACLF in patients with decompensated cirrhosis

Katja Waterstradt[1], Maurizio Baldassarre[2], Kerstin Schnurr[3], Agnese Antognoli[2], Giacomo Zaccherini[4], Manuel Tufoni[4], Paolo Caraceni[2]. *[1]Berlin, MedInnovation GmbH, Berlin, Germany; [2]Center for Biomedical Applied Research (CRBA), Department of Medical and Surgical Sciences, Bologna, Italy; [3]Berlin, MedInnovation GmbH, Berlin, Germany; [4]Department of Medical and Surgical Sciences, Bologna, Italy*
Email: k.waterstradt@medinnovation.de

Background and Aims: A major non-oncotic property of human albumin (HA) is the capacity of binding, transporting and detoxifying many endogenous and exogenous compounds. Structural HA damage occurs in patients with cirrhosis and, to a greater extent, in those with acute-on-chronic liver failure (ACLF), likely leading to functional impairment of the molecule. The Albumin-functionality-test (AFT) directly evaluates the ability of conformational mobility of HA, thus reflecting its residual binding function. This study aimed to assess the changes of AFT can discriminate patients with Acute Decompensation (AD) from those with ACLF and predict their prognosis.
Method: 319 patients with cirrhosis with acute decompensation (AD) were prospectively enrolled within 48 h from hospitalization. Serum samples were obtained at admission to measure the residual HA binding capacity by using the AFT based on electron paramagnetic resonance (EPR) spectroscopy to detect modified binding and functional characteristics of serum albumin. This is done by a comparison of three different mixtures of albumin, a spin labeled fatty acid and ethanol to simulate binding, transport and release conditions in vitro. Clinical and laboratory data were also collected and survival was recorded up to 1 year.
Results: AD alone was present at admission in 241 patients (76%) and ACLF in 78 (24%). Binding efficiency (BE) of AFT at admission was progressively reduced in patients with AD (38% [95%CI 36%–41%]) and to a more extent in those with ACLF (29% [95%CI 25%–32%]) as compared to the standard normal values. Moreover, AFT was inversely correlated with MELD (BE rho −0.346, p < 0.001; Detoxification efficiency (DTE) rho −0.342, p < 0.001) and Child-Pugh scores (BE rho −0.379, p < 0.001; DTE rho −0.362, p < 0.001).
32 patients (13%) developed ACLF within 30 days. Parameters derived from the AFT predict ACLF in patients with an AUC of 0.73 [95%CI 0.67–0.79] equal to that of the CLIF-C AD score (0.73 [95%CI 0.67–0.79]). However, when CLIF-C-AD score is combined with AFT parameters this significantly improves to an AUC of 0.83 [95%CI 0.78–0.88; p = 0.01]. AFT was also able to discriminate patients with a different probability of 1-year-survival: a binding efficiency higher than 35% at admission present a significantly higher survival rate than those with lower values (65% vs 48%, p = 0.001).
Conclusion: Based on these results, the AFT appears to be a promising tool to assess the residual binding function of the HA molecules in patients with decompensated cirrhosis, carrying also a potential role as a test for predicting ACLF and patient prognosis.

AS036

AXL-expressing homeostatic liver macrophages are reduced in patients with progression of cirrhosis

Oltin-Tiberiu Pop[1,2], Robert G. Brenig[1,3], Evangelos Triantafyllou[4,5], Anne Geng[3], Arjuna Singanayagam[4,5], Patrizia Kuenzler[1], Petr Hruz[3], Julia Wendon[4], Jan Hendrik Niess[3], Markus Heim[3], David Semela[1], Harry Antoniades[4,5], Lucia Possamai[5], Luigi Maria Terracciano[6], Christine Bernsmeier[3]. *[1]Cantonal Hospital St. Gallen, Liver Biology Laboratory and Gastroenterology & Hepatology, St. Gallen, Switzerland; [2]Cantonal Hospital St. Gallen, Institute of Immunobiology, St. Gallen, Switzerland; [3]University of Basel, Department of Biomedicine and University Centre for Gastrointestinal and Liver Diseases, Basel, Switzerland; [4]King's College London, Institute of Liver Studies, London, United Kingdom; [5]Imperial College London, St. Mary's Hospital, Hepatology Department, London, United Kingdom; [6]University Hospital Basel, Institute of Pathology, Basel, Switzerland*
Email: oltintiberiu.pop@kssg.ch

Background and Aims: AXL and MERTK are phagocytic receptors with distinct patterns of expression. Their expression on circulating monocytes modulated innate immune responses in patients with advanced cirrhosis (CD14+HLA-DR+AXL+) and acute-on-chronic liver failure (ACLF, CD14+MERTK+) in relation to disease severity. AXL expression increased in response to PAMPs, phagocytosis and efferocytosis and involved enhanced efferocytosis, sustained phagocytosis and reduced TNF-α/IL-6 production and T cell activation, suggesting a homeostatic function. In tissues, AXL expression has been described on murine airway but not interstitial lung

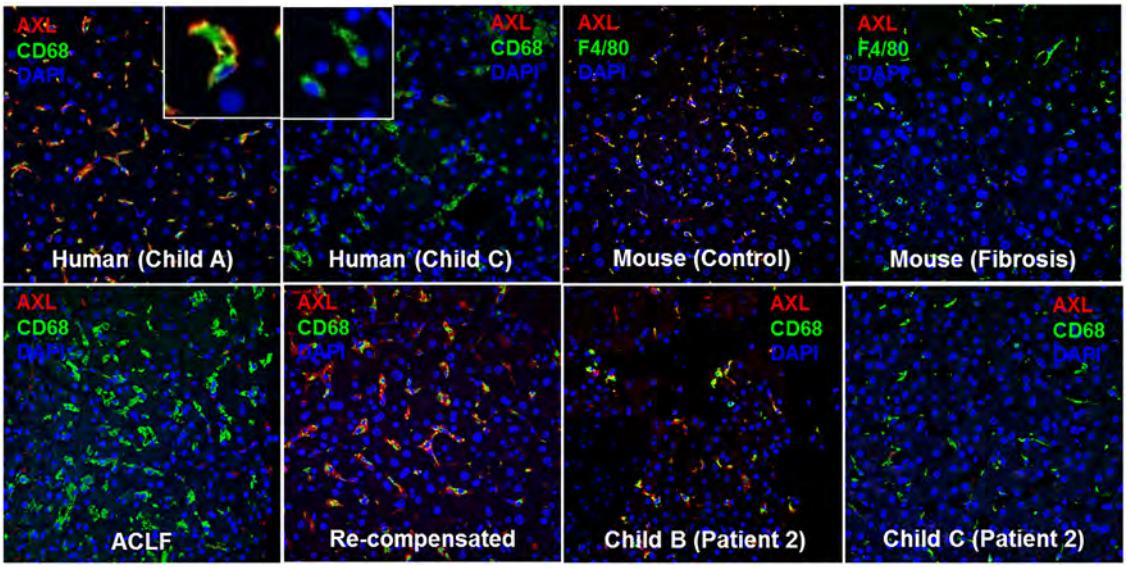

Figure: (abstract: AS036)

macrophages under homeostatic conditions, human Langerhans cells, and murine tissue-resident synovial lining macrophages. We sought to assess AXL expression in the liver of patients with cirrhosis.
Method: We used multiplexed immunofluorescence to compare AXL expression in liver biopsies from patients with cirrhosis (Child A n = 8; B n = 7; C n = 12) with healthy controls (HC n = 15), chronic liver disease (CLD n = 8), and nodular regenerative hyperplasia with portal hypertension (n = 3), and in a mouse model of CCl4 induced liver fibrosis (n = 5) and controls (n = 3). Longitudinal assessment of AXL expression was done in two patients: (1) with ACLF before and after re-compensation and (2) with progressive cirrhosis (from Child B to C). We evaluated AXL expression in gut biopsies from cirrhotic patients (Child A n = 7; B n = 5; C n = 4) compared to HC (n = 5) and ulcerative colitis (UC n = 5).
Results: AXL^+ cells were predominantly resident macrophages ($CD68^+$) but barely recently infiltrated macrophages ($MAC387^+$). Hepatocytes, stellate cells (SMA^+), and sinusoidal endothelial cells ($CD31^+CD34^+vWF^+$) did not express AXL. $CD68^+AXL^+$ cells significantly decreased with cirrhosis progression: (HC 90.2%; CLD 82.2%; Child A 76.1%; Child B 64.5%; Child C 18.7%; all $p < 0.05$). $CD68^+AXL^+$ cells in the liver of patients with non-cirrhotic portal hypertension were similarly reduced (59.4%). AXL^+CD68^+ cells negatively correlated with Child-Pugh ($p < 0.0001$), MELD score ($p = 0.0027$), and CRP ($p < 0.05$). AXL and MERTK were not co-expressed. AXL expression on macrophages from fibrotic mouse livers was lower compared to HC (21.7% vs. 95.4%, $p < 0.05$). Compared to HC, $CD68^+AXL^+$ cells were decreased also in gut biopsies from cirrhotic patients (HC 81.5%; Child A 65.6%, B 42.8%, C 36.6%; all $p < 0.05$).
Conclusion: We newly described AXL expression on the majority of resident macrophages in healthy liver which was reduced in advanced cirrhosis and portal hypertension. Loss of AXL expression was further observed on macrophages in gut tissue from cirrhosis patients. The data suggest a role for AXL expressing macrophages in hepatic immune homeostasis and barrier function of the liver and the gut.

Hepatitis C elimination

AS037

Community-based point-of-care hepatitis C testing and general practitioner initiated direct-acting antiviral therapy in Yangon, Myanmar (CT2 study)

Bridget Draper[1,2], Win Lei Yee[3], Alisa Pedrana[1,2], Jess Howell[1,4], Hla Htay[3], Win Naing[5,6], Khin Sanda Aung[7], Nwe Nwe[8], Sonjelle Shilton[8], Jessica Markby[8], Khin Pyone Kyi[9], Margaret Hellard[2,3]. *[1]Burnet Institute, Disease Elimination, Melbourne, Australia; [2]Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia; [3]Burnet Institute, Disease Elimination, Yangon, Myanmar; [4]St Vincent's Hospital, Australia; [5]University Of Medicine (1), Hepatology, Yangon, Myanmar; [6]Yangon Specialty Hospital, Hepatology, Yangon, Myanmar; [7]National Hepatitis Control Program, Department of Public Health, Ministry of Health and Sports, Myanmar; [8]Foundation of Innovative New Diagnostics, Geneva, Switzerland; [9]Myanmar Liver Foundation, Yangon, Myanmar*
Email: bridget.draper@burnet.edu.au

Background and Aims: The advent of direct-acting antivirals (DAAs) and near point-of-care testing for hepatitis C (HCV) facilitate improved community-based care. In many countries, access to DAAs is limited to tertiary hospitals but there is increasing recognition of the need for decentralizing care. This study demonstrates a decentralized hepatitis C care model in Myanmar.
Method: This study assessed the feasibility, acceptability and effectiveness of community-based POC testing and DAA therapy for HCV among people who inject drugs (Burnet Institute (BI) site) and general population (Myanmar Liver Foundation (MLF) site) in Yangon, Myanmar. Rapid diagnostic test (SD Bioline) for anti-HCV antibodies was performed on-site; if reactive, GeneXpert HCV RNA test was performed. External laboratory investigations for liver staging were undertaken for viremic patients. Results were given to the participant at next appointment with GP; participants commenced DAA therapy (sofosbuvir 400 mg/daclatasvir 60 mg) if specialist review was not required. Outcome data on HCV test positivity, treatment uptake and SVR12 rates as well as responses to behavioral surveys were collected.
Results: 633 participants were enrolled (n = 255 at BI; n = 378 at MLF). 256 (40%) reported lifetime injecting of drugs, of whom 236

(89%) had injected in the past six months. Other commonly reported risk factors included: family history (n = 87, 14%), surgery (n = 50, 8%), dental treatment (n = 32, 5%) and blood transfusion (n = 31, 5%). Of 633 enrolled, 606 (96%) were HCV antibody positive; of these, 606 (100%) received an RNA test. 537 (89%) were RNA positive and proceeded to pre-treatment assessments. Of these, 466 were eligible for DAA therapy on initial assessment, 22 required specialist review (all deemed eligible to start DAAs) and 488 (91%) were prescribed DAA therapy. Median number of days from RNA test to DAA prescription was 2 (IQR: 1, 5). To date, 244 have completed therapy and 126 are eligible for SVR12 assessment. Of those who have completed SVR12 assessment (n = 116 (92%)), 108 (93%) achieved SVR12.

Conclusion: The study results suggest providing community based POC testing and treatment initiated by general practitioners is feasible in low/middle income settings. Retention in care from diagnosis to treatment initiation and SVR12 rates were high among people who inject drugs and those with chronic liver disease. Evidence from this study will inform scale-up of hepatitis C treatment programs in Myanmar and globally.

AS038

Population-level hepatitis C cascade of care among men who have sex with men in British Columbia, Canada

Naveed Janjua[1,2], Amanda Yu[1], James Wilton[1], Prince Adu[1,2], Dr. Margo Pearce[1,2], Hasina Samji[1], Geoff McKee[3], Sofia Bartlett[1,4], Zahid Butt[5], Mawuena Binka[1], Younathan Abdia[1,2], Stanley Wong[1], Dahn Jeong[1,2], Emilia Clementi[1,2], Maria Alvarez[1], Dr. Jason Wong[1,2], Mel Krajden[1,4]. *[1]BC Centre for Disease Control, Vancouver, Canada; [2]School of Population and Public Health, Vancouver, Canada; [3]Vancouver Coastal Health, Vancouver, Canada; [4]The University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada; [5]University of Waterloo, School of Public Health & Health Systems, Waterloo, Canada*

Email: naveed.janjua@bccdc.ca

Background and Aims: Gay, bisexual and other men who have sex with men (MSM) are at higher risk of hepatitis C virus (HCV) acquisition. Although monitoring progress of MSM across the care cascade is critical to achieving HCV elimination goals, there is lack of data from the population based systems for monitoring progress among MSM. We constructed the cascade of care among people diagnosed with HCV infection living in British Columbia (BC), Canada in 2018, stratified by MSM status, to compare progress in care and treatment in this population.

Method: The BC Hepatitis Testers Cohort (BC-HTC) was used for this analysis. The BC-HTC includes all individuals tested for HCV in BC since 1990, with their data linked to all prescription drugs, medical visits, hospitalizations and mortality data. We defined six cascade of care stages: 1) anti-HCV positive (diagnosed); 2) RNA tested; 3) RNA positive, 4) genotyped; 5) initiated treatment; and 6) achieved a post-treatment sustained virologic response (SVR). We compared progression through the care cascade by MSM status. MSM identification was based on self-report as well as validated algorithm which imputed missing information with 95% specificity.

Results: Of 33,647 males diagnosed with HCV and alive in 2018, 3,940 were MSM and 29,707 were non-MSM. Slightly more MSM (3,314, 84%) received confirmatory HCV RNA testing compared non-MSM (24,264, 82%). Among those with a positive RNA test, there was no difference in progression to genotyping between the MSM and non-MSM groups (2,231, 90% vs 16,514, 90%). However, slightly more MSM initiated treatment than non-MSM (1,406, 63% vs 9,964, 60%). There was a substantial increase in treatment uptake between 2012 and 2018 among both groups (MSM: 37% to 63%; Non-MSM: 36% to 60%). Among those who were RNA positive, treatment uptake was slightly higher among MSM than non-MSM (1,406/ 2,473, 57% vs. 9,964/ 18,427, 54%). Among those who received treatment and were assessed for SVR, a similar proportion achieved SVR (MSM: 1,011/ 1,111, 91% vs non-MSM: 6,608/7,319, 90%).

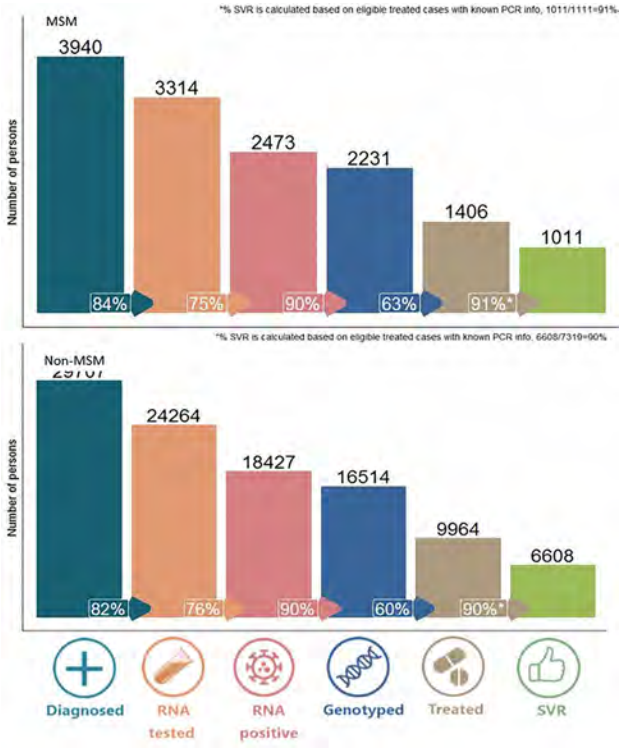

Figure: HCV care cascade among MSM and non- MSM groups in British Columbia in 2018

Conclusion: There has been substantial progression across the care cascade stages after introduction of DAAs. MSM had slightly better progression than non-MSM across the testing, care and treatment cascade.

AS039

Decline in HCV incidence in HIV positive MSM - progress to HCV micro-elimination in the UK?

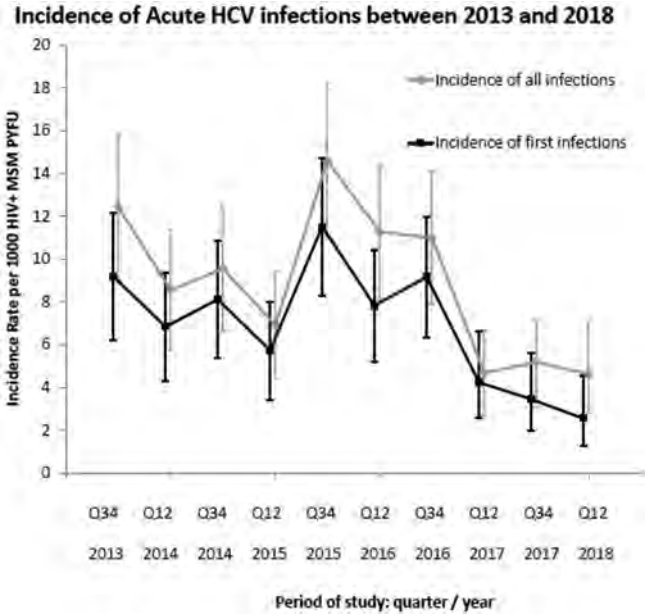
Lucy Garvey[1], Graham Cooke[1,2], Colette Smith[3], Christof Stingone[4], Indrajit Ghosh[5], Subathira Dakshina[5], Lakshmi Jain[5], Laura Jane Waters[5], Tabitha Mahungu[4], Filippo Ferro[4], Chandni Sood[1], Carolyn Freeman[1], Sadna Ullah[6], Clare Phillips[7], Harriet Sharp[7], Ruth Burholt[7], Rageshri Dhairyawan[6], Yvonne Gilleece[7], Ashley Brown[8], Chloe Orkin[6,9], Alison Rodger[3,4], Sanjay Bhagani[4]. *[1]Imperial College Healthcare NHS Trust, HIV/GUM, London, United Kingdom; [2]Imperial College, Infectious Diseases, London; [3]University College London, London; [4]Royal Free Hospital NHS Trust, London; [5]Mortimer Market Centre, London; [6]Barts Health NHS Trust, London; [7]Brighton and Sussex University Hospitals NHS Trust, Brighton; [8]Imperial College Healthcare NHS Trust, Hepatology, London; [9]Queen Mary University, London*

Email: lucy.garvey@nhs.net

Background and Aims: Modelling of the London hepatitis C (HCV) epidemic in HIV-positive (HIV+) men who have sex with men (MSM) suggested early access to direct acting antiviral (DAA) treatment may reduce incidence. With high rates of linkage to care, micro-elimination of HCV within HIV+ MSM may be realistic, ahead of 2030 WHO targets. We examine trends in HCV incidence in the pre- and post-DAA eras for HIV+ MSM in London and Brighton.

Method: A retrospective cohort study was conducted at 5 HIV clinics in London and Brighton between 2013 and 2018. Each site reported all acute HCV episodes (first and reinfections) during the study period. Treatment pathway and timing were collected. Incidence rates and reinfection proportion were calculated.

Results: 378 acute HCV infections were identified, comprising 292 first infections and 86 reinfections. Incidence rates of acute HCV in HIV+ MSM peaked at 14.57/1000 PYFU [95%CI 10.95–18.20] in the second half of 2015. Rates fell to 4.63/1000 HIV+ MSM PYFU [95%CI 2.60–6.67] by 2018. Proportion of reinfections increased to 45% by 2018. Time from diagnosis to starting treatment reduced from 29.8 (2013) to 3.7 months (2018).



Conclusion: We observed a 78% reduction in incidence of first HCV episode and 68% reduction of overall HCV incidence in HIV+ MSM since the epidemic peak of 2015 which coincides with wider access to DAAs in England. However reinfection may be increasing. Further interventions to reduce transmission, including earlier access to treatment and for reinfection, are likely needed for micro-elimination to be achieved in this population.

AS040

Hepatitis C infection in the Spanish prison system. Elimination is a dream at our fingertips

Joaquin Cabezas[1,2], Olga Muñoz Castrejon[3], Enrique Acín[4], Francisco Fernandez Gonzalez[5], Carmen Martinez Aznar[3], Miguel Mateo[6], Javier Crespo[1,2,7]. *[1]University Hospital Marques de Valdecilla, Hepatology Unit, Santander, Spain; [2]Health Research Institute - IDIVAL, Santander, Spain; [3]Ministry of Interior, Subdirectorate General of Prsion Health Coordination, Madrid, Spain; [4]Ministry of Interior, General Directorate of Penitentiary Institutions, Madrid, Spain; [5]University Hospital Gregorio Marañón, Unit Of Restricted Area, Madrid, Spain; [6]Social Insertion Center "José Hierro", General Secretariat of Penitentiary Institutions, Santander, Spain; [7]University of Cantabria, Santander, Spain*
Email: joweycabezas@gmail.com

Background and Aims: Spanish Program to tackle hepatitis C infection included the prison setting as priority to treat all inmates regardless fibrosis stage from the early beginning of the plan. Actually, HCV treatment is extended to almost all the prisons, thus it is speeding up the goal of elimination. Many microelimination programs are ongoing, however we lack global data regarding HCV management within the Spanish Prison System. We aim to describe hepatitis C situation in Prison across the Spanish Country.
Method: We analyzed the systematic registry of the informatic database of Health Penitentiary Coordination Department of Spain, including registries from January 2015 to June 2019. This involved 71 prisons, and it did not include those in Catalonia.
Results: We found: 49,976 inmates in 2015, 49,224 in 2016; 47,803 in 2017; 47,901 in 2018 and 47,499 in 2019. Mean turnover rate was 58% (±47). Screening rate was 60.9% in 2015, 66.5% (2016), 48% (2017), 79% (2018) and 79% in 2019 ($p < 0,001$). This rate was lower in centers with higher turnover rate. Viremia prevalence is greatly decreasing across these years: 11% – 2016; 9% – 2017; 3% – 2018 and 1.9% – 2019. Regarding HCV genotype, globally we found 1a (31%), then 3 (18%) and 4 (12%); 1b (8%) and 1 (3%); 28% was undetermined. Overall, advance fibrosis (F3-F4) was found in 34%, however it has decreased from 57% in 2015 to 25% in 2019. SVR rates were independent of viral load, genotype, fibrosis stage and prison features. The decrease in prevalence has been independent of the region, the type of the prison, the number of inmates or the turnover rate. We observed a reduction in the incidence, going down from 0,47 in 2010 to 0,29 (per 1000 inmates/year) in 2018 ($p < 0.01$). Mean global mortality in the penitentiary setting is 0.28% in the last years. HCV-related mortality has come down from 0.018 in 2015 to 0.002 in 2018.
Conclusion: The emergence of direct acting antiviral for HCV and its universal access in the penitentiary setting has led to a significant decrease in the prevalence of HCV infection. The prison system provides high screening and treatment rates that are close to WHO recommendations to achieve elimination in this group.

AS041

Evaluating and communicating hepatitis C cascades of care data: a journey towards elimination in Tayside, Scotland

Cassandra Baiano[1,2], Emma Robinson[3], John Dillon[3]. *[1]University of St Andrews, School of Medicine, St Andrews, United Kingdom; [2]University of Dundee, School of Medicine, Dundee, United Kingdom; [3]School of Medicine - University of Dundee, Division of Molecular and Clinical Medicine, Dundee, United Kingdom*
Email: cbaiano@dundee.ac.uk

Background and Aims: Chronic Hepatitis C Virus (HCV) is one of the leading causes of liver cirrhosis and hepatocellular carcinoma, presenting a significant burden to global health systems, but is curable. The WHO 2030 Elimination Goals need each country to evaluate their response to their epidemics. This can be achieved by visualisation of Cascades of Care, depicting how infected cases move through disease stages. However, current methods of displaying HCV data are debated and lack practical application. This project proposes a fresh way of codifying and displaying HCV data using Tayside, Scotland as a case study.
Method: 1164 cases of active HCV infections in those that were alive and resident in Tayside between January 2015 and December 2018 were analysed from NHS Tayside's HCV Database. All those diagnosed, treated, and cured before 2015 were removed from the prevalence. Variables were evaluated to create a systematic coding framework that was then used to code each patient's diagnosis, treatment, and cure status each year from 2015–2018.
Results: Graphical representation of the data in the form of stacked clustered bar charts and cumulative line graphs demonstrate general trends and conversion rates: Tayside has seen a steady new HCV diagnosis rate and increase in treatment and cures, leading to a 3-fold increase in diagnosis-to-cure conversion rates from 15.36% (2015) to 43.77% (2018). This graphical representation also demonstrates how effectively previously diagnosed people and newly diagnosed people are accessing treatment: on average 24.94% of previously diagnosed and 34.31% of newly diagnosed patients are successfully engaging in treatment each year in Tayside. Cumulative data graphs show clear progress towards goals: Tayside shows encouraging progress towards WHO elimination targets with 77.9% of prevalent cases since 2015 were diagnosed, 71.0% treated, and 66.6% cured.
Conclusion: This project proposes a novel way of displaying Cascades of Care data that relays yearly snapshots of an epidemic, cumulative progression over time, nuanced information of each stage, and progression towards elimination targets. This method can be used in a meaningful way to improve local service planning, knowledge

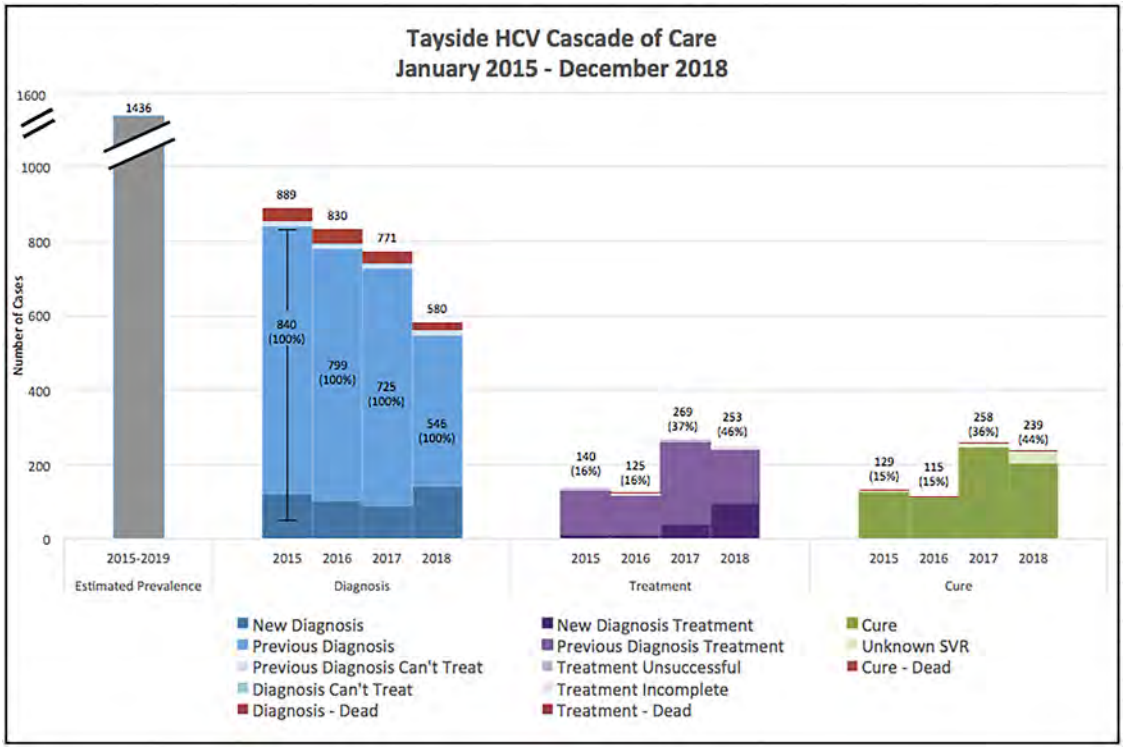


Figure: (abstract: AS041)

exchange across health systems globally, and reporting to bodies like the WHO.

AS042

Progress towards achieving hepatitis C elimination in the country of Georgia, April 2015-October 2019

Tengiz Tsertsvadze[1,2], Amiran Gamkrelidze[3], Nikoloz Chkhartishvili[1], Akaki Abutidze[1,2], Lali Sharvadze[2,4], Vakhtang Kerashvili[1], Maia Butsashvili[5], David Metreveli[6], Lia Gvinjilia[7], Shaun Shadaker[8], Muazzam Nasrullah[8], Tamar Gabunia[9], Ekaterine Adamia[9], Stefan Zeuzem[10], Nezam Afdhal[11], Sanjeev Arora[12], Karla Thornton[12], Francisco Averhoff[8]. *[1]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia; [2]Ivane Javakhishvili Tbilisi State University (TSU) Faculty Of Medicine, Tbilisi, Georgia; [3]National Center for Disease Control and Public Health, Tbilisi, Georgia; [4]Hepatology Clini HEPA, Tbilisi, Georgia; [5]Clinic Neolab, Tbilisi, Georgia; [6]Medical Center Mrcheveli, Tbilisi, Georgia; [7]TEPHINET; [8]Centers for Disease Control and Prevention, Division of Viral Hepatitis National Center for HIV, Hepatitis, STD&TB Prevention; [9]Ministry of IDPs from the Occupied Territories, Labour, Health, and Social Affairs of Georgia, Tbilisi, Georgia, Tbilisi, Georgia; [10]Goethe University Frankfurt, Frankfurt, Germany; [11]Beth Israel Deaconess Medical Center (BIDMC), Boston, United States; [12]ECHO Institute University of New Mexico, Albuquerque, USA, Albuquerque*
Email: tt@aidscenter.ge

Background and Aims: In April 2015 with the technical assistance of U.S. CDC and commitment from Gilead Sciences to donate direct acting antivirals (DAAs), Georgia launched the world's first HCV elimination program. A key strategy of the program is nationwide HCV screening, active case finding, linkage to care, provision of treatment for all HCV-infected persons and effective prevention interventions. The elimination program aims at achieving 90–95–95 targets by 2020: a) diagnose 90% of HCV-infected persons, b) treat 95% of those diagnosed, and c) cure 95% of those treated. We report progress towards elimination targets 4 years into the elimination program.

Method: A hepatitis C care cascade was constructed using data from the national HCV treatment program (Figure). A national serosurvey in 2015 estimated that 150,000 over 18 years of age were infected with HCV in the country. The program collects data on all persons registered with the treatment program. Treatment was provided with Sofosbuvir, Ledipasvir/Sofosbuvir or Velpatasvir/Sofosbuvir-based regimens. Data on persons tested for chronic HCV infection through sustained virologic response (SVR) were extracted as of October 31, 2019.

Results: Overall 121,043 persons tested positive for HCV antibodies and of those 97,348 (80.4%) underwent HCV confirmatory testing. Chronic HCV infection was confirmed in 79,955 (82.1%) persons, representing 53.3% of the estimated 150,000 adults living with HCV. A total of 62,927 (78.7%) patients initiated treatment – 49.1% of the estimated target population to be treated (128,250). Of the 41,220 patients who were evaluated for SVR, 40,693 (98.7%) tested negative for HCV by PCR, representing 33.4% of the estimated target population to be cured (121,837). Very high cure rates were achieved for all HCV genotypes: 98.9% in genotype 1, 98.9% in genotype 2 and 98.3% in most challenging to treat genotype 3. Treatment effectiveness was comparable among persons with advanced fibrosis (F3 and F4) with 98.2% achieving SVR, and among patients with mild or no liver fibrosis (≤F2), SVR = 99.0%.

Conclusion: Georgia has made substantial progress towards eliminating hepatitis C, with more than half of persons with HCV infection identified and registered for treatment. Very high cure rates have been achieved among those who received SVR testing. Challenges remain in identifying and especially linking to care persons living with HCV in Georgia. Nationwide integrated, decentralized model of HCV treatment, which is already implemented, will be critical to improve linkage to care and close the gaps in HCV cascade.

Complications of cirrhosis and ACLF

AS043

Adherence to surviving sepsis campaign 3-hour bundles improves survival in non-critically ill patients with cirrhosis and sepsis

Salvatore Piano[1], Leopoldo Torresan[1], Simone Incicco[1], Marta Tonon[1], Carmine Gabriele Gambino[1], Silvano Fasolato[1], Umberto Cillo[2], Patrizia Burra[3], Paolo Angeli[1]. [1]*University of Padova, Department of Medicine, Padova, Italy;* [2]*University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy;* [3]*University of Padova, Gastroenterology/Multivisceral Transplant Unit, Padova, Italy*
Email: salvatorepiano@gmail.com

Background and Aims: Sepsis is a common and life-threatening complication in cirrhosis. Surviving Sepsis Campaign recommendations suggest treatment bundles for sepsis. The early administration of sepsis bundles reduces mortality in general population, however no data is currently available in patients with cirrhosis. The aim of this study was to evaluate whether the adherence to 3-hour bundles could modify clinical outcomes in patients with cirrhosis and sepsis.
Method: From January 2012 to May 2019 consecutive non critically-ill patients with cirrhosis and bacterial infections were enrolled. Clinical, laboratory, microbiological and treatment data were collected at the diagnosis of infection and during the whole hospitalization. Adherence to 3-hour bundles (namely microbiological cultures obtained before the administration of antibiotics, administration of broad spectrum antibiotics within 3 hours and assessment of blood lactates) was assessed. Patients with sepsis were identified according to Sepsis-3 criteria recently adapted to patients with cirrhosis. Patients were followed up until death, liver transplantation (LT) or up to 90 days. LT was considered a competing event for death in survival analysis.
Results: 144 out of 329 patients with cirrhosis and infections had sepsis and were included in the analysis. (Age = 62 ± 11 years; MELD score = 23 ± 7). The most common infections were SBP (24%), pneumonia (22%) and spontaneous bacteremia (19%). Microbiologic cultures were obtained before antimicrobial therapy in 98 (68%) patients, broad spectrum antibiotics were given within 3 hours in 79 (55%) patients while lactates were measured in 69 (48%) patients. The adherence to the full 3-hour bundle was achieved in 27 (19%) patients.

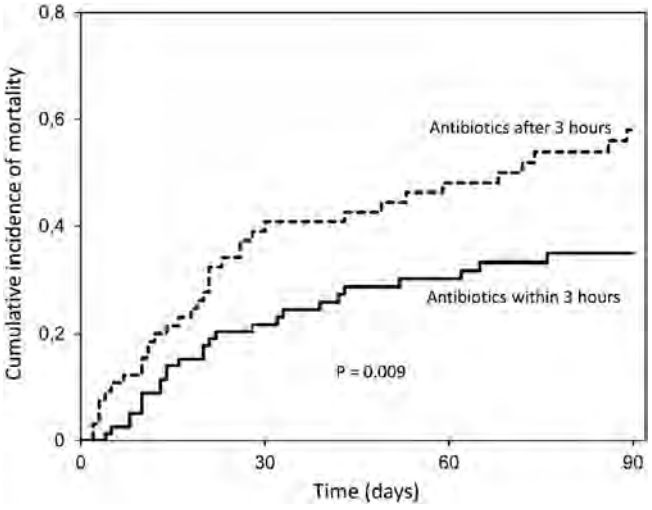

Figure: Cumulative incidence of mortality according to timing of antibiotic treatment.

The administration of empiric broad-spectrum antibiotics within 3 hours was associated with lower 28-day (22% vs 39%; p = 0.024) and 90-day cumulative incidence of mortality (35 vs 58%; p = 0.009; Figure). Mortality was further reduced in patients receiving antibiotics within 1 hour.
In multivariate competing risks analysis (adjusted for age, MELD score, ascites and hepatic encephalopathy) both adherence to the 3-hour antibiotic bundle (sHR = 0.46; p = 0.019) and culture bundle (sHR = 0.47;p = 0.027) were independently associated with better 28-day survival, while the measurement of lactates did not influence 28-day survival (sHR = 0.85; p = 0.63).
Conclusion: The adherence to the 3-hour antibiotic and culture bundles was associated with lower mortality in patients with cirrhosis and sepsis. However, the adherence to these bundles was not optimal and strategies should be developed to improve the adherence to sepsis bundles in patients with cirrhosis.

AS044

Stage 1b acute kidney injury in cirrhosis is likely due to underlying chronic kidney disease and would be more appropriately re-classified as acute-on-chronic kidney disease

Florence Wong[1], Rajender Reddy[2], Puneeta Tandon[3], Jacqueline O'Leary[4], Scott Biggins[5], Guadalupe Garcia-Tsao[6], Benedict Maliakkal[7], Jennifer Lai[8], Michael Fallon[9], Hugo E. Vargas[10], Ram Subramanian[11], Paul J. Thuluvath[12], Patrick S. Kamath[13], Leroy Thacker[14], Jasmohan S. Bajaj[15]. Email: florence.wong@utoronto.ca

Background: Stage 1 acute kidney injury (AKI) in cirrhosis (rise in serum creatinine [sCr] by ≥ 0.3 mg/dL in <48 hrs, or by 1.5 to 2.0 times from baseline) has been subdivided by EASL into stages 1a & 1b, with the final sCr being < or ≥ 1.5 mg/dL respectively, with stage 1a patients having a benign course but not stage 1b patients. However, stage 1b AKI diagnosis requires a relatively high baseline sCr (between 1.0 mg/dL for 50% increase of sCr, to 1.2 mg/dL for a Δ of 0.3 mg/dL), suggesting that there may be background chronic kidney disease (CKD). **Aim:** To test the hypothesis that a high baseline sCr is the basis of stage 1b AKI development, and is associated with a worse prognosis than stage 1a AKI.
Method: Admitted ascitic cirrhotic patients who developed stage 1 AKI per the International Ascites Club 2015 definition from the NACSELD database were included, comparing patients with stage 1a vs. 1b AKI with respect to demographics, laboratory values, AKI treatment response and survival.
Results: 419 of 2297 enrolled patients developed stage 1 AKI (1a: 43%). Stage 1b patients were older (60 ± 10 vs. 57 ± 10 years, p = 0.04), more had refractory ascites (60% vs. 39%, p < 0.0001), and more were on rifaximin (51% vs. 39%, p = 0.014). Otherwise, both subgroups had similar demographics, prevalence of diabetes, 6-month history of hospital admissions, and medication use. Significant differences were noted in their baseline renal function, MELD scores and response to treatment (Table). Significantly more stage 1b patients were treated for their AKI with midodrine (30% vs. 13%, p < 0.0001), with more

albumin being infused (289 ± 218 gm vs. 229 ± 245 gm, p = 0.005). More stage 1b patients needed RRT initiation (10% vs. 1%; p = 0.0001), with worse survival (Table).

	Stage 1a (n = 180)	Stage 1b (n = 239)	P value
Baseline sCr (mg/dL)	1.02 ± 0.30	2.02 ± 1.17	<0.0001
Baseline eGFR (ml/min)	66 ± 27	31 ± 12	<0.0001
Admission sCr (mg/dL)	1.16 ± 0.23	2.47 ± 1.34	<0.0001
Peak sCr (mg/dL)	1.49 ± 0.40	2.79 ± 1.52	<0.0001
Δ sCr (mg/dL)	0.48 ± 0.26	0.78 ± 0.66	<0.0001
Admission MELD	18.33 ± 6.27	24.58 ± 7.32	<0.0001
Course of AKI:			<0.0001
Transient	74% (125/168)	54% (126/232)	
Persistent	22% (37/168)	28% (66/232)	
Progressive	4% (6/168)	17% (40/232)	
30 day transplant free survival	88% (158/180)	77% (183/239)	0.0035

Conclusion: The worse prognosis in Stage 1b AKI patients is related to a more progressive AKI course, likely due to the presence of underlying CKD in the majority. Therefore, stage 1b AKI in cirrhosis should be assessed separately for natural history and treatment strategies.

AS045

Prophylaxis with norfloxacin is not associated with multi-drug resistant bacterial infections

Email: nelly.gutierrez@hospitalitaliano.org.ar

Background and Aims: The role of norfloxacin in the development of bacterial infections by multi-drug resistant organisms (MDRO) is controversial. We evaluated the effect of prophylaxis with norfloxacin in the development of MDRO infections in patients with cirrhosis.

Methods: Multicenter prospective cohort study (clinicatrials.gov NCT03919032) of cirrhotic patients with bacterial infections throughout Argentina. The outcome variable was infection caused by MDRO (culture-negative infections were classified as non-MDRO). The main exposure of interest was norfloxacin prophylaxis at the time of the bacterial infection (patients with other prophylaxis were excluded). We evaluated the effect of norfloxacin on MDRO using a weighted logistic regression model for the inverse of the probability of treatment. We used stabilized weights generated through a logistic regression model considering age, gender, cirrhosis etiology, MELD, medications (beta-blockers, proton pump inhibitors, immunosupressors and rifaximin); recent invasive procedures, therapeutic antibiotic use and hospitalizations; history of ascites, bacterial infections and infection/colonization by MDRO; diabetes; and whether patients were treated in a transplant center or not.

Results: A total of 383 patients from 20 centers were included, 46 (12%) were on prophylaxis with norfloxacin. The most frequent infections were SBP (29%) and urinary tract infection (24%). MDRO were isolated in 85 (22%) patients: 11 (24%) with norfloxacin prophylaxis and 74 (22%) without norfloxacin prophylaxis (p = 0.765). The most frequent MDRO were enterobacteriaceae (63%) and methicillin-resistant staphylococcus aureus (15%). Patients with norfloxacin had higher MELD and were more likely to have received rifaximin and proton pump inhibitors and to have a history of invasive procedures than patients without norfloxacin (Table). No association was found between norfloxacin use and infection by MDRO in the weighted analyses considering the variables detailed in methods (OR_{IPW} 2.84, 95% CI, 0.66 to 12.32; p = 0.162).

	Without norfloxacin (n = 337)	With norfloxacin (n = 46)	p
Age – years*	59 (51–66)	50 (60–64)	0.810
Male**	220 (65.3)	34 (74.0)	0.751
MELD*	17 (13–23)	20 (16–27)	0.012
Diabetes**	107 (31.9)	15 (32.6)	0.927
Rifaximin**	84 (25.1)	24 (52.2)	<0.001
Proton pump inhibitor**	123 (37.2)	29 (63.0)	<0.001
Recent antibiotic treatment**	107 (32.8)	20 (43.5)	0.156
Recent invasive procedures**	113 (35.3)	26 (59.2)	0.003
Prior isolation of MDRO**	15 (4.7)	3 (6.7)	0.571
Nosocomial/HCA infection**	153 (45.3)	30 (65.2)	0.053
Ascites**	251 (74.5)	40 (86.9)	0.070
Prior bacterial infections**	63 (20.0)	15 (35.0)	0.025

*Median (IQR); **Number (%).

Conclusion: The results of our study, which applies methods that strengthen causal inference, reinforces that prophylaxis with norfloxacin is not associated with infections by MDRO.

AS046

Risk of mortality in patients with uncontrolled variceal bleeding is determined by the presence and severity of acute on chronic liver failure (ACLF) and early transjugular intrahepatic portosystemic shunt (TIPSS) reduces long term mortality

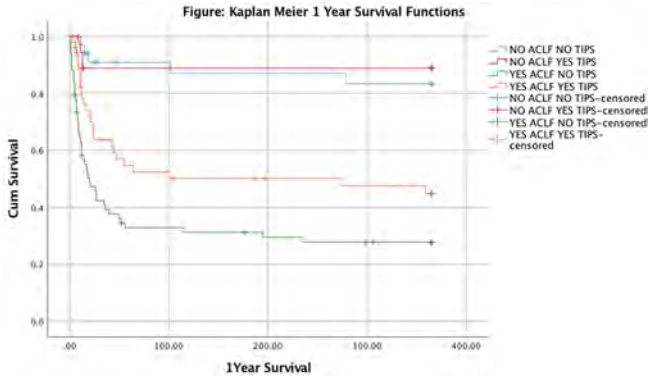
Rahul Kumar[1,2], Annarein Kerbert[1], Joana Calvão[1], Raj Mookerjee[1], Banwari Agarwal[3], David Patch[4], Rajiv Jalan[1,4]. *[1]University College of London, Liver Failure Group, London, United Kingdom; [2]Changi General Hospital, Gastroenterology and Hepatology, Singapore; [3]Royal Free Hampstead NHS Trust, Critical Care, London; [4]Royal Free Hampstead NHS Trust, Hepatology, London*
Email: rahul.kumar@singhealth.com.sg

Background and Aims: Mortality of patients with variceal bleeding (OGVB) that is uncontrolled with endoscopic therapy is associated with a high-risk of mortality. ACLF occurs in cirrhotics and is

characterized by organ failure(s) and high-risk of mortality but whether it is of prognostic significance in OGVB patients is not known. Early TIPSS insertion in patients with ongoing bleeding is thought to improve survival, but whether patients with ACLF will benefit is not clear. The aims of this study were to determine whether ACLF and its severity defines the risk of death and whether TIPSS improves the survival of patients with poorly controlled OGVB and ACLF.

Method: From a prospectively maintained registry kept by the ICU, Royal Free Hospital (RFH), data of 174 consecutive patients with OGVB and evidence of ongoing bleeding despite endoscopic therapy between 2005 and 2015, who were admitted to ICU were included. All patients were managed according to the standard of care for acute OGVB and organ support was instituted when required. Early TIPSS was defined as technically successful TIPSS done within 72 hours of an acute OGVB episode. Standard statistical tests were used to address the above questions and Cox regression was used for multivariate modelling.

Results: ACLF patients (n = 120) were significantly different to AD (n = 54) [older age: p = 0.03; ascites: p = 0.002; hepatic encephalopathy: p < 0.001; >organ failures (p < 0.001); >white cell count (p = 0.007); >INR (p < 0.001); >bilirubin and creatinine (p < 0.001)] but the number of bleeds and transfusion requirements were similar. 28-day, 90-day and 1-year mortality in the AD patients was 9.3%, 9.3% and 13% compared with 46.7%, 55.8% and 60.8% in the ACLF groups (p < 0.001) respectively (Fig); mortality increased with increasing ACLF grade (p < 0.001). TIPSS was inserted in 72 patients [(Median time to TIPSS from Index bleed 1 day, (IQR: 0–3)] (AD: 20 (37%); ACLF: 52 (43%) (p = 0.4), which reduced mortality of ACLF (p = 0.01) but not in AD patients. In the multivariable model in patients who had ACLF, age (p = 0.009), temperature (p = 0.022), white cell count (p = 0.029), CLIF-OF score (1.323(1.111–1.576); p = 0.002) and TIPS placement (0.546(0.302–0.987); p = 0.045) (Fig) were independent predictors of mortality.



Conclusion: This study shows for the first time that, OGVB that is not controlled with endoscopic therapy, the presence and severity of ACLF and systemic inflammation determines the risk of 28-day and 1-year mortality. Early TIPSS improves the survival of ACLF patients.

AS047

Increased survival in patients with hepatic encephalopathy treated with rifaximin-alpha in combination with lactulose: an observational study from UK clinical practice

Bethan Jones[1], Ellen Berni[1], Chris Poole[1], Sara Jenkins-Jones[1], James Orr[2], Bharat Amlani[3], Sean Walsh[3], Craig Currie[4].
[1]*Pharmatelligence, Cardiff, United Kingdom;* [2]*University Hospitals Bristol, Hepatology Department, Bristol, United Kingdom;* [3]*Norgine Ltd, Harefield, United Kingdom;* [4]*Cardiff University, School of Medicine, Cardiff, United Kingdom*
Email: bethan.jones@pharmatelligence.co.uk

Background and Aims: Hepatic encephalopathy (HE) is a neuropsychiatric complication of cirrhosis signalling hepatic decompensation. Overt HE episodes are medical emergencies that render patients' incapable of self-care, and frequently result in hospitalisation, coma, and/or death. In randomized studies, rifaximin-alpha (RFX) in combination with lactulose (LCT) significantly reduced the risk of HE episodes and overt HE-related hospitalisations compared with LCT alone. It has been postulated that treatment with RFX should increase life expectancy in these patients. In this study, our aim was to evaluate the impact of RFX treatment on survival in "real-world" patients with HE in the United Kingdom (UK).

Method: Anonymised primary and secondary care health records from the Clinical Practice Research Datalink (CPRD) sourced HE patients treated with RFX and LCT, either as monotherapy or in combination, from 2003 to 2019 in primary care. Treatment was assumed to last for 28 days either side of prescription date. The primary endpoint was all-cause mortality (ACM) confirmed by national registration. Time to event from first proxy HE diagnosis (index) was analysed by extended Cox proportional hazards regression, where treatment and other covariates were modelled as monthly, updated, time-dependent parameters to maximise data availability.

Results: There were 4,669 patients newly diagnosed with HE, of which 61% were male, with a mean age of 59 years (SD 13), for whom 1,107 years of RFX, 1,500 years of LCT, and 1,157 years of RFX+LCT treatment were recorded. In total, 2,039 deaths were observed, at a rate of 271 per 1,000 person years. Compared to LCT-alone, RFX+LCT had an adjusted hazard ratio for ACM of 0.82 (95%CI: 0.70 to 0.96), while for RFX-treatment the aHR was 1.11 (95%CI: 0.94 to 1.30). Other ACM co-variables included age, gender, prior liver cancer, ascites, platelet count, estimated glomerular filtration rate, albumin and sodium.

Conclusion: Treatment with RFX+LCT improved survival compared to LCT-alone in routine clinical practice in the UK.

AS048

Supplementation with branched-chain amino acids improves muscle mass of cirrhotic patients with sarcopenia

Marta Hernández Conde[1], Elba Llop[1], Beatriz Tormo[1], Christie Perelló[1], Marta López-Gómez[1], Javier Abad Guerra[1], Luis Rodríguez[1], José Luis Martínez Porras[1], Natalia Fernández Puga[1], Carlos Ferre[1], Maria Trapero[1], Enrique Fraga[1], José Luis Calleja Panero[1]. [1]*Hospital Puerta de Hierro-Majadahonda, Majadahonda, Spain*
Email: marta.hernandez.conde@gmail.com

Background and Aims: It is controversial whether sarcopenia can be reversed in patients with liver cirrhosis. On the other hand, the effect of branched-chain amino acids(BCAA) supplementation on protein

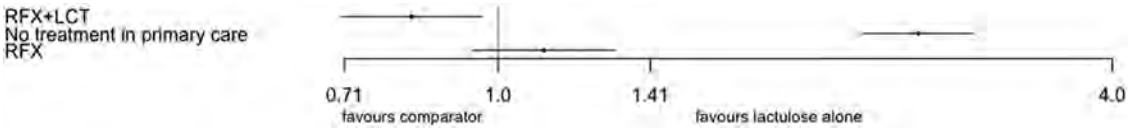


Figure: (abstract: AS047): Forest plot for RFX+LCT, RFX, and no treatment in primary care versus lactulose.

and albumin synthesis is known. However, the role of BCAA on skeletal muscle mass in patients with cirrhosis and sarcopenia is unknown.
Method: Pilot, prospective, randomized and double-blind study of a cohort of patients with cirrhosis and sarcopenia diagnosed by CT scan. Each envelope of BCAA contained: 15 g of protein, 8.5 g of fat, 68 g of carbohydrates, BCAA(leucine, isoleucine and valine), additional vitamins and minerals. The study protocol was approved by the Institutional Review Boards(PI11.17) and was registered at ClinicalTrials.gov(NCT04073693).
Results: 32 patients performed nutritional and physical activity intervention for 12 weeks. Divided into2groups: 17patients in placebo group and 15patients in BCAA group. Baseline characteristics were similar in both groups. No adverse effects or hepatic decompensation were reported during the intervention. All patients maintained good adherence to nutritional supplements and increased a median of 2000steps(1000; 2500) in both groups($p = 0.22$). At 12 weeks after the start of treatment, BCAA group had a higher increase in zinc levels than placebo group(Δzinc:12.3 vs. 5.5;$p = 0.026$). In addition, there was a tendency for higher improvement of albumin in the BCAA group(Δalbumin:0.19 vs. 0.04;$p = 0.091$). After treatment, only BCAA group presented a significant improvement in muscle mass(Δmuscle mass: 2.3 vs. 0.04; $p = 0.022$). Muscle mass after treatment with BCAA was significantly higher than baseline (43.7 vs. 46 cm^2/m^2; $p = 0.023$). This difference between post and pre-muscle mass was not evident in the placebo group (44.5 vs. 44.6 cm^2/m^2; $p = 0.936$). 5 patients (18.5%) presented resolution of sarcopenia. Although this resolution was more prevalent in the BCAA group, the difference was not statistically significant (25 vs. 13.3%; $p = 0.628$). Likewise, there was improvement in muscle mass in 17 patients(63%). Muscle mass improvement was more frequent in the BCAA group (83.3 vs. 46.7%; $p = 0.056$). Regarding the evaluation of frailty after 12 weeks of intervention, there were no differences between groups(ΔLiver Frailty index: −0.37 vs. −0.31; $p = 0.581$). However, in the global cohort of patients ($n = 32$), there was a significant improvement in the Liver Frailty index after 12 weeks of intervention (4.2 vs. 3.9; $p < 0.001$). This difference was significant in both groups, both in the placebo group (4.2 vs. 3.8; $p < 0.001$) and in the BCAA group (4.2 vs. 3.9; $p < 0.001$). Regarding liver function, there were no differences in the modification of MELD score during the follow-up (ΔMELD: 0.6 vs. 0.3; $p = 0.695$).
Conclusion: BCAA supplementation for 12 weeks improves muscle mass measured by CT scan in patients with cirrhosis and sarcopenia.

Immunity and Hepatocellular Carcinoma

AS049
Identification of a panel of safe immunogenic antigens for therapeutic vaccination strategies in hepatocellular carcinoma

Lisanne Noordam[1], Zhouhong Ge[1], Hadiye Öztürk[1], Shanta Mancham[1], Michael Doukas[2], Patrick Boor[1], Guoying Zhou[1], Isabel Vögler[3], Qiuwei Pan[1], Jan IJzermans[4], Marco J. Bruno[1], Dave Sprengers[1], Jaap Kwekkeboom[1]. *[1]Erasmus MC, Gastroenterology and Hepatology, Rotterdam, Netherlands; [2]Erasmus MC, Pathology, Rotterdam, Netherlands; [3]Biopharmaceutical New Technologies (BioNTech) Corporation, Mainz, Germany; [4]Erasmus MC, Surgery, Rotterdam, Netherlands*
Email: j.kwekkeboom@erasmusmc.nl

Background and Aims: Cancer/testis antigens (CTAs) are frequently overexpressed in tumor cells and most lack expression in healthy adult tissues, excluding the immune-privileged testis. This, combined with being immunogenic, makes CTAs attractive targets for therapeutic vaccination in cancer patients. We aimed to define a panel of immunogenic testis-restricted CTAs, of which each CTA is expressed in ≥ 10% of hepatocellular carcinoma (HCC) tumors, that can be used for off-the-shelf vaccination-strategies in HCC.
Method: Literature and database study identified 50 CTAs supposedly expressed in HCC and not in healthy tissues. mRNA expression of CTAs was determined by RT-qPCR in healthy livers ($n = 21$), healthy adult tissues ($n = 22$ different tissues), and paired tumor and tumor-free liver (TFL) tissues ($n = 100$; obtained after resection with curative intent). Immunogenicity was established by measuring proliferation of peripheral blood T-cells from 14 HCC patients (treated with local ablative therapy) against autologous B-cell blasts transfected with CTA-encoding mRNA.
Results: Of the 50 selected CTAs, 24 were excluded due to mRNA expression in healthy livers. Of the remaining 26 CTAs, 12 were expressed in tumors of ≥ 10% of HCC patients and not in any healthy tissue except testis. Seventy-nine percent of HCC patients expressed at least one of these CTAs and >50% of patients expressed at least 3. Interestingly, in 45% of HCC patients CTA expression was detected in TFL, which was a negative independent prognostic factor for HCC-recurrence (hazard ratio [HR] 2.28; $p = .003$) and HCC-specific survival (HR 2.51; $p = .026$) after resection. See Figure for the Kaplan Meier curves.
Up to now six CTAs have been tested for immunogenicity. Ten out of fourteen HCC patients displayed CD4 and/or CD8 T-cell responses

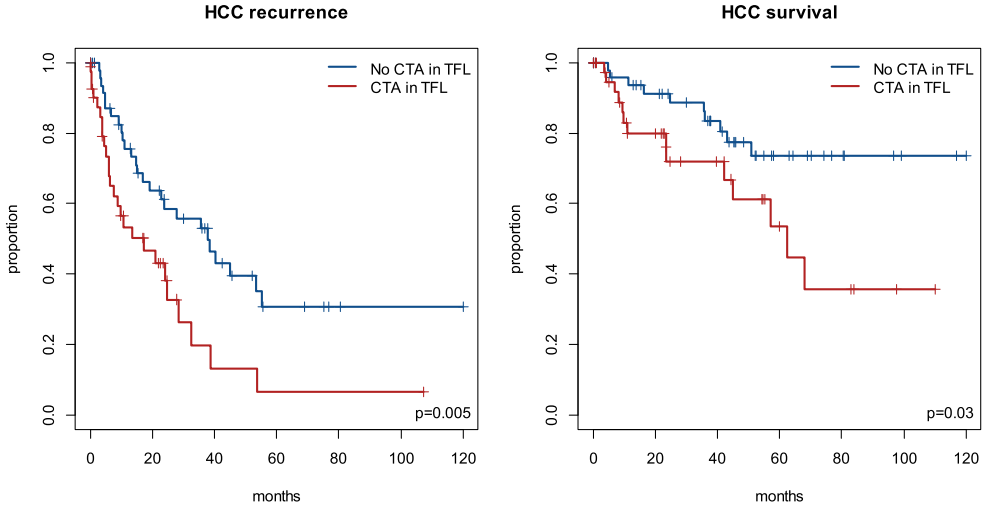

Figure: (abstract: AS049)

against one or multiple CTAs, and all CTAs induced a T-cell response in at least one patient. MAGE-A1 and MAGE-C2 most frequently invoked T-cell responses, both in 5 patients.
Conclusion: In this comprehensive study, we established a panel of 12 testis-restricted CTAs which are expressed in almost 80% of HCC tumors. The negative association between expression of these CTAs in TFL and HCC-recurrence and -survival shows the relevance of targeting of these antigens. Preliminary immunogenicity tests show that the 6 examined CTAs are immunogenic. In HCC, immunotherapeutic strategies targeting these CTAs may therefore be a valuable addition to currently available immunotherapies like checkpoint blockade, to improve systemic anti-tumor immunity.

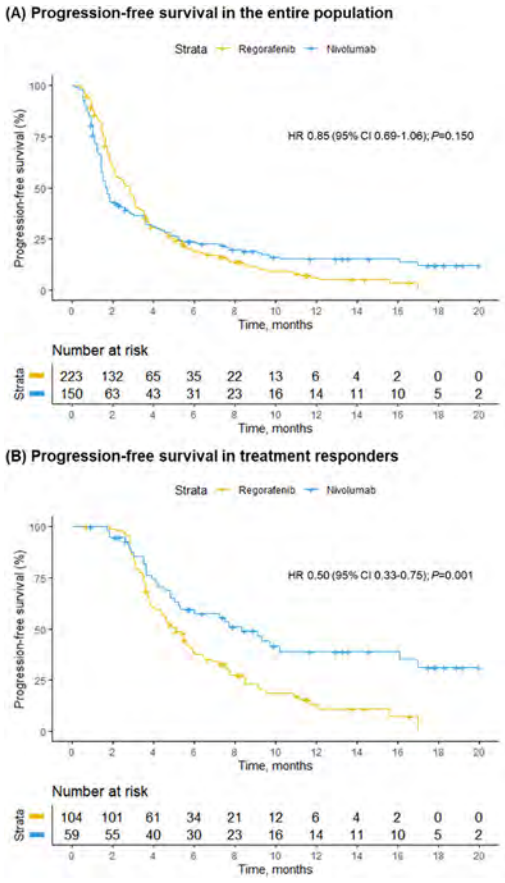
Regorafenib versus nivolumab after sorafenib failure: real-world data in patients with hepatocellular carcinoma

Won-Mook Choi[1], Jonggi Choi[1], Ju Hyun Shim[1], Young-Suk Lim[1], Han Chu Lee[1], Kang Mo Kim[1]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Liver Center, Seoul, Korea, Rep. of South*
Email: kimkm70@amc.seoul.kr

Background and Aims: Regorafenib and nivolumab are drugs approved for second-line treatment of patients with hepatocellular carcinoma (HCC) after sorafenib failure. However, the effectiveness of regorafenib and nivolumab following sorafenib has not been directly compared in a real-world clinic setting.
Method: This study retrospectively evaluated 373 patients with HCC who were treated with regorafenib (n = 223) or nivolumab (n = 150) as a second-line treatment after sorafenib failure between July 2017 and February 2019.



Results: Progression-free survival (PFS; hazard ratio [HR], 0.85; 95% confidence interval [CI], 0.69–1.06; P = 0.150), time to progression (TTP; HR, 0.95; 95% CI, 0.77–1.19; P = 0.680), and overall survival (OS; HR, 0.83; 95% CI, 0.64–1.07; P = 0.154) did not differ significantly between groups of patients treated with regorafenib and nivolumab, findings consistently observed by multivariable-adjusted, propensity score-matched, and inverse probability treatment weighting (IPTW) analyses. However, the objective response rate was significantly higher in the nivolumab than in the regorafenib group (13.3% vs, 4.0%; P = 0.002). When the effectiveness of regorafenib and nivolumab was compared in treatment responders, defined as patients who achieved complete response, partial response, or stable disease after first response evaluation, PFS (HR, 0.50; 95% CI, 0.33–0.75; P = 0.001), TTP (HR, 0.48; 95% CI, 0.31–0.73; P < 0.001), and OS (HR, 0.51; 95% CI, 0.31–0.87; P = 0.013) were significantly longer in the 59 responders to nivolumab than in the 104 responders to regorafenib, findings also observed by multivariable-adjusted and IPTW analyses.
Conclusion: Survival outcomes in patients treated with regorafenib and nivolumab after sorafenib failure did not differ significantly. However, nivolumab may be more effective than regorafenib in treatment responders.

AS051

Identification of neoantigen-reactive T cells in hepatocellular carcinoma: implication in adoptive T cell therapy

Enric Vercher[1], Ibon Tamayo[1], Uxua Mancheño[1], Edurne Elizalde[1], Enrique Conde[1], David Reparaz[1], Juan J. Lasarte[1], Virginia Villar[2], Mercedes Iñarrairaegui[3], Bruno Sangro[3], Pablo Sarobe[1], Sandra Hervás-Stubbs[1]. *[1]Centro de Investigación Médica Aplicada (CIMA), Universidad de Navarra, Immunology and Immunotherapy Program, Centro de Investigación Médica Aplicada (CIMA), Universidad de Navarra, Pamplona, Spain; IdiSNA, Instituto de Investigación Sanitaria de Navarra, Pamplona, Spain; CIBEREHD, Pamplona, Spain, Pamplona, Spain; [2]Centro de Investigación Médica Aplicada (CIMA), Universidad de Navarra, IdiSNA, Instituto de Investigación Sanitaria de Navarra, Pamplona, Spain; Biobanco, Centro de Investigación Médica Aplicada (CIMA), Universidad de Navarra, Pamplona, Spain, Pamplona, Spain; [3]Clinica Universidad de Navarra, IdiSNA, Instituto de Investigación Sanitaria de Navarra, Pamplona, Spain; CIBEREHD, Pamplona, Spain; Liver Unit, Clínica Universidad de Navarra, Pamplona, Spain, Pamplona, Spain*
Email: evercher@alumni.unav.es

Background and Aims: Emerging evidence has suggested that neoantigens (NeoAgs) play a critical role in antitumor immune response. Tumor-infiltrating T lymphocytes (TILs) specific for NeoAgs have been identified in patients with high mutational load (ie: melanoma), but also in tumor with intermediate mutational load, such as cholangiocarcinoma. Hepatocellular carcinoma (HCC) ranks in the group of tumors with moderated mutation load but evidence for the existence of neoAgs-specific TILs is still lacking. Our aim was to investigate if patients with HCC harbor T lymphocytes that recognize neoAgs expressed by autologous tumors.
Method: Whole exome (WES) and transcriptome (RNAseq) sequencing of tumor lesions and normal tissues were performed in 4 HCC patients submitted to surgery. Somatic variants, including single nucleotide variants (SNVs) and indels, were analyzed using a bioinformatic pipeline that incorporates 4 variant callers and data from WES and RNAseq. All somatic variants, independent of prediction algorithms, were tested for TIL recognition. For each patient, we generated multiple TIL cultures from tumor fragments. To determine if any of the TIL cultures specifically recognized the mutant gene products (25 amino acid peptides containing the mutant amino acids), autologous antigen presenting cells were transfected with tandem minigenes (encoding all the mutations) or pulsed with synthetic peptide pools (containing the mutations) and then co-cultured with TILs. The specific T-cell response was evaluated by ELISPOT of IFNγ and detection of CD137 by flow cytometry.
Results: WES and RNAseq analysis of the tumor lesions revealed variable numbers of non-synonymous somatic mutations, ranging

from 11 to 78 mutations. SNVs were the most common mutation types (93%). Interestingly, CD4+ TILs from the patient harboring the highest number of somatic mutations recognized patient's specific neoAgs, as determined by both ELISPOT assay and upregulation of CD137 molecule. We are currently working on the further characterization of these neoAg-specific TIL populations.
Conclusion: This finding suggests that neoAg-reactive TILs reside in HCC and provides a rationale for the future use of adoptive T cell therapy targeting neoAgs in this tumor. Fundings by Gobierno de Navarra Salud (45/2017).

PD1Hi CD103+ CD8+ T cells with exhausted-like Trm features promote tumor progression, but predict a favorable response to anti-PD1 treatment in hepatocellular carcinoma

Xiaolong Chen[1], Qing Yang[1], Shuguang Zhu[1], Xuejiao Li[2], Haoqi Chen[1], Genshu Wang[1]. [1]*The third affiliated hospital of Sun Yat-sen university, Department of Hepatic Surgery, Liver Transplantation, Guangzhou, China;* [2]*The third affiliated hospital of Sun Yat-sen university, Guangdong Key Laboratory of Liver Disease Research, Guangzhou, China*
Email: wgsh168@163.com

Background and Aims: Tissue resident memory cells (TRM) define a subset of T cells commitment to their tissue of residence. Conventional identified TRM cells exhibit higher levels of expression effector cytokines that are thought to provide potent front line defense against infectious diseases and carcinomas. While recently exhausted TRM cells have been reported to involved in immune balance of some infectious diseases. So, the features of TRM cells are far from elaborated and its role in hepatocellular carcinoma (HCC) remains elusive.
Method: Forty-four paired peripheral blood, nontumor tissues and HCC specimens from patients received surgical resection were obtained to identify the phenotype features, functional state and clinical significance of TRM cells. In addition, the formation and maintenance of exhausted TRM cells were explored in vitro. Furthermore, the association between TRM cells and anti-PD1 treatment efficacy was determined in HCC patients.
Results: We identified a novel subset of tumor- infiltrated CD8 +CD103+ T cells that coexhibit exhaustion and tissue residence features. These exhausted-like TRM cells exhibited high levels of PD1 and other immune check points (Tim3, LAG3) with inferior expression effector cytokines of IFN-g and TNF-a. Persistent TCR stimulation in HCC environment was crucial for exhausted PD-1^{hi} CD103+ T cells induction, which can be abolished by inhibiting MAPK signals mediated autophagy. Furthermore, exhausted-like TRM cells can be further reinvigorated by PD1 blockade in vitro and predict a favorable response to Anti-PD1 therapy in HCC patients.
Conclusion: PD1^{hi}TRM cells were accumulated in HCC but exhausted that invades anti-tumor immunity. Exhausted TRM cells can be further reinvigorated by PD1 blockade and might initiate a favorable response to Anti-PD1 therapy in HCC patients.

AS053

Cabozantinib enhances the efficacy and immune modulatory activity of anti-PD1 therapy in a syngeneic mouse model of hepatocellular carcinoma

Roger Esteban-Fabró[1], Catherine E. Willoughby[1], Marta Piqué-Gili[1], Judit Peix[1], Carla Montironi[1], Jordi Abril-Fornaguera[1], Laura Torrens[1,2], Roser Pinyol[1], Josep M. Llovet[1,2,3]. Email: jmllovet@clinic.cat

Background and Aims: Immune checkpoint inhibitors (ICPIs) including anti-PD1 therapies have shown promising results for the treatment of hepatocellular carcinoma (HCC), however responses are only observed in a subset of patients (15–20%). Cabozantinib is an FDA-approved tyrosine kinase inhibitor with anti-angiogenic, anti-proliferative and immune-stimulatory activity, thus potentially promoting a switch among immunologically "cold" tumours towards a favourable "hot" immune profile and improved responses to ICPIs. Here we aimed to assess the anti-tumour effects and mechanism of action of cabozantinib alone and in combination with anti-PD1 treatment in an immunocompetent murine model of HCC.
Method: C57BL/6J mice bearing subcutaneous Hepa1-6 tumours (200–300 mm^3) were randomised to receive anti-PD1 or placebo IgG (10 mg/kg *i.p.* every 3 days for a total of 5 doses) ± cabozantinib (30 mg/kg daily *p.o.*) (20 mice per treatment). Six mice per arm were culled after the last anti-PD1 dose and 2 hours after cabozantinib administration (day 14 of treatment). The remaining mice were sacrificed at study termination (day 32). Blood and tumour samples were collected for histological and molecular analyses, immune cell characterisation by flow cytometry, and cytokine profiling using a multiplex assay.
Results: Both cabozantinib and anti-PD1 monotherapies significantly reduced tumour growth or induced tumour regression compared to placebo ($p < 0.05$). Combination treatment exhibited the greatest anti-tumour effect, inducing the highest objective response rate (79%) and shortest time to objective response (7 days, $p < 0.03$ *vs.* placebo). Histological examination revealed that cabozantinib and combination-treated tumours had significantly reduced viable tissue volumes ($p < 0.001$) and higher rates of necrosis ($p < 0.01$) compared to placebo. Flow cytometry analysis revealed increased proportions of tumour-infiltrating neutrophils, lower proportions of tumour-infiltrating exhausted CD8+ T cells, and higher overall proportions of circulating T lymphocytes in cabozantinib and combination-treated animals ($p < 0.05$). Furthermore, significantly increased circulating memory/effector T cell proportions were observed in combination-treated mice ($p < 0.05$ *vs.* placebo). Peripheral blood profiling of 31 cytokines revealed changes including increases in the T lymphocyte chemo-attractants IL-16 and CCL27 in combination-treated mice compared to placebo ($p < 0.05$). Gene expression and IHC analyses of tumour samples are ongoing.
Conclusion: Cabozantinib increased the response rate to anti-PD1 therapy and had beneficial immunomodulatory activity in our syngeneic model, thus supporting further investigation into combining cabozantinib and anti-PD1 for the treatment of HCC.

AS054

Treatment-related toxicity predicts for improved outcome in patients with hepatocellular carcinoma (HCC) treated with immune checkpoint inhibitor therapy

Email: david.pinato@imperial.ac.uk

Background and Aims: Reversal of cancer immune-tolerogenesis with immune checkpoint inhibitors (ICI) is an emerging therapeutic modality in HCC, although the precise molecular mechanisms underscoring ICI efficacy are poorly understood. The development of treatment-related adverse events (trAE) favourably influences outcome in ICI recipients. In this multi-center study we aimed to verify its prognostic role in HCC.
Method: We established an international consortium of 9 tertiary referral centres located in Europe (n = 68), United States (n = 226) and Asia (n = 47) to derive a prospectively maintained cohort of 341 patients who underwent ICI treatment. We tested whether the development of clinically significant trAE (ie. graded >2) predicted for improved overall response rates (ORR) and overall (OS), using time-dependent survival analyses.
Results: Of 331 eligible patients, 254 (76%) had Barcelona Clinic Liver Cancer stage C HCC, 233 were cirrhotic (70%) mostly due to Hepatitis C infection (n = 129, 39%). Patients had received at least 1 line of prior systemic therapy (n = 297, 90%) before anti-PD-1/PD-L1 ICI mono-therapy (n = 280, 85%) or combinations (n = 51, 15%). Median OS was 12.1 months (95%CI 9.2–15 months) and ORR was 19% with 23 complete (6%) and 42 partial responses (13%). Overall, 133 patients (40%) experienced at least 1 trAE. Seventy were of grade >2 (21%), most frequently affecting the liver (n = 24, 7%). Permanent ICI discontinuations were secondary to disease progression (n = 160, 48%) or unacceptable toxicity (n = 12, 4%).
Emergence of trAEs graded >2 whilst on ICI predicted for improved OS (median 19.7 versus 11.0 months, Hazard Ratio [HR] 0.32, 95%CI 0.16–0.65, p = 0.001) and increased ORR (30% vs. 16%, Chi-square 5.9, p = 0.01). Other univariable prognostic factors included AFP>400 ng/mL (HR 1.49 95%CI 1.1–2.0, p = 0.01), Child Pugh Class (B vs. A, HR 2.74, 95%CI 1.8–4.0, p < 0.0001) and geographical origin (Europe vs. Asia HR 0.50 95%CI 0.27–0.92, p = 0.02). Following time-dependent Cox regression analyses, the occurrence of trAEs remained a predictor of improved OS (HR 0.39, 95%CI 0.16–0.92, p = 0.03) independent of Child Pugh Class (HR 1.99, 95%CI 1.18–3.35, p = 0.009), BCLC stage (p = 0.43), AFP levels (p = 0.11), geographical origin (p = 0.67) corticosteroid therapy (p = 0.54) and type of immunotherapy regimen received (monotherapy vs. combination, p = 0.58).
Conclusion: This is the first study to demonstrate that trAEs may influence response and survival in patients with HCC receiving ICI. Mechanistic studies highlighting the immune-biologic foundations of such relationship are warranted.

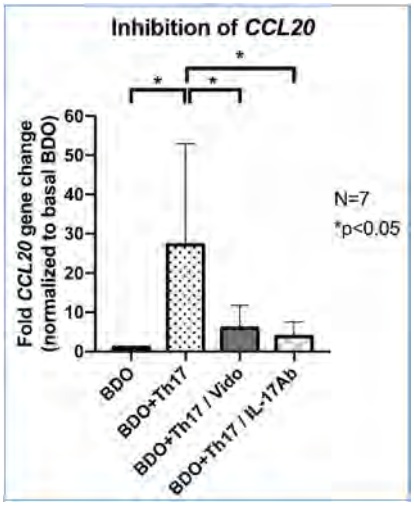
Immune-mediated and chronic cholestasic liver disease: Experimental and pathophysiology

AS055

Co-culture of bile-derived organoids from primary sclerosing cholangitis patients with CD4+ T cells replicates pathogenic, CCL20 dependent biliary-immune interactions

Carol J. Soroka[1], Scott Roberts[1], Simon Hohenester[2], James L. Boyer[1], David N. Assis[1]. [1]*Yale School of Medicine, Medicine - Digestive Diseases, United States;* [2]*Medical Center of the University of Munich, Germany*
Email: david.assis@yale.edu

Background and Aims: The difficulty in obtaining primary cholangiocytes has limited advances in Primary Sclerosing Cholangitis (PSC). We recently reported that human PSC Bile-Derived Organoids (BDOs) exhibit biliary cell features and an inducible reactive inflammatory phenotype (Soroka et al Hepatology 2018). This suggests that BDOs can be used for biliary-immune studies, however co-culture testing has not been reported. We studied human PSC BDO/T-cell interactions and inhibition of pathogenic inflammatory signaling.
Methods: Transwell migration assays were performed with healthy control CD4+ T-cells activated by CD3/CD28 crosslinking and conditioned culture supernatants from PSC BDO stimulated with IL-17A or TNF-alpha. Naïve control CD4+ T-cells were co-cultured with unstimulated BDOs for 48 hrs. CD4+ T-cells were differentiated to a Th17 phenotype then co-cultured with unstimulated BDOs for 48 hrs ± anti-IL17 Ab or vidofludimus (Vido), a T-cell inhibitor. BDO genes were analyzed by RT-qPCR, cytokine secretion by ELISA, and T-cell activation by FACS.
Results: BDOs stimulated with IL-17A or TNF-alpha significantly increased CCL20 secretion vs. unstimulated BDOs (IL-17A: 41,764; TNF-alpha: 167,763; unstimulated: 7,095 pg/mL, p < 0.005). Transwell migration assays showed that significantly more activated (CD69+) T-cells migrated toward supernatants from IL-17A (1.27-fold) and TNF-alpha (1.55-fold) stimulated vs. unstimulated BDOs (p < 0.05, p < 0.005, respectively). Co-culture of unstimulated BDOs with naïve CD4+ T-cells revealed that some BDOs can directly induce the T-cell activation marker CD69. Furthermore, co-culture of unstimulated BDOs with Th17 cells revealed a significant increase in BDO *CCL20* expression (30-fold) and CCL20 secretion (11.5-fold) compared to BDOs without Th17 cells (p < 0.05 for each). Importantly, gene expression and protein secretion of CCL20, and of IL-17A, were significantly reduced (80–85%) by anti-IL17A Ab and by Vido, suggesting that the inflammatory recruitment signaling by BDOs can be inhibited in an IL-17 dependent manner (Figure).



Conclusions: BDOs from PSC patients can activate and induce migration of CD4+ T-cells, while co-cultured Th17 cells induce reactive gene expression and secretion of BDO-derived inflammatory molecules. This supports the hypothesis that Th17 cells damage biliary epithelia through CCL20 inflammatory responses in PSC. BDOs are a novel technology to study pathogenic biliary-immune cell interactions, and a personalized drug-testing platform in human PSC.

AS056

Protective effects of MBT-1805 on alpha-naphthalene isothiocyanate induced cholestasis animal model

Chang Wang[1], Bohua Zhong[2], Fei Peng[1], Ying Shi[1], Mengru Zhan[1], Xu Liu[1], Junqi Niu[1]. [1]*The First Hospital of Jilin University, Department of Hepatology, Changchun, China;* [2]*Beijing JK HuaYuan Med Tech Company LTD, China*
Email: junqiniu@aliyun.com

Background and Aims: Primary biliary cholangitis (PBC) is an immune-related liver disease with unclear mechanism. UDCA is currently the preferred treatment, with inadequate response in some

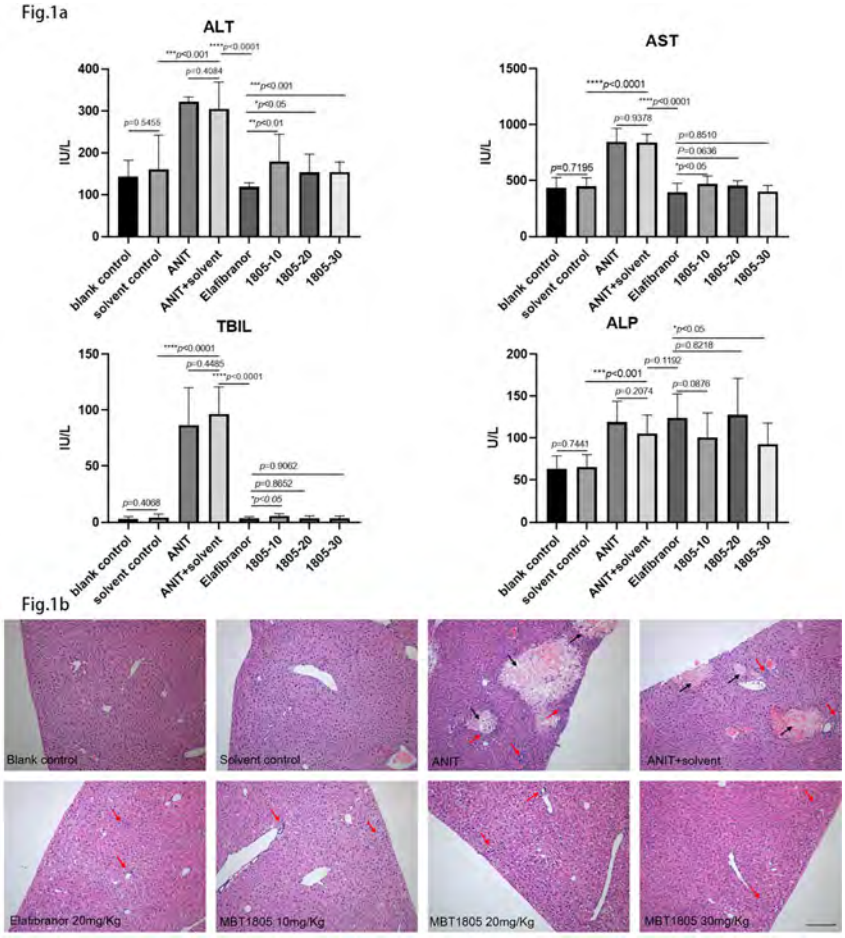


Figure 1a: (abstract: AS056): Serological testing. 1b. Pathologic results. Black arrows for necrosis, red arrows for inflammation infiltration. (scale bar: 400 μm).

patients. ANIT (alpha-naphthalene isothiocyanate) can lead to liver injury and rapid cholestasis. We verified the effects of newly developed MBT-1805 on ANIT-induced cholestasis compared with Elafibranor. MBT-1805 is a novel drug candidate built on resveratrol scaffolds and it is the most balanced PPAR-α/γ/δ agonist with moderate activity (EC_{50}: 8.46 μM, 11.94 μM, 11.5 μM respectively).
Method: Eight groups of C57BL/6J mice (8 weeks) were raised in SPF environment, with 10 mice each group. The mice were pretreated suitable dose of drugs for 7 days before ANIT administration by gavage. Experiment was terminated after ANIT administration (75 mg/Kg) for 24 hours. We recorded the body weight before administration and before mice sacrificed, as well as the weight of liver, spleen and gallbladder after organs isolation. Serum was collected for testing ALT, AST, TBIL and ALP. HE staining of liver tissues were also detected.
Results: All experimental mice survived. Severe liver injury occurred in ANIT/ANIT+solvent treated mice. Levels of ALT, AST, TBIL, ALP ($p < 0.05$,Fig. 1a) and weight of gallbladder ($p < 0.0001$) were elevated obviously compared with blank/solvent control groups. The above indicators in mice of Elafibranor group (20 mg/Kg) improved, except ALP ($p = 0.1192$). All groups of MBT1805 (10 mg/Kg, 20 mg/Kg and 30 mg/Kg) showed perfect efficiency on protecting mice from injury of ANIT, and efficiency showed dose-dependent. Particularly, 30 mg/Kg group was more effective than Elafibranor in reducing ALP. ($p < 0.05$,Fig. 1a). Pathological results also showed good protective effects, no obvious necrosis and less inflammation infiltration were observed in all groups of MBT-1805 treated mice. 30 mg/Kg group showed less inflammation infiltration than Elafibranor particularly (Fig. 1b).
Conclusion: The newly developed MBT-1805 showed good protective effects on ANIT-induced cholestasis, and efficiency showed dose-dependent. 30 mg/Kgof MBT-1805 performed better compared with Elafibranor.

AS057

Transcriptome and colocalisation analysis of CCR9+ gut-homing T cells and other immune cells identifies important genes and biological pathways potentiating primary sclerosing cholangitis risk

Elizabeth Goode[1,2], Nikolaos Panousis[1], Laura Fachal[1], Loukas Moutsianas[1], Ben Bai[1], Rebecca McIntyre[1], Tim Raine[3], Simon Rushbrook[4], Carl Anderson[1]. *[1]Wellcome Sanger Institute, Human Genetics, Hinxton, United Kingdom; [2]University of Cambridge, Institute of Metabolic Science, Cambridge, United Kingdom; [3]University Of Cambridge, Department of Medicine, Cambridge, United Kingdom; [4]Norfolk and Norwich University Hospital, Department of Gastroenterology, Norwich*
Email: ecg44@cam.ac.uk

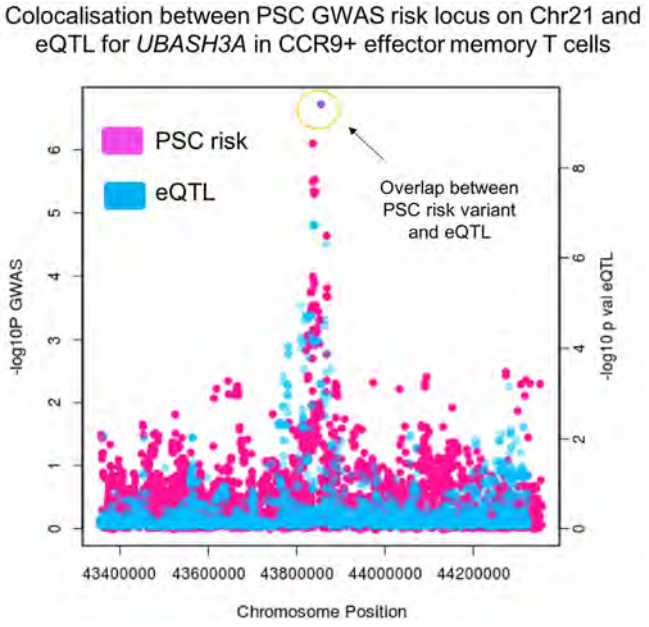
Background and Aims: 23 regions of the genome have been associated with primary sclerosing cholangitis (PSC) risk. The majority are in non-coding regions, and identifying the affected genes and cell-types remains a major hurdle in translating these genetic associations into therapeutic targets. We, and others, have shown that identifying cis-eQTLs (genetic variants that affect expression level of a nearby gene) that share causal variants with disease risk loci (colocalise) can identify genes, cell-types and

mechanisms underlying complex disease risk. However, identifying disease-relevant eQTLs is challenging as some are only active in specific cell-types or activation states and have no observable impact on gene expression in naïve cells.

Method: We generated eQTL maps for six T-cell subtypes, including rare CCR9+ gut-homing T-cells hypothesised to be pathogenetic in PSC, derived from peripheral blood of 80 donors with PSC. We analysed our PSC-specific T-cell eQTL maps alongside existing eQTL maps for other immune cells, in total covering >12 immune cell types and >10 different activation states. We called cell-type-specific and shared eQTLs using *MashR*. To identify genes and cell-types perturbed in PSC we performed Bayesian tests of colocalisation across PSC risk loci and eQTLs for all cell-types.

Results: We identified >9000 eQTLs across our PSC-specific T-cell subsets at 5% FDR, many clustered within pathways involved in inflammation and immune-modulation. Approximately 15% of eQTLs were specific to a single PSC T-cell-subtype. Colocalisation analysis confirmed the importance of CCR9+ and CCR9- effector memory T-cells and CD14+ monocytes in PSC pathogenesis, as 12 PSC risk loci colocalised with >1 eQTL with a posterior probability >80% in at least one of these cell-types.

Some PSC-risk loci were highly specific to a single cell-type. For instance, the Chr21 PSC risk locus colocalised with an eQTL for *UBASH3A*, a gene potentiating IL-2 secretion, across all T-cell subtypes (including CCR9+ T-cells), from donors with and without PSC. In contrast, other risk loci affected the same gene across several different cell-types; e.g. the Chr19 risk locus colocalised with an eQTL for *PRKD2* in monocytes, neutrophils and T-regs. Interestingly, we observed several PSC-risk loci, for which the affected gene differed per cell type. One such region was the Chr11 PSC locus which colocalised with an eQTL for *CCDC88B* in CD14+ monocytes and neutrophils, but colocalised with an eQTL for lncRNA *AP003774.2* in B-cells, PSC T-regs and CCR9+ effector memory T-cells but not in T-cells from healthy donors.



Conclusion: Our analyses confidently identify the genes and cell-types affected by multiple PSC-risk loci, forming the basis for further functional follow-up and bringing us closer to drug-target discovery.

AS058

Double resin casting micro computed tomography (CT) reveals biliary and vascular pathology in tandem in a mouse model for alagille syndrome

Simona Hankeova[1,2], Jakub Salplachta[3], Tomas Zikmund[3], Michaela Kavkova[3], Noémi K. M. Van Hul[1], Adam Brinek[3], Veronika Smekalova[3], Jakub Laznovsky[3], Josef Jaros[2], Vitezslav Bryja[2], Urban Lendahl[1], Ewa Ellis[1], Edouard Hannezo[4], Jozef Kaiser[3], Emma Andersson[1]. [1]*Karolinska Institutet, Sweden;* [2]*Faculty of Medicine Masaryk University, Czech Republic;* [3]*CEITEC - Vysoké učení technické v Brně, Czech Republic;* [4]*Institute of Science and Technology Austria (IST Austria), Klosterneuburg, Austria*
Email: emma.andersson@ki.se

Background and Aims: Malformation of lumenized structures, such as the intrahepatic circulatory or biliary systems, is a hallmark of several liver disorders, from vascular hepatic disease to Alagille syndrome. Liver architecture in mice has typically been studied using 2D sections and, more recently, with thicker tissue sections and whole mount immunofluorescence, neither of which resolves 3D architecture adequately. Importantly, the vascular and biliary systems are inter-dependent, and we therefore aimed to develop a robust method to image, digitalize and quantify 3D architecture of the biliary and vascular systems in tandem.

Method: The biliary and portal vein trees of the mouse liver were injected with Microfil resin, followed by microCT scanning. Tomographic data was segmented and analyzed using a MATLAB script we wrote to investigate length, volume, tortuosity, branching, and the relation between the vascular and biliary systems. We applied this pipeline (Double resin casting micro computed tomography (DUCT)) to a mouse model for Alagille syndrome ($Jag1^{Ndr/Ndr}$ mice), in which the biliary system is absent at postnatal stages, but regenerates by adulthood. Phenotypes discovered using DUCT were validated with cumbersome consecutive liver sections from mouse. Phenotypes identified using DUCT, and confirmed in sections of mouse liver, were further validated in liver samples from patients with Alagille syndrome.

Results: DUCT revealed tortuous bile ducts either placed further from portal veins, or ectopically traversing the parenchyma and connecting two portal areas, in $Jag1^{Ndr/Ndr}$ mice. Furthermore, bile ducts either ended abruptly, or branched independently of portal vein branching, with bifurcations placed hilar or peripheral to portal vein branches. Branch lengths were stochastic in $Jag1^{Ndr/Ndr}$ mice, with shorter hilar branches, suggesting ectopic regenerative sprouting occurs in the hilar region. The branching defects, parenchymal bile ducts, and blunt endings were confirmed in samples from patients with Alagille syndrome.

Conclusion: DUCT is a powerful technique that provides 3D reconstruction of resin-cast networks and quantification of 3D architecture. It exposes and quantifies previously unknown vascular and biliary phenotypes in mouse models, and thus can reveal new phenotypes in patients. Application of this technique to mouse models of liver disease will improve and standardize our 3D understanding of healthy and pathological liver states.

Email: ibone.labiano@biodonostia.org

Background and Aims: Cholestasis is a common feature of different cholangiopathies such as PBC and PSC. This condition causes liver inflammation and injury in epithelial cells, thereby inducing a specific wound healing response which involves ductular reaction, activation of kupffer cells (KCs), hepatic stellate cells (HSCs) and immune cells, finally leading to biliary fibrosis. In this regard, bacterial components that translocate to the liver act as pro-inflammatory signals, binding to toll-like receptors, thus promoting disease progression. Importantly, our group and others have reported that the triggering receptor expressed on myeloid cells 2 (TREM2) inhibit TLR-mediated signaling. This study aims to evaluate the role of TREM2 in cholestasis.
Method: *TREM2* expression was analyzed in the liver of patients with PBC and PSC and in mouse models of cholestasis, compared to healthy livers. Wild type (WT) and *Trem-2* knockout (*Trem2*$^{-/-}$) mice were subjected to bile duct ligation (BDL), or sham operated. In parallel, WT and *Trem2*$^{-/-}$ mice were treated with an antibiotic cocktail and then subjected to BDL. *In vitro*, *TREM2* was experimentally overexpressed in human hepatic stellate cells and inflammatory and fibrotic responses were analyzed. Effects of the treatment with bile acids in TREM2 expression in human hepatic stellate cells were assessed.
Results: *TREM2* expression is upregulated in the liver of patients with PBC and PSC as compared to controls; this receptor is also upregulated in murine models of cholestasis. Interestingly, TREM2 expression in patients positively correlated with inflammatory, fibrotic and cholestatic markers. *Trem2*$^{-/-}$ mice showed augmented biliary expansion after BDL. Likewise, *Trem2*$^{-/-}$ livers displayed enhanced profibrogenic (*Col1a1*) and hepatic stellate cell activation marker (*Acta2*) expression. *Trem2*$^{-/-}$ livers also exhibited enhanced pro-inflammatory marker expression (*Tnf, Mcp1, Cxcl1*) and augmented neutrophil recruitment into the liver as detected by NIMP-R14 inmunohistochemistry. This was accompanied by enhanced necroptotic cell death, while no differences were detected in apoptosis. Treatment with antibiotics abolished some of the effects observed in *Trem2*$^{-/-}$ mice after BDL. *In vitro*, *TREM2* overexpression in LX-2 cells leads to diminished profibrotic *(ACTA2, COL1A1, FIBRONECTIN)* and pro-inflammatory (*TNF* and *MCP1*) gene expression. Interestingly, treatment with UDCA induced *TREM2* expression in these cells.
Conclusion: TREM2 is overexpressed in the liver of patients with PBC and PSC and during experimental cholestasis. TREM2 acts as a negative regulator of inflammatory responses during cholestatic injury in mice. On the other hand, UDCA increases *TREM2* expression in HSCs, suggesting this could be and additional hepatoprotective mechanism of UDCA in cholestasis.

AS060

24-nor-ursodeoxycholic acid ameliorates intestinal inflammation by counteracting Th17/Treg imbalance via redirecting mTOR metabolic sensing programs in CD4+ T cells

Ci Zhu[1], Nicole Boucheron[2], Claudia Fuchs[1], Daniela Hainberger[2], Valentina Stolz[2], Ramona Rica[2], Teresa Preglej[2], Lisa Sandner[2], Marlis Alteneder[2], Alexandra Gülich[2], Patricia Hamminger[2], Veronika Mlitz[1], Jelena Remetic[1], Tatjana Stojakovic[3], Hubert Schargl[3,4], Shinya Sakaguchi[2], Wilfried Ellmeier[2], Michael Trauner[1]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria; [3] Medical University Hospital of Graz, Clinical Institute of Medical and Chemical Laboratory of Diagnostics, Graz, Austria; [4]Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory of Diagnostics, Graz, Austria*
Email: michael.trauner@meduniwien.ac.at

Background and Aims: 24-nor-ursodeoxycholic acid (*nor*UDCA) is a novel therapeutic bile acid for treating primary sclerosing cholangitis (PSC) which is strongly associated with inflammatory bowel disease (IBD). Th17/Treg imbalance is a key immunopathological factor driving PSC-IBD. We hypothesized that *nor*UDCA has immunomodulatory potency on Th17/Treg balance contributing to its therapeutic efficacy besides previously established effects in CD8$^+$ T cells. Since Th17/Treg lineage determination is controlled by metabolic reprogramming in activated CD4$^+$ T cells, we aimed to explore how *nor*UDCA affects CD4$^+$ T cell metabolic sensing programs and Th17/Treg balance.
Method: *nor*UDCA effects on CD4$^+$ T cell development and Th17/Treg balance were assessed by *in vitro* proliferation and differentiation assays, as well as in the model of CD25$^-$CD45RB^{high}CD4$^+$ T cell induced colitis, a Th17 cell driven experimental IBD model.
Results: *In vitro*, *nor*UDCA reduced CD4$^+$ T cell proliferation and lymphoblast formation by 46.8% (vs control, $p < 0.05$). *nor*UDCA inhibited Th17 cell differentiation while promoting FoxP3 expression. Mechanistically, *nor*UDCA suppressed mTORC1 and mTORC2 kinase activities as reflected by lower phosphorylation level of P70 S6 Kinase(Thr421/Ser424) and pAKT(Ser473) by 40.7% ($p < 0.005$) and 51.2% ($p < 0.05$), respectively. Consequently, *nor*UDCA decreased gene expression of mTOR regulated glycolytic enzymes, such as hexokinase2 and lactate dehydrogenase A ($p < 0.05$) and subsequently reduced glycolysis in developing CD4$^+$ T cells with lower extracellular acidification rate. Conversely, fatty acid oxidation was enhanced by *nor*UDCA as indicated by increased gene expression of *Cpt1alpha* ($p < 0.005$). Supporting *in vitro* data, *nor*UDCA reduced CD4$^+$RORγt$^+$ T cells in intraepithelial mucosa ($p < 0.05$), while expanded CD4$^+$CD25$^+$Foxp3$^+$ Tregs in spleen ($p < 0.05$), intraepithelial mucosa ($p < 0.05$) and lamina propria ($p = 0.0635$) after colitis induction. *nor*UDCA induced-Tregs demonstrated immunosuppressive functions *in vivo* as evidenced by reduced frequencies of CD4$^+$ T cells expressing IL17A/IFNgamma and IL17A/IL22 in intraepithelial mucosa, lamina propria and mesenteric lymph nodes and improved colon immunopathology.
Conclusion: *nor*UDCA redirects mTOR-associated metabolic sensing programs in activated CD4$^+$ T cells to counteract Th17/Treg imbalance, indicating *nor*UDCA may represent a promising immunometabolic drug for treating T cell based inflammatory diseases, such as PSC.

Assessing the burden of liver disease

AS061

Increasing burden of cirrhosis projected to 2040 in Canada: implications for prevention, screening, and management

Jennifer Flemming[1], Maya Djerboua[2], Christopher Booth[1], Norah Terrault[3]. [1]*Queen's University, Medicine, Kingston, Canada;* [2]*ICES, Kingston, Canada;* [3]*University of Southern California, Medicine, Los Angeles, United States*
Email: jennifer.flemming2@kingstonhsc.ca

Background and Aims: Disease burden related to cirrhosis varies by etiology and age with a recent increase evident in younger generations. The aim of this study was to describe the incidence of cirrhosis by etiology and birth cohort and estimate future cirrhosis burden to guide future intervention efforts.
Method: Retrospective population-based cohort study using provincial healthcare data from Ontario, Canada from 2000–2017. Adults with incident cirrhosis were identified using a validated case definition and described by year of birth. Cirrhosis etiology was assigned to one of five categories as either hepatitis B (HBV), hepatitis C (HCV), non-alcoholic fatty liver disease (NAFLD)/cryptogenic, alcohol-related liver disease (ALD), or Other using a validated hierarchical algorithm, incorporating results of viral hepatitis testing, and administrative diagnostic codes. Annual age and sex adjusted cirrhosis incidence was calculated per 100,000 person-years standardized to the 2011 Canadian population overall and stratified by etiology and birth cohort. Projected annual incidence rates of cirrhosis were calculated based on Ontario population projections to the year 2040 using age-period-cohort analysis and cubic splines.
Results: 159,549 incident cases of cirrhosis were identified (59% male, median age 57 years [IQR 47–68], 53% NAFLD/cryptogenic, 25% ALD, 12% HCV, 6% HBV, 5% Other). The overall incidence of cirrhosis increased in all birth cohorts (Figure A). However importantly, these trends varied by both birth cohort and etiology (Figure B–F). For NAFLD/cryptogenic cirrhosis, the incidence is projected to increase in all birth cohorts (Figure B); rates for ALD are expected to increase only in cohorts born after 1965 (Figure C), rates of HCV cirrhosis are projected to decline for all birth cohorts except those born >1980 (Figure D), while the incidence for both HBV and Other causes are projected to decline or stabilize for all cohorts (Figure E and F).
Conclusion: Without intervention by 2040, 73% of all new diagnoses of cirrhosis will be secondary to NAFLD, 20% from ALD, and 5% from HCV. Although NAFLD will be the primary driver of these trends, our results highlight the significant contribution of both ALD and HCV in birth cohorts after the baby boomers. Wide-scale public health, lifestyle, and pharmacologic interventions are needed in order to potentially reverse these trends, especially in young adults.

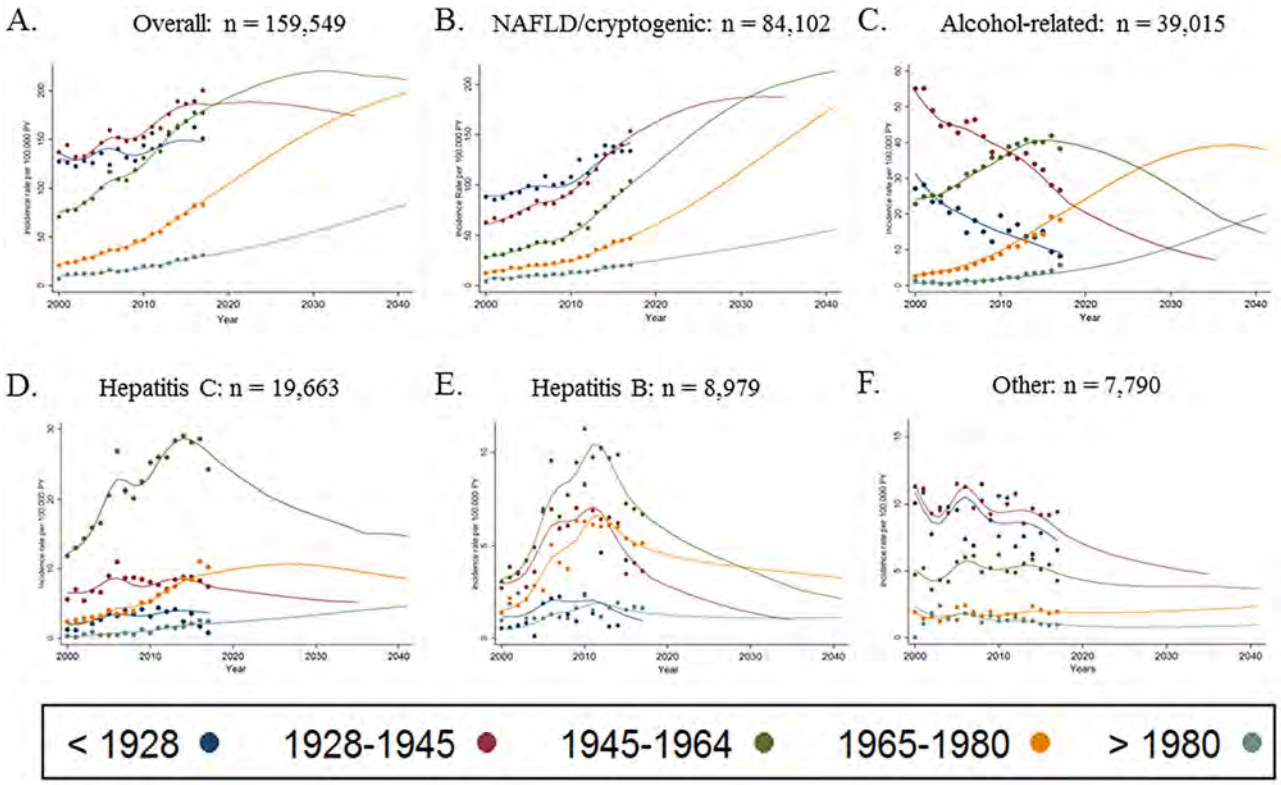

Figure: Calculated (dots) and projected (lines) age and sex standardized incidence rates of cirrhosis by birth cohort in Ontario, Canada. A: all etiologies; B: non-alcoholic fatty liver disease/cryptogenic; C: alcohol-related; D: hepatitis C; E: hepatitis B; F: Other (includes autoimmune hepatitis, primary sclerosing cholangitis, primary biliary cholangitis, Wilson disease, alpha-1 antitrypsin deficiency, hemochromatosis.

The progression of liver disease in 69,290 individuals in Wales from 1999–2019: tracking the evolution of liver disease

Tom Pembroke[1,2], Gareth John[3], Oliwia Michalak[2], Berry Puyk[3], Jane Salmon[4], Andrew Godkin[1,2], Andrew Yeoman[5]. *[1]University Hospital of Wales, Gastroenterology and Hepatology, Cardiff, United Kingdom; [2]Cardiff University, Division of Infection and Immunity, Cardiff, United Kingdom; [3]NHS Wales Informatics Service, Cardiff, United Kingdom; [4]Public Health Wales, Cardiff, United Kingdom; [5]Royal Gwent Hospital, Gastroenterology and Hepatology, Newport, United Kingdom*
Email: pembroket@cardiff.ac.uk

Background and Aims: Major epidemiological studies of liver disease to date are based upon mortality data limiting our understanding of morbidity on a population scale. We established a Wales Liver Disease registry to understand the true burden and progression of liver disease.

Method: The registry is populated by ICD10 code diagnoses for Welsh residents derived from Office of National Statistics mortality data and inpatient/day case activity derived from NHS Wales Informatics Service Patient Episode Database for Wales between 1999–2019. Pseudo-anonymised linkage of i) causative diagnoses, ii) cirrhosis, iii) portal hypertension, iv) decompensation and v) liver cancer codes enabled tracking the progression of liver diseases.

Results: The population of Wales is 3.1 million, 69,290 individuals were diagnosed with liver disease between 1999–2019. There were 16,990 (24.5%) diagnoses of cirrhosis, 12,860 (18.6%) with portal hypertension, 10,400 (15%) with hepatic failure/decompensation and 6055 (8%) with liver cancers and mortality reached 53% (36,770 died). The incidence of alcohol liver disease (ALD), chronic viral hepatitis and non-alcoholic fatty liver disease (NAFLD) increased 1.23, 1.7 and 10-fold respectively. NAFLD is now the predominant cause of liver disease in Wales (incidence 1894 in 2018–19).

Progression of liver disease over 10 years was assessed in 25,390 individuals with an initial inpatient diagnosis between 1999–2009. Progression and mortality were more marked in ALD (cirrhosis 41.7%, decompensation 25% and liver cancer 2.4%, mortality 79%) than NAFLD (cirrhosis 11%, decompensation 8% and liver cancer 2%, mortality 46%) and HCV (cirrhosis 15%, decompensation 8% and liver cancer 5%, mortality 29%).

Conclusion: Liver disease in Wales is increasing. Whilst ALD is associated with increased disease progression, the marked increase in NAFLD incidence indicates that the modest conversion to decompensation will cause significantly increased mortality and morbidity.

The progression of 7374 patients diagnosed with alcoholic liver disease between 1999 and 2009 in Wales over the following 10 years. Vertical bars demonstrate stage of disease (red = ALD diagnosis 100%, dark blue = cirrhosis 41.7%, light green = portal hypertension/portal vein thrombosis (PH/PVT) 32%, orange = decompensation 25%, light orange = liver cancer 2.4%, dark green = survival 21%, light blue = death 79%). Blocks of horizontal colour between bars demonstrate the flow of individuals moving to later stages of disease and mortality or survival at 10 years post diagnosis. Light blue progression to mortality, dark blue progression to cirrhosis, light green progression to PH/PVT, orange progression to decompensation, light orange progression to liver cancer and dark green survival to follow up end point. Black dot indicates HCC diagnosis precedes decompensation.

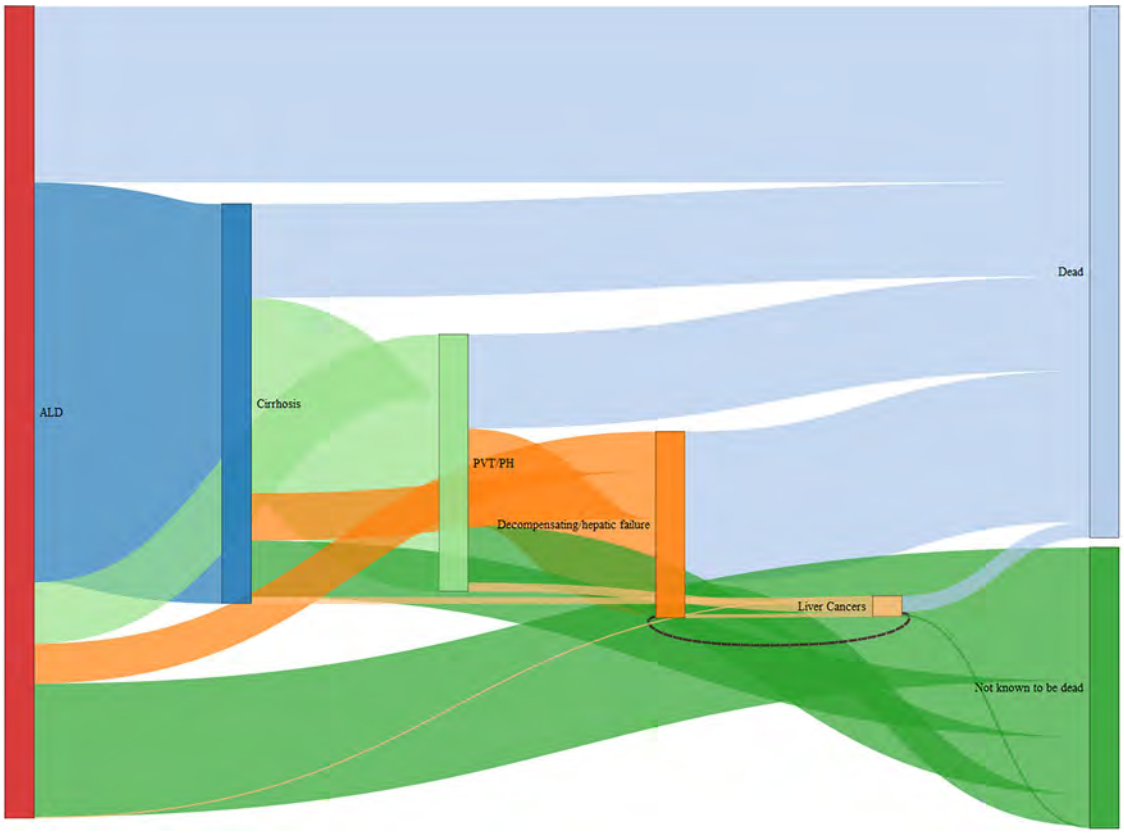

Figure: (abstract: AS062)

AS063

The growing burden of disability related to non-alcoholic fatty liver disease: data from global burden of disease 2007–2017

James Paik[1], Pegah Golabi[1], Youssef Younossi[2], Manirath Srishord[1,3], Alita Mishra[3], Zobair Younossi[1,3]. *[1]Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; [2]Center for Outcomes Research in Liver Diseases, DC, United States; [3]Inova Fairfax Medical Campus, Center for Liver Disease, Department of Medicine, Falls Church, United States*
Email: zobair.younossi@inova.org

Background and Aims: Although chronic liver disease (CLD) is an important cause of mortality worldwide, data on CLD-related morbidity and disability is not widely available. Our aim is to assess the global burden of disability associated with complications of CLD [primary liver cancer (LC) and cirrhosis] according to the most common causes of liver disease from 2007 through 2017.
Method: The Global Burden of Disease (GBD) study estimation methods were used to assess years lost due to disability (YLD), years of life lost (YLL) and disability-adjusted life-years (DALYs), obtained from the GBD 2017 study. Results were presented at 21 GBD regions as well as 195 countries. Temporal trends were assessed by percent change from 2007 through 2017.
Results: In 2017, there were 6.1 million worldwide incident cases of CLD (15.6% LC and 84.4% cirrhosis), 2.14 million liver-related deaths (38.3% LC and 61.6% cirrhosis) which contributed to 62.16 million DALYs (33.4% LC and 66.5% cirrhosis). The majority of DALYs from CLD was attributed to years of life lost (96.8%) and only 3.2% from years of life lived with disability. The highest age-standardized-years-of-DALYs-per-100,000 (ASDALYs) attributed to CLD were observed in Asia, Africa and East European regions (1,064 to 1,420), whereas the lowest ASDALYs were observed in high income regions (250 to 480). From 2007–2017, the global number of DALYs from CLD increased from 54.8 million to 62.6 million. This change represented an increase of 21.4% (17.3%–27.5%) for LC and 9.8% (4.5%–15.2%) for cirrhosis. Although HBV and HCV accounted for most DALYs in 2017 (21.8 million and 15.3 million; respectively), NAFLD showed the largest increase in DALYs from 2007 to 2017 (Figure). In fact, the highest increase in ASDALYs for LC due to NAFLD/NASH was seen in Australasia, Tropical Latin America, and South Asia (Figure).
Conclusion: In the last decade, disability from CLD related to viral hepatitis (ASDALYs from LC and cirrhosis) has improved, while the disability related to NAFLD/NASH remains important and growing. National, regional and global policies are needed to address the disability burden of NAFLD across the world.

AS064

Incorporating assessment of liver fibrosis into routine diabetic review in primary care: a pilot

Dina Mansour[1], Marc Herscovitz[2], Paul Cassidy[3]. *[1]Queen Elizabeth Hospital (Gateshead), Hepatology, United Kingdom; [2]Bewick Road Surgery, Gateshead, United Kingdom; [3]Teams Medical Practice, Gateshead, United Kingdom*
Email: Dina.mansour@nhs.net

Background and Aims: Screening for non-alcoholic fatty liver disease (NAFLD) in primary care remains controversial, with guidelines conflicting. The risk of developing advanced liver fibrosis is increased in patients with type 2 diabetes, particularly those with alcohol use disorders. Diabetic patients also have regular blood tests

Figure. Percent Change in Age-Standardized DALY Rates for Liver Cancer and Cirrhosis from 2007 to 2017

Improving
Worsening

MENA: Middle East & North Africa; HBV, Hepatitis B virus; HCV, Hepatitis C virus; ALD, Alcohol-related liver disease

Figure: (abstract: AS063)

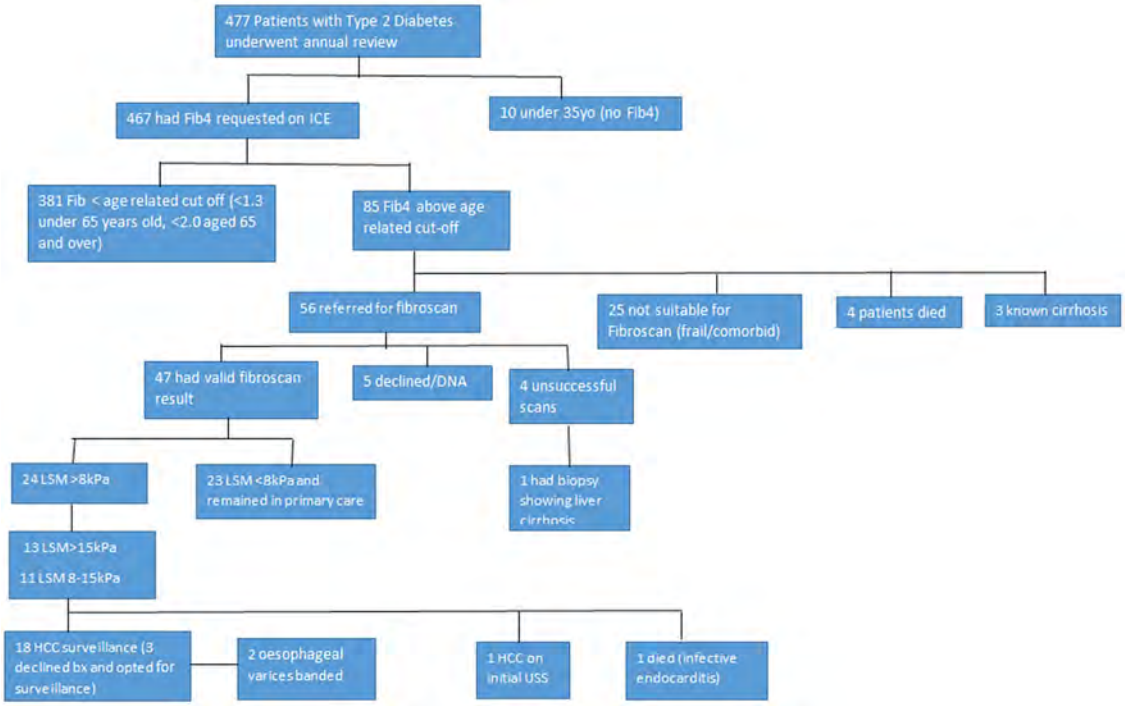

Figure: (abstract: AS064)

as part of routine review, which makes them an ideal population to screen using simple biomarkers. We present the results of a pilot incorporating two-tier assessment of liver fibrosis into routine diabetic review in primary care.

Method: 477 successive patients with Type 2 diabetes from 2 primary care practices in the North East of England underwent diabetic review April 2018–September 2019. All patients over 35 years old had a Fib4 score requested on the Electronic Medical Record (EMR) system, irrespective of alcohol intake. In patients with a Fib4 above the age related cut off, GPs were advised via EMR to request a FibroScan. Patients with a liver stiffness (LSM) of ≤8 kPa had results returned to the GP, with advice to repeat staging in 3 years' time. Patients with LSM >8 kPa were seen in secondary care. Patients thought to have advanced fibrosis/cirrhosis on specialist assessment were enrolled into surveillance programs. Where there was uncertainty, patients were offered liver biopsy. Screening for varices was performed according to Baveno VI criteria. At the end of the pilot, outcomes of patients undergoing screening were assessed.

Results: A summary of the results can be seen in the Figure. The overall rate of advanced fibrosis/cirrhosis was 4.8%, but significantly higher in patients drinking more than 14/21 units per week (31% versus 4.4% p = <0.0001). This pathway led to a 500% increase in the diagnosis of advanced liver disease/cirrhosis. 50% of patients with significant fibrosis (LSM >8 kPa) and 53.8% of patients with "advanced liver disease" (LSM >15 kPa) had "normal" ALT, and so would have been missed by following national guidelines.

Conclusion: To our knowledge, this is the first pathway incorporating two-tier liver fibrosis assessment into routine diabetic reviews in primary care. We identified a significant number of patients with advanced liver disease, over half of whom had normal ALT. Making Fib4/FibroScan accessible through EMR in primary care allows liver fibrosis assessments to be embedded into routine assessment of diabetic patients, and ensures the correct patients are referred to secondary care.

Background and Aims: The importance of the maternal-infant dyad in the genesis of nonalcoholic fatty liver disease (NAFLD) is of increasing interest. The Avon Longitudinal Study of Parents and Children (ALSPAC) has prospectively phenotyped its participants over the last 28 years. Other studies have found a protective effect of longer breastfeeding duration and normal pre-pregnancy body mass index (BMI) on development of NAFLD in young people. ALSPAC identified a NAFLD prevalence of over 20% by transient elastography (TE) and controlled attenuated parameter (CAP) amongst its participants as young adults (mean age 24 years). We test the association between maternal pre-pregnancy BMI and breastfeeding duration on offspring developing NAFLD in young adulthood using ALSPAC.

Method: 4021 participants attended clinic for TE and CAP results using the Echosens 502 Touch®. Participants with excessive alcohol consumption were excluded from analysis. Exposures of interest were

exclusive and non-exclusive breastfeeding duration of ≥ 6 months and maternal pre-pregnancy BMI. Our outcome was NAFLD at 24years. Multivariable regression models tested the association between the exposures and outcome adjusted for maternal age at parturition, smoking during pregnancy, birthweight and socio-economic status (SES). We also assessed participants' waist circumference at 24 years as a surrogate adiposity marker. Statistical analysis was performed using Stata MP 15.1.

Results: Mean age was 24 years (SD 0.8). 3128 participants had valid CAP results of whom 680 participants (20.8%) had steatosis; 331 (10.1%) had S3 steatosis (≥ 66% steatosis). 2539 participants had maternal characteristics available. A pre-pregnancy obese BMI was associated with steatosis in offspring following adjustment for covariates (OR 3.18 [95% CI 2.13–4.74]; p < 0.001). Exclusive breastfeeding for >6 months was associated with an 11% reduction in steatosis in offspring, with the CI including the null after adjustment for covariates (OR 0.89 [0.63–1.27]; p = 0.71). Similarly, non-exclusive breastfeeding duration had a protective effect on steatosis in offspring, but the CI again included the null after adjustment of the same covariates (OR 0.92 [0.67–1.26]; p = 0.71). An increased waist circumference was positively associated with steatosis presence following adjustment for covariates (OR 10.08 [7.73–13.16]; p < 0.001).

Conclusion: This is one of the largest studies to explore the relationship of breastfeeding duration and maternal pre-pregnancy BMI on NAFLD outcomes in young adulthood. Maternal pre-pregnancy BMI is strongly associated with development of NAFLD in offspring with the relationship appearing to persist into young adulthood. Further emphasis on addressing the obesogenic environment contributing to obesity in women of child-bearing age in the UK is required to mitigate development of NAFLD in their offspring.

AS066

Association of metabolic risk factors with risk of cancer and all-cause mortality in patients with chronic hepatitis B virus infection: a Korean nationwide cohort study

Yun Bin Lee[1], Hyemi Moon[2], Eun Ju Cho[1], Jeonghoon Lee[1], Su Jong Yu[1], Yoon Jun Kim[1], Juneyoung Lee[2], Jung-Hwan Yoon[1]. *[1]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South; [2]Korea University, Department of Biostatistics, Seoul, Korea, Rep. of South*
Email: yoonjh@snu.ac.kr

Background and Aims: Long-term antiviral therapy can effectively suppress viral replication and improve clinical outcomes, but it cannot eliminate the risk of hepatocellular carcinoma (HCC) in patients with chronic hepatitis B. This study aimed to elucidate the association of metabolic risk factors with the risk of developing HCC, non-HCC cancer, and all-cause mortality.

Method: This nationwide population-based study from the Korean National Health Insurance Service database consisted of adults with chronic hepatitis B virus (HBV) infection who underwent health examinations from 2007 through 2012. We collected baseline data of the study patients on metabolic risk factors, including obesity, hypercholesterolemia, insulin resistance, and hypertension. The risks of developing HCC, non-HCC cancer, and death from any cause were analyzed according to metabolic risk profile. Patients were followed up until the date of cancer diagnosis, death, or December 31, 2017. The risk of HCC and non-HCC cancer were analyzed after adjusting death as a competing risk event.

Results: The study population comprised of 317,856 patients (median age, 46 years [interquartile range, 37–54 years], 219,418 men [69.0%]) had 2,609,523.8 person-years of follow-up. During a median follow-up period of 8.5 years, 18,850 HCCs, 22,164 non-HCC cancers, and 15,768 deaths were observed. The cumulative incidences of HCC (p < 0.0001; panel A), non-HCC cancer (p < 0.0001; panel B), and death (p < 0.0001; panel C) rose with increasing number of metabolic factors. The number of metabolic factors were positively associated with the risks of HCC (p < 0.0001 for trend), non-HCC cancer (p < 0.0001 for trend), and all-cause mortality (p < 0.0001 for trend). In patients with 3 or more metabolic risk factors, the adjusted hazard ratios for HCC, non-HCC cancer, and all-cause mortality were 1.23 (95% confidence interval [CI], 1.16–1.31), 1.34 (95% CI, 1.27–1.41), and 1.31 (95% CI, 1.23–1.39), respectively, compared to those with the lowest metabolic risk profile. Among patients who received antiviral treatment for over 5 years, the risks of HCC (n = 34,725; p < 0.0001), non-HCC cancer (n = 36,809; p < 0.0001), and mortality (n = 39,061; p < 0.0001) increased substantially as the sum of metabolic risk factors increased.

Conclusion: In this Korean nationwide cohort study, the burden of metabolic risk factors was associated with increased risk of HCC, non-HCC cancer, and all-cause mortality in patients with chronic HBV infection.

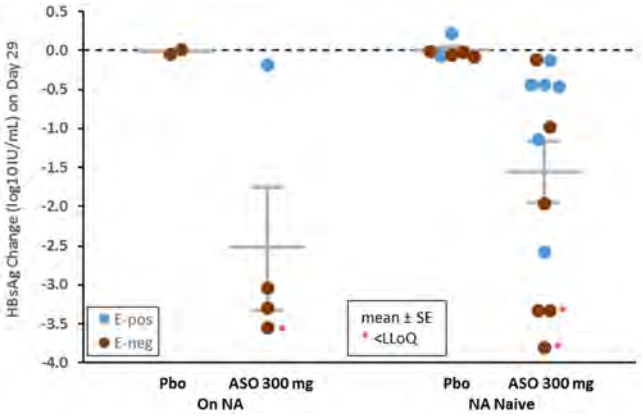
Figure: (abstract: AS066)

Background and Aims: HBsAg plays a major role in enabling and maintaining persistent HBV infection by repressing host immune responses against the virus. ISIS 505358 (now known as GSK3228836) is a 2´-MOE modified antisense oligonucleotide (ASO) targeting all HBV RNAs. The aim of the current study was to evaluate antiviral activity and safety in CHB patients.
Method: All patients were HBsAg positive ≥ 6 month and were >50 IU/mL at screening. Patients on NA were on stable regimen ≥ 12 months with plasma HBV DNA below lower limit of quantitation (LLoQ, 20 IU/mL). NA-naïve patients had HBV DNA ≥ 2×10^3 IU/mL. Exclusion criteria included: liver cirrhosis; HCV, HIV, or HDV coinfection; ALT or AST >5xULN, or bilirubin >1.1xULN. Both HBeAg positive and negative patients were eligible. ASO (300 mg) or placebo was administered subcutaneously on Days 1, 4, 8, 11, 15, and 22. The primary assessment for effect on HBV was on Day 29.



Results: For patients on NA, mean HBsAg log10 IU/mL ±SE change from baseline was −2.514 ± 0.783 for ASO (n = 4) and −0.008 for placebo (Pbo, n = 2). In ASO group, 3 patients had reductions >3.0 log10 IU/mL where one was <LLoQ (0.05 IU/mL). Another reached <LLoQ on Day 36. For NA-naïve patients, HBsAg mean changes for ASO (n = 12) were −1.556 ± 0.398 (p = 0.001 vs Pbo, n = 6) and was −1.655 ± 0.427 (p < 0 001) for HBV DNA. Three and 4 ASO patients had HBsAg and HBV DNA reductions >3.0 log10 IU/mL, respectively, where 2 and 1 also had levels reduced to <LLoQ. One SAE occurred in the study: post-ASO treatment ALT flare to 781 U/L (24xULN) in a patient with HBsAg and HBV DNA reductions to <LLoQ. Post-ASO ALT flares with peaks ranging from 1.7 to 15xULN occurred in the other HBsAg<LLoQ patients. ALT flares were asymptomatic and self-resolved. The most common adverse events for the 300 mg ASO patients (5 of 17) were at injection sites [erythema, pain, pruritus, swelling, and/or bruising].
Conclusion: Significant reductions of HBsAg levels were observed with 4-week ISIS 505358/GSK3228836 treatment in both patients on stable NA regimens and NA-naïve patients. Significant reductions in HBV DNA were also observed in naïve patients. The tolerability and safety were acceptable for proceeding to longer treatment durations.
This study was financially supported by GlaxoSmithKline.

AS068

Preliminary safety and antiviral activity of VIR-2218, an X-targeting HBV RNAi therapeutic, in chronic hepatitis B patients

Edward Gane[1], Young-Suk Lim[2], Pisit Tangkijvanich[3], James O'Beirne[4], Tien Huey Lim[5], Anna Bakardjiev[6], Xiao Ding[6], Lynn Connolly[6], Stephen Huang[7], Jae Kim[7], Phil Pang[6], Man-Fung Yuen[8]. Email: abakardjiev@vir.bio

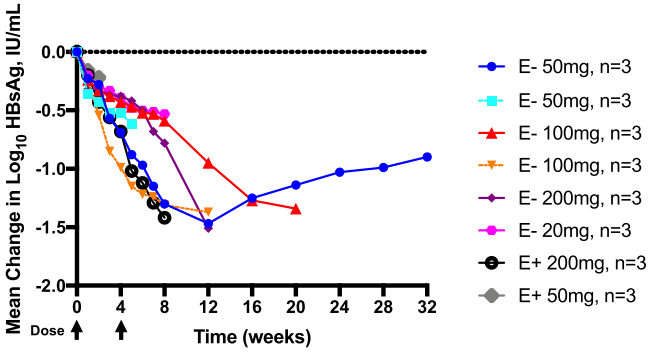
Background and Aims: VIR-2218 is an investigational GalNAc-conjugated ribonucleic acid interference (RNAi) therapeutic in development for functional cure of chronic hepatitis B virus infection (CHB). VIR-2218 was created using Enhanced Stabilization Chemistry Plus (ESC+), which retains enhanced metabolic stability needed for in vivo potency while reducing sequence matched off-target effects. VIR-2218 is designed to silence all HBV transcripts, from both cccDNA and integrated DNA, across all 10 HBV genotypes. We present interim safety and antiviral activity data from a Phase 2 trial of VIR-2218 in patients with CHB.
Method: HBeAg- or HBeAg+, virally suppressed patients on nucleos(t)ide reverse transcriptase inhibitor therapy and without significant fibrosis/cirrhosis received 2 subcutaneous doses of VIR-2218 or placebo on Day 1 (Week 0) and Day 29 (Week 4). Four cohorts of HBeAg- subjects received 20, 50, 100 or 200 mg; two cohorts were added at the 50 and 100 mg dose levels. Two cohorts of HBeAg+ subjects received 50 or 200 mg. Each cohort includes 4 subjects randomized 3:1 to receive VIR-2218 or placebo. Assessments included safety and HBsAg levels with 12 week follow-up after the second dose for all patients and an additional 32 weeks follow-up for patients achieving a pre-specified HBsAg decline target.



Results: In this ongoing trial, 24 patients with CHB have received VIR-2218 and are at varying stages of follow-up. No patients discontinued due to an adverse event (AE) and the majority of treatment emergent AEs were mild in severity. No clinically significant ALT elevations were observed. A subset of patients in the 50 mg dose level have achieved maximal decline in HBsAg levels at Week 12, with a mean decline of 1.5 $\log_{10}$ from baseline in VIR-2218 treated patients (see Figure). Notably, a mean decline of 1.0 $\log_{10}$ in HBsAg has been maintained through Week 28 in this cohort. Declines in HBsAg continue in other cohorts with at least two patterns observed: an early response and a delayed response. Data through at least Week 16 will be presented for all dose levels.

Conclusion: Two monthly doses of VIR-2218 at 20–200 mg were well tolerated in CHB patients. Substantial reductions in HBsAg were observed in both HBeAg- and HBeAg+ patients and across all dose levels. Differential patterns of decline suggest that early responses (<8 weeks) in HBsAg may not predict the final magnitude of decline. Evaluation of VIR-2218 in CHB patients is ongoing.

AS069

RO7062931 antisense oligonucleotide phase 1 study demonstrates target engagement in patients with chronic hepatitis B on established nucleos(t)ide therapy

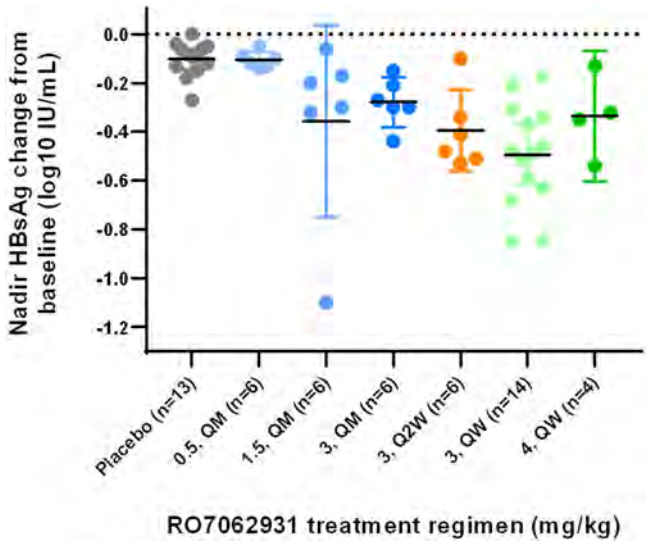
Man-Fung Yuen[1], Edward Gane[2], Dong Joon Kim[3], Henry Chan[4], Bernadette Surujbally[5], Vedran Pavlovic[5], Miriam Triyatni[6], Joseph Grippo[7], Hyung Joon Kim[8], Apinya Leerapun[9], Tien Huey Lim[10], Young-Suk Lim[11], Tawesak Tanwandee[12], Won Kim[13], Wendy Cheng[14], Tsung-Hui Hu[15], Cynthia Wat[16]. *[1]Queen Mary Hospital, Hong Kong, Hong Kong; [2]Auckland Clinical Studies, Auckland, New Zealand; [3]Chuncheon Sacred Heart Hospital, Chuncheon, Korea, Rep. of South; [4]Chinese University of Hong Kong, Prince of Wales Hospital, Shatin, Hong Kong; [5]Roche Innovation Centre, Welwyn Garden City, United Kingdom; [6]Roche Innovation Centre, Basel, Switzerland; [7]Roche Innovation Centre, New York, Switzerland; [8]Chung-Ang University Hospital, Seoul, Korea, Rep. of South; [9]Maharaj Nakorn Chiang Mai Hospital, Chiang Mai, Thailand; [10]Middlemore Hospital, Auckland, New Zealand; [11]Asan Medical Center, Seoul, Korea, Rep. of South; [12]Siriraj Hospital, Bangkok, Thailand; [13]SMG-SNU Boramae Medical Center, Seoul, Korea, Rep. of South; [14]Linear Clinical Research, Perth, Australia; [15]Chang Gung Medical Foundation, Kaohsiung, Taiwan; [16]Roche Innovation Centre, Basel, Switzerland*
Email: ved.pavlovic@roche.com

Background and Aims: RO7062931 is a N-acetylgalactosamine (GalNAc) conjugated single-stranded oligonucleotide (SSO) with locked nucleic acid (LNA) that results in RNAse H mediated degradation of HBV transcripts. We previously reported (AASLD 2019) results from Part 1 of the Phase 1 study (NCT03505190) where single doses of RO7062931 up to 4 mg/kg were safe and well tolerated in healthy volunteers (HVs). Herein we present the results from Study Part 2 of multiple dose RO7062931 treatment regimens in patients with chronic hepatitis B (CHB).

Method: 59 CHB patients on established nucleos(t)ide therapy were randomized 3:1 to RO7062931 (0.5, 1.5, 3, or 4 mg/kg) or placebo across six 4-week treatment regimens. Eligible subjects were HBeAg-positive or negative at screening with serum levels of HBsAg ≥ 1,000 IU/mL, HBV DNA ≤90 IU/mL and ALT ≤1.5× upper limit of normal (ULN). Depending on the dosing frequency (monthly [QM], bi-weekly [Q2W] or weekly [QW]), subjects received between 2–5 subcutaneous RO7062931 doses in total. Subsequently, all subjects entered a 12-week post-treatment follow-up.

Results: Majority of subjects were male (88%), Asian (90%), with a mean (range) age of 45 (25 to 65) years. At baseline, 58% were HBeAg-negative, 86% had ALT ≤ULN, and the mean HBsAg level was 5,172 (952 to 27,620) IU/mL. No serious AEs, severe AEs, or withdrawals due to AEs were reported. Injection site reactions were reported for 7 (12%) subjects, of which 5 and 2 were of mild and moderate intensity, respectively. Laboratory safety parameters were unremarkable except for 2 subjects (3 mg/kg QW group) with transient ALT >3× ULN elevations that were associated with declining HBsAg levels.

RO7062931 treatment was associated with dose-dependent reductions in HBsAg. At Day 29, mean (SD) change in HBsAg IU/mL levels were –0.03 (0.05) in the placebo group; –0.03 (0.04), –0.15 (0.21) and –0.17 (0.07) in the 0.5, 1.5 and 3 mg/kg QM groups; –0.23 (0.17) and –0.38 (0.25) in the 3 mg/kg Q2W and QW groups; and –0.14 (0.28) in the 4 mg/kg QW group. Nadir HBsAg change from baseline data with mean ± 95CI are shown in below Figure, which were similar regardless of baseline HBeAg status. A rebound in HBsAg levels was typically evident by 2–3 weeks post-treatment, which returned to baseline levels by 12-weeks post-treatment. Pharmacokinetic data in CHB patients was consistent to that previously reported for HVs.



Conclusion: RO7062931 administered over 4-weeks, at doses of up to 4 mg/kg, in CHB patients is safe, well tolerated, and demonstrates target engagement by antiviral activity.

AS070

Antiviral activity and safety of the hepatitis B core inhibitor ABI-H0731 administered with a nucleos(t)ide reverse transcriptase inhibitor in patients with HBeAg-negative chronic hepatitis B infection

Email: scott.fung@uhn.ca

Background and Aims: Nucleos(t)ide reverse transcriptase inhibitors (NrtI) are the standard of care for the treatment of chronic HBV (CHB) infection. While these agents achieve viral suppression in most patients (pts), sustained response is rarely achieved following cessation of treatment. The HBV core inhibitor ABI-H0731 (731) in combination with a NrtI is currently being evaluated in Phase 2 clinical studies.

Method: ABI-H0731-201 is a double-blind, placebo (Pbo)-controlled study in NrtI-suppressed pts with CHB. Patients were randomized 3:2 to receive 731 (300 mg QD) +NrtI or Pbo+NrtI for 24 wks. Eligible pts had HBV DNA ≤LLOQ for ≥ 6 mos, HBsAg >1000 IU/mL, ALT ≤5× ULN and Metavir F0-F2. HBV DNA was measured by COBAS TaqMan 2.0 (LLOQ = 20 IU/mL) and an in-house (ASMB) semi-quantitative PCR assay (LLOQ = 5 IU/mL). HBV pgRNA was measured by an ASMB RT-qPCR assay (LLOQ = 35 IU/mL). Safety was assessed through reporting of adverse events (AE) and laboratory abnormalities. This report summarizes the antiviral activity and safety for the HBeAg-negative pts only.

Results: Of the 26 HBeAg-negative pts enrolled in the study, 16 received 731+NrtI and 10 received Pbo+NrtI. Overall, the mean (range) age was 48 (34–64) years, 16 (62%) were male, 21 (81%) were Asian. Results are shown in the table. Treatment with 731+NrtI resulted in a higher proportion of pts achieving TND by the ASMB HBV DNA assay compared with Pbo+NrtI. At baseline and throughout the study, the pgRNA and HBcrAg levels were low and the HBsAg levels did not change. The safety profile of 731+NrtI was similar to Pbo +NrtI. Both treatments were well-tolerated, with no serious adverse events or discontinuations due to AEs. All AEs and lab abnormalities were mild or moderate in severity. Only one pt receiving 731+NrtI reported a Grade 1 rash that resolved on study without treatment interruption. No Grade 3 ALT elevations were observed.

	ABI-0731 + NrtI (N=16)		Placebo + NrtI (N=10)	
	Baseline	Week 24	Baseline	Week 24
HBV DNA (COBAS)[1], n (%)				
≥20 IU/mL	0	1 (6)	0	0
<20 IU/mL, TD	6 (38)	2 (13)	3 (30)	4 (40)
<10 IU/mL, TND	10 (63)	13 (81)	7 (70)	6 (60)
HBV DNA (ASMB)[2], n (%)				
TD	6 (38)	1 (6)	2 (20)	3 (30)
TND	10 (63)	15 (94)	8 (80)	7 (70)

[1]TaqMan 2.0; [2] LLOQ=5 IU/mL; [3] LLOQ=35 U/mL

Conclusion: In 24 weeks of treatment, a higher proportion of HBeAg-negative pts receiving 731+NrtI achieved HBV DNA TND by highly sensitive PCR methodology compared to Pbo+NrtI. 731 has a favorable safety and tolerability profile. These data suggest the contribution of 731 to the standard of care in achieving deeper viral suppression and support continued treatment with 731+NrtI in the open-label Phase 2 study ABI-H0731-211.

Email: edgane@adhb.govt.nz

Background and Aims: Selgantolimod (GS-9688, SLGN), an oral selective small molecule agonist of Toll-like receptor 8 (TLR8), in clinical development for the treatment of chronic hepatitis B. Here we present the results through Week 48 (24 weeks post-SLGN) on the safety and efficacy.

Method: Patients were randomized in 2 cohorts (HBeAg-positive and -negative) to SLGN 3 mg, 1.5 mg, and PBO (2:2:1) once a week for 24 weeks while maintaining OAV. Safety assessments included monitoring of adverse events (AE) and laboratory abnormalities. The primary efficacy endpoint was the proportion of patients with ≥ 1 log10 IU/mL decline in HBsAg levels from baseline at week 24. Secondary endpoints include the proportion of patients with HBsAg and HBeAg loss and changes in pharmacodynamic (PD) markers including cytokines (IL-1RA and IL-12p40) and immune cell subsets evaluated using spectral flow cytometry (four 23- to 26-colour panels covering myeloid, T-, B-, and NK-cell subsets).

Results: 48 patients randomized (24 HBeAg-positive and 24 -negative). Baseline characteristics were similar across groups: majority were Asian (58%), male (75%) with a mean (SD) age of 47 (9) y and HBsAg of 2.9 (1.1) log10 IU/mL. Week 48 serologic responses are shown in the table. HBsAg loss, HBeAg loss, and HBsAg decline were more apparent in SLGN arms v PBO, with 21–30% of patients in SLGN arms having HBsAg declines ≥ 0.1 log10 IU/mL at Week 48. No patients experienced virologic breakthrough in the study. There were no Grade 3 or 4 AEs in the 3 mg SLGN or PBO groups; 3 patients in the 1.5 mg arm had Grade 3 AEs, none of which led to early discontinuation. Most frequently (≥ 20% SLGN-treated) reported AEs (SLGN v PBO) were: nausea (46% v 0), URTI (23% v 33%), headache (21% v 44%), vomiting (23% v 0), and fatigue (21% v 11%). GI disorders were mostly mild and transient. Dose-proportional increases in cytokines were observed. The 4 h post-SLGN, Days 1 and 23 median (IQR) IL-12p40 for 3 mg, 1.5 mg, and PBO were 6.0 (3.9–10.4) and 6.9 (4.7–8.2), 3.0 (1.9–4.4) and 3.9 (2.9–4.9), 0.9 (0.8–1.0) and 1.0 (0.9, 1.0) pg/mL, respectively. No tachyphylaxis were observed during 24 weeks of SLGN treatment. Further immunologic characterizations of patients with serologic responses is underway.

Week 48 Results	SLGN 3mg	SLGN 1.5mg
HBsAg loss	1/19 (5%)	1/20 (5%)
HBeAg loss	2/9 (22%)	1/10 (10%)
HBsAg decline >0.1log_{10}	4/19 (21%)	6/20 (30%)

Conclusion: Oral SLGN up to 3 mg once weekly for 24 weeks is generally safe and well-tolerated. ≥ The dose-dependent PD changes and no tachyphylaxis observed during treatment support once weekly administration of SLGN. HBsAg loss were observed in 2 patients and HBeAg loss in 3 patients by follow up Week 24.

Email: schoeneweis@myr-pharma.com

Background and Aims: Bulevirtide (BLV) is a first-in-class entry inhibitor to treat HBV/HDV co-infected patients. BLV monotherapy as well as combination with Peginterferon alfa-2a (PEG-IFNα) for 48 weeks induced serum and intrahepatic HDV RNA declines in two phase 2 trials (MYR202/203). Combination therapy with low-dose (2 mg and 5 mg) BLV and PEG-IFNα showed strong synergistic effects on HDV RNA and induced HBsAg responses (>1log decline, negativation and seroconversion) in a substantial number of patients. We here present the results of 48 weeks end of treatment of chronically HBV/HDV infected patients receiving high-dose (10 mg) BLV as monotherapy or in combination with PEG-IFNα.
Method: 30 patients with chronic HBV/HDV co-infection were randomized in 2 arms receiving: 10 mg BLV q.d./day s.c. in combination with 180 µg PEG-IFNα once weekly (E; n = 15) or 5 mg BLV b.i.d./ day s.c. (total daily dose of 10 mg BLV; F; n = 15) for 48 weeks. Tenofovir (TDF) was co-administered in F to control the underlying HBV infection. Patients were followed for 24 weeks: treatment-free follow-up (E) and continuous TDF treatment (F). The primary endpoint was defined as undetectable HDV RNA (LOD <10 IU/ml) at week 72 (24 weeks off therapy); secondary endpoints included ALT normalization, combined treatment response (≥ 2log serum HDV RNA decline + normal ALT levels), and HBsAg response.
Results: *Safety:* BLV was well tolerated during 48 weeks of therapy: overall 487 AEs were reported of which 143 AEs were considered related to BLV with most frequent AE being asymptomatic bile salt increase. No SAE was reported. *Efficacy:* At week 48, serum HDV RNA levels declined in both arms with median reductions from baseline by −6.09 $\log_{10}$ IU/ml (E) and −4.58 $\log_{10}$ IU/ml (F). HDV RNA was undetectable in 86.7% and 40% of patients at week 48, respectively. Mean ALT levels progressively declined during treatment in both groups, with 26.7% and 40% ALT normalization at week 48 in E and F, respectively. HBsAg became undetectable in one patient treated with BLV/PEG-IFNα.
Conclusion: High-dose administration of BLV co-administered with PEG-IFNα or TDF for 48 weeks was safe and well tolerated. Continuous linear HDV RNA decline was maintained over 48 weeks of treatment in monotherapy group. Strong synergy against HDV was confirmed using 10 mg BLV in combination with PEG-IFNα. 24-week follow-up data will be presented during the meeting.

NAFLD – Pharmacological therapy

VK2809, a novel liver-directed thyroid receptor agonist, produces durable reductions in liver fat in patients with non-alcoholic fatty liver disease: results of 4-week follow-up assessment from a 12-week phase 2 randomized, placebo-controlled trial

Brian Lian[1], Rohit Loomba[2], Joel Neutel[3], Carmen Margaritescu[4], Ken Homer[4], Amy Luk[1], Marianne Mancini[1], Summer Ji[1], Geoff Barker[1], Randall Severance[5], Rizwana Mohseni[6], David Bernard[7], Michael Dao[8]. [1]*Viking Therapeutics, Inc., San Diego, United States;* [2]*University of California San Diego, NAFLD Research Center, La Jolla, United States;* [3]*Orange County Research Center, Tustin, United States;* [4]*Integrium, LLC, Tustin, United States;* [5]*Radiant Research, Chandler, United States;* [6]*Catalina Research Institute, Montclair, United States;* [7]*CHEAR, Bronx, United States;* [8]*SC Clinical Research, Garden Grove, United States*
Email: blian@vikingtherapeutics.com

Background and Aims: Thyroid hormone is an important regulator of lipid metabolism, particularly acting via the beta isoform of the hepatic T3 receptor. VK2809 is a small molecule prodrug of a potent thyroid receptor agonist. VK2809 is selectively cleaved in hepatic tissues by the action of cytochrome P450 isozyme 3A4, to release a pharmacologically active metabolite. A 12-week study in patients with non-alcoholic fatty-liver disease (NAFLD) and hypercholesteremia demonstrated robust liver fat reductions and encouraging safety and tolerability. We report herein the results of liver fat assessments taken at 16 weeks; 4-weeks post-completion of dosing.
Method: This was a multi-center, randomized, double-blind, placebo-controlled, Phase 2 trial. Patients having liver fat content ≥ 8% as assessed by magnetic-resonance-imaging, proton-density-fat-fraction (MRI-PDFF), LDL-C ≥ 110 mg/dL and triglycerides ≥ 120 mg/dL were randomized to receive either oral VK2809 doses of 5 mg QD, 10 mg QOD, 10 mg QD, or placebo for 12 weeks. Patients returned for MRI-PDFF and safety assessments at 16 weeks, 4 weeks following completion of dosing.
Results: Patients receiving VK2809 experienced statistically significant reductions in liver fat content by MRI-PDFF, relative to placebo following 12 weeks of treatment. These effects were maintained at the Week-16 assessment, with patients continuing to demonstrate significantly reduced liver fat relative to baseline and placebo. At Week 16, mean relative change from baseline in liver fat content was 53% for VK2809 5 mg QD ($p < 0.0001$), 42% for VK2809 10 mg QOD ($p = 0.0004$), and 34% for 10 mg QD ($p = 0.0018$), vs 18% for placebo. Among all patients receiving VK2809 therapy, 70% maintained a ≥ 30% reduction in MRI-PDFF at Week 16 vs. 22% for placebo ($p = 0.0083$). The proportion of VK2809 patients maintaining ≥ 5% absolute liver fat reduction was 56%, vs. 0% for placebo ($p = 0.013$). VK2809 was well-tolerated in this study; no serious adverse events were reported in any cohort.
Conclusion: These data are the first to show that treatment of NAFLD patients with the novel oral thyroid receptor-beta agonist VK2809 for 12 weeks produces a durable improvement in liver fat content. Significant reductions in MRI-PDFF are maintained 4 weeks following completion of dosing. These results provide strong rationale for further development of VK2809 and may indicate opportunities for intermittent dosing regimens or potential cycling of treatment modalities in the setting of NAFLD or NASH.

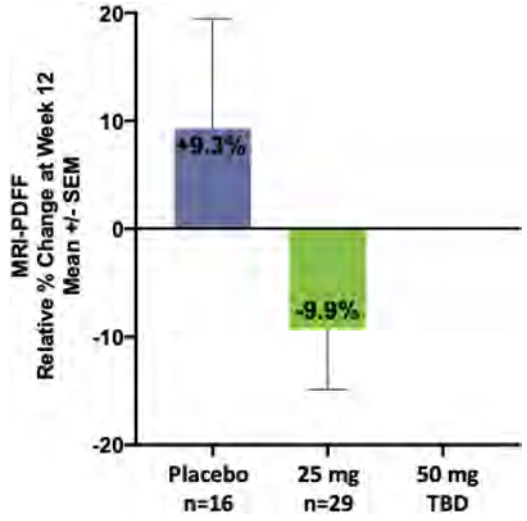
Email: roloomba@health.ucsd.edu

Background and Aims: TVB-2640 is an oral, first-in-class, small molecule reversible FASN inhibitor. FASN mediates the last committed step in de novo lipogenesis (DNL) which converts dietary sugar into palmitate. Increased hepatic DNL increases liver fat content and has been linked to lipotoxicity, a hallmark for non-alcoholic steatohepatitis. This Phase 2 study assessed the efficacy and safety of TVB-2640 in NASH (NCT03938246).
Method: Patients with NASH were randomized to either placebo or TVB-2640 at 25 mg or 50 mg QD in sequential cohorts, for 12 weeks. The primary endpoints were changes in liver fat content by Magnetic

Resonance Imaging Proton Density Fat Fraction (MRI-PDFF) and percentage of patients with at least a 30% reduction in liver fat at Week 12. Secondary and additional endpoints include the effect on safety evaluations, serum ALT and AST, cholesterol, triglycerides, lipoproteins, eicosanoids and liver fibrosis markers.

Results: The 25 mg versus placebo cohort has been completed (n = 45). The patients were predominantly Hispanic and 75% had type 2 diabetes. Twelve weeks of treatment with 25 mg TVB-2640 (n = 29) decreased liver fat by MRI-PDFF with a mean relative difference of 19.2% compared to placebo (n = 16). Seven of 29 patients treated with TVB-2640 achieved a ≥ 30% relative decrease (MRI-PDFF responders). The MRI-PDFF responders also had a statistically significant 34.6% reduction in mean serum ALT compared to a 9.3% increase in MRI-PDFF non-responders (p = 0.005). Serum fibrosis (TIMP1, PIIINP) and inflammation (IP-10) biomarkers were significantly decreased in responders versus non-responders. A significant trend was demonstrated between reductions in plasma tripalmitin and reductions in liver fat. Eicosanoid analysis is ongoing. No serious adverse events were observed and adverse events were primarily grade 1 (mild). Compared to placebo there was no significant difference in triglycerides and no hematologic or serum chemistry toxicities. The 50 mg dose cohort (30 active, 15 placebo) is ongoing and TVB-2640 continues to be well tolerated.



Conclusion: In this proof-of-concept randomized controlled trial, a novel, first in class, FASN inhibitor, TVB-2640, has shown clinically significant decreases in liver fat and serum biomarkers of liver injury, fibrosis and inflammation with impressive safety and tolerability. FASN inhibition is a promising therapeutic approach in patients with NASH and further investigation of TVB-2640 is underway.

Obeticholic acid improves experimental non-invasive markers of non-alcoholic steatohepatitis and advanced fibrosis: a secondary analysis of the phase 3 regenerate study

Jerome Boursier[1], Rohit Loomba[2], Quentin Anstee[3], Stephen Harrison[4], Arun Sanyal[5], Mary Rinella[6], Zobair Younossi[7], Zachary Goodman[7], Pierre Bedossa[8], Céline Fournier[9], Michael Stenkilsson[10], Reshma Shringarpure[10], Luna Zaru[10], Aditya Venugopal[10], Leigh MacConell[10], Vlad Ratziu[11]. *[1]Angers University Hospital, Angers, France; [2]University of California, San Diego, San Diego, United States; [3]Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; [4]Pinnacle Clinical Research Center, San Antonio, United States; [5]Virginia Commonwealth University, Richmond, United States; [6]Northwestern University, Feinberg School of Medicine, Chicago, United States; [7]Betty and Guy Beatty Center for Integrated Research, Inova Health System, Falls Church, United States; [8]Hôpital Beaujon, Assistance Publique-Hôpitaux de Paris, Service d'Anatomie Pathologique, Paris, France; [9]Echosens, Paris, France; [10]Intercept Pharmaceuticals, Inc., San Diego, United States; [11]Sorbonne Université, Hôpital Pitié–Salpêtrière, Paris, France*
Email: jeboursier@chu-angers.fr

Background and Aims: The REGENERATE month-18 interim analysis showed that treatment with OCA improved liver fibrosis in patients with NASH[1] as well as established non-invasive assessments of fibrosis and NASH. New biomarker indices are being developed to improve ability to predict NASH grade and fibrosis stage. FibroMeter (FM) is designed to predict presence of significant fibrosis (F ≥ 2). FM combines age, gender, alpha 2 macroglobilin (A2M), INR, platelets, urea and GGT, while FM VCTE uses the same biomarkers except urea and includes liver stiffness (LS) by vibration-controlled transient elastography (VCTE). The FAST score, designed to identify patients with NASH and NAFLD Activity Score (NAS) ≥ 4 and F ≥ 2, combines LS by VCTE with Controlled Attenuation Parameter (CAP) score and AST.

Method: NASH patients with fibrosis stages 2 and 3 were randomized (1:1:1) to placebo (N = 311), OCA 10 mg (n = 312) or OCA 25 mg (N = 308) QD. In a subset of patients with available values, changes in FM (N = 604), FM VCTE (N = 604), and FAST (N = 391) were analyzed using mixed-effect repeated measures model with treatment, baseline, visit, visit by treatment interaction and stratification factors to be included in the model. LS mean and p-values are based on mixed-effect repeated measure model.

Results: At baseline, there was no significant difference in scores across treatment groups (Figure). Patients with stage 3 fibrosis at baseline had higher scores than those with stage 2 fibrosis, consistent with prior publications (data not shown).

OCA-treated patients experienced improvements in FM, FM VCTE and FAST as of the first assessed timepoint (month 6) which were sustained through month 18. While this therapeutic response was observed in both OCA dose groups, no improvement was observed in the placebo group (Figure).

Conclusion: OCA treatment resulted in early and sustained improvements in experimental non-invasive assessments of fibrosis NASH, consistent with previously reported histologic improvements. Specifically, improvements in FM and FM VCTE are consistent with OCA's anti-fibrotic effect, while improvements in FAST are consistent with amelioration of key histologic features of NASH, including both inflammation and fibrosis.

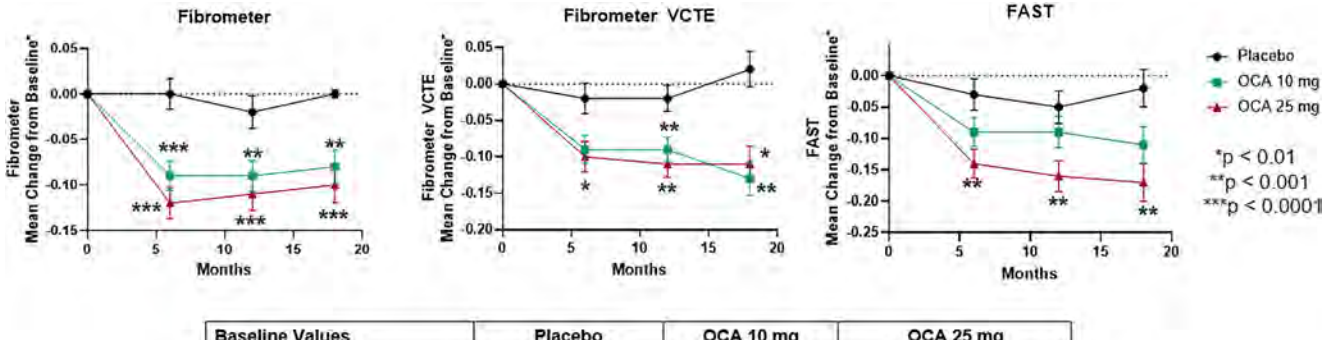
Effects of cotadutide on biomarkers of non-alcoholic steatohepatitis in overweight or obese subjects with type 2 diabetes mellitus: a 54-week analysis of a randomized phase 2b study

Rajaa Nahra[1], Kishore Gadde[2], Boaz Hirshberg[1], Lutz Jermutus[1], Jill Maaske[1], Michael Stumvoll[3], Tao Wang[1], Philip Ambery[4]. *[1]AstraZeneca, Gaithersburg, MD, United States; [2]Pennington Biomedical Research Centre, Baton Rouge, LA, United States; [3]University Hospital Leipzig, Leipzig, Saxony, Germany; [4]AstraZeneca, Gothenburg, Sweden*
Email: jill.maaske@astrazeneca.com

Background and Aims: Cotadutide, a dual-receptor agonist with glucagon-like peptide-1 and glucagon activity, significantly decreased hepatic fat in obese or overweight T2DM subjects in an exploratory analysis of a phase 2b study. We evaluated effects of cotadutide at week 54 (W54) on hepatic parameters and metabolic profiles of obese or overweight T2DM subjects.

[1]Interim analysis results at 18 months are based on surrogate endpoints and impact on clinical outcomes has not been confirmed. The REGENERATE study remains ongoing and will continue through clinical outcomes to characterize OCA's clinical benefit.



Baseline Values	Placebo	OCA 10 mg	OCA 25 mg

[a]Mean (SD).
[b]Least-square mean for % change from BL.

Method: Eligible subjects (N = 834) were randomized to once-daily subcutaneous cotadutide 100, 200, or 300 μg; placebo; or open-label once-daily liraglutide 1.8 mg (NCT03235050). Change from baseline (BL) to W54 in body weight was secondary endpoint; changes in ALT, AST, and gamma-glutamyl transferase (GGT) were post hoc analyses (per-protocol population). Changes from BL to W54 in fatty liver disease fibrosis score (NFS) and fatty liver index (FLI) were also assessed as post hoc analyses (as-treated population).

Results: Significant reductions in body weight were observed at all cotadutide doses vs placebo ($p < 0.001$) and cotadutide 300 μg vs liraglutide ($p = 0.009$). Numerical reductions from BL to W54 in ALT, AST, and GGT levels were observed with all cotadutide doses (Table). Greatest ALT reductions were in 4th quartile (LS mean difference for % change from BL) vs placebo; with cotadutide 100, 200, and 300 μg, −12.3 ($p = 0.259$), −27.1 ($p = 0.002$), and −31.3 ($p < 0.001$), respectively. At BL, 91% had fatty liver (FLI ≥ 60) and 13% had advanced liver fibrosis (NFS >0.675). Clinically significant reductions were observed at W54 in NFS ($p \leq 0.001$) for all cotadutide doses and in FLI ($p = 0.010$) for cotadutide 300 μg vs placebo.

Conclusion: Cotadutide 300 μg yielded greater reductions in body weight and ALT levels vs liraglutide. The improvements in FLI and NFS with cotadutide may indicate reduced liver fat and fibrosis, respectively. These data support prospective clinical trials with cotadutide for a NASH indication.

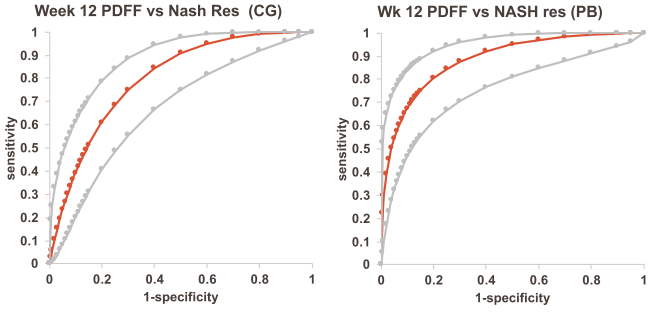
AS077

Magnetic resonance imaging-proton density fat fraction (MRI-PDFF) to predict treatment response on NASH liver biopsy: a secondary analysis of the resmetirom randomized placebo-controlled phase 2 clinical trial

Rohit Loomba[1], Cynthia Guy[2], Pierre Bedossa[3], Rebecca Taub[4], Mustafa Bashir[5], Stephen Harrison[6]. *[1]University of San Diego, Hepatology, San Diego, United States; [2]Duke University Medical Center, Pathology, Durham, United States; [3]University of Newcastle, Cellular Medicine, Paris, France; [4]Madrigal Pharmaceuticals, Research and development, Conshohocken, United States; [5]Duke University Medical Center, Radiology, Durham, United States; [6]Oxford University, Hepatology, San Antonio, United States*
Email: rebeccataub@yahoo.com

Background and Aims: Resmetirom treatment resulted in significant reduction in hepatic fat as assessed by MRI-PDFF after 12 and 36 weeks that was associated with higher rates of NASH resolution compared to placebo on week 36 liver biopsy assessment. A few placebo patients who lost body weight also demonstrated MRI-PDFF reduction and NASH resolution. The aim of this secondary analysis was to examine the potential of reduction in MRI-PDFF to predict histologic response in NASH.

Method: The analysis included the subset of patients (n = 107; placebo, n = 34; resmetirom, n = 73) who had MRI-PDFF at baseline, week 12, week 36 and week 36 liver biopsy in the Phase 2 randomized controlled trial of resmetirom versus placebo (pbo) for treatment of NASH. We examined the overall relationship in resmetirom plus pbo patients between PDFF and NASH resolution as evaluated by two blinded, independent central biopsy reviewers (CG, PB). The study cohort was assessed for those who had a ≥ 30, ≥ 40 and ≥ 50% decline in MRI-PDFF between week 0 and week 12 as predictors of NASH resolution.



Results: Baseline characteristics have been reported (Lancet https://doi.org/10.1016/S0140-6736(19)32517-6). Among pbo (n = 5,4 (CG, PB)) (3/5 pbo patients with ≥ 10% weight loss) and resmetirom (n = 18) patients with NASH resolution, the mean week 12 fat reduction on MRI-PDFF was 56%, the optimal PDFF cutoff was 41.5% with a sensitivity of 0.82 (95% confidence interval (CI) 0.61,0.93) and specificity of 0.83 (95% CI 0.74,0.90), p < 0.001, observed by both central readers (Figure). Compared to MRI-PDFF non-responders with <30% fat reduction (n = 56), MRI-PDFF responders (≥ 30% fat reduction) (n = 51) had significantly higher odds of NASH resolution (40% versus 3.7%) with odds ratio 9.1,18.0 (CG, PB) (95% CI 3.9, 82.3), p < 0.0001. The odds of NASH resolution were higher with greater reductions in liver fat content, ≥ 40% and ≥ 50% MRI-PDFF reduction showing an OR of 16.5, and 25.3, respectively, compared to PDFF non-responders, p < 0.0001. In patients with ≥ 50% fat reduction at week 12 (pbo = 2; resmetirom = 22) 46% (CG) and 64% (PB) had NASH resolution with a component response driven primarily by ballooning and inflammation reduction. Change in ALT was not strongly associated with a histologic response.

Conclusion: MRI-PDFF response robustly predicted NASH biopsy response for resmetirom and pbo. Doses of resmetirom, 80 mg and 100 mg, used in the ongoing Phase 3 study MAESTRO-NASH had average PDFF reduction of 50% and 64%, respectively, and may predict higher rates of NASH resolution than observed in the Phase 2 study (27%) in which half of the resmetirom treated patients received a lower dose (60 mg).

HDL (mmol/L)	−0.21 (0.03)	−0.05 (0.03)	−0.004 (0.04)	**<0.0001**	0.348

Data represents LS mean (SE) for change (or %change) from baseline at week 12.

Here, we present the final results at week 12 (W12) of a randomized, double-blind, placebo-controlled trial (NCT03421431).

Method: Non-cirrhotic subjects with fibrotic NASH diagnosed by historical biopsy or phenotypically (high BMI, diagnosis of T2DM/prediabetes), and with elevated ALT and MRI-PDFF >8%, were randomized to receive EDP-305 2.5 mg or 1 mg, or placebo (PBO), for 12 weeks. Liver enzymes and liver fat measured by MRI-PDFF were assessed at baseline (BL) and through W12.

Results: A total of 134 subjects were randomized. Mean age was 52 years; 52% were women; 74% had T2DM; mean ALT was 83U/l and MRI-PDFF, 20%. At W12, pre-specified endpoints were met in EDP-305 2.5 mg (Table). Overall, EDP-305 was generally safe, with the most common ($\geq$ 5%) TEAEs including pruritus, gastro-intestinal symptoms (nausea, vomiting, diarrhea), headache and dizziness. Pruritus was present in 51% of the subjects in 2.5 mg arm, <10% in 1 mg arm, <5% in PBO. Pruritus led to treatment discontinuation in 1.8% with 1 mg and 20.8% with 2.5 mg (due to moderate pruritus). Effects of EDP-305 on lipids were modest.

Conclusion: After 12-weeks of therapy, EDP-305 2.5 mg achieved statistically significant improvements in liver biochemistry and hepatic steatosis. EDP-305 exhibited strong target engagement with reduction in C4 and increase in FGF-19. EDP-305 was generally safe; mild to moderate pruritus was more frequent with 2.5 mg, with more treatment discontinuations. No statistical difference in LDL was observed. These results support further development of EDP-305 in patients with NASH in a longer-term trial with liver histology assessment.

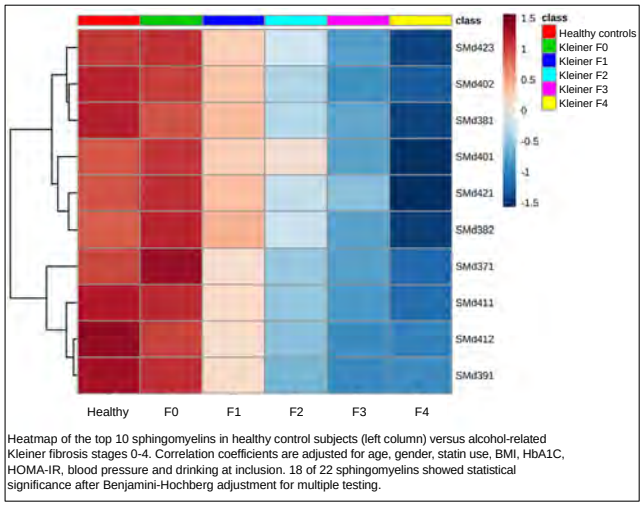
Background and Aims: Alcohol-related liver fibrosis (ALD) is the leading cause of cirrhosis and liver-related deaths. Identification of disease drivers is pivotal to better understand individual susceptibility and identify potential treatment targets. Studies in histology and genetics point towards lipid metabolism as a key feature. Advances in mass spectrometry today allow detailed analysis of individual lipids in liver tissue and in the circulation. Consequently, we aimed to fully characterize circulating and liver lipids in ALD by lipidomics analysis.

Method: We included 350 asymptomatic ALD patients and 50 healthy control subjects matched for age, gender and BMI. Plasma and liver were sampled on the same day and histology scored according to the NAFLD activity score and Kleiner fibrosis stage. We did ultra high-performance chromatography coupled with time-of-flight mass spectrometry to identify 250 lipids from 17 lipid classes, including sphingomyelins (SM), ceramides (Cer), lysophosphatidylcholines (LPC), phosphatidylcholines (PC), and triglycerides (TG). We correlated lipids with histology by adjusted ANCOVA regression, with p-value correction for multiplicity. We combined lipidomics with data from the whole-blood transcriptome and proteome to evaluate potential mechanistic effects.

Results: Sphingomyelins decreased dramatically both in circulation and liver through every fibrosis stage and were lowest in cirrhosis (Figure). We observed a similar, early decrease in SM with inflammation and steatosis. Cer, LPC, PC, and TG also correlated negatively with severe fibrosis and cirrhosis. The circulating lipidomics signature of healthy controls were comparable only to ALD patients with no fibrosis (F0). The negative correlation between SM and fibrosis stage was independent of age, gender, statin use, BMI, HbA1C, HOMA-IR, liver steatosis and drinking pattern. Circulating mRNA for enzymes in the SM biosynthesis and degradation pathways were dysregulated, but without clear evidence of either decreased formation of SM or increased degradation. Plasma proteome analysis revealed a downregulation of several apolipoproteins, suggesting hepatic and extra-hepatic decreased lipid-binding and -transporting capacity.



Heatmap of the top 10 sphingomyelins in healthy control subjects (left column) versus alcohol-related Kleiner fibrosis stages 0-4. Correlation coefficients are adjusted for age, gender, statin use, BMI, HbA1C, HOMA-IR, blood pressure and drinking at inclusion. 18 of 22 sphingomyelins showed statistical significance after Benjamini-Hochberg adjustment for multiple testing.

Conclusion: Progressive fibrosis in ALD is characterized by selective lipid depletion in blood and liver tissue, with sphingomyelins showing the most dramatic decreases. Sphingomyelins are involved in cell signaling and apoptosis, which implies a mechanistic role.

Interaction between neutrophils and cholangiocytes causes cholestasis in alcoholic hepatitis

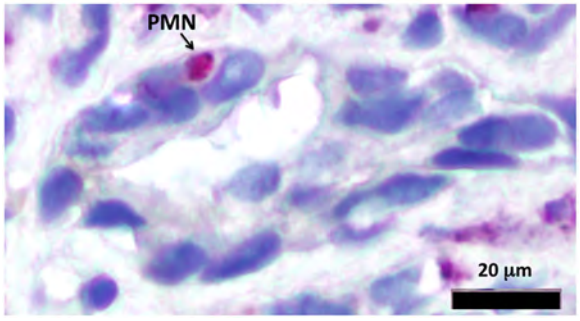
Masahiro Takeuchi[1], Paula Vidigal[1], Mateus Guerra[1], Melanie Hundt[1], Marie Robert[1], Maria Olave-Martinez[1], Satoshi Aoki[1], Tanaporn Khamphaya[1], Remco Kersten[1], Emma Kruglov[1], Jesus M. Banales[2], Michael Nathanson[1], Jittima Weerachayaphorn[1]. *[1]Yale University, New Haven, United States; [2]Campus De Bizkaia - Campus of Biscay, Lejona, Spain*
Email: takeuchi.masahiro@yale.edu

Background and Aims: Alcoholic hepatitis (AH) is a life-threatening disease with limited treatment options. The presence of cholestasis worsens prognosis but the responsible mechanism is unknown. AH results in infiltration of polymorphonuclear neutrophils (PMNs) in the liver, and cholestasis often reflects bile duct pathology, so we investigated whether and how PMNs interact with cholangiocytes in AH.

ELSEVIER

Method: PMNs in contact with bile ducts were identified (Fig.) and quantified in archived liver biopsy specimens from patients with AH, alcoholic cirrhosis, and normal controls, then these results were correlated with clinical and pathological findings. NHC cells derived from human bile ducts were co-cultured with PMNs isolated from AH patients or normal controls. Type 3 inositol trisphosphate receptor (ITPR3) expression in NHC cells was used as a marker for cholestasis because loss of this apical calcium channel is responsible for impaired secretion in AH and other, more classical cholangiopathies.

Results: PMNs were adjacent to bile ducts in most AH specimens but not in alcoholic cirrhosis or normal control specimens. The frequency of PMN-bile duct contacts correlated with serum bilirubin and alkaline phosphatase ($p < 0.0005$), and cholestasis in the hepatic lobule was only seen when PMNs were in contact with bile ducts ($p < 0.0001$). ITPR3 expression in NHC cells was markedly reduced by PMN co-culture, and PMNs from AH patients were more potent than healthy control PMNs ($p < 0.05$). This effect was not reduced by blocking components of the LPS/TLR4/NFkB pathway. ITPR3 in NHC cells also was not reduced by PMN-conditioned medium or by PMNs separated by a semi-permeable membrane, suggesting that direct contact was necessary. Consistent with this, ITPR3 expression in NHC cells was only minimally reduced by co-culture with "naked" PMNs in which surface membrane proteins were removed in a non-damaging fashion. Bioinformatic analysis of RNA-seq data suggested the involvement of β1-integrin in PMN-NHC cell interactions, and PMNs did not decrease ITPR3 expression in NHC cells in the presence of an integrin blocking antibody.



Conclusion: Neutrophils often are in contact with bile ducts in alcoholic hepatitis, and this interaction correlates with jaundice and cholestasis in these patients. This is an integrin β1-mediated process that decreases ITPR3 expression in the cholangiocytes, which impairs secretion. This previously unrecognized pathway suggests new treatment targets.

Fecal microbial transplant reduces short-term cravings, improves quality of life and microbial diversity in cirrhosis and alcohol use disorder: a randomized, placebo-controlled, clinical trial

Jasmohan S. Bajaj[1], Andrew Fagan[1], Edith Gavis[1], Michael Fuchs[1], Puneet Puri[1], Samarth Patel[1], Brian Davis[1], Melanie White[1], Jill Meador[1], Masoumeh Sikaroodi[2], Patrick Gillevet[2]. [1]*Virginia Commonwealth University and McGuire VA Medical Center, Richmond, United States;* [2]*George Mason University*
Email: jasmohan.bajaj@vcuhealth.org

Background and aims: An altered gut-liver-brain axis underlies alcohol use disorder (AUD). AUD can result in cirrhosis and often patients continue to drink despite cirrhosis development. Fecal microbiota transplant (FMT) can change gut microbiota & brain function in cirrhosis, but its effect on AUD is unclear. Aim: Define safety and effect on alcohol craving in cirrhotic pts with AUD who continue to drink in a clinical trial.

Method: Cirrhotic pts with AUD (AUDIT-10 score>8) with several unsuccessful attempts at rehabilitation, MELD<17, without alcoholic hepatitis were randomized 1:1 into placebo or FMT in a blinded randomized trial. FMT material was derived from one donor containing high relative abundance of *Lachnospiraceae* and *Ruminococcaceae*. FMT/placebo were administered once via enema. Visits were carried out at days 1, 8, 15 & 30 post-intervention. Safety, adverse events(AE) were inquired at every visit. Alcohol craving questionnaire (ACQ: high = worse), Sickness impact profile (SIP) for quality of life (QOL; has total, physical & psychosocial score, high = worse) & stool for 16S microbial analysis were obtained at baseline & day 15.

Results: 20 cirrhotic men with ongoing AUD (65 ± 6.4 yrs, MELD 8.9 ± 2.7) & median (IQR) AUDIT of 16.0(12.0) were enrolled.

Baseline: No differences were seen, MELD 9.5 vs 9.3, $p = 0.35$, age 67.1 ± 5.2 vs 62.9 ± 7.1, $p = 0.15$, AUDIT score, 15.5 ± 7.7 vs 16.7 ± 7.9, $p = 0.74$, SIP ($p > 0.05$ all) & ACQ,2.7 (1.8–4.7) vs 3.1(2.4–4.5), $p = 0.53$.

Course: 2 placebo-assigned pts needed urgent attention within 30 days (1 hyponatremia & 1 atrial fibrillation); none in the FMT group. One pt each from placebo & FMT dropped out before day 30. The FMT pt restarted problem drinking. No AEs or changes in safety labs were seen.

Craving/QOL: A significant reduction in alcohol craving & improvement in total & psychosocial SIP was seen only in the FMT group at day15 (Figure). No change in placebo group or in physical SIP was seen.

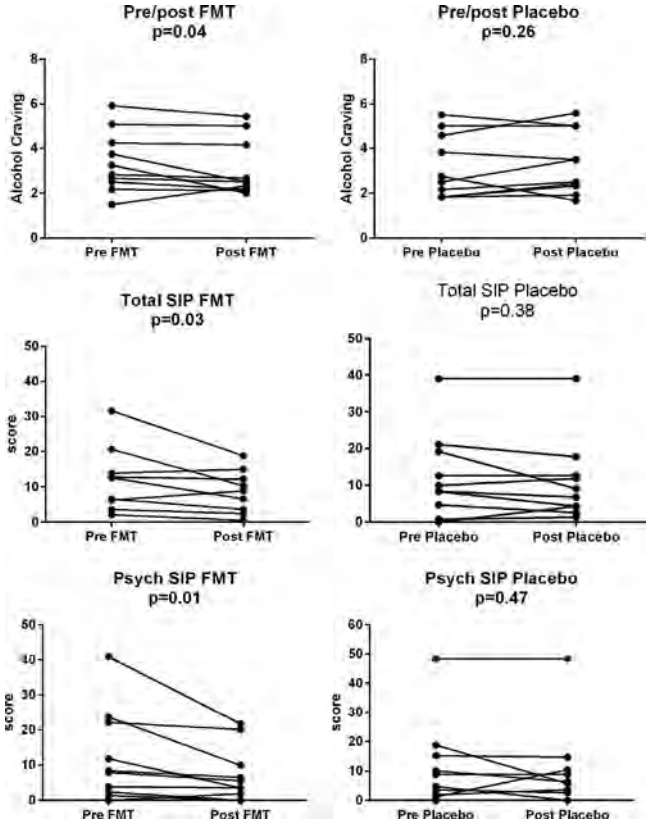

Figure: Changes in Alcohol Craving (high = worse) and Sickness Impact Profile (SIP) (high = worse) in baseline vs day 15 in placebo and FMT groups.

Microbiota: A significant increase in diversity was seen post-FMT vs baseline (1.67 ± 0.21 vs 1.83 ± 0.26, p = 0.29) but not in placebo (1.73 ± 0.30 vs 1.79 ± 0.19, p = 0.56). Unlike the others, diversity reduced vs baseline in the FMT pt who restarted problem drinking before day 30. At day 15, FMT pts had higher relative abundance of *Odoribacter* compared to baseline. At day 15, *Alistipes* and *Roseburia* were higher in FMT vs placebo.
Conclusion: Alcohol craving was significantly reduced accompanied by improvement in QOL after FMT in cirrhotic patients with AUD. These were associated with higher diversity & relative abundance of fatty acid producing taxa (*Roseburia, Alistipes & Odoribacter*) in FMT compared to placebo and baseline. Altering the gut-brain axis beneficially with FMT could be a potential avenue to alleviate AUD in cirrhosis.

AS082

Definition and prognostic relevance of the salve grading and staging system for alcohol-related liver disease

Carolin Lackner[1], Dina Tiniakos[2], Annette Gouw[3], Peter Schirmacher[4], Valérie Paradis[5], Hans-Peter Dienes[6], Luigi Maria Terracciano[7], Davies Susan[8], Maria Guido[9], Viviane Gnemmi[10], Rosa Miguel[11], Rudolf E. Stauber[12], Helmut Denk[13]. *[1]Medical University of Graz, Institute of Pathology, Graz, Austria; [2]Faculty of Medical Sciences Newcastle University, Institute of Cellular Medicine, Newcastle upon Tyne, United Kingdom; [3]University Medical Center Groningen, Department of Pathology and Medical Biology, Groningen, Netherlands; [4]University Hospital Heidelberg, Institute of Pathology, Heidelberg, Germany; [5]Hopital Beaujon, Department d'Anatomie Pathologique, Clichy, France; [6]Medical University of Vienna, Institute of Pathology, Vienna, Austria; [7]University Hospital Basel, Institute of Pathology, Basel, Switzerland; [8]Cambridge University Hospitals, Histopathology, Cambridge, United Kingdom; [9]University of Padova School of Medicine, Padova, Italy; [10]University of Lille, Institute de Pathologie, Lille, France; [11]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [12]Medical University of Graz, Department of Internal Medicine, Graz, Austria; [13]Medical University of Graz, Institute of Pathology, Graz, Austria*
Email: karoline.lackner@medunigraz.at

Background and Aims: Alcohol misuse is among the most frequent causes of cirrhosis and liver transplantation. However, while elementary histologic features are well recognized a histologic grading and staging system specific for alcohol-related liver disease (ALD) is lacking. The Histopathology Group of the Consortium for the Study of Alcohol-related LiVer disease in Europe (SALVE) aimed to define a scoring system for the semiquantitative evaluation of grade (SALVE activity score, SAS) and fibrosis (SALVE fibrosis stage, SFS) intended for routine application and clinical studies.
Method: Interobserver variation and prognostic utility (endpoint: liver-related death) of the SAS and SFS system was assessed in a cohort of 172 biopsied patients comprising the whole clinical spectrum of ALD and long-term (5-year) follow-up.
Results: SAS is a combined score of macro vesicular steatosis (scores 0–2), hepatocellular ballooning (scores 0–2) OR Mallory-Denk bodies (scores 0–2), lobular neutrophils (scores 0–2), and cholestasis, the sum of canalicular and ductular cholestasis (CC and DC, respectively; both scored 0–1). Interobserver kappa of each grade feature was >0.6. Patients with alcoholic steatohepatitis (ASH) based on ballooning and neutrophil scores ≥ 1 and ASH with DC score 1 had a significantly worse 5-year survival compared to patients without ASH (p = 0.003, log-rank test). The SFS staging system is defined on a 4-step scale with respect to the type (dense portal-based and/or central-based pericellular fibrosis (PCF)) and extent of fibrosis allowing the subclassification of precirrhotic and cirrhotic SFS in several degrees of severity. Interobserver kappa for SFS was 0.86. Patients with SFS 3 and 4 showed significantly worse survival than patients with SFS 0–2 (p = 0.001, log-rank test). On multivariable Cox regression adjusted for bilirubin, INR, albumin, platelets, leukocytes, sodium, sex and abstinence, independent histological predictors of short-term (90 days) and long-term outcome were SFS (p = 0.01 and 0.004, respectively), CC (p = 0.028 and 0.034, respectively), and DC (p = 0.040 and 0.021, respectively).
Conclusion: The SALVE grading and staging system is a reproducible and prognostically relevant method for semiquantitative assessment of disease activity and fibrosis in ALD. Following validation, it may prove useful to stratify patients and evaluate therapeutic interventions.

AS083

The selective PPAR-delta agonist seladelpar reduces ethanol-induced liver disease by restoring gut barrier function and bile acid homeostasis in mice

Huikuan Chu[1,2], Bei Gao[1], Yanhan Wang[1], Lu Jiang[1], Ed Cable[3], Bernd Schnabl[1]. *[1]University of California San Diego, Medicine, La Jolla, United States; [2]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Gastroenterology, Wuhan, China; [3]CymaBay Therapeutics, Newark, United States*
Email: beschnabl@ucsd.edu

Background and Aims: Chronic alcohol-related liver disease is associated with dysregulation of bile acid metabolism and gut barrier dysfunction. PPAR-delta agonists are key metabolic regulators and anti-inflammatory agents. Here, we evaluated the effect of the selective PPAR-delta agonist seladelpar (MBX-8025) in a mouse model of ethanol-induced liver disease.
Method: Wild type C57BL/6 mice were fed a Lieber DeCarli diet containing 0% to 36% ethanol (caloric) for 8 weeks followed by one binge of ethanol (5 g/kg). Pair fed mice received an isocaloric liquid diet as control. Seladelpar (10 mg/kg/d) or vehicle was added to the liquid diet during the entire feeding period (prevention trial), or during the last four weeks of ethanol feeding (intervention trial).
Results: In both prevention and intervention trials, seladelpar protected mice from ethanol-induced liver disease, characterized by lower serum alanine aminotransferase levels and hepatic triglycerides. Chronic ethanol intake disrupted bile acid metabolism by increasing the total bile acid pool and secondary bile acids. Seladelpar reduced total serum bile acids, secondary serum bile acids and the total bile acid pool as compared with vehicle treatment in the prevention and intervention trials. Ethanol feeding is also associated with gut barrier dysfunction. Seladelpar stabilized the gut barrier function, characterized by lower fecal albumin in the prevention trial and lower serum lipopolysaccharides in the intervention trial. We confirmed that systemic blood ethanol levels were similar in all conditions, indicating that intestinal absorption and hepatic metabolism of ethanol are not affected by seladelpar. Furthermore, we confirmed that serum levels of seladelpar were similar in the ethanol treated mice, compared with the levels of seladelpar in the isocaloric control diet mice, indicating that ethanol did not affect exposure to seladelpar.
Conclusion: The selective PPAR-delta agonist seladelpar restored ethanol-induced gut barrier function, reversed dysregulation of bile acid metabolism and protected mice from ethanol-induced liver disease. The data from this study demonstrate that seladelpar prevents or treats ethanol-induced damage in mice by direct PPAR-delta agonism in both the liver and the intestine.

AS084

Genetic variation in HSD17B3 reduces the risk for developing severe alcoholic hepatitis

Stephen Atkinson[1], Thomas Buckley[2], Pavel Strnad[3], Mark Thursz[1], Andrew McQuillin[4], Marsha Morgan[2]. [1]*Department of Metabolism, Digestion & Reproduction, Imperial College London, London;* [2]*UCL Institute for Liver & Digestive Health, Division of Medicine, Royal Free Campus, University College London, London, United Kingdom;* [3]*Medical Clinic III, Metabolic Diseases and Intensive Care, University Hospital RWTH, Aachen, Germany;* [4]*Molecular Psychiatry Laboratory, Division of Psychiatry, University College London, London*
Email: marsha.morgan@ucl.ac.uk

Background and Aims: Carriage of *PNPLA3*:rs738409:G increases the risk for developing severe alcoholic hepatitis. Carriage of *HSD17B13*:rs72613567:TA decreases the risk for developing alcohol-related cirrhosis and HCC and attenuates the risk associated with *PNPLA3*:rs738409:G. The aims of this study were to: (i) determine the effect of rs72613567 on the risk for developing severe alcoholic hepatitis and the risk relationship between rs72613567A and rs738409; and (ii) examine for associations between these gene variants, disease severity, and markers of epithelial cell death.

Method: Genotyping for rs738409 and rs72613567 was undertaken in 3511 subjects including: 898 participants in the STOPAH trial; 327 with alcohol-related cirrhosis; 1911 alcohol misusers with no liver injury; and, 1095 healthy controls. Genetic associations with the risk for developing severe alcoholic hepatitis were determined; the relationships between genotype, disease severity and serum markers of epithelial cell death (CK18M30 and CK18M65) were explored; population attributable fractions (%PAF) were calculated for both variants.

Results: Carriage of rs738409:G was associated with an increased risk for developing severe alcoholic hepatitis (OR: 1.85 [95% CI: 1.58–2.16], $p = 8.4^{e-15}$), while carriage of rs72613567:TA was associated with a decreased risk (OR: 0.85 [95% CI: 0.74–0.98]; p = 0.029). The % PAFs associated with carriage of rs738409:G and rs72613567:TA were 25.5% [17.2 to 34] and −6.3% [−15.8 to 3.5] with a combined %PAF of 20.8% [4.1 to 36.3] indicating attenuation of the effect of rs738409:G by rs72613567:TA. Carriage of rs72613567:TA was associated with lower prothrombin times (β −0.9445, SE: 0.3132, p = 0.0026), lower Maddrey DF (β: −4.369, SE: 1.49, p = 0.0035) and GAH scores (OR: 0.80 [95% CI: 0.64–0.99], p = 0.039) and lower serum concentrations of CK18M30 (β: −801, SE: 264.6, p = 0.003) and CK18M65 (β: −1092, SE: 328.9, p = 0.0009) (Figure). Survival at 28 days and 90 days was not influenced by either variant.

Conclusion: Carriage of *PNPLA3*:rs738409:G and *HSD17B13:* rs72613567:TA differentially affect the risk for developing severe alcoholic hepatitis. Carriage of rs72613567:TA is associated with less severe liver dysfunction, lower disease severity scores and a reduction in serum CK18 fragments suggesting that its protective effect is ultimately mediated *via* a reduction in hepatocyte death.

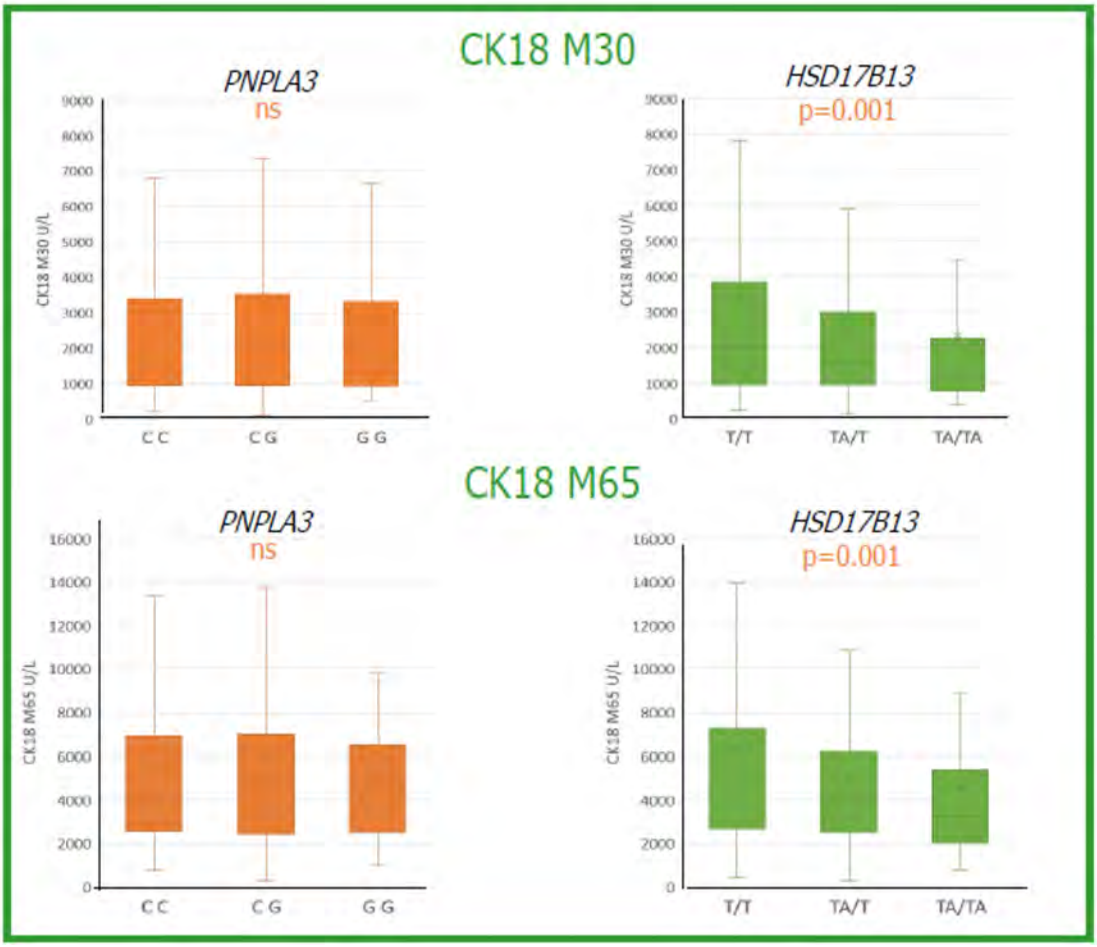

Figure: (abstract: AS084): Serum CK18M30 and M65 in alcoholic hepatitis, by genotype.

Email: eliane.sardh@sll.se

Background and Aims: Acute hepatic porphyria (AHP) is a family of rare genetic diseases due to enzyme defects in hepatic heme biosynthesis. Induction of 5-aminolevulinic acid synthase 1 (ALAS1), the rate-limiting step in heme biosynthesis, can lead to accumulation of toxic heme intermediates 5-aminolevulinic acid (ALA) and porphobilinogen (PBG), causing neurovisceral attacks and chronic manifestations. Givosiran, an investigational RNAi therapeutic, targets liver ALAS1 to reduce ALA/PBG and ameliorate attacks and clinical manifestations.
Method: ENVISION (NCT03338816) is an ongoing Phase 3 global, multicenter, randomized, placebo-controlled trial, evaluating the efficacy and safety of subcutaneous monthly doses of 2.5 mg/kg givosiran in AHP patients in a 6-month double-blind (DB) period and an open label extension (OLE) period (up to 30 months). During the OLE, patients received either 2.5 mg/kg or 1.25 mg/kg monthly givosiran. Outcome measures included composite annualized attack rate (AAR) requiring hospitalization, urgent care, or IV-hemin at home, ALA/PBG levels, hemin use, daily worst symptoms, and quality of life (QoL). Analyses were descriptive.
Results: As of July 23, 2019, 93 patients entered the OLE: 56 (placebo/givosiran = 29; givosiran/givosiran = 27) received 2.5 mg/kg monthly givosiran, and 37 (placebo/givosiran = 17; givosiran/givosiran = 20) received 1.25 mg/kg. In givosiran patients (both doses), median AAR was 1.1 (range: 0–20.5) through Month 12. In placebo patients who crossed over to givosiran in the OLE, median AAR (DB = 10.65; OLE = 1.81) and proportion of attack-free patients (DB = 17.4%; OLE = 42.2%) were similar to the givosiran group in the DB period (median AAR = 1.04; attack free patients = 48.9%). In addition, sustained lowering of ALA/PBG in the OLE was accompanied by reductions in hemin use, daily worst pain and analgesic use, and improvements in QoL. Among patients on givosiran through Month 12, 62% had ≥ 1 drug-related adverse event (AE) and 3% had ≥ 1 drug-related serious AE. There were no new AEs leading to discontinuation and no deaths. No new safety concerns occurred in the OLE. There was a trend toward increased efficacy with the 2.5 mg/kg dose compared to 1.25 mg/kg dose, and safety was acceptable at both doses.
Conclusion: In an ongoing Phase 3 study, givosiran 2.5 mg/kg monthly demonstrated maintenance or enhancement of clinical efficacy and an acceptable safety profile consistent with that observed in the 6-month DB period.

AS086
Primary liver cancer in acute hepatic porphyria: a national cohort study

Mattias Lissing[1], Daphne Vassiliou[2,3], Ylva Floderus[3], Pauline Harper[3], Matteo Bottai[4], Marianna Kotopouli[4], Hannes Hagström[1], Eliane Sardh[2,3], Staffan Wahlin[1]. *[1]Karolinska University Hospital, Dept of Upper GI Diseases, Sweden; [2]Karolinska University Hospital, Dept of Endocrinology and Metabolism; [3]Karolinska University Hospital, Porphyria Centre Sweden; [4]Karolinska Institute, Institute of Environmental Medicine, Division of Biostatistics*
Email: mattias.lissing@ki.se

Background and Aims: The porphyrias are a group of diseases caused by defects in the different enzymes of the heme synthesis pathway. In acute intermittent Porphyria (AIP), Variegate Porphyria (VP) and Hereditary Coproporhyria (HCP), commonly grouped as acute hepatic porphyrias (AHP), increased levels of 5-aminolevulinic acid (ALA) and porphobilinogen (PBG) are associated with the typical acute neurovisceral attacks. Previous studies show that AHP-patients carry an increased risk of primary liver cancer (PLC). However, risk estimates are uncertain, and little is known about how AHP subtype, AIP mutation, biochemical activity or disease severity affect the risk. Our aim was to assess the risk of PLC in correlation to these variables in a large population-based cohort.
Method: All patients in the Swedish porphyria registry with verified AIP, VP and HCP were included and matched to reference individuals from the general population 1:10 by age, sex and municipality. Data on incident PLC were collected from national health registries and validated by a set of criteria to minimize risk of misclassification. PLC incidence were compared by incidence rate ratio. For the AIP-subgroup, data were collected on type of HMBS-mutation, maximal U-PBG and number of hospitalizations for porphyria.
Results: We identified 1244 patients with AHP between 1987 and 2015, of which 1063 (85%) had AIP. Health registries identified 108 subjects with a verified PLC diagnosis, 83 among AHP patients (6.7%) and 25 among reference individuals (0.2%), corresponding to an incidence risk ratio of 34.2 (95% confidence interval:21.9–53.5). For the AIP subgroup, elevated U-PBG levels and hospitalizations for porphyria, but not mutation, were associated with an increased PLC risk. AIP patients >50 years of age with a previously recorded elevated U-PBG (n = 158) had an annual PLC-incidence rate of 1.8%. There was only one case of PLC in the VP (n = 125) and one case in the HCP (n = 56) group, indicating a low risk for incident PLC compared to AIP.
Conclusion: Patients with AIP have a markedly increased risk of PLC compared to a matched reference group. The increased risk is associated with biochemical and clinical activity but not with mutation.

Background and Aims: Cirrhosis develops in <10% of individuals with hereditary haemochromatosis homozygous for the C282Y variant in the *homeostatic iron regulator* (*HFE*) gene. Carriage of *PCSK7*:rs236918:C is known to be associated with an increased risk for developing cirrhosis in this population. This study aimed to determine if carriage of variants associated with the risk for developing alcohol- and NAFLD-related cirrhosis, *viz PNPLA3*: rs738409, *TM6SF2*:rs58542926, *MBOAT7*:rs641738, and *HSD17B13*: rs72613567, also modulate the risk for developing cirrhosis in C282Y homozygotes.

Methods: Variants in *PCSK7, PNPLA3, TM6SF2, MBOAT7, and HSD17B13* were genotyped in 1337 C282Y homozygotes, from six European countries, of whom 181 (13.5%) had established cirrhosis. Genotypic and allelic associations with the risks for developing cirrhosis were assessed using logistic regression analysis, adjusting for age and sex. Fixed-effect meta-analyses of the adjusted summary data for each country were performed. Post-hoc testing was undertaken in 137 (75.7%) cases and 284 (24.6%) controls with available liver histology. Population-attributable fractions (%PAFs) were calculated for any significantly associated alleles.

Results: Significant associations were observed between *PCSK7:* rs236918 (OR = 1.44 [95% CI 1.01–2.05]; p = 0.042; I^2 = 0%); *PNPLA3:* rs738409 (OR = 1.60 [95% CI 1.22–2.09]; p = 5.9×10^{-4}; I^2 = 65.9%) and *TM6SF2:*rs58542926 (OR = 1.80 [95% CI 1.20–2.70]; p = 4.8×10^{-3}; I^2 = 0%) and the risk for developing cirrhosis in C282Y homozygotes. These findings remained significant in the subpopulations with available liver histology. The PAFs were 4.9% for *PCSK7*:rs236918:C; 13.8% for *PNPLA3*:rs738409:G, 5.7% for *TM6SF2*:rs58542926:T, and 22.7% for carriage of all three variants combined. The associations with *MBOAT7*:rs641738, and *HSD17B13*:rs72613567 were not significant (Figure).

Conclusion: The risk for developing cirrhosis associated with carriage of *PCSK7*:rs236918 was confirmed in this large, well-characterized population of C282Y homozygotes. In addition, *PNPLA3*:rs738409 and *TM6SF2*:rs58542926 were established as significant additional risk modulators. More detailed genetic testing and use of genotypic-phenotypic risk scores could identify C282Y homozygotes at particular risk for developing cirrhosis and facilitate their management.

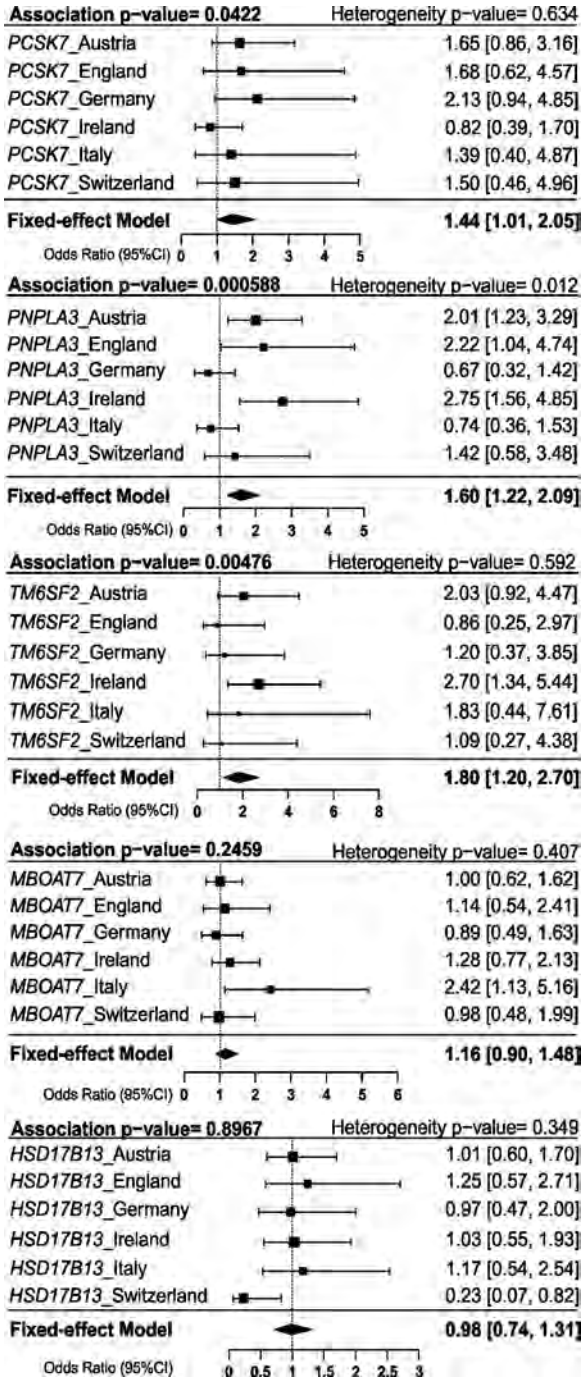

Figure: (abstract: AS087): Genotypic associations with the risk for developing cirrhosis in C282Y homozygotes, adjusted for age, sex, by country.

Email: martamagazm@gmail.com

Background and Aims: Polycythemia vera (PV) and essential thrombocythemia (ET) are myeloproliferative neoplasms (MPN) characterized by an increased risk of thrombosis. In a minority of these patients, splanchnic venous thrombosis (SVT) is the first manifestation of the disease. These patients appear to have different biological/phenotypic characteristics from the remaining patients with PV/ET (they are younger, predominantly female and with lower JAK2V617F mutational load). However, their natural history has not been well described.
The objective of this study was to characterize the natural history of patients with PV/ET in whom SVT is the first clinical manifestation in comparison to patients with the same age/sex without this complication at diagnosis.
Method: Patients with PV and ET with SVT as first manifestation were identified from three prospective multicenter national registries (PV Registry, ET Registry and Spanish registry of hepatic vascular diseases (REHEVASC). Of a total of 3705 patients with PV/ET, 118 (3.2%) presented SVT as the first manifestation. Survival was the main objective of the study and risk of retrombosis, bleeding, disease progression or the appearance of second malignancies were secondary objectives. COX regression analysis adjusted for age, sex and presence of SVT as first manifestation was used.. Competing risk analysis was used for analyzing secondary objectives.
Results: Patients with PV/ET with SVT as first manifestation (25 Budd-Chiari Syndrome (BCS), 74 splenoportal thrombosis (PVT), 3 mixed cases (SBC + PVT) and 16 unspecified) were significantly younger, with a PV predominance and with a lower prevalence of cardiovascular risk factors. These patients had an increased risk, adjusted for age and sex, of death (HR: 2.47, 95% CI: 1.5–4.01, $p < 0.001$), venous thrombosis (IRR: 3.4, 95% CI: 2.1–5.5, $p < 0.001$), of a second malignancy (IRR: 2.4, 95% CI: 1.4–4.2, $p = 0.002$) and major bleeding (symptomatic bleeding in a critical or asymptomatic organ associated with need for transfusion or a hemoglobin drop of >20 g/L: IRR: 7.2, 95% CI: 4.3–12.1, $p < 0.001$). No cases of leukemic transformation were documented among these patients and 7 (6%) progressed to myelofibrosis after a mean follow-up of 6 years.
Conclusion: Patients with PV and ET who had SVT as a first manifestation have a reduced survival compared to those patients with PV/TE without SVT of their same age and sex. The excess mortality seems to be more related to the liver disease itself, the higher incidence of bleeding and the appearance of second malignancies than with the evolution of the base PV/ET.

Remarkable long-term outcome of step-wise management strategy for Budd-Chiari syndrome in China: a nationwide 20-year retrospective study of 1366 patients

Qiuhe Wang[1], Bohan Luo[1], Xulong Yuan[1], Jiahao Fan[1], Kai Li[1], Wengang Guo[1], Tianlei Yu[1], Zhengyu Wang[1], Jie Yuan[1], Xiaomei Li[1], Ying Zhu[1], Na Han[1], Jing Niu[1], Yong Lv[1], Jing Li[1], Shihao Tang[1], Shuai Guo[1], Enxin Wang[1], Dongdong Xia[1], Zhexuan Wang[1], Chuangye He[1], Hongwei Cai[2], Zhanxin Yin[1], Jielai Xia[2], Daiming Fan[3], Guohong Han[1]. *[1]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Liver Disease and Digestive Interventional Radiology, Xi'an, China; [2]Fourth Military Medical University, Department of Statistics, Xi'an; [3]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, State Key Laboratory of Cancer Biology, Xi'an, China*
Email: hangh@fmmu.edu.cn

Background and Aims: There lacks comprehensive data of step-wise strategy for Budd-Chiari syndrome (BCS) in typical Asian countries, despite a higher prevalence and greater demand for in-depth studies in this region. We conducted this nationwide study to investigate the possibly different roles of angioplasty and transjugular intrahepatic portosystemic shunt (TIPS) in the whole picture of step-wise strategy as well as their efficacy and safety profiles.
Method: A total of 1366 consecutive BCS patients admitted to six Chinese tertiary hospitals and received management conforming to step-wise principle from July 1998 to May 2019 were included. The last follow-up ended on July 15th, 2019.
Results: Median follow-up was 64 (36–100) months. The 10-year OLT-free survival was 79.1% (76.2–82.0%); TIPS-OLT-free survival 72.1% (69.2–75.2%); stenting-TIPS-OLT free survival 45.8% (42.6–49.2%); and the intervention-free survival 6.0% (4.5–7.9%, Fig. A). All patients received medical treatment and 169 (12.4%) had no further procedures. A total of 1137 (83.2%) patients received angioplasty (435 [38.3%] with initial stenting and 702 [61.7%] without). Although 10-year survival did not differ (80.0% [75.5–84.7%] vs. 83.3 [79.3–87.5%], log-rank $p = 0.653$), initial stenting reduced 10-year restenosis (23.1% [17.8–28.1%] vs. 34.4% [28.8–39.5%], log-rank $p < 0.001$, Fig. B) and symptom recurrence rate (21.7% [16.6–26.5%] vs. 30.0% [24.2–35.4%], log-rank $p = 0.015$, Fig. C). Stent-related complications occurred in 11 (2.5%), with an event-free survival in all but one patient who died of intracranial bleeding. TIPS was performed in 126 (9.2%) patients (57 initial TIPS, and 69 converted TIPS), with 22 (17.5%) bare TIPS and 104 (82.5%) covered TIPS. Covered TIPS significantly lowered shunt dysfunction rate (51.1% [37.3–61.8%] vs. 70.4% [40.4–85.3%] at 5 years, log-rank $p = 0.038$, Fig. D), but did not improve recurrence rate (76.8% [62.7–85.5%] vs. 79.4% [46.4–92.1%] at 5 years, log-rank $p = 0.647$, Fig. E) or survival (64.8% [51.2–81.9%] vs. 57.7% [39.9–83.3%] at 10 years, log-rank $p = 0.621$). Only 1 (0.1%) patient with progressive liver failure received transplantation and died 27 days later due to multiple organ failure.
Conclusion: The current study corroborated that step-wise strategy can achieve remarkable long-term outcome in typical Chinese BCS patients, yet the predominant application of angioplasty with or without stenting contributed over 80% survival benefits while TIPS contributed 10%, constituting an inverted proportion of European reports. Moreover, the patency and efficacy of angioplasty could be boosted with initial stenting with adequate safety, whereas TIPS is less liberally used and can be eventful with high dysfunction and symptom recurrence rates even with covered stents, thus the optimal indication and candidates of early-TIPS still require cautious investigation.

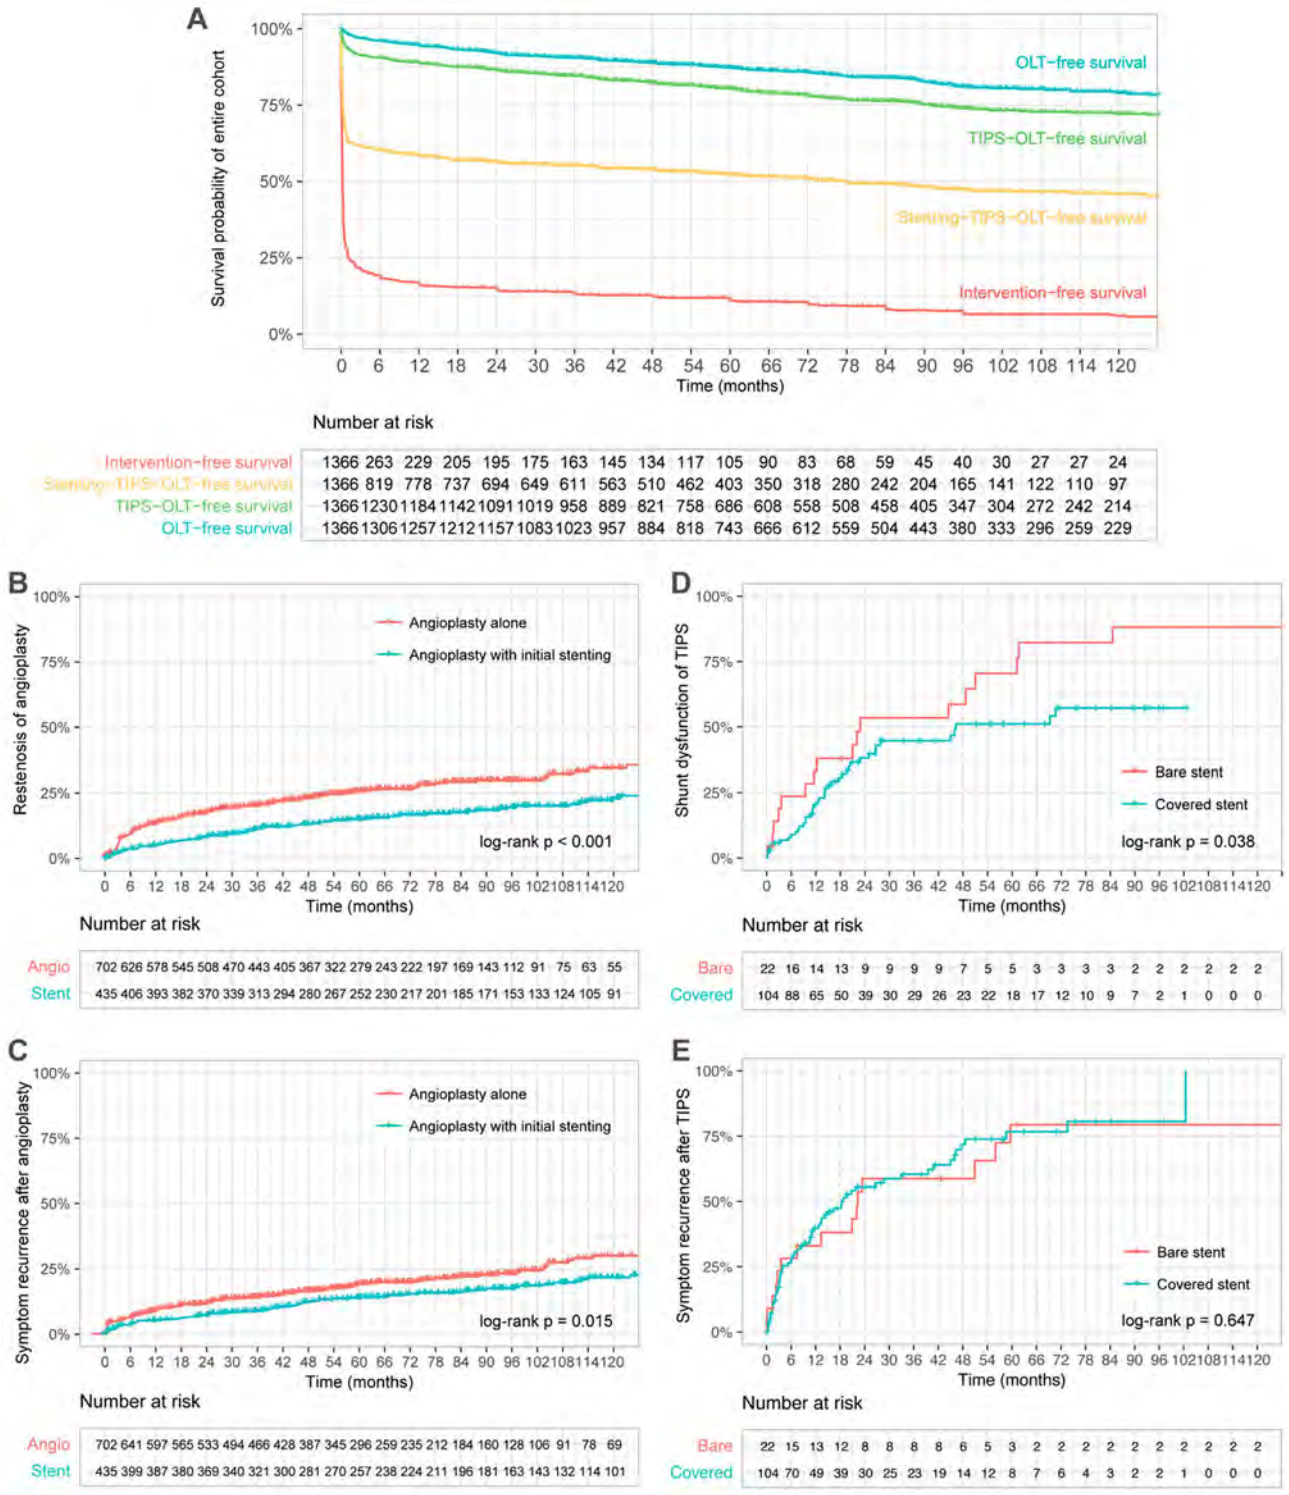

Figure: (abstract: AS089)

AS090

Liver disease in common variable immunodeficiency (CVID) is characterised by a high frequency of portal hypertension and significant burden of inflammatory liver pathology

Niall Burke[1,2], Neil Halliday[1,2,3], Fernando Moreira[3,4], Ronnie Chee[3,4], Siobhan Burns[3,4], David M. Lowe[3,4], Douglas Thorburn[1,2]. *[1]Royal Free Hospital, The Sheila Sherlock Liver Centre, United Kingdom; [2]University College London, Institute for Liver and Digestive Health, London; [3]University College London, Institute of Immunity and Transplantation, London, United Kingdom; [4]Royal Free Hospital, Department of Immunology, London, United Kingdom*
Email: neilhalliday@doctors.org.uk

Background and Aims: CVID is characterised by impaired B-cell function and hypogammaglobinaemia. There is heterogeneity in organ involvement which may manifest as granulomatous, infective,

autoimmune or malignant processes. Here we describe the frequency, severity and natural history of liver disease, which are relatively unexplored, in the largest cohort of patients with CVID reported to date.

Method: Patients with CVID were identified from the Royal Free Hospital Immunology database. Liver involvement was defined as: i) persistently elevated liver enzymes ii) imaging features of chronic liver disease, or iii) splenomegaly or thrombocytopaenia with features of portal hypertension (PHTN).

Results: 220 patients with CVID were identified, of which 76 (34.5%) had liver involvement. The median age of patients with liver involvement was 53.5 (IQR 43.5–64) and 59% were female, compared to 53 (IQR 40.8–67) years and 53% female for those without. Elevated liver enzymes, either progressively worsening or intermittently elevated, were observed in 72/76 (95%) patients.

10 (13%) patients with liver disease had radiological features of PHTN and 12 /20 (60%) patients who underwent OGD had varices. Hepatic venous pressure gradients (HVPG) were measured in 20 patients, 14 (70%) had portal hypertension (≥ 5 mmHg) and 5 (25%) had significant portal hypertension (≥ 10 mmHg). 35 patients underwent liver biopsy; 12 (35%) had features of nodular regenerative hyperplasia (NRH), 7 (20%) had granulomata and 8 (23%) had moderate to severe inflammatory activity.

9 (12%) patients with liver disease had histologically proven cirrhosis, of which 6 had end-stage liver disease (ascites or variceal bleeding). The median age of those with cirrhosis was 50 and the number of years between diagnoses of CVID and cirrhosis was 11 (IQR 8–12).

Crude mortality rates were higher amongst CVID patients with liver involvement than those without (19.1% vs 13.1%). 2 deaths occurred due to decompensated liver disease and one patient underwent liver transplantation.

Conclusion: In this study of the largest CVID cohort to date, we have demonstrated that liver involvement is a frequent occurrence and is associated with a high frequency of PHTN. Histologically, NRH and granulomatous disease are common and, notably, moderate-severe inflammatory infiltrates are common, hence evaluation of any role for immunosuppression in CVID-related liver disease is needed. Patients with CVID and liver involvement have a poor prognosis and liver disease should be actively sought out and patients offered comprehensive assessment and dedicated follow up.

HBV – Clinical

Email: pietro.lampertico@unimi.it

Background and Aims: We have previously demonstrated at Week 48 that switching to TAF vs continued TDF treatment in CHB patients who were virally suppressed on long-term TDF has shown noninferior efficacy of TAF to TDF with superior bone and renal safety. Here we report the final, efficacy and safety results from this study at Week 96.

Method: In this Phase 3 study (NCT02979613), CHB patients taking TDF for ≥48 weeks with HBV DNA <LLOQ (local lab) for ≥12 weeks and <20 IU/mL at screening were randomized (1:1) to TAF 25 mg QD or TDF 300 mg QD, each with matching placebo, and treated for 48 weeks in a double-blind (DB) fashion. At Week 48, all patients received open-label (OL) TAF 25 mg once daily for an additional 48 weeks. Safety assessments including changes in bone (hip and spine BMD) and renal (CrCl by Cockcroft-Gault [$eGFR_{CG}$], serum creatinine) parameters; viral suppression, and serological and biochemical responses were also assessed in all patients.

Table. Efficacy and Safety at Week 96 in CHB Patients Treated with TAF for 2 Years vs TDF Treatment for 1 Year Followed by 1 Year of TAF

N (%) or n/N (%)	TAF-TAF (N=243)	TDF-TAF (N=245)	P value
Efficacy parameters[a]			
HBV DNA <20 IU/mL	230 (95)	230 (94)	
Difference in proportions (95% CI)	0.9% (-3.5% to 5.2%)		0.686
ALT normalization[b]	29/52 (56)	39/53 (74)	0.051
HBeAg loss / seroconversion[c]	14/78 (18) / 4/78 (5)	7/78 (9) / 2/78 (3)	0.101 / 0.415
HBsAg loss / seroconversion	4 (2) / 2 (1)	6 (2) / 1 (0.4)	0.537 / 0.585
Safety parameters			
Hip BMD, mean (SD) % change (g/cm²)	1.16 (2.85)	0.18 (2.68)	<0.001
Spine BMD, mean (SD) % change (g/cm²)	2.33 (3.93)	1.73 (3.82)	0.097
CTX, median (Q1, Q3) % change (ng/mL)[d]	-25 (-38.2, -5.1)	-24.1 (-42.2, -6.9)	0.635
P1NP, median (Q1, Q3) % change (ng/mL)[e]	-17.9 (-30.7, -3.2)	-21.4 (-37.7, -6.8)	0.017
$eGFR_{CG}$, median (Q1, Q3) change (mL/min)	+0.51 (-5.98, 5.32)	-0.39 (-6.76, 6.28)	0.871
RBP/Cr, median (Q1, Q3) % change[f]	-19.7 (-41.7, 23.2)	-13.4 (-41.5, 29.4)	0.304
β2MG/Cr, median (Q1, Q3) % change[g]	-32.6 (-67.1, -7.2)	-37.5 (-68.4, 4.3)	0.935

[a]All efficacy results are missing=failure. TAF-TAF and TDF-TAF are DB TAF to OL TAF and DB TDF to OL TAF, respectively. [b]AASLD ULN 33 U/L males, 25 U/L females; [c]Patients who were HBeAg-positive at baseline; [d]C-type collagen sequence (bone resorption marker); [e]Procollagen type 1 N-terminal propeptide (bone formation marker); [f]Retinol binding protein/creatinine (tubular marker); [g]Beta-2 microglobulin/creatinine (tubular marker)

Results: Of 488 (TAF 243, TDF 245) patients randomized and treated, 472 (97%; TAF 235, TDF 237) completed 48 weeks of DB treatment, and 465 (95%; TAF 233, TDF 232) completed study treatment through Week 96. At baseline, patient characteristics were similar between groups and have been previously reported. Key efficacy/safety results are summarized in the Table. Virologic suppression (HBV DNA <20 IU/mL) was similarly maintained at Wk96 in patients switched to TAF treatment at BL vs those switched to TAF after 48 weeks of DB TDF treatment; rates of ALT normalization were increased in both groups at Wk 96. In patients switched to TAF at BL vs those switched at Wk48, similar increases in spine BMD were seen while increases in hip BMD were smaller. In the TDF group, $eGFR_{CG}$ decreased at Wk48 (−2.7 mL/

min); an improvement was seen after switching to TAF at Wk96 (–0.39 mL/min).
Conclusion: In CHB patients on long-term TDF treatment, viral suppression was maintained, ALT normalization increased, and bone and renal safety parameters were improved at Wk 96.

AS092
Immune checkpoint inhibitors and hepatitis B viral kinetics – a territory-wide cohort study

Grace Lai-Hung Wong[1,2], Terry Cheuk-Fung Yip[1,2], Vincent Wai-Sun Wong[1,2], Yee-Kit Tse[1,2], Henry Chan[1,2], Stephen L. Chan[3]. *[1]The Chinese University of Hong Kong, Medicine and Therapeutics, Hong Kong, Hong Kong; [2]The Chinese University of Hong Kong, Institute of Digestive Disease, Hong Kong; [3]The Chinese University of Hong Kong, Clinical Oncology, Hong Kong, Hong Kong*
Email: wonglaihung@cuhk.edu.hk

Background and Aims: Immunotherapy using immune checkpoint inhibitors (ICI) have dramatically improved the survival of patients with advanced or metastatic malignancies. Recent studies suggest that the new programmed death receptor 1 (PD-1) and programmed cell death ligand 1 (PD-L1) inhibitors have potential in the treatment of patients with chronic HBV infection. We evaluated the kinetics of hepatitis B virus (HBV) in patients with chronic hepatitis B or past HBV infection.
Method: This was a territory-wide retrospective observational cohort study in Hong Kong. We identified patients through the Clinical Data Analysis and Reporting System (CDARS) based on the drug record of immune checkpoint inhibitors from 1 January 2014 to 31 October 2018. Patients who were hepatitis B surface antigen (HBsAg)-positive or HBsAg-negative but antibody to hepatitis B core antigen (anti-HBc) positive were included.

No. of subjects	HBsAg positive N = 237	HBsAg negative, anti-HBc positive N = 158
Male gender (n, %)	200 (84.4)	110 (69.6)

Alanine aminotransferase, alkaline phosphatase, aspartate aminotransferase, and alpha-fetoprotein were expressed in median (interquartile range), whereas other continuous variables were expressed in mean ± standard deviation.

Figure: Hepatitis B reactivation after immunotherapy.

Results: 395 patients (237 HBsAg-positive and 158 HBsAg-negative/antiHBc-positive) were identified (male 84% and 70%; mean age 58 and 63 years; mean HBV DNA 1.9 and 0.06 log10 IU/mL respectively). 97% of HBsAg-positive and 28% HBsAg-negative/antiHBc-positive patients were put on oral antiviral treatment. Hepatitis flare (ALT >2× ULN) occurred in 31% of HBsAg-positive and 22% HBsAg-negative/antiHBc-positive patients; severe hepatitis flare (ALT >5× ULN) 13% and 12% respectively. HBV DNA increased to >2,000 IU/mL or >1 log10 IU/mL in 2 and 6 HBsAg-positive subjects respectively; whereas none of the HBsAg-negative/antiHBc-positive subjects had such HBV reactivation. No HBsAg-positive patients cleared HBsAg and no HBsAg-negative/antiHBc-positive patients had HBsAg seroreversion during follow-up period.
Conclusion: HBV reactivation is rare in patients received immunotherapy in patients with chronic hepatitis B or past HBV infection. None of our patients achieved HBsAg seroclearance after immunotherapy.

AS093
Characterization of serologic responses following ALT flares in >3000 CHB patients pooled from 5 clinical trials

Maurizia Brunetto[1], Wan-Long Chuang[2], Patrick Marcellin[3], Thomas Berg[4], Hongyuan Wang[5], Vithika Suri[5], Lanjia Lin[5], John F. Flaherty[5], Anuj Gaggar[5], Edward Gane[6], Maria Buti[7], Kosh Agarwal[8]. *[1]Hepatology Unit, University Hospital of Pisa, Pisa, Italy; [2]Hepatobiliary Division, Department of Internal Medicine, Kaohsiung Medical University Hospital; [3]Department of Hepatology, AP-HP Hôpital Beaujon, Clichy, France; [4]Department of Gastroenterology and Rheumatology, Section of Hepatology, University Hospital Leipzig; [5]Gilead Sciences Inc., Foster City, CA, USA; [6]Auckland Clinical Studies, Auckland, New Zealand; [7]Hospital General Universitario Valle Hebron and Ciberehd, Barcelona; [8]Institute of Liver Studies, King's College Hospital*
Email: brunettomaurizia@gmail.com

Background and Aims: ALT flares in patients treated for Chronic Hepatitis B (CHB) infection have been associated with improvements in viral parameters. The timing, frequency, severity and consequences of these elevations in ALT have not been completely characterized. Here, we pool data from 5 Phase 3 studies evaluating tenofovir-based regimens to determine the associations of ALT flares with different treatment outcomes.
Method: Clinical data from 5 studies (GS-US-174-102, GS-US-174-103, GS-US-174-0149, GS-US-320-0108, and GS-US-320-0110) were evaluated for the presence of ALT flares on treatment, defined as ALT >5× ULN and >2× Baseline (Low Flares) or ALT >10× ULN and >2× Baseline (High Flares). Endpoints of HBsAg loss, HBeAg loss, and HBsAg decline of >=1log_{10} were evaluated at 12, 24, or 48 weeks after the flare.
Results: The overall population was 3013 patients of whom 70% were Asian and 67% were male. Overall, 58% were HBeAg positive at baseline and 8%, 22%, 41%, and 27% had Genotype A, B, C, and D infection, respectively. Of these subjects, Low Flares were observed in 297 (9.9%) subjects with High Flares observed in 141 (4.7%) patients; the median week (Q1,Q3) to ALT flare was 8 (4, 59) for low flare and 14 (4,61) for high flare. In the overall population, HBeAg and HBsAg loss was observed in 634 and 93 subjects, respectively, during the treatment phase. The rates of serologic outcomes following these flares are shown in the table. Briefly, the presence of low and high flares were associated with increased rates of serologic outcomes that increased with longer duration follow-up. Rates of serologic outcomes were observed more often in patients having higher flares, though the higher flares identified overall fewer cases of patients achieving the clinical endpoints. Interestingly, the majority of patients with HBeAg loss and HBsAg loss did not have a measured ALT flare in the preceding 48 weeks of treatment.

Timepoint Post Flare	Outcome, n/N (%)	Low Flare	High Flare
Week 12	HBsAg loss	7/297 (2.4%)	4/141 (2.8%)
	HBsAg decline >=1 log_{10}	78/278 (28%)	52/131 (40%)
	HBeAg loss	25/206 (12%)	13/99 (13%)
Week 24	HBsAg loss	12/297 (4.0%)	6/141 (4.3%)
	HBsAg decline >=1 log_{10}	95/289 (33%)	59/135 (44%)
	HBeAg loss	38/206 (18%)	20/99 (20%)
Week 48	HBsAg loss	21/297 (7.1%)	13/141 (9.2%)
	HBsAg decline >=1 log_{10}	114/293 (39%)	65/137 (47%)
	HBeAg loss	63/206 (31%)	37/99 (37%)

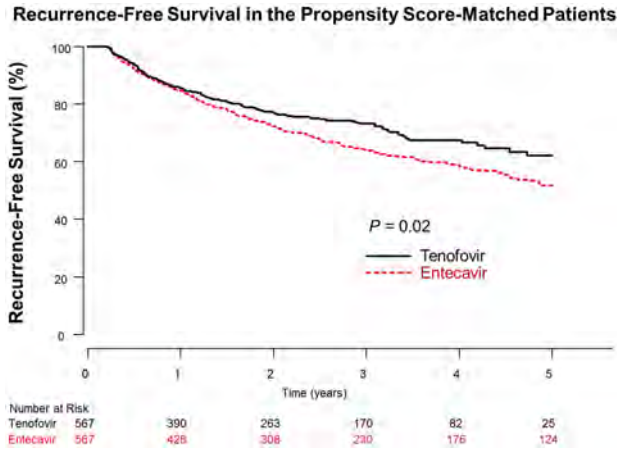
Conclusion: Serologic outcomes of HBeAg loss and HBsAg decline and loss occurred following on-treatment ALT flares. These data demonstrate that the majority of patients achieved clinical endpoints 24 weeks after the ALT flare, though additional follow-up may identify more patients achieving these endpoints. These data inform current strategies for achieving important clinical outcomes for CHB patients, and suggest that some patients can achieve HBsAg/HBeAg loss without ALT flares.

AS094

Tenofovir vs entecavir on post-operative recurrence-free and overall survival of patients with hepatitis B virus-related hepatocellular carcinoma

Jonggi Choi[1], Chanyoung Jo[2], Young-Suk Lim[1]. *[1]Asan Medical Center, University of Ulsan College of Medicine, Department of Gastroenterology, Seoul, Korea, Rep. of South; [2]Asan Medical Center, University of Ulsan College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: jkchoi0803@gmail.com

Background and Aims: Studies have suggested that tenofovir disoproxil fumarate (TDF) treatment was associated with a significantly lower risk of hepatocellular carcinoma (HCC) occurrence compared to entecavir therapy in chronic hepatitis B patients. We aimed to compare tenofovir and entecavir on the recurrence-free and overall survival of patients after curative hepatectomy for hepatitis B virus (HBV)-related HCC.
Method: This historical cohort study included 1,695 consecutive patients who were treated with entecavir (n = 813) or TDF (n = 882) after curative hepatectomy for HBV-related HCC of BCLC stage 0 or A in Korea between 2010 and 2018. Recurrence-free and overall survival were compared between entecavir and tenofovir groups by propensity score (PS)-matched and multivariable-adjusted Cox regression analyses.



Results: Of the study patients, mean age was 54.8 years and 1,294 patients (76.3%) were male. Median duration of follow-up was 37.6 months. Compared with entecavir, tenofovir therapy was associated with a significantly lower rate of HCC recurrence by PS-matched analysis of 567 pairs of patients (P = 0.02) and multivariable-adjusted analysis of the entire patients (hazard ratio [HR], 0.82; 95% CI, 0.68–0.98; P = 0.03; Figure). Overall mortality was also significantly lower in the tenofovir group compared with entecavir group by PS-matched analysis (P = 0.03) and multivariable analysis (HR, 0.62; 95% CI, 0.44–0.88; P = 0.01). Tenofovir therapy was an independent protective factor for both early (<2 years; HR, 0.79; 95% CI, 0.64–0.97; P = 0.03) and late (≥2 years; HR, 0.68; 95% CI, 0.47–0.97; P = 0.03) HCC recurrence.
Conclusion: Among patients who undergo curative hepatectomy for HBV-related HCC, tenofovir therapy was associated with significantly better recurrence-free and overall survival rate compared with entecavir therapy.

AS095

A prospective study of nucleot(s)ide analogue discontinuation in non-cirrhotic HBeAg-negative chronic hepatitis B patients: interim analysis at week 48 demonstrates profound reductions of HBsAg associated with ALT flare

Samuel Hall[1], Gareth Burns[1], Miriam Levy[2], John Lubel[3], Amanda Nicoll[3], Gail Matthews[4], Paul Desmond[1], William Sievert[5], Scott Bowden[6], Stephen Locarnini[6], Jacinta Holmes[1], Kumar Visvanathan[1], Alexander Thompson[1]. *[1]St. Vincent's Hospital Melbourne, Gastroenterology, Fitzroy, Australia; [2]Liverpool Hospital, Gastroenterology, Liverpool, Australia; [3]Eastern Health, Gastroenterology, Box Hill, Australia; [4]St Vincent's Hospital Sydney, Gastroenterology, Darlinghurst, Australia; [5]Monash Medical Centre, Gastroenterology, Clayton, Australia; [6]Victorian Infectious Diseases Reference Laboratory, Melbourne, Australia*
Email: sammy.hall86@gmail.com

Background and Aims: Current guidelines recommend indefinite Nucleot(s)ide Analogue (NA) therapy for patients with HBeAg-negative CHB. However, sustained virological response (SVR) has been described in patients after discontinuation of long-term NA therapy, as well as HBsAg loss. The HBV-STOP study is a prospective multi-centre study of NA discontinuation in patients who have achieved long-term virological suppression on treatment. The study describes clinical outcomes post-treatment discontinuation, with the aim of identifying determinants of SVR.
Method: An interim narrative analysis of outcomes at week 48 post-NA discontinuation was performed. The primary endpoint for the study is outcomes at week 96. Inclusion criteria for the study were HBeAg-negative, non-cirrhotic & virological suppression for ≥18 months on NA therapy uninterrupted for ≥2 years. Criteria for recommencing NA therapy were HBV DNA >2000 IU/mL with either ALT >5× ULN for ≥16 weeks or ALT >10× ULN for ≥8 weeks, INR ≥1.5, Bilirubin >2× ULN, ascites, hepatic encephalopathy and investigator discretion.
Results: The cohort is fully enrolled and data are currently available for 90/111 patients. At baseline, median age was 55 yrs, 58% were male, 83% were Asian. Median HBsAg level was 699 (250–1819) IU/mL. All patients were non-cirrhotic. Virological reactivation occurred in all, with median time to detection 8 (4–12) weeks. At week 48, four (4%) patients have experienced HBsAg loss, 42 (47%) had DNA <2,000 IU/mL, 13 (14%) had DNA >2,000 and ALT >2× ULN, and 10 (11%) had restarted treatment. Patients who achieved HBsAg loss had low baseline HBsAg levels (HBsAg loss: median baseline HBsAg level = 3.1 IU/ml in HBsAg loss vs. 776 IU/mL in patients with no HBsAg loss). The overall median reduction in HBsAg was 68 IU/mL at week 48. 21 (23%) have experienced an ALT flare >10× ULN. ALT flare was associated with reduction in HBsAg level. Median reduction of HBsAg level from the flare time-point to week 48 was 2800

(106–6090) IU/mL (vs 41.7 IU/mL in patients with peak ALT <10× ULN, p-value =<0.001).
Conclusion: In this interim analysis, stopping NA therapy was associated with virological relapse, but at week 48 only 11% had restarted NA therapy. ALT flare >10xULN was observed in 23% and was associated with profound reductions in HBsAg levels, suggesting that immunological flare may be important for achieving HBsAg loss. HBsAg loss itself was observed in a minority at week 48.

Email: adam.finn@bristol.ac.uk.

Background and aims: Hepatitis B Virus (HBV) infection remains a significant and rising global public health concern, one for which vaccination is a critical measure to prevent transmission. Sci-B-Vac® is a trivalent HepB vaccine (TV), containing S, pre-S1, and pre-S2 antigens, that has shown enhanced seroprotection rates (SPR) in adult populations when compared to monovalent vaccines (MV), such as Engerix-B®.
Method: In a double-blind 4-arm study (NCT03408730), the consistency of immune response elicited by vaccination with TV (at Days 0, 28, and 168) from 3 separate lots (A, B, C) was assessed, and the pooled immunogenicity of TV was compared to MV. Participants were randomized across 32 clinical study sites in USA, Europe, and Canada. The primary endpoint was manufacturing equivalence of 3 consecutive lots of TV, defined as the 95% confidence intervals (CI) of each pairwise comparison of the ratios of geometric mean concentration (GMC) of Hepatitis B antibodies (HBsAb) being between 0.67 and 1.5. The secondary objectives included (1) demonstration of non-inferiority of SPR, defined as % participants with anti-HBsAg titers ≥ 10 mIU/mL, of TV vs. MV and (2) safety and tolerability, including solicited adverse events (AEs) within 7 days and unsolicited AEs within 28-days after vaccination, serious AEs (SAEs), medically-attended events or new onset of chronic illness (NOCI) to end of study, at least 24 weeks after the third dose of vaccine.
Results: 2,838 participants, age 18-45 years, were randomized across 4 arms – MV (n=712), TV Lots A (n=711), B (n=709) and C (n=706). The primary objective of lot-to-lot manufacturing consistency was met, with each pairwise comparison falling within the pre-defined 95% CI intervals for the GMC ratios, A & B [0.67, 1.00], B & C [0.95, 1.41], A & C [0.78, 1.15]. Compared to MV, the pooled antibody GMC achieved with TV was >7.5x after 2 vaccinations and >3x after 3 vaccinations (Fig. A). The secondary objective — SPR of the pooled TV was non-inferior to MV and was also higher than MV after both two (90.4% vs. 51.5%) and three (99.3% vs. 94.8%) vaccinations (Fig. B). Slightly higher pain and tenderness rates were noted with TV. Unsolicited and medically-attended AEs were well-balanced; the number of SAEs (<2.5%) and NOCIs (≤1.6%) were low in both treatment arms.
Conclusion: TV met both the primary and secondary endpoints of the study. In this second pivotal Phase 3 study, TV continued to demonstrate its ability to safely and quickly elicit robust immune responses in adults.

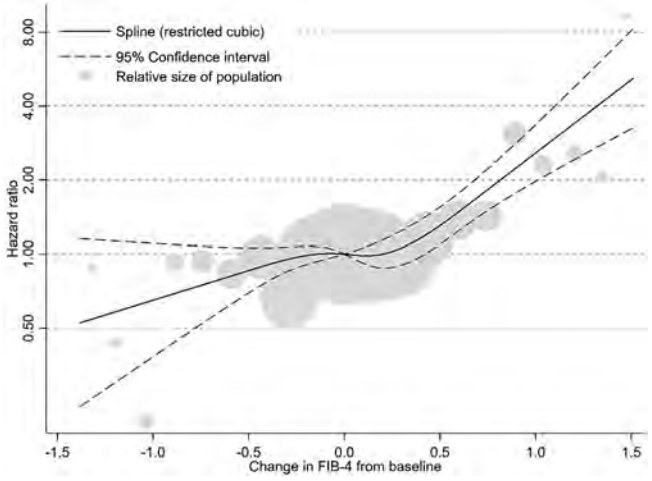
NAFLD – Non invasive assessment

AS096
Repeated measures of FIB-4 improve prediction of severe liver disease: population-based cohort study of 40,729 individuals

Hannes Hagström[1,2,3], Mats Talbäck[4], Anna Andreasson[5], Göran Walldius[4], Niklas Hammar[4]. *[1]Karolinska University Hospital, Unit of Hepatology, Department of Upper GI Diseases, Sweden; [2]Karolinska Institutet, Department of Clinical Epidemiology, Department of Medicine, Solna, Sweden; [3]Karolinska Institutet, Department of Medicine, Huddinge, Sweden; [4]Karolinska Institutet, Department of Epidemiology, Institute of Environmental Medicine, Stockholm, Sweden; [5]Stockholm University, Stress Research Institute, Stockholm, Sweden*
Email: hannes.hagstrom@ki.se

Background and Aims: Non-invasive scores to detect advanced liver fibrosis are commonly used and can to some extent also detect future liver-related events. There is limited data on if repeated

measurements can improve prediction, especially in a general population or primary care setting.
Method: We used data from the population-based AMORIS cohort in Stockholm, Sweden (N > 800,000 examined 1985–1996). Persons with liver diseases other than NAFLD were excluded. We calculated the commonly used FIB-4 index in those with available data at two separate times within five years, and associated changes in FIB-4 as well as transitions between low/intermediate/high-risk groups with outcomes. For those with multiple measurements, the first and last measurements were used. Incident severe liver disease was ascertained after the second measurement. This was a composite outcome that included diagnoses of cirrhosis, decompensated cirrhosis, hepatocellular carcinoma and death in liver disease, ascertained though linkage with national registers until the end of 2011. Cox regression models adjusted for age, sex, socio-economy and time between measurements were applied to obtain hazard ratios (HR).
Results: Of 126,942 persons with available FIB-4 data, 40,729 (32.1%) had a repeated measurement of FIB-4 within 5 years. Median FIB-4 increased from 0.91 (IQR 0.67–1.24) to 0.96 (IQR 0.69–1.29), or 0.02 per year. During >613,000 person-years of follow-up, there were 581 events of severe liver disease (1.4%). An increase of one unit in FIB-4 was associated with an increased risk of severe liver disease (aHR 1.81, 95%CI 1.67–1.96). Transitioning from low/intermediate risk groups to high risk groups were also associated with increased risk compared to those at consistent low risk (aHR 7.99 and 8.64 respectively). A particularly increased risk was found in persons defined as high-risk at both testing occasions (aHR 17.04, 95%CI 11.67–24.88). However, almost half of the 581 events occurred in persons that were in the low risk group at both testing occasions. A restricted cubic spline graph on the risk of severe liver disease by change in FIB-4 is presented in Fig. 1.



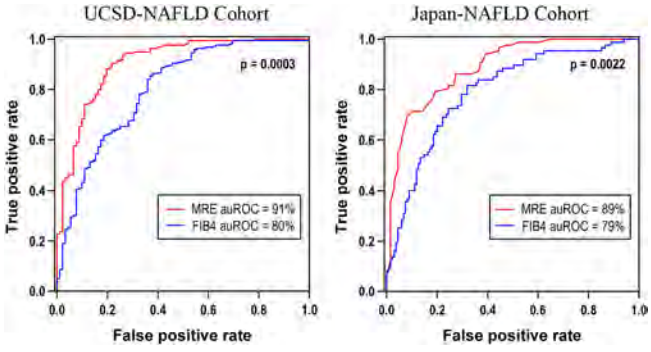
Conclusion: These results suggest that repeated testing of FIB-4 within five years improves prediction of incident cirrhosis or complications thereof, but that currently used risk assessment tools need to be improved.

AS097

Utility of magnetic resonance elastography in accurate identification of candidates for pharmacologic treatment of NASH related fibrosis: a prospective cohort study

Jinho Jung[1], Rohan Loomba[1], Kento Imajo[2], Egbert Madamba[1], Sanil Gandhi[1], Ricki Bettencourt[1], Seema Singh[1], Carolyn Hernandez[1], Mark Valasek[3], Cynthia Behling[4], Kathryn Fowler[5], Lisa Richards[1], Atsushi Nakajima[2], Claude Sirlin[5], Rohit Loomba[1,6]. [1]*University of California at San Diego, NAFLD Research Center, La Jolla, United States;* [2]*Yokohama University Graduate School of Medicine, Department of Gastroenterology, Yokohama, Japan;* [3]*University of California at San Diego, Department of Pathology, La Jolla, United States;* [4]*Sharp Medical Group, Department of Pathology, San Diego, United States;* [5]*University of California at San Diego, Liver Imaging Group, Department of Radiology, La Jolla, United States;* [6]*University of California at San Diego, Department of Medicine, Division of Gastroenterology, La Jolla, United States*
Email: roloomba@ucsd.edu

Background and Aims: Patients with non-alcoholic fatty liver disease (NAFLD) with stage 2 fibrosis or higher are at increased risk for liver related mortality and are candidates for pharmacologic therapies for treatment of NAFLD. However, there is paucity of data on utility of non-invasive biomarkers for identifying patients who are candidates for treatment in registrational trials without a liver biopsy. The aim of this prospective study was to examine the diagnostic accuracy of magnetic resonance elastography (MRE) in well-characterized patients with biopsy-proven NAFLD and then validate these findings in an external validation cohort.
Method: This is a *cross-sectional* analysis of a *prospective cohort* (UCSD-NAFLD) including 311 consecutive patients with biopsy-proven NAFLD and contemporaneous MRE. Patients underwent standardized research visit including history, physical examination, laboratory analysis, MRE, and liver biopsy using NASH-CRN-Histologic Scoring System. The radiologist and pathologist were blinded to clinical, pathological, and imaging data respectively. Receiver operating characteristics were determined to examine the diagnostic accuracy of MRE for diagnosis of ≥ stage 2 fibrosis in NAFLD. We then validated these findings in an independent validation cohort derived from Yokohama University in Japan (Japan-NAFLD) Cohort.
Results: The mean (±SD) age and BMI of the UCSD-NAFLD Cohort was 50.9 (±13.6) years and 31.6 (±5.9) kg/m^2, and the Japan-NAFLD Cohort was 55.5 (±15.1) years and 28.8 (±5.1) kg/m^2, respectively. In the UCSD-NAFLD (training) Cohort, MRE demonstrated a robust and clinically significant diagnostic accuracy for the detection of ≥ stage 2 fibrosis with an AUROC of 0.91 (95% CI: 0.87–0.94) versus FIB-4 alone with an AUROC of 0.80 (95% CI: 0.75–0.86), which was both clinically and statistically significant ($p < 0.0005$). The diagnostic accuracy of MRE remained statistically significant in the Japan-NAFLD (validation) Cohort with an AUROC of 0.89 (95% CI, 0.85–0.93, $p < 0.0001$). We then combined MRE with FIB-4 (MRE ≥ 3.2 kPa and FIB-4 ≥ 1.5) to develop a clinical prediction rule to rule in ≥ stage 2 fibrosis patients which had positive predictive value (PPV) of 89.5% in the UCSD-NAFLD Cohort [MRE ≥ 3.2 kPa adjusted OR: 22.88 (11.47–45.66), and FIB-4 ≥ 1.5 adjusted OR 4.7 (2.33–9.47); p-value <0.0015] and remained significant at 89.7% in the Japan-NAFLD Cohort (p-value <0.002).



Conclusion: MRE coupled with FIB-4 may be used for non-invasive identification of candidates for (≥ stage 2 fibrosis) pharmacologic therapy among patients with NAFLD.

AS098

Machine learning outperforms existing non-invasive tests as screening tool for liver fibrosis in the general population

Email: pgines@clinic.cat

Background: Risk stratification is key to reduce unnecessary testing in liver disease screening. While transient elastography (TE) could be considered the non-invasive gold standard for liver fibrosis diagnosis, evidence regarding which features or scoring systems help to discriminate at-risk patients in the general population is built upon heterogeneous and small studies. Therefore we aimed to evaluate which risk factors better predict elevated TE values by means of using supervised learning models.

Patients and Methods: Data from six prospective cohorts (5 Europe, 1 Hong Kong) from the general population who underwent screening for liver fibrosis with TE was included. In total, 32 variables, including demographics, biometrics, and analytical parameters, were used in training a diagonal discriminant analysis model. TE values above 9.1 kPa were considered positive cases for significant liver fibrosis (≥F2). A SMOTE sampling algorithm was used to balance positive/negative cases. Missing values were imputed by means of multiple imputation forests. Internal validation was accomplished via 5-fold cross-validation. Discriminatory accuracy, measured as area under the ROC curves, of the final model was compared to the one of univariate traditional risk factors.

Results: The analysis included 6,199 patients(mean age 54.7 yrs, sd 12.2, 52% women, mean LSM 5.6 kPa, sd 5) with 5,856 negative and 343 positive cases. The final machine learning (ML) model, with 32 variables, presented AUC of 0.88(95%CI: 0.87–0.9). Analyzing individual variables, we detected that AUC for abdominal perimeter was 0.71(0.68–0.74), AST 0.73(0.70–0.76), and albumin 0.68(0.64–0.71). The ML model had higher accuracy than FIB-4 score or NFS in our population [AUC 0.88(0.86–0.90) for ML, 0.68(0.65–0.71) for FIB-4, 0.71(0.68–0.74) for NFS]. If a different ML model was constructed using a cutoff value of TE of 14 kPa, suggestive of cirrhosis, the accuracy of the model was 0.95 (0.94–0.97), compared to 0.79(0.75–0.83) and 0.78(0.74–0.82) for FIB-4 and NFS, respectively.

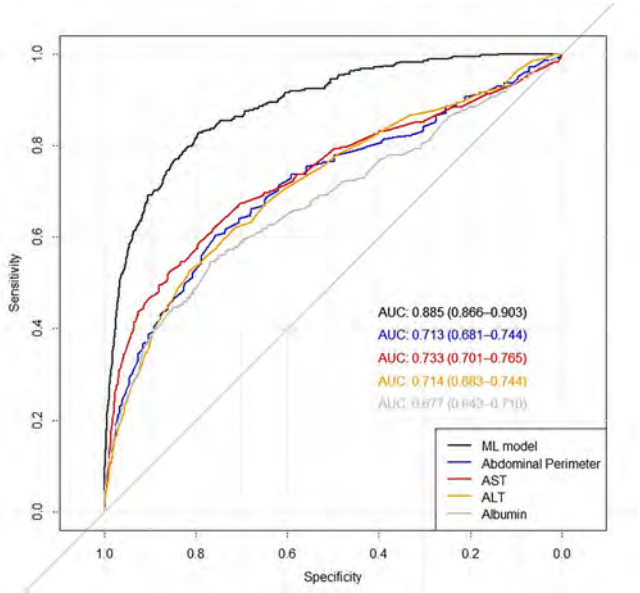

Figure: ROC curves of final ML model vs individual risk factors.

Conclusions: The ability to predict pre-test individual risk of liver fibrosis may prove useful as a mean of reducing unnecessary testing. Our results suggest that pre-test risk stratification is feasible and accurate with routine check-up data. Moreover, abdominal perimeter alone might have similar predictive value than common liver function serologic markers, highlighting its potential usefulness in settings with limited resources.

AS100

Progression of liver stiffness and the development of cirrhosis in histologically characterized patients with non-alcoholic fatty liver disease

Naga Chalasani[1], Mark Van Natta[2], Samer Gawrieh[1], Raj Vuppalanchi[1], Arun Sanyal[3], Rohit Loomba[4], James Tonascia[2]. *[1]Indiana University School of Medicine, Gastroenterology and Hepatology, Indianapolis, United States; [2]The Johns Hopkins University School of Public Health, Epidemiology, Baltimore, United States; [3]Virginia Commonwealth University, Gastroenterology, Hepatology and Nutrition, Richmond, United States; [4]University of California San Diego, Gastroenterology, La Jolla, United States*
Email: nchalasa@iu.edu

Background and Aims: Vibration Controlled Transient Elastography (VCTE) is widely used for assessing the presence and progression of liver stiffness (LS), a surrogate for liver fibrosis, in patients (pts) with nonalcoholic fatty liver disease (NAFLD). However, the natural history of LS in pts with NAFLD is not well understood. Our aims were to characterize 1) longitudinal changes in LS stratified per baseline histological fibrosis stage and 2) time to and factors associated with developing LS defined cirrhosis (LSM >14.9 kPa) in pts without cirrhosis on initial VCTE.

Method: VCTE was performed annually per protocol starting in 2014 in the NASH CRN Database 2 study, which enrolled and prospectively followed pts with biopsy-proven NAFLD from 2009 to 2019. Random effects models were used for estimation of change in LS over time and Kaplan-Meier with staggered entry methods for time-to-event statistics; stepwise Cox regression was used for risk factor analysis selecting from a candidate set of 22 clinical, anthropometrics, histological, and laboratory variables at first VCTE visit.

Results: We studied 1,010 individuals (mean age 51 years, 63% women, and 86% Caucasian), of whom 58% had definite NASH and 8% had cirrhosis on biopsy. The number of serial VCTEs performed were 2 in 289, 3 in 246, 4 in 272 and ≥ 5 in 203 pts. The LS increased significantly over time only in pts with baseline stage 3 liver fibrosis

(0.57 (95% CI: 0.22, 0.93) kPa/year, p = 0.001) but not in pts with other liver fibrosis stages (Table). In pts without cirrhosis by LS at first VCTE visit, the annual risk of developing cirrhosis by LS criteria was 6.8% and the 25th percentile time to developing LS defined cirrhosis was 4.4 years (95% CI: 1.3–6.0 years). Risk factors associated with progression to cirrhosis were: increasing waist circumference per cm (HR 1.01, 95% CI: 1.00–1.02), increasing platelet count per 1 K/mm^3 (HR: 0.995, 95% CI: 0.992–0.998), higher portal inflammation by each point (HR: 1.5, 95% CI: 1.0–2.2), higher fibrosis by one stage (HR: 1.7, 95% CI: 1.4–2.0), higher INR by 0.1 (HR 3.3, 95% CI: 1.0–10.6), lobular inflammation by each point (HR: 0.8, 95% CI: 0.6–1.0), and higher GGT per U/L (HR: 1.003, 95% CI: 1.000–1.006).

Baseline liver histological fibrosis	Number of pts	Total Number of VCTE	Median (IQR) Years of Follow-up	Annual change in LS (95% CI)	P-value
F0	254	850	2.6 (1.7, 3.4)	0.16 (−0.02, 0.33)	0.08
F1	253	855	2.6 (1.7, 3.3)	−0.01 (−0.18, 0.16)	0.93
F2	185	633	2.7 (1.9, 3.4)	0.14 (−0.12, 0.39)	0.30
F3	**231**	**801**	**2.8 (1.8, 3.4)**	**0.57 (0.22, 0.93)**	**0.001**
F4	85	277	2.5 (1.3, 3.2)	0.45 (−0.40, 1.31)	0.30

Conclusion: In a cohort of NAFLD pts enriched with NASH, the annual risk of cirrhosis by LS criteria was ~ 7%. LS significantly worsened only in those with stage 3 fibrosis on baseline liver biopsy. These observations might be useful in clinical practice and for designing early phase clinical trials with noninvasive endpoints.

AS101

Convolutional neural networks of H&E -stained biopsy images accurately quantify histologic features of non-alcoholic steatohepatitis

Francesco Paolo Casale[1], Michael D. Bereket[1], Rohit Loomba[2], Arun Sanyal[3], Stephen Harrison[4], Zobair M. Younossi[5], Catherine Jia[6], Marianne Camargo[6], Chuhan Chung[6], Mani Subramanian[6], Robert Myers[6], Eilon Sharon[1], Matthew Albert[1], Daphne Koller[1].

Background and Aims: Current staging systems for NASH have limited utility for quantitative analyses due to their low resolution and ordinal nature. To address these limitations, we trained convolutional neural networks (CNNs) to produce continuous scores for key NASH features from biopsy images and assessed the explanatory power of these models to predict NASH-related biomarkers as compared to pathologist-derived scores.
Method: We analyzed 4,641 whole-slide images of H&E-stained biopsies from five NASH clinical trials evaluating simtuzumab and selonsertib. All biopsies were evaluated by a central pathologist (CP) according to the NASH CRN and Ishak classifications. Based on CP readings, we trained end-to-end deep CNNs to predict scores for steatosis, lobular inflammation, ballooning, and fibrosis. These models extract histological features for multiple tiles (192 × 192 μM) of a single slide and integrate them to predict biopsy-level CP scores. The model incorporated an attention mechanism to weight the importance of tiles used for predictions, which permitted identification of informative tiles without explicit supervision. We used 90% of the slides for training and validation, and the remaining 10% to evaluate the agreement between the CNN-derived and CP scores (Spearman ρ; test slides from different patients and sites). The ability of the histological scores to predict 60 NASH-related serum markers was examined using linear regression models adjusted for age, sex, BMI, and treatment. Out-of-sample predictive performance was assessed using Spearman correlation between predicted and true values.
Results: In the test set, the CNN-derived scores were highly correlated with those of the CP for Ishak stage (ρ = 0.90), steatosis (ρ = 0.70), ballooning (ρ = 0.71), and lobular inflammation (ρ = 0.67; all $p < 10^{-50}$). Agreement did not differ in a sensitivity analysis based on the number of evaluated tiles. Despite the model being trained on biopsy-level scores, the attention mechanism weighted tiles with features that align with those used by a pathologist (Fig. A). Notably, the weighting of tiles for each histological score was different for steatosis, lobular inflammation, and fibrosis (Fig. B-C). Compared with CP-derived scores, the CNN-derived scores had improved prediction accuracy for most NASH biomarkers, with significant improvements for ELF, TIMP-1, PIII-NP, α_2-macroglobulin, insulin, HOMA-IR, and monocyte/leukocyte ratio (Δρ = 0.08–0.15; Bonferroni-adjusted p < 0.05).

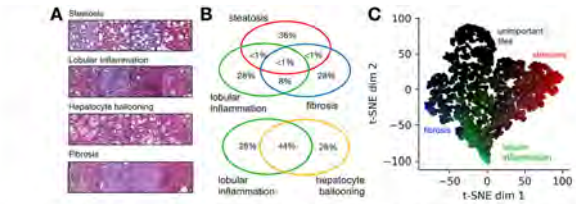

Figure | Results from the convolutional neural network (CNN) approach. (A) Example of tiles with high importance weights for steatosis, lobular inflammation, hepatocyte ballooning and fibrosis. **(B)** Venn diagrams showing the overlap among the sets of the top 10% of the tiles for each score. We observed a high overlap for lobular inflammation and hepatocyte ballooning. **(C)** t-SNE map of tile-level histological features extracted from our model for 10,000 randomly selected tiles. Tiles with high importance weights for steatosis, lobular inflammation and fibrosis are colored in red, green and blue, respectively. Hepatocyte ballooning has been omitted given the overlap with lobular inflammation.

Conclusion: CNNs trained on whole slide liver biopsy images can be utilized to extract continuous scores that recapitulate the key histologic features of NASH. These scores show improved correlations with multiple biomarkers of NASH severity, and represent a novel strategy for quantitative histological analysis and association studies with other data types.

AS102

Serum levels of miR-34a to rule-out NAFLD in healthy subjects and identify NAFLD patients with active NASH (NAS>= 4) and significant liver fibrosis (F >= 2)

Stephen Harrison[1], Quentin Anstee[2], Vlad Ratziu[3], Pierre Bedossa[4], Genevieve Cordonnier[5], Zouher Majd[5], Alice Roudot[5], Fouad Ben Sudrick[5], Noémie Dam[5], John Brozek[5], Pascal Birman[5], Pierre Chaumat[5], Bart Staels[6,7,8,9], Dean Hum[10], Suneil Hosmane[10], Remy Hanf[5], Arun Sanyal[11]. *[1]Pinnacle Clinical Research Center, San Antonio, United States; [2]Institute of Cellular Medicine, Newcastle University, Newcastle, United Kingdom; [3]Hopital Pitié-Salpêtrière, Paris, France; [4]Liverpat, Paris, France; [5]GENFIT SA, Loos, France; [6]Inserm U1011, Lille, France; [7]Institut Pasteur de Lille, Lille, France; [8]CHU Lille, Lille, France; [9]Egid Université Lille, Lille, France; [10]GENFIT CORP, Cambridge, United States; [11]Virginia Commonwealth University, Richmond, United States*
Email: sharrison@pinnacleresearch.com

Background and Aims: MiR-34a has been proposed as a biomarker for NASH. The aim was three fold: i) to assess the potential of circulating levels miR-34a to eliminate healthy subjects from those with liver disease, ii) to cross-validate diagnostic performance of miR-34a in independent cohorts to be able to identify patients with NASH (NAS ≥ 4) and fibrosis (F ≥ 2) (i.e. NAS ≥ 4+F ≥ 2), who are at higher risk of liver-related outcomes, and iii) to compare miR-34a with other blood-based biomarkers and scores.
Method: MiR-34a was measured by RT-qPCR in serum samples from 100 blood donors considered as healthy subjects and from 1,214 patients with a liver biopsy because of suspicion of NAFLD. Patient data was derived from 4 independent cohorts: GOLDEN-505 (N = 264), RESOLVE-IT (N = 484), Angers (N = 228) and Antwerp (N = 238). Liver biopsies, NAFLD activity score (NAS) and fibrosis stage were evaluated using NASH-CRN scoring systems and were centrally read

by expert pathologists. Diagnostic performance of miR-34a and other blood tests were assessed by AUROC and comparative statistics were done by De Long test.
Results: Blood donors had 4-fold lower levels of miR-34a as compared to patients with NAFLD (Cq = 33.95 ± 0.56 vs 31.97 ± 1.15, p < 0.0001). Among patients with NAFLD, miR-34a levels in NAFL were 2-fold lower than in patients with NASH (Cq = 32.79 ± 1.01 vs 31.84 ± 1.11, p < 0.0001). Thus, miR-34a is a robust biomarker to discriminate healthy subjects from patients with NAFLD (AUC = 0.94), NAFL (AUC = 0.85) or NASH (AUC = 0.96). In all patients, levels of miR-34 increased with NAS and fibrosis stage (p < 0.0001). MiR-34a showed similar performance to identify patients with NAS ≥ 4+F ≥ 2: AUCs were 0.73 in GOLDEN, 0.79 in RESOLVE-IT, 0.77 in Angers, 0.79 in Antwerp. In the meta-cohort (N = 1,214), miR-34a levels were higher in patients with NAS ≥ 4+F ≥ 2 vs NAS<4/F < 2 (Cq = 31.38 ± 1.02 vs 32.55 ± 1.02, p < 0.0001) with an AUC = 0.80. In head-to-head comparisons, miR-34a outperformed all other single biomarkers for NASH and fibrosis (ALT, AST, CK18-M30 and M65, A2M, TIMP1 or hyaluronic acid) and composite scores FIB4, NFS or ELF.
Conclusion: MiR-34a is a reliable biomarker that can efficiently rule-out NAFLD in healthy subjects. In patients with suspicion of NAFLD, miR-34a can be a significant contributor towards the identification of NAS ≥ 4+F ≥ 2 in patients with suspected disease. This study further supports the use of miR-34a-based candidate diagnostic test score NIS4 to screen populations with risk factors for NASH.

Email: marika.rudler@aphp.fr

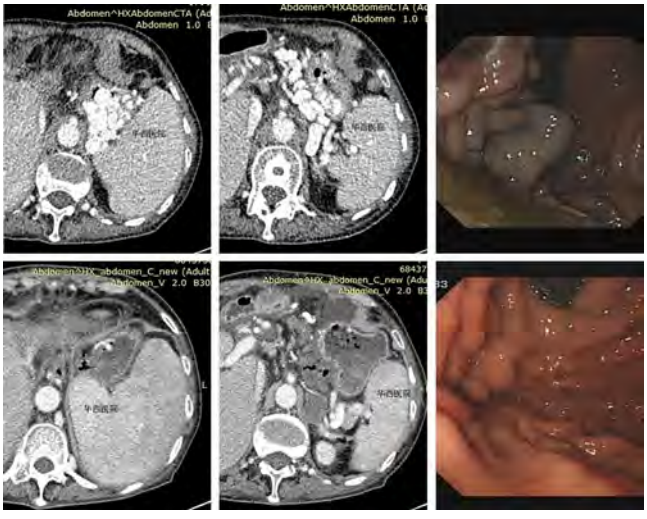
Background and Aims: Baveno VI recommendations state that early transjugular intrahepatic portosystemic shunt (TIPS) must be considered in high-risk cirrhotic patients (pts) with acute variceal bleeding (AVB), i.e pts with child-Pugh B cirrhosis and active bleeding or with Child-Pugh C10–13. Despite this, recent real-life studies point out that less than 10% of pts eligible for early-TIPS effectively undergo TIPS, mainly because of the fear of hepatic encephalopathy (HE) development after TIPS, especially in pts presenting HE at admission. The aims of this study were: (1) to assess the prevalence of HE at admission in pts with AVB; (2) to evaluate the outcome of pts presenting HE at admission after early-TIPS placement; (3) to determine if HE at admission was an independent factor of death and further development of HE.
Method: Multicenter, international, real-life observational study including 2138 pts from 34 centers between April 2013 and April 2015. Pts were managed according to current guidelines. Placement of TIPS in high-risk pts was based on individual centre policy. Exclusion criteria were: age>75, pregnancy, hepatocellular carcinoma outside the Milan criteria, a creatinine level>265 μmol/L, a Child–Pugh score>13, active sepsis, heart failure and total portal-vein thrombosis; pts were followed up to 1 year, death, or liver transplantation.
Results: 1521 pts met inclusion criteria and were analysed (age 56 ± 11 yrs, male gender 75%, Child-Pugh A/B/C = 49/29/22%, MELD score 21 ± 7). Among them, 671 were considered at high-risk, 66 received early-TIPS and 605 endoscopic +drug treatment. At admission, HE was significantly more frequent in high-risk than in low-risk pts (38.1% vs 10.6%, p = 0.008). In high-risk pts with HE at admission, early-TIPS placement was associated with a significantly better survival than endoscopic + drug treatment (HR 0.453 [0.218–0.940], p = 0.03), even in the subgroup of Child-Pugh C pts (HR 0.419 [0.203–0.868], p = 0.02). In pts without HE at admission, the occurrence of HE during follow-up was not different between pts who underwent early-TIPS vs endoscopic + drug treatment (16.7% vs 17.6%, p = 0.86). Recurrent HE was less frequent in pts with HE at admission treated with early-TIPS than in those receiving endoscopic + drug treatment (16.7 vs 27.3%, p = 0.04). In multivariate analysis, age, the presence of shock, a MELD score>15, endoscopic + drug treatment and HE at admission were independent factors predicting death in high-risk pts.
Conclusion: HE at admission is independently associated with poor survival in high-risk pts with AVB. In the subgroup of high-risk pts with HE at admission, early-TIPS significantly improved survival, recovery of HE and decreased the occurrence of new HE episodes after AVB. There is no rationale for the fear of early TIPS in pts with AVB and HE at admission.

AS104

Endoscopic cyanoacrylate injection versus balloon-occluded retrograde transvenous obliteration as secondary prophylaxis of gastric variceal bleeding: a prospective randomized controlled trial

Xuefeng Luo[1], Xiaoze Wang[1], Jinlin Yang[1], Li Yang[1]. [1]*West China Hospital, Gastroenterology and Hepatology, China*
Email: luo_xuefeng@yeah.net

Background and Aims: It is generally considered that gastric varices (GVs) bleed less frequently than esophageal varices (EVs); however, rupture of GVs are associated with more severe hemorrhage and higher mortality. The evidence to support recommendations for the management of GVs rebleeding is much less robust than that for EVs. The optimal treatment of GVs has not fully been determined. The current study aimed to compare the efficacy and safety of endoscopically cyanoacrylate injection and balloon-occluded retrograde transvenous obliteration (BRTO) in the prevention of rebleeding in patients with GVs after primary hemostasis.
Method: Between June 2015 and Feb 2018, 64 patients with previous GOV2 or IGV1 bleeding were randomly assigned either cyanoacrylate injection (n = 32) or BRTO (n = 32). Primary outcomes were gastric variceal rebleeding and all-cause bleeding.
Results: The mean follow-up time was 27.1 ± 12 months in the cyanoacrylate injection group and 27.6 ± 14.3 months in the BRTO group. The technical success rate was 96.9% in the BRTO group. The amount of polidocanol was 12.5 ± 4.5 ml. Complete obliteration rate of GVs was higher in the BRTO group (96.9% vs. 81.3%). 11 patients in the cyanoacrylate injection group and 2 patients in the BRTO group rebled. The most common bleeding source was GVs or glue injection-related ulcer. The 1-year and 2-year cumulative probability of remaining free of GV rebleeding and all-cause rebleeding was significantly higher in the BRTO group than in the cyanoacrylate group. The cumulative survival rates at 1 and 2 years for cyanoacrylate injection versus BRTO were 90.6% versus 93.8% and 87% versus 86.2%, respectively. There was no difference in aggravation of EVs. The mean number of hospitalizations, days in hospital and overall charges of hospitalization were also higher in the cyanoacrylate injection group.



Conclusion: The results of our study clearly show that BRTO is remarkably more effective than cyanoacrylate injection in the prevention of rebleeding from GVs, with similar frequencies of complications and mortalities. Therefore, BRTO could be recommended as the first choice for secondary prevention in patients with fundal GVs when technically applicable.

Email: ablasi@clinic.cat

Background and Aims: Prophylactic administration of platelets and fresh frozen plasma (FFP) is commonly recommended in patients with cirrhosis with low platelets and/or prolonged INR without scientific evidence to support this practice. In this analysis we evaluated the use of prophylactic administration of blood products in outpatients with cirrhosis undergoing endoscopic band ligation (EBL).
Methods: This is a multicenter retrospective analysis of consecutive EBL procedures in patients with cirrhosis at 4 hospitals in Spain (Hospital Clinic, Barcelona Hospital Universitari Mutua de Terrassa, Consorci Sanitari de Terrassa and Corporació Sanitària Parc Taulí) from 01/2010-01/2017. FFP and/or platelet transfusion were administered at the discretion of the physician if INR was >1.5 and/or platelet count $<50 \times 10^9$/L. Patient demographics, endoscopic findings, bleeding events after EBL, and the use of prophylactic FPP or platelets were recorded.
Results: 536 patients underwent 1472 EBL procedures: (72% male), the main etiology was HCV and alcohol (72%), median MELD 11, Child A/B/C (59/33/8%). EBL procedures were performed for primary (51%) or secondary (49%) prophylaxis. Median procedure per patient was 2 (1–4). The prophylactic transfusion protocol was followed in 12.5% and 32.4% of procedures with high INR and/or low platelets respectively. FPP and/or platelets were administered in 37 patients (6.9%). Post EBL-bleeding occurred in 26 patients out of 1472 procedures (1.7%). Bleeding was due to post-EBL ulcers in 21 patients and due to band dislodgment in 5. In six patients, bleeding occurred within 24 hrs and in the remaining it occurred within 2 weeks after EBL. In those that bled, 7 met criteria for transfusion (2 for FFP and 5 for platelets); of these only 1 received FPP and 3 platelet transfusion; the remaining 19 patients did not meet criteria for transfusion. There was no association between INR or platelet count and bleeding events. Patients that bled had higher Child and MELD scores compared to those that did not bleed (p = 0.03 and p = 0.02, respectively).
Conclusion: The incidence of post EBL bleeding is <2% and is associated with advanced liver disease. There was no relationship between post-EBL bleeding and the baseline INR/platelet count before the procedure. In addition, the majority of outpatients with post-EBL bleeding did not meet criteria for the standard prophylactic transfusion policy.

AS106

Anticoagulation and transjungular intrahepatic portosystemic shunt for the management of portal vein thrombosis in cirrhosis: a prospective observational study

Yong Lv[1], Kai Li[1], Zhengyu Wang[1], Chuangye He[1], Wei Bai[1], Wengang Guo[1], Tainlei Yu[1], Xulong Yuan[1], Jianhong Wang[2], Qiuhe Wang[1], Hui Chen[1], Enxin Wang[1], Dongdong Xia[1], Bohan Luo[1], Xiaomei Li[1], Jie Yuan[1], Na Han[1], Ying Zhu[1], Jing Niu[1], Zhanxin Yin[1], Daiming Fan[3], Guohong Han[1]. *[1]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Liver Diseases and Digestive Interventional Radiology, Xi'an, China; [2]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Ultrasound, Xi'an, China; [3]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, State Key Laboratory of Cancer Biology, Xi'an, China*
Email: hangh@fmmu.edu.cn

Background and Aims: Limited data are available on the management algorithm for portal vein thrombosis (PVT) in cirrhosis. The study aimed to prospectively evaluate anticoagulation and transjugular intrahepatic portosystemic shunt (TIPS) to treat PVT.
Method: Between February 2014 and June 2018, 396 consecutive cirrhotic patients with non-malignant PVT were prospectively included in a tertiary-care center. Covered TIPS with (before 2017.05) or without (after 2017.05) post-TIPS anticoagulation was indicated in those with symptomatic portal hypertension (variceal bleeding in the past 6 weeks or refractory ascites). Anticoagulation along were indicated in those without symptomatic portal hypertension but with PVT >50% of the lumen or extended to superior mesenteric vein (SMV). Patients without symptomatic portal hypertension and PVT<50% and no SMV extension were not anticoagulated nor received TIPS. Primary endpoint was portal vein recanalization.
Results: Per the management algorithm, TIPS, anticoagulation, and un-treatment were indicated in patients 324 patients, 54 patients and 18 patients, respectively. TIPS was successfully placed in 285 of 324 patients (88.0%), of which 197 patients was anticoagulated after TIPS while 88 patients was not anticoagulated. Among the 39 patients who failed TIPS, 9 patients received anticoagulation and 30 patients were not treated. Finally, 197 patients (49.8%) received TIPS plus post-TIPS anticoagulation (TIPS+AC group), 88 patients (29.7%) received TIPS alone (TIPS group), 63 patients (17.4%) received anticoagulation

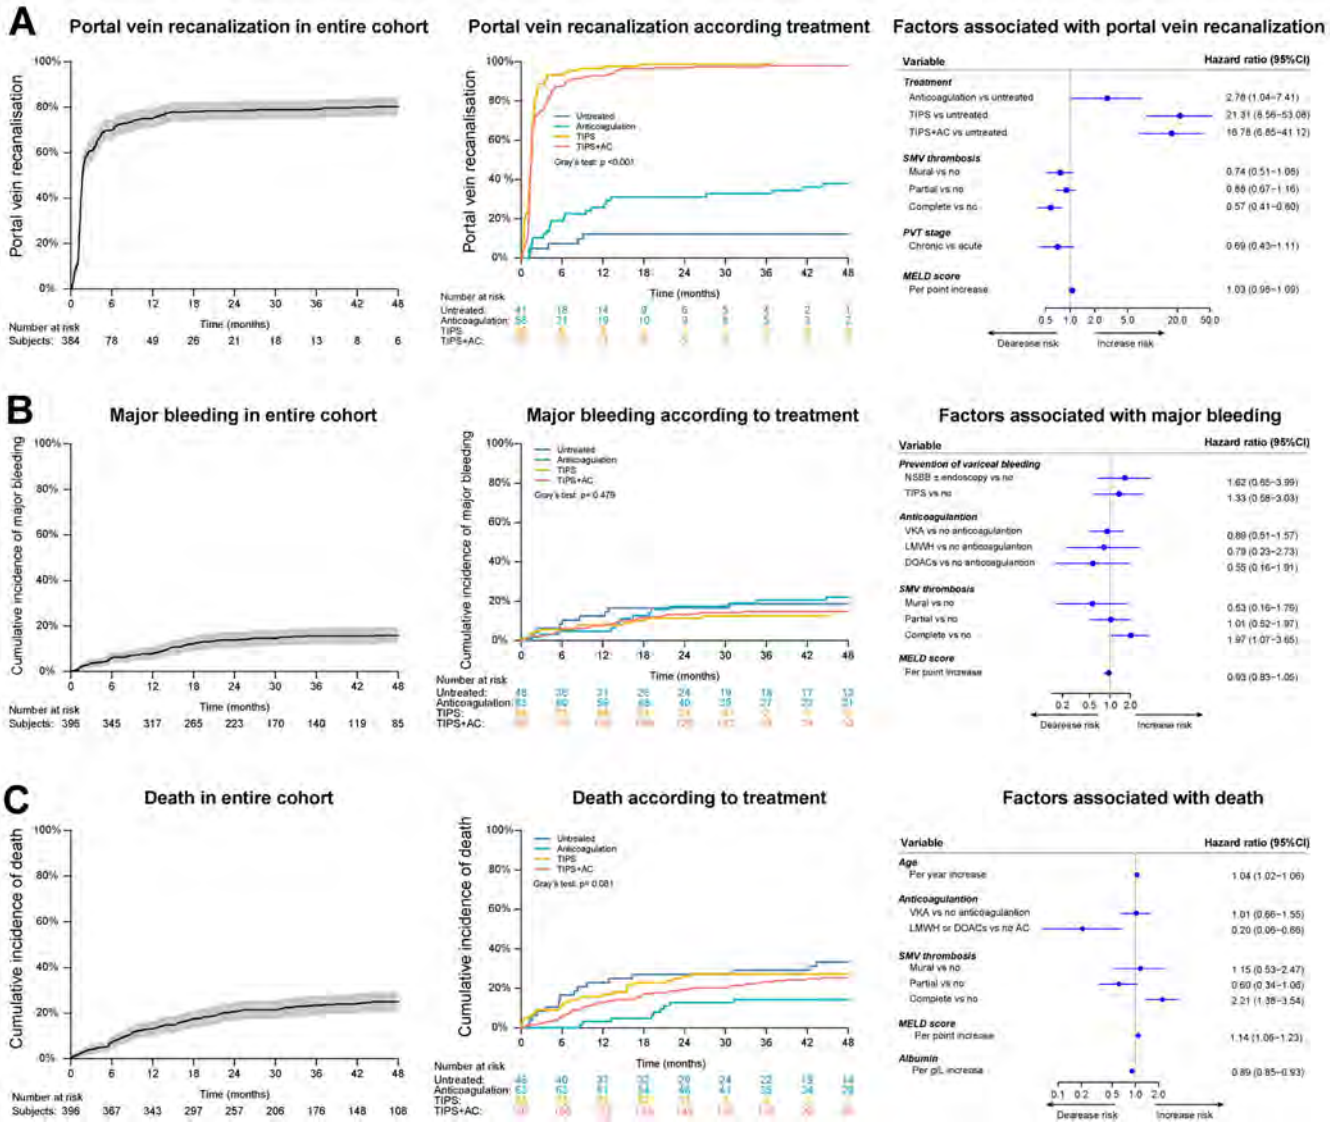

Figure: (abstract: AS106)

alone (anticoagulation group) and 48 patients (12.1%) were not treated (untreated group). Follow-up imaging studies were not available in 12 patients. In the remaining 384 patients, recanalization (partial or complete) was observed in 312 (81.3%) patients. TIPS creation and anticoagulation was associated with a higher probability of portal vein recanalization, while complete SMV thrombosis is inversely associated with recanalization (Figure A). During a median 31.7 months (IQR 18.1to 49.5) of follow-up, major bleeding (defined in accordance with the International Society of Thrombosis and Haemostasis criteria) occurred in 64 patients (16.2%, 57 variceal bleeding, 7 non-gastrointestinal bleeding) and did not differ among groups. In multivariate analysis, complete SMV thrombosis but not anticoagulation was associated with increased risk of major bleeding (Figure B). Overall, 100 patients (25.3%) died. Anticoagulation with LMWH or DOACs but not VKAs was associated improved survival while complete SMV thrombosis was associated with higher risk of death (Figure C).

Conclusion: In cirrhotic patients with PVT, a treatment algorithm using anticoagulation and TIPS achieves a high probability of portal vein recanalization, reduces portal hypertensive complications and decreases the risk of death.

AS107

Assessment of Baveno VI and expanded Baveno VI criteria for screening and follow-up of all-size esophageal varices in patients with compensated viral cirrhosis (ANRS/CO12 CirVir cohort)

Charlotte Bouzbib[1], Pierre Nahon[2,3], Layese Richard[4], Tarik Asselah[5], Dominique Guyader[6], Stanislas Pol[7], Etienne Audureau[4], Françoise Roudot-Thoraval[4], Dominique Thabut[1,8]. *[1]Groupe Hospitalier Pitié-Salpêtrière – Charles Foix, Hepatology Department, Paris, France;[2]Hôpitaux Universitaires Paris Seine Saint-Denis, Site Jean Verdier, Hepatology Department, Bondy, France; [3]Université Paris 13, Sorbonne Paris Cité, Bobigny, France; [4]Hôpital Henri Mondor, Public Health Department, Clinical Research Unit, Créteil, France; [5]Hôpital Beaujon, Hepatology Department, INSERM UMR 1149, Clichy, France; [6]CHU de Rennes - Hôpital Pontchaillou, Hepatology Department, Rennes, France; [7]Hôpital Cochin, Hepatology Department, Paris, France; [8]Sorbonne Université, UPMC Université Paris 06, AP-HP, Hôpital Pitié-Salpêtrière, Paris, France*
Email: charlotte.bouzbib@gmail.com

Background and Aims: In compensated cirrhosis, endoscopy can be avoided for screening of esophageal varices (EV) when Baveno VI (BVI) criteria are favorable (platelet ≥ 150 G/L and liver stiffness measurement (LSM) ≤20 kPa). Expanded Baveno VI criteria (eBVI) (favorable when platelet ≥ 110 G/L and LSM ≤25 kPa) were suggested to avoid more endoscopies. BVI criteria were previously validated for screening and follow-up of large EV in viral cirrhosis, but eBVI criteria were never validated in this indication. Moreover, a recent trial showed that beta-blockers improved prognosis in patients with viral cirrhosis and small EV. The aims of this study were: (1) to validate eBVI criteria for screening and follow-up of large EV in patients with compensated viral cirrhosis; (2) to study BVI and eBVI criteria for screening of small EV.

Method: Patients were prospectively followed-up in 35 french centers from 2006 to 2012 (CirVir cohort). Inclusion criteria: HCV/HBV infection, compensated biopsy-proven cirrhosis, endoscopy, platelet count and LSM available and interpretable. Progression of portal hypertension (PHT) was defined as the onset of EV, an increase of variceal size or PHT-related bleeding.

Results: We included 768 patients (male 69%, HCV 82%, no viral suppression 78%): 221 (25%) and 354 patients (46%) of whom had favorable BVI and eBVI criteria respectively. Among them, all-size EV were present in 16 (7%) and 42 (12%) patients and large EV in 3 (1%) and 7 (2%) patients respectively. eBVI criteria were favorable in 112/172 patients (65%) with viral suppression at baseline: 11 (10%) had small EV and none had large EV. During follow-up (median 82.3 months), endoscopy was performed in 511 patients. Progression of PHT was observed in 173 patients (34%) and was significantly associated with unfavorable eBVI criteria at baseline, no viral suppression and GGT. Overall, 21/313 patients (7%) with viral suppression during follow-up had PHT progression, which was associated in multivariate analysis with unfavorable eBVI criteria and GGT. eBVI criteria were unfavorable at the time of progression in only 60% of patients with viral suppression.

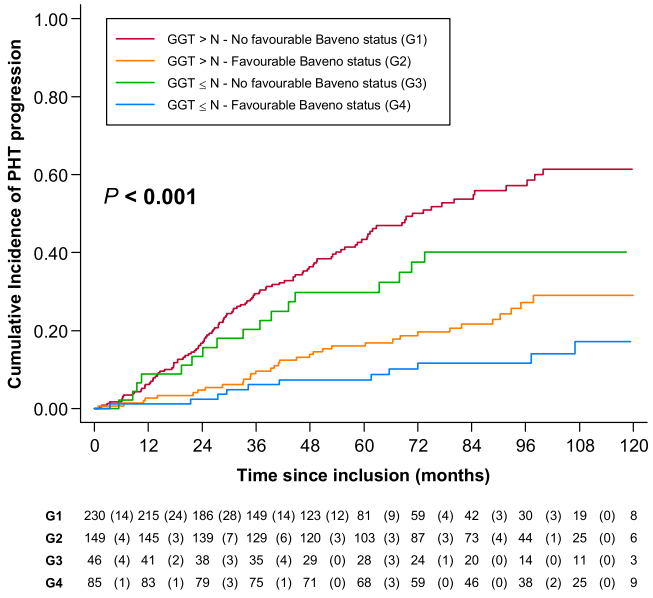

Figure: Progression of PHT was associated with unfavorable eBVI criteria and GGT.

Conclusion: eBVI criteria are sensitive enough to rule out large EV, even after viral suppression, but aren't sensitive enough to select a subgroup of patients not at risk of PHT progression. BVI and eBVI criteria aren't sensitive enough to predict small EV.

Results of the PROFIT trial, a PROspective randomised placebo-controlled feasibility trial of Faecal mIcrobiota Transplantation in advanced cirrhosis

Charlotte Woodhouse[1], Lindsey Edwards[1], Benjamin H. Mullish[2], Victoria Kronsten[1], Thomas Tranah[1], Ane Zamalloa[1], Clare Flach[3], Abdel Douiri[3], Julian Marchesi[2], Vishal Patel[1], Simon Goldenberg[4], Debbie L. Shawcross[1]. *[1]King's College Hospital, Institute of Liver Studies, London, United Kingdom; [2]Division of Digestive Diseases, Department of Metabolism, Digestion and Reproduction, Faculty of Medicine, Imperial College London, United Kingdom; [3]King's College London, School of Population Health & Environmental Sciences, Faculty of Life Sciences & Medicine, United Kingdom; [4]Centre for Clinical Infection and Diagnostics Research, Department of Infectious Diseases, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom*
Email: charlotteawoodhouse@gmail.com.

Background and aims: Patients with cirrhosis exhibit dysbiotic gut microbiota, with an over-representation of pathobionts such as *Enterobacteriaceae* e.g. *E. coli*. Dysbiosis worsens with increasing severity of disease and correlates with endotoxaemia. Patients with cirrhosis are predisposed to small intestinal bacterial overgrowth and disrupted gut permeability, allowing translocation of bacteria directly into the circulation, driving systemic inflammation and disease progression. Faecal microbiota transplantation (FMT) is extremely effective in the treatment of recurrent *C. difficile* infection, with cure rates >90%. As such, interest in FMT to treat conditions linked to gut dysbiosis has grown exponentially. This is the first FMT trial undertaken in patients with advanced cirrhosis in Europe [NCT02862249].

Method: 32 patients with confirmed cirrhosis (MELD score of 10–16) consented to participate. 23 were randomised to FMT or placebo (3:1) with 21 treated (free from antibiotics for at least 14-days). After screening, patients were randomised to FMT or placebo (0.9% saline and 12.5% glycerol, without faecal material). Single donor FMT (200 ml) was prepared from six donors in a MHRA-licensed facility and administered *via* a nasojejunal tube inserted at gastroscopy (after bowel preparation with Moviprep®). Donors were rigorously screened for pathogens and samples stored for analysis in case of transmissible infection. Patients were reviewed at day 7, 30 and 90 and samples of blood, stool, urine and saliva were obtained for plasma/stool ammonia, metagenomic and metabolomic analyses.

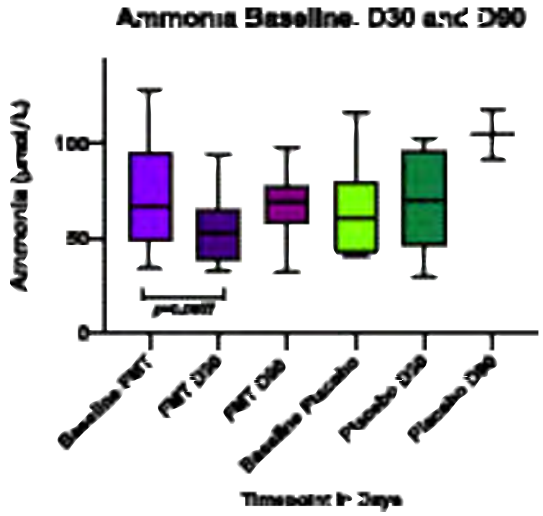

Figure: Plasma ammonia.

Results: 15 patients received FMT and 6 placebo. 76.2% of patients were male; mean age 57.8 years. The majority (52%) had alcohol-related cirrhosis (abstinent for >6-weeks). There were 10 serious adverse events (SAEs) during the follow-up period, 9 in the FMT group. None were treatment-related. There was a significant reduction in plasma ammonia between baseline and day 30 ($p = 0.0007$) and day 7 and day 30 ($p = 0.0448$), with a trend to an increase in ammonia in the placebo group. Stool ammonia levels increased in the placebo group, but not the FMT group. There were no statistically significant differences in MELD, leucocyte count and CRP.
Conclusion: FMT is safe and feasible in patients with advanced stable cirrhosis. FMT treated patients showed a striking reduction in plasma ammonia. This supports the recently published US pilot study of FMT in patients with hepatic encephalopathy.

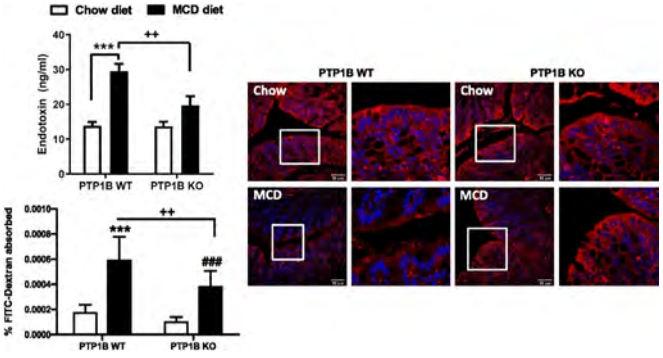
Background and Aims: Protein tyrosine phosphatase 1B (PTP1B) has been largely studied for its role as a negative regulator of the insulin receptor as well as other tyrosine kinase receptors related to inflammatory cascades. Therefore, PTP1B plays different roles in non-immune and immune cells, in the latter inhibiting pro-inflammatory signaling. Non-alcoholic steatohepatitis (NASH) is associated with a strong pro-inflammatory response at both hepatic and systemic level also concurring with a specific gut microbiome signature. In this work we aimed to decipher the role of PTP1B in the gut-to- liver axis in a preclinical model of NASH induced by methionine/choline-deficient (MCD) diet.
Method: Gut features and gut barrier dynamics were determined in wild-type and global PTP1B-deficient mice fed a chow or a MCD diet during 4 weeks. The effect of a pro-inflammatory environment was studied in enteroendocrine and intestinal epithelial cells. Glucagon-like peptide (GLP)-1 secretion was analyzed in primary colonic cultures and plasma from mice.



Results: We found a shift in gut microbiota shape, increased serum bile acid levels, disruption of gut barrier function and reduced GLP1 circulating levels in mice with NASH. Unexpectedly, despite the pro-inflammatory phenotype of global PTP1B-deficient mice, they presented a better gut barrier integrity. The preservation of gut barrier function in PTP1B-deficient mice is displayed in Figure 1 where better integrity of the tight junction protein ZO-1, minor permeability to FITC-dextran and lower levels of systemic endotoxemia are shown. Furthermore, these effects concurred with a protection against the drop of GLP-1 circulating levels during NASH in PTP1B-deficient mice compared to their wild-type counterparts together with increased expression in GLP-2-sensitive genes in the gut. Moreover, PTP1B inhibition in STC-1 enteroendocrine cells provoke an exacerbated pro-inflammatory signaling when these cells were challenged with a pro-inflammatory conditioned medium (CM) collected from lipopolysaccharide (LPS)-stimulated macrophages. Likewise, the pro-inflammatory CM induced GLP-1 secretion in primary colonic cultures, an effect augmented by PTP1B inhibition.
Conclusion: Altogether our results have unraveled a potential role of PTP1B in the gut-to-liver axis during NASH, probably mediated by increased sensitivity to GLPs, with potential therapeutic value.

MCJ deficiency results in gut barrier dysfunction and macrophage-elicited inflammation following ethanol consumption, facilitating alcoholic endotoxemia

Naroa Goikoetxea-Usandizaga[1,2], Marc Clos[2,3,4], Leticia Abecia[5,6], David Fernández Ramos[2,7], Miguel Pascual Itoiz[5], Ainize Peña Cearra[5,8], Begoña Rodriguez Iruretagoyena[1,2], Maider Bizkarguenaga[2,7], Diego Barriales[5], Marina Serrano-Macia[1,2], Sofia Lachiondo-Ortega[1,2], Rubén Rodríguez Agudo[1,2], Maria Mercado-Gómez[1,2], Oscar Lorenzo[9], Mercedes Rincón[10], Juan Falcon-Perez[2,3,11,12], Marta Varela-Rey[1,2], Franz Martin-Bermudo[13,14], Juan Anguita[5,12], María Luz Martínez-Chantar[1,2]. *[1]CICbioGUNE, Liver Disease Laboratory, Derio, Spain; [2]CIBERehd; [3]CICbioGUNE, Exosomes Laboratory, Derio, Spain; [4]Biodonostia, Gastroenterology; [5]CICbioGUNE, Inflammation and Macrophage Plasticity Laboratory; [6]University of the Basque Country, Microbiology, Immunology and Parasitology; [7]CICbioGUNE, Liver Metabolism Laboratory; [8]University of the Basque Country, Science and Technology Faculty; [9]Fundación Jiménez Díaz, Nefrología e Hipertensión, Patología Vascular y Diabetes; [10]University of Colorado, Immunology and Microbiology Department; [11]CiCbioGUNE, Metabolomics Platform; [12]IKERBASQUE; [13]CABIMER, Islotes pancreaticos y celulas madre; [14]CIBERdem*
Email: naroago03@gmail.com

Background and Aims: Endotoxin-mediated hepatic damage plays an essential role in the pathogenesis of Alcoholic liver disease (ALD). Alcohol consumption leads to changes in the composition of the gut microbiome, the disruption of the gut barrier and increased intestinal permeability. Silencing of MCJ, an endogenous negative regulator of mitochondria complex I, and subsequent accelerated mitochondrial activity, has proved to prevent and rescue drug induced liver injury, and improve liver regeneration. This work aims to study the implication of MCJ in the pathogenesis of ALD, including the intestine, source of the alcoholic endotoxemia.

Method: 3-month-old wild-type (WT) and MCJ deficient ($MCJ^{-/-}$) mice were fed either with control liquid diet not supplemented or with added 5% ethanol for 10 days, followed by a single binge control or ethanol feeding, as in the NIAAA model. Hepatic and intestinal injury, gut permeability, junctional integrity and changes in gut microbiota were then assessed.

Results: Whole-body MCJ knockout proved to be detrimental in endotoxin-mediated hepatic damage. 85% of ethanol-fed WT mice survived compared to just 54% of ethanol-fed $MCJ^{-/-}$ mice. Although no differences were observed in both ethanol-fed WT and $MCJ^{-/-}$ livers, histological score was higher in the intestine of ethanol-fed $MCJ^{-/-}$ mice. Elevated expression of TNF and Il-1β were detected by qPCR, and IHC revealed higher levels of F4/80 in the gut of ethanol-fed $MCJ^{-/-}$ mice; suggesting that MCJ silencing causes an elevated infiltration of macrophages in the intestine, increasing the proinflammatory response. V3-V4 regions of 16S rDNA amplicon sequencing identified alterations of the gut microbiota in control-fed $MCJ^{-/-}$ mice, which are worsened after ethanol diet, indicating a dysbiosis event in ethanol-fed $MCJ^{-/-}$ mice. Lower abundance of Ruminococcaceae and higher levels of Bifidobacteriaceae were found in control-fed $MCJ^{-/-}$ mice. Higher levels of *Prevotella*, known to degrade mucin leading to gut barrier disruption, and lower abundance of Bifidobacteriaceae, Lactobacillaceae and Ruminococcaceae, which maintain mucosal barrier integrity, were identified in ethanol-fed $MCJ^{-/-}$ mice. Evaluation of intestinal permeability with FITC-labelled dextran showed higher levels in ethanol-fed $MCJ^{-/-}$ mice serum. Reduced expression of tight junction proteins detected by qPCR and IHC, confirms augmented intestinal permeability and decreased junctional integrity in ethanol-fed $MCJ^{-/-}$ mice; facilitating bacterial and microbial products translocation.

Conclusion: Enhanced mitochondrial activity, due to MCJ silencing, results in bacterial alterations, increased macrophage infiltration and augmented inflammatory response after ethanol consumption. These events induce the disruption of the gut barrier and elevated gut permeability, which facilitate alcohol endotoxemia and worsen ALD.

Effects of tips on gut microbiota and its relationship with postoperative hepatic encephalopathy

Menghao Li[1], Kai Li[1], Shihao Tang[1], Zhengyu Wang[1], Ying Zhu[1], Yong Lv[1], Qiuhe Wang[1], Xulong Yuan[1], Tainlei Yu[1], Wengang Guo[1], Jing Niu[1], Wei Bai[1], Chuangye He[1], Bohan Luo[1], Xiaomei Li[1], Jing Li[1], Shuai Guo[1], Enxin Wang[1], Dongdong Xia[1], Zhexuan Wang[1], Jie Yuan[1], Na Han[1], Zhanxin Yin[1], Guohong Han[1]. *[1]National Clinical Research Center for Digestive Diseases and Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Department of Liver Diseases and Digestive Interventional Radiology, Xi'an, China*
Email: hangh@fmmu.edu.cn

Background and Aims: Hepatic encephalopathy (HE) is a major complication after transjugular intrahepatic portosystemic shunt (TIPS) and has been related to gut microbiota. The purpose of this study was to observe the effect of TIPS on gut microbiota and the relationship between the effect and postoperative HE.

Method: From May 2017 to August 2019, 78 consecutive patients with cirrhosis who were treated with TIPS due to portal hypertension were prospectively enrolled in a tertiary-care center. 23 patients developed HE (HE+ group) and 55 did not (HE- group) within 1 month after TIPS. We collected the fecal samples in all patients 1–3 days before and 1 month (range 31–37 days) after TIPS, microbiomes were analysed by 16S ribosomal RNA gene sequencing. A longitudinal study was performed to compared the taxa of patients between post- and pre-TIPS in this two groups respectively and the change amplitude of bacterial taxa between the two groups (relative abundance post-/pre-TIPS).

Results: Alpha diversity increased (Shannon and Simpson index, both $p < 0.01$) and beta diversity changed significantly (Adonis, $p = 0.002$) in HE- group while those were no significant change in HE+ group. The difference of microbiota showed that in HE-, the autochthonous taxa such as Ruminococcaceae, Lachnospiraceae and Rikenellaceae or their subordinate bacterial genus increased significantly after TIPS, moreover some harmful taxa (OHE-enriched bacteria and potential pathogenic taxa showed by previous literatures) such as Leuconostocaceae and Enterococcaceae were significantly reduced (Figure A). Meanwhile Lachnospiraceae decreased while Leuconostocaceae increased though did not withstand multiple testing correction in HE+. It was noteworthy that the synergism among harmful bacteria was significantly reduced in HE- but the HE+ group was opposite that the synergistic effect among the harmful bacteria was enhanced and the antagonistic effect between the autochthonous and harmful taxa appeared after TIPS by correlation analysis and correlation coefficient comparison (Figure B). Furthermore, multiple stepwise regression analysis was performed for the change amplitude of taxa and clinical indicators. Results showed that the decreased amplitude of Leuconostocaceae, total bilirubin and increased amplitude of Lachnospiraceae were the protective factors for development of postoperative encephalopathy and the area under receiving operating characteristics curves (AUROC) of using them was 0.784 (Figure C).

Conclusion: The occurrence of postoperative encephalopathy is closely related to the change of gut microbiota after TIPS. Specifically, the status of gut microbiota was significantly improved in HE- while the dysbiosis status in HE+ group remained poor after TIPS. Gut microbiota can be used as a potential biomarker for prevention and treatment of postoperative HE.

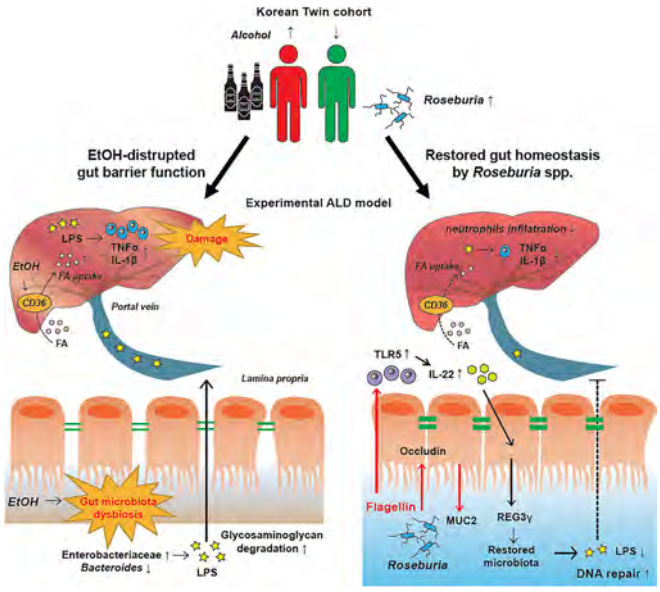
Roseburia spp. abundance associates with alcohol consumption in humans and its administration ameliorates alcoholic fatty liver in mice

GwangPyo Ko[1], Boram Seo[1], Won Kim[2]. [1]*Seoul National University, Department of Environmental Health Sciences, Seoul, Korea, Rep. of South;* [2]*Boramae Hospital, Seoul National University Hospital*
Email: gko@snu.ac.kr

Background and Aims: Although a link between the gut microbiota and alcohol-related liver diseases (ALDs) has previously been suggested, the causative effects of specific taxa and its functions have not been fully investigated to date.

Method: Here, we analyze the gut microbiota of 410 fecal samples from 212 Korean twins using the AUDIT (Alcohol Use Disorders Identification Test) scales to adjust for host genetics. Also, the causal effects of the administration of single gut commensal strains were investigated in the experimental ALD model.

Results: This analysis revealed strong association between low AUDIT scores and abundance of the butyrate-producing genus *Roseburia*. When *Roseburia* spp. are administered to ALD murine models, both hepatic steatosis and inflammation significantly improves regardless of bacterial viability. Specifically, the flagellin of *R. intestinalis*, possibly through TLR5 recognition, recovers gut barrier integrity through upregulation of the tight junction protein Occludin and helps to restore the gut microbiota through elevated expression of *IL-22* and *REG3γ*.



Conclusion: Our study demonstrates that *Roseburia* spp. improve the gut ecosystem and prevents leaky gut, leading to ameliorated ALDs.

Gut microbiota maintains FXR activation and protects from fatal liver damage in a murine model of primary sclerosing cholangitis

Kai Markus Schneider[1], Lena Candels[1], Antje Mohs[1], Carsten Elfers[1], Annika Wahlström[2], Lijun Liao[1,3], Eveline Bennek[1], Konrad Kilic[1], Ayham Zaza[4], Dirk Drasdo[5], Sebastian Zuehlke[6], Maiju Myllys[4], Mick Frissen[1], Galvez Eric[7], Till Strowig[7], Tom Hemming Karlsen[8], Johannes R. Hov[8], Jan G. Hengstler[4], Hanns-Ulrich Marshall[2], Ahmed Ghallab[4], Christian Trautwein[1]. *[1]University hospital RWTH Aachen, Department of Medicine III, Aachen, Germany; [2]Institute of Medicine, Department of Molecular and Clinical Medicine, Göteborg, Sweden; [3]Department of Anesthesiology and Pain Management, Tongji University, Shanghai, China; [4]TU Dortmund, Leibniz-Institut für Arbeitsforschung, Dortmund, Germany; [5]INRIA de Paris, Paris Cedex 12; [6]Technische Universität Dortmund, Analytische Chemie und Umweltchemie (INFU), Dortmund, Germany; [7]Helmholtz Centre for Infection Research HZI, Research Group Microbial Immune Regulation (MIKI), Braunschweig, Germany; [8]UiO Institute of Clinical Medicine, Oslo, Norway*
Email: ctrautwein@ukaachen.de

Background and Aims: Primary Sclerosing cholangitis (PSC) is a chronic cholestatic liver disease (CLD) leading to liver cirrhosis, malignant transformation and eventually hepatic failure. Gut microbiome deregulation and altered bile acid composition are prominent features of PSC. However, the functional role of gut microbiota and microbial bile acid metabolism in CLD needs to be defined. Here, we used *Mdr2*$^{-/-}$ mice as an appropriate PSC model to study the functional role of microbial bile acid metabolism for the development of CLD.

Methods: Comprehensive serum bile acid (BA) profiling was performed using UPLC-MS/MS. To characterize the functional role of microbial bile acid metabolism within the FXR-FGF15/19 axis, microbiota was modulated using broad-spectrum antibiotics (ABx). The pathophysiological consequences of this dynamic intervention was studied based on histology, flow cytometry, Matrix Assisted Laser Desorption imaging of spatial BA distribution, as well as intravital two-photon imaging of bile flux. The FXR axis was therapeutically targeted using the FXR-agonist GW4064.

Results: Microbiota depletion with ABx in adult *Mdr2*$^{-/-}$ mice prompted severe hepatic bile infarcts and devastating liver injury within 7 days. Microbiota depletion abrogated microbial bile acid metabolism, enzymatic conversion of primary conjugated bile acids into secondary bile acids resulting in the loss of FXR-mediated negative feedback suppression of Cyp7A1 and hepatic bile acid synthesis. This induced a sharp elevation of bile acid concentrations in interlobular bile ducts in a monomolecular form leading to cholangiocyte damage and bile leakage into the liver parenchyma. Therapeutic reconstitution of FXR signalling upon microbiota depletion by the FXR-agonist GW4064 completely rescued *Mdr2*$^{-/-}$ mice from this lethal phenotype.

Conclusion: This is the first report of a vital function of gut microbiota in a mammalian host. Our data define microbial bile acid metabolism as an essential compensatory modulator of CLD in a murine PSC model. This biologically intriguing and medically relevant finding opens up a new avenue for future microbiome-targeted interventions in human PSC.

AS114

Gut virome changes with disease progression in patients with cirrhosis and is inversely related to the bacterial metagenome

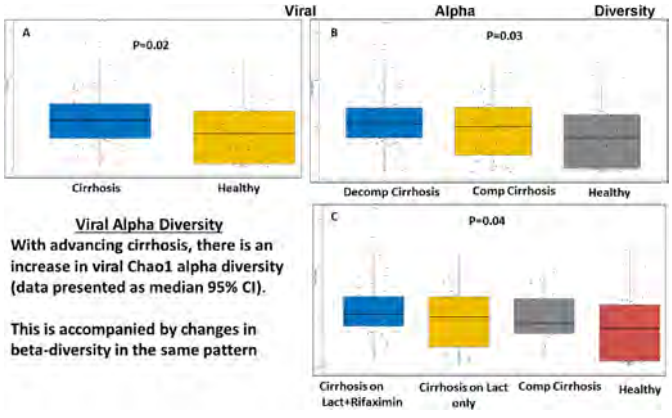
Jasmohan S. Bajaj[1], Ali Faruqi[2], Masoumeh Sikaroodi[3], Andrew Fagan[1], Edith Gavis[1], Dan Knights[2], Melanie White[1], Tonya Ward[2], Patrick Gillevet[3]. *[1]Virginia Commonwealth University and McGuire VAMC, United States; [2]Corebiome, United States; [3]George Mason University, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: Cirrhosis bacterial microbiome is linked with disease progression but the role of viromes is unclear. Aim: Define alterations in gut virome & association with bacterial microbiota as cirrhosis progresses.

Method: Healthy controls (Ctrl) & cirrhotic outpts [compensated, lactulose only (L), & on lactulose+rifaximin (L+R)] underwent stool collection for metagenomics for bacterial & viral DNA. Viral & bacterial diversity (α = within & β = between groups) & individual differentiating species were determined. Correlations between the viral and bacterial species were performed.

Results: 167 patients [40 ctrl, 42 compensated, 85 decompensated (29 on L & 56 L+R)]. MELD was lowest in compensated (median 7) vs others (L, 12, L+R, 12,p = 0.001).

Virome: α diversity: Cirrhotics had higher chao1 vs Ctrl (Fig A), decompensated ones had higher diversity than others (Fig B), & L+R had highest (Fig C). β diversity: was significant across groups(p = 0.04). MELD & viral diversity were not correlated(r = –0.1, p = 0.37). *Individual viruses*: 36 species were different, mostly Caudovirales phages & crAssphage (Cross-assembly phages; found in normal microbiota). Phages were highest against Lactobacillales, *Lactobacillus* (n = 14), *Streptococcus* (n = 1), *Enterococcus* (n = 1), then against *Enterobacteriaceae Escherichia* (n = 9), *Enterobacteria* (n = 3), *Klebseilla* (n = 2) & *Salmonella* (n = 1). Highest diversity & abundance of phages against Enterobacteriacee & Lactobacillaceae was in L+R group while crAssphages was the reverse.



Bacterial metagenome: α diversity: chao1 was lower in cirrhosis vs ctrl, decompensated vs others and lowest L+R & highest in controls (p = 7.1e −0.5). β diversity: was also different in the same pattern (p = 0.001). A weak negative correlation between MELD & chao1 was found (r = −0.22, p = 0.01). Individual species: 347 taxa, across 102 different genera were different between groups. 10 topmost ones were 3 *Lactobacillus, 2 Veillonella & 1 Enterobacteriaceae,* which were higher while *2 Lachnospira, 1 Ruminococcus, & 1 Alistipes* were lower in advanced pts.
Correlations: 10,117 significant bacterial & viral abundance correlations were found. Positive linkages were between phages & bacterial targets (Enterobacteria, Escherichia, Lactobacillus). Negatively linked were Lactobacillus phages & beneficial taxa (Lachnospiraceae, Clostridiaceae & Ruminococcaceae). crAssphages were negatively linked with Enterobacteriaceae.
Conclusion: With decompensation, virome diversity increases but abundance decreases, which is opposite of bacteria that reduce in diversity with decompensation. Cirrhosis gut virome consists of phages targeted towards Lactobacillus & Escherichia, which increase & crAssphages which decrease with decompensation. Knowledge of phages could enhance drug discovery against bacteria that are linked with cirrhosis progression.

Interferon-gamma and CTLA-4 drive liver-induced systemic CD4 T cell tolerance

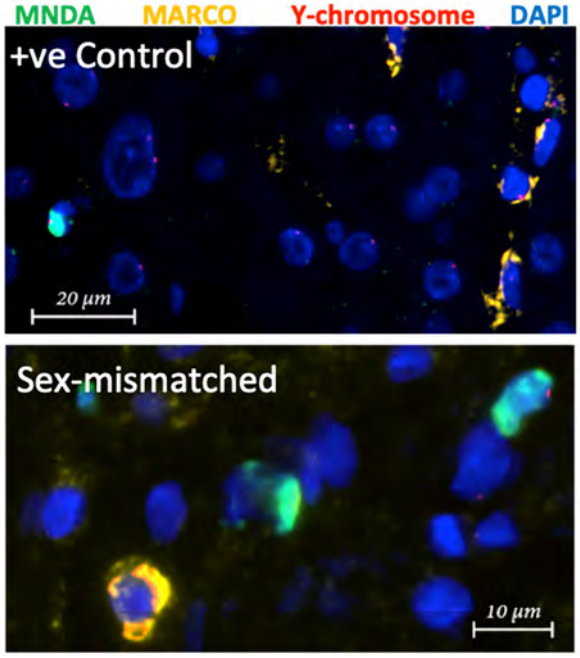
Daria Krzikalla[1], Alena Laschtowitz[1], Lisa Leypoldt[1], Dorothee Schwinge[1], Christoph Schramm[1], Ansgar Lohse[1], Antonella Carambia[1], Johannes Herkel[1]. [1]*I. Medizinische Klinik und Poliklinik, Hamburg, Germany*
Email: d.krzikalla@uke.de

Background and Aims: We have previously shown that ectopic expression of myelin basic protein (MBP) in the liver can prevent autoimmune encephalomyelitis (EAE); however, the mechanisms explaining how the liver can effectively protect distant tissues are not entirely clear.
Method: MBP-specific tg4 T cells were adoptively transferred into CRP-MBP mice expressing MBP in the liver. These congenic T cells were re-analysed *ex vivo* following antigen-recognition in the liver to identify tolerance-associated molecules. Blocking antibodies were used to test the importance of the identified molecules for the protection from autoimmune neuroinflammation in CRP-MBP mice.
Results: Transferred tg4 T cells upregulated IFN-gamma and accumulated in the livers of CRP-MBP recipients, as compared to non-transgenic littermates (> 10-fold). T cell accumulation was dependent on IFN-gamma-induced activation of the CXCL9 - CXCR3 axis, which enabled endothelial transmigration. Interestingly, IL-10 production was induced in transferred tg4 T cells in CRP-MBP mice and some of these T cells displayed a CD49+ Lag-3+ Tr1-like phenotype. However, inhibition of IL-10 via *in vivo* antibody blockade did not break tolerance. In addition to Lag-3, the accumulated tg4 T cells in the livers of CRP-MBP mice significantly upregulated several co-inhibitory receptors together with IFN-gamma, including PD-1, Tim-3, TIGIT and, most notably, CTLA-4. However, blockade of CTLA-4 alone by *in vivo* administration of an anti-CTLA-4 antibody did not impair tolerance. In contrast, blockade of IFN-gamma reduced expression of *Cxcr3* and *Cxcl9* and prevented hepatic accumulation of tg4 T cells, resulting in partial impairment of systemic tolerance and development of mild EAE. Intriguingly, concomitant blockade of IFN-gamma and CTLA-4 completely abolished tolerance to MBP and induced severe EAE.
Conclusion: Our findings demonstrate that systemic CD4 T cell tolerance induction in the liver and resulting protection from autoimmune disease depends on 1) IFN-gamma/CXCL9/CXCR3-mediated accumulation of autoreactive T cells in the liver and 2) up-regulation of multiple co-inhibitory receptors, notably CTLA-4.

AS116
TIMD4 expression distinguishes a population of self-renewing human liver macrophages

Elena Dora[1], Thomas Dalhuisen[2], John Wilson-kanamori[1], Prakash Ramachandran[1]. [1]*The University of Edinburgh, Centre for Inflammation Research;* [2]*The University of Edinburgh, School of Biological Sciences*
Email: e.dora1@ed.ac.uk

Background and Aims: Hepatic macrophages play a key role in liver health and disease. Recent work in mice shows that liver macrophages can be divided into two ontogenically-distinct subsets – tissue-resident Kupffer Cells (KC) which are embryologically-derived and self-renew throughout adult life and monocyte-derived macrophages (MDM) which derive from recruited blood monocytes. Murine KC and MDM populations have distinct functions in regulating liver homeostasis and injury. However, there remains minimal definition of the ontogeny of human liver macrophages. We aimed to determine whether human KCs are long-lived and self-renewing.
Method: We interrogated single-cell RNA-sequencing (scRNAseq) data from human liver samples generated via the 10X Genomics platform and analyzed using the Seurat R-package. Y-chromosome fluorescent in-situ hybridization probe (Y-FISH) staining was performed on archival liver biopsy sections from patients who underwent sex-mismatched liver transplantation. Experimental samples were male recipient-female donor patients, whilst male recipient-male donor and female recipient-female donor served as positive and negative controls respectively. Y-FISH staining was combined with multiplex fluorescent immunofluorescence (IHCF) to enable simultaneous detection of macrophage subpopulation markers. Images were analyzed using Fiji software.



Results: Analysis of scRNAseq data distinguished 3 populations of human liver macrophage; MNDA+MARCO-TIMD4-, MNDA-MARCO +TIMD4+ and MNDA-MARCO-TIMD4+. IHCF staining demonstrated

that MNDA+ macrophages had a monocyte-like morphology. Combined IHCF and Y-FISH staining on female-to-male transplant biopsies confirmed all MNDA+ cells to be Y-chromosome positive, highlighting MNDA as a marker of human liver MDMs. In contrast, MARCO+ macrophages were only 27.84% Y-FISH positive (Figure). This low level Y-FISH positivity remained consistent for up to 5 years post-transplant. Combined TIMD4 and Y-FISH staining indicated lower Y-chromosome positivity than MARCO+ macrophages, defining TIMD4 as the more distinguishing marker of long-lived self-renewing human KCs.

Conclusion: This study demonstrates ontological heterogeneity within the human liver macrophage compartment for the first time. The markers MNDA and TIMD4 allow distinction of circulation-derived and liver resident macrophages and in the future can be used to enable functional analyses of ontogenically-distinct macrophage subpopulations in health and disease.

Targeting p53 and histone methyltransferases to restore fully exhausted CD8+ T cells in human HCV infection before and after DAA-therapy

Valeria Barili[1], Paola Fisicaro[2], Barbara Montanini[3], Greta Acerbi[1], Anita Filippi[1], Alessandra Zecca[2], Carolina Boni[2], Chiara Romualdi[4], Manuela Ferracin[5], Francesca Guerrieri[6], Alessandra Orlandini[2], Marco Massari[7], Gabriele Missale[1,2], Massimo Levrero[6], Simone Ottonello[3], Carlo Ferrari[1,2]. *[1]University of Parma, Department of Medicine and Surgery, Parma, Italy; [2]Azienda Ospedaliero-Universitaria di Parma, Laboratory of Viral Immunopathology, Unit of Infectious Diseases and Hepatology, Parma, Italy; [3]University of Parma, Biomolecular, Genomic and Biocomputational Sciences Unit, Department of Chemical Life Sciences & Environmental Sustainability, Parma, Italy; [4]University of Padova, Department of Biology, Padova, Italy; [5]University of Bologna, Department of Experimental, Diagnostic and Specialty Medicine—DIMES, Bologna, Italy; [6]Cancer Research Center of Lyon (CRCL), INSERM U1052, Lyon, France; [7]Azienda Ospedaliera S. Maria Nuova, Unit of Infectious Diseases, IRCCS, Reggio Emilia, Italy*
Email: carlo.ferrari@unipr.it

Background and Aims: New direct-acting anti-virals (DAA) can cure the great majority of chronic HCV infections but a limited proportion of patients who do not respond to therapy, especially those who fail more than one retreatment, might benefit from immune modulation. In order to deepen our understanding of CD8 T cell exhaustion as a general mechanism of virus escape and identify suitable molecular targets to restore an efficient anti-viral CD8 T cell function as a candidate immune reconstitution therapy for chronic HCV infection, aim of our study was to characterize deregulated genes and pathways underlying early and late HCV-specific CD8 T cell exhaustion.

Method: Genome-wide expression profiling was performed on HCV-specific CD8 T cells in early and late acute HCV infection and in chronic HCV patients. Deregulated pathways were validated by flow-cytometry and studied also in DAA-treated chronic patients. Target-specific compounds were tested for their ability to correct dysregulated cell functions and reconstitute antiviral activity in acute and chronic HCV infection.

Results: Early development of CD8+ T cell exhaustion was marked by the up-regulation of genes related to oxidative phosphorylation and TCA cycle and the down-regulation of glycolysis-related transcripts, in the context of a predominant transcriptional up-regulation. This condition evolved in chronic HCV patients into a broader metabolic down-regulation associated to deregulated chromatin histone marks and epigenetic control. A strong improvement of HCV-specific CD8 T cell metabolic and antiviral functions was induced by pharmacological inhibition of p53 and of G9a and EZH2 histone methyltransferase activity. In chronic DAA-treated patients, a complete correction of metabolic and repressive histone methylation marks was not obtained in virus-specific CD8+ T cells.

Conclusion: Fully exhausted CD8+ cells are characterized by a widespread transcriptional down-regulation that may primarily result from epigenetic silencing. A number of metabolic and functional T cell defects appear to be present in exhausted HCV-specific CD8+ cells from chronic HCV patients with lack of full restoration after DAA-therapy. HMTs/p53 inhibitors may represent possible candidates for combination therapies with DAA in HCV-positive patients not properly responding to last-generation anti-virals and as novel and effective T cell reconstitution strategies for other T cell exhaustion-associated diseases.

AS118

Controlling regulatory T cell populations in the liver by enclysis, a CD4+ T cell engulfment process

Scott Davies[1], Gary Reynolds[1], Xiaoyan Li[2], Maanav Leekha[1], Ratnam Gandhi[1], Joe Grove[3], Stefan G. Hübscher[1], David Adams[1], Yuehua Huang[2], Omar Qureshi[4], Zania Stamataki[1]. *[1]Institute for Immunology and Immunotherapy, National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre, Birmingham, United Kingdom; [2] The Third Affiliated Hospital of Sun Yat-sen University, Department of Infectious Diseases and Guangdong Provincial Key Laboratory of Liver Disease Research, Guangzhou, China; [3]Institute of Immunity and Transplantation, Royal Free Hospital, London, United Kingdom; [4]Celentyx Ltd., BioEscalator Innovation Building, Oxford, United Kingdom*
Email: z.stamataki@bham.ac.uk

Background and Aims: Regulatory T cells (Treg) dampen inflammation and they are increased in the liver compared to blood, contributing to a tolerising environment. The swift neutralisation of Treg cells is important to enable immune effector functions to combat infection, but the mode of this is not understood. We noted that hepatocytes preferentially engulfed live Treg cells, and we set out to characterise the mechanism and outcome of this new phenomenon we termed "enclysis."

Method: We measured enclysis, the enclosure and lysis of Treg cells, *in vitro* and *ex vivo* using perfused liver wedges, in the presence of inhibitors of known cell-in-cell processes. Reporter dyes for viability, mitochondrial activity and acidification were used to determine enclysis outcome. Cell-in-cell structures were documented by light, confocal, electron and multiphoton microscopy. Foxp3+ Treg and T-bet+ T helper cells were enumerated in donor and in end-stage disease livers of AIH, PBC, PSC, ALD, NASH, HBV and HCV origin.

Results: Hepatocytes preferentially engulfed live Treg cells in a process that differed in mechanism and kinetic to previously described cell-in-cell structures (efferocytosis, suicidal emperipolesis, entosis). Enclysis reflected the enclosure and lysis of Treg cells inside hepatocytes, and enclytic vesicles were connected to the endocytic pathway. Enclysis was increased in patients with autoimmune compared to viral hepatitis ($p = 0.0011$).

Conclusion: Enclysis is the preferential engulfment and deletion of live Treg cells by hepatocytes and can be modulated pharmacologically, offering a new therapeutic target for immune regulation in the liver.

AS119

T cell receptor-engineered mucosal-associated invariant T cells with antiviral cytotoxic potential against hepatitis virus replicating hepatoma cells

Katie Healy[1], Andrea Pavesi[2], Tiphaine Parrot[3], Haleh Davanian[1], Anthony Tan[4], Johan K. Sandberg[3], Antonio Bertoletti[4], Margaret Sällberg Chen[1]. *[1]Karolinska Institutet, Department of Dental Medicine, Stockholm, Sweden; [2]A*STAR, Institute of Molecular and Cell Biology, Singapore, Singapore; [3]Karolinska Institutet, Center for Infectious Medicine, Stockholm, Sweden; [4]Duke-NUS Medical School, Programme of Emerging Infectious Diseases, Singapore, Singapore*
Email: katie.healy@ki.se

Background and Aims: Virus-specific T cells are known to be protective against hepatitis B (HBV) and hepatitis C (HCV) infections.

Mucosal-associated invariant T (MAIT) cells are a $CD3^+TCRValpha7.2^+CD161^+$ T cell subset which is naturally enriched in the liver. Because of their inherent liver-homing capacity they may represent a novel therapeutic alternative for hepatitis virus-associated liver diseases, including liver cancer, if they express the virus-specific T cell receptors (TCRs). The aim of this study was to compare the function of TCR-redirected MAIT cells with conventional T (ConT) cells that are currently being used in cancer immunotherapy.

Method: Donor-matched MAIT cells and ConT cells from healthy donor peripheral blood were redirected with HBV-Env183-TCR or HCV-NS31073-TCR mRNA. Surface expression of virus-specific TCR was quantified by flow cytometry. Real-time killing assays (xCELLigence) were performed with the HBV-expressing hepatoma cell line HepG2.2.15, with HBV peptide pulsed/unpulsed HepG2 cells as controls. T cell responses against HCV was assessed in Huh-7/Lunet HCV replicon cells using a luciferase read-out system. Intracellular cytokine staining following target cell coculture was also done in parallel to assess the polyfunctional profiles.

Results: Expression of HBV and HCV TCR transgenes in MAIT cells was comparable to ConT cells after TCR-redirection. HBV TCR-MAIT cells displayed an antigen-specific, rapid and potent cytolytic capacity, similar to that of ConT cells, resulting in total killing of HepG2.2.15 cells by experimental end-point. Similarly, HCV TCR-MAIT cells reduced HCV replicon luciferase expression in an HLA- and dose-dependent manner. Following coculture with hepatoma target cells, virus-specific MAIT cells were not only capable of degranulating and producing IFNγ and TNF, they also secreted the pro-inflammatory cytokine IL17, an effect not observed in conventional T cells.

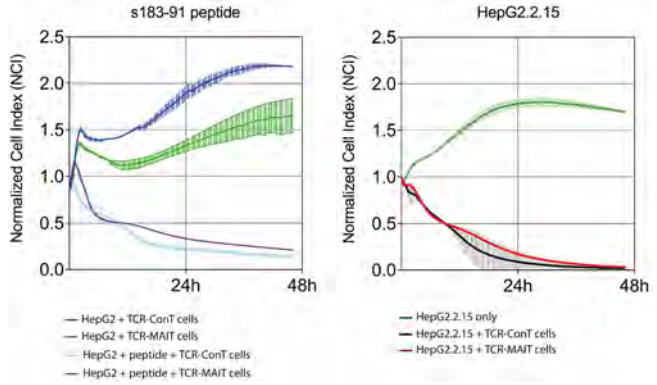

Figure: Real-time cytotoxicity assay of TCR-redirected ConT and MAIT cells with HepG2 cells (negative control), HepG2 cells pulsed with HBV envelope s183-91 peptide (positive control), and the full-HBV expressing cell line, HepG2.2.15.

Conclusion: TCR-redirected MAIT cells display comparable cytotoxic potential to conventional T cells. Further studies are required to compare the target-specific effects in the liver microenvironment.

AS120

Metabolic programming of exhausted CD8 T cells in chronic viral hepatitis

Frances Winkler[1], Nina Hensel[1], Matteo Villa[2], Erika Pearce[2], Bianca Martin[1], Dirk Wohlleber[3], Robert Thimme[1], Maike Hofmann[1], Bertram Bengsch[1,4]. *[1]Medical Center - University of Freiburg, Department of Medicine II, Freiburg, Germany; [2]Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany; [3]Institute of Molecular Immunology and Experimental Oncology, Munich, Germany; [4]BIOSS Centre for Biological Signalling Studies, Freiburg, Germany*
Email: frances.winkler@uniklinik-freiburg.de

Background and Aims: Accumulation of exhausted T cells (T_{EX}) is a major concern in patients with chronic hepatitis B and C virus (HBV/HCV) infection. These T_{EX} are characterized by an increased inhibitory receptor expression, poor effector function and substantial changes in their transcriptional profile compared to functional T cells. The regulation of energy metabolism is thought to induce dysfunction of T_{EX}. However, the metabolic programs of HBV- and HCV-specific CD8T cells in chronic infection and their links to T cell function remain poorly characterized.

Method: We profiled key metabolic pathways involved in energy metabolism in patients with cHBV and cHCV using metabolism-directed flow cytometry and transcriptome analysis.

Results: In chronic infection, HCV-specific CD8T cells exhibit enhanced glucose uptake but reduced mitochondrial polarization when compared to HBV-specific CD8T cells. These features were linked to the higher expression of inhibitory receptors suggesting more severe exhaustion in HCV infection. Therapy with direct antiviral agents induced an accumulation of HCV-specific CD8T cells after two weeks, but did not fully reprogram the metabolic phenotype of these cells. Interestingly, glucose uptake remained stable, but the uptake of long-chain fatty acids increased and depolarized mitochondria decreased upon therapy. Transcriptome analysis of metabolic pathways revealed an upregulation of *ACSS1/ACSS2* mRNA encoding for acetyl-CoA synthetase in HCV-specific CD8T cells, suggesting a higher ability to metabolize acetate as a potential anaplerotic TCA substrate. Addition of acetate to exhausted CD8T cells obtained from cHCV patients was able to improve functional exhaustion.

Conclusion: These results demonstrate differential metabolic regulation of HBV- and HCV-specific CD8 T cells. The elucidation of the molecular mechanisms underlying these distinct metabolic programs will allow metabolism-directed interventions to improve T cell function.

FRI356

Interleukin-15 restores the reactivity of the peripheral memory-like pool in the exhausted hepatitis B virus-specific CD8+ T cell population during persistent HBeAg(-) infection

Julia Peña Asensio[1,2], Eduardo Sanz-de Villalobos[1], Joaquín Míquel[1], Alejandro González Praetorius[1], Juan Ramón Larrubia[1,3]. *[1]Hospital Universitario de Guadalajara, Translational hepatology Unit, Guadalajara, Spain; [2]Facultad de Medicina-UAH, Departamento de Biología de Sistemas, Alcalá de Henares; [3]Facultad de Medicina-UAH, Departamento de Medicina y Especialidades Médicas, Alcalá de Henares*
Email: juan.larrubia@uah.es

Background and Aims: The peripheral CD8T cell memory-like (MLP) subset is responsible for tissue surveillance and maintaining an exhausted effector response during chronic viral infections. This population is characterised by TCF1 expression and increased size and complexity after Ag encounter. In persistent infections such as hepatitis B virus (HBV) eAg(-) chronic hepatitis (CHB), IL-15 could induce the homeostatic proliferation of this pool after a metabolic reset, leading to the generation of a progeny (P) with improved effector abilities.

Method: In 6 HLA-A2+ eAg(-) CHB patients coinfected with cytomegalovirus CMV, longitudinal tracking of Ag-specific CD8T cells was carried out. Lymphocytes were in-vitro challenged for 20 days with HBVcore18–27 or CMVpp65495-504 peptides in presence of IL-2 or IL-15. Ag-specific CD8T cells were visualized by staining with labelled HLA-A2/peptide pentameric complexes (pentamer) by flow cytometry. MLP pool was gated on Pentamer+ TCF1+ FSChigh population and the P subset on the Pentamer+ TCF1- gate. On day 7, PD-1, CD127, Glut1, Mitotracker green (MTG), PGC1α phenotype in the MLP pool and on day 12, the effector function (IFNγ, TNFα, CD107a) in the P subset were tested.

Results: The kinetics of HBV-specific CD8 MLP pool with IL-2 treatment was different between CMV and HBV. Specifically, the number of MLP cells in HBV was 10-folds lower in the peak day of this pool's proliferation and this gave rise to a P subset that was 12-folds lower than for CMV-specific cells on day 12 ($p < 0.05$), (Fig 1). HBV-specific MLP population showed higher PD-1, Glut1 and lower CD127, MTG, PGC1α expression than CMV-specific progenitors ($p < 0.05$).

This correlated with lower IFNγ, TNFα secretion, and lower CD107a expression on HBV-specific P than on the CMV-specific subset ($p < 0.05$). IL-15 in-vitro treatment of HBV-specific CD8 cells increased 6-folds the MLP pool on day 7 and maintained this population up to day 9 with a later progressive decrease (Fig 1). This change on the MLP kinetics correlated with a decrease of Glut1 level and an increase in PGC1α expression ($p < 0.05$) linked to an improvement of the P pool effector abilities on day 12 ($p < 0.05$).

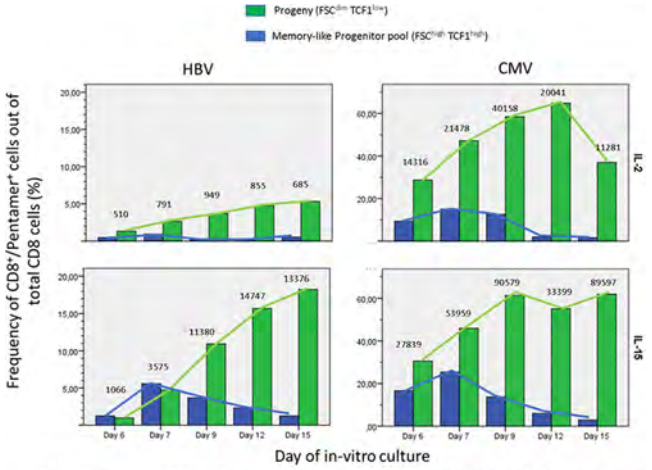

Fig 1. HBV-core$_{18-27}$ and CMV pp65$_{495-504}$ memory like progenitor and progeny pool kinetics in a representative CHB eAg negative CMV co-infected patient during Ag-specific in-vitro challenge. Figures on top of bars represent the absolute number of CD8+/Pentamer+ cells isolated per culture well in each experimental condition.

Conclusion: IL-15 in-vitro treatment increases the memory-like pool and modifies its metabolism to a less glycolytic one that leads to an improvement in the effector abilities of the progeny.

Immune-mediated and chronic cholestasic liver disease – Clinical aspects

AS121

The impact of geographical region on outcomes of patients with primary biliary cholangitis from western Europe

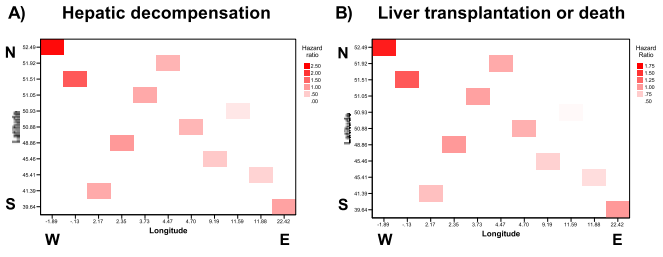
Email: w.lammers@erasmusmc.nl

Background and Aims: Although the incidence and prevalence rates of primary biliary cholangitis (PBC) vary according to geographical region, the disease affects people from all geographical regions. It is unknown whether regions with a higher prevalence for PBC, such as Northern Europe, have distinct disease characteristics or outcomes. The aim of this study was to determine whether geographical region contributes to differences in outcomes of patients with PBC within Western Europe.

Method: Patients from the Global PBC database from European centers diagnosed from 1990 onwards that were ursodeoxycholic-acid (UDCA) treated were included in the study. Patients with a time lag greater than 1 year from diagnosis to the start of follow-up were excluded. Differences in baseline characteristics and outcomes (transplant-free survival and decompensation) were studied. The impact of geographical region was studied according to North/South and East/West, as well and longitude and latitude.

Results: A total of 1878 patients were included in the study. Patients in North Europe were more often of a moderately advanced or advanced Rotterdam biochemical stage (28.4%) compared to those in South Europe (20.6%). Additionally, they exhibited higher median alkaline phosphatase (ALP [2.0 × ULN vs. 1.4 × ULN]) and transaminases (AST: 1.4 × ULN vs. 1.3 × ULN; ALT: 1.7 × ULN vs. 1.4 × ULN). Similarly, West Europe also presented with higher ALP and transaminases. North Europe, as compared to South Europe, was associated with lower transplant-free survival and higher decompensation rates, with 15-year survival rates of 66% vs 79% ($P = 0.001$) and decompensation incidence of 21% vs 10% ($P < 0.001$). The association of geographical region with outcome was assessed with longitude and latitude in multivariable analysis while adjusting for biochemical markers of disease severity and cirrhosis as a time-dependent covariate, as well as age, sex, and diagnosis year. There was a significant interaction between latitude and longitude in the prediction of transplant-free survival ($P = 0.001$) and decompensation ($P < 0.001$). An increased risk for poor outcomes was observed for the Northwestern area of the evaluated region compared to the reference (Paris) (Figure).



Conclusion: Patients from Northwestern Europe with PBC and of similar disease severity have increased risk of decompensation and liver transplantation of death. This suggests that in the Northwestern part of Europe, geographical region may have an impact on patient outcome.

AS122

Combination of quantitative 3D MRCP and multi-parametric MRI demonstrates increased periductal iron-corrected T1 in large-duct primary sclerosing cholangitis

Emmanuel Selvaraj[1,2,3], Ged Ridgway[4], Emma Culver[2], Jane D. Collier[2], John Michael Brady[4], Adam Bailey[2,3], Michael Pavlides[1,2,3]. [1]*Oxford Centre for Clinical Magnetic Resonance Research (OCMR), Radcliffe Department of Medicine, University of Oxford, United Kingdom;* [2]*Translational Gastroenterology Unit, Nuffield Department of Medicine, University of Oxford, United Kingdom;* [3]*Oxford NIHR Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust and the University of Oxford, United Kingdom;* [4]*Perspectum Diagnostics, United Kingdom*
Email: emmanuel.selvaraj@cardiov.ox.ac.uk

Background and Aims: One of the features of primary sclerosing cholangitis (PSC) is a characteristic "onion skin" periductal fibrosis usually seen on liver biopsy. The aim of this study was to evaluate whether a related feature to this can be diagnosed macroscopically from quantitative MRI scans.
Method: Standardised 3D MRCP and axial liver T1 and T2* maps were acquired on patients with a known diagnosis of large-duct PSC and healthy participants. LiverMultiScan (Perspectum Diagnostics (PD), Oxford, UK) was used to generate axial maps with cT1 measurements at each voxel over multiple slices in the liver. Biliary data was analysed using MRCP+ (PD, Oxford, UK) to build a parametric biliary tree model which was aligned to the axial liver cT1 maps as demonstrated in Figure 1. Periductal cT1 was quantified over fixed radial distances surrounding the bile ducts at 1 mm increments up to 10 mm, restricted to a delineation of the liver that excluded prominent blood vessels. Region of interest (ROI) 1 was defined as the ring-shaped area between the circles with radius 2 and 5 mm. ROI 2 was the area between circles with radius 6 and 9 mm. Mean cT1 was measured in each ROI and compared to the mean cT1 for the whole axial segment (reference), using the Friedman test with Dunn's post-hoc correction for multiple comparisons. Advanced fibrosis (≥ F3) was defined according to transient elastography (Echosens, France) liver stiffness measurement (LSM) cut-off of 9.6 kPa.

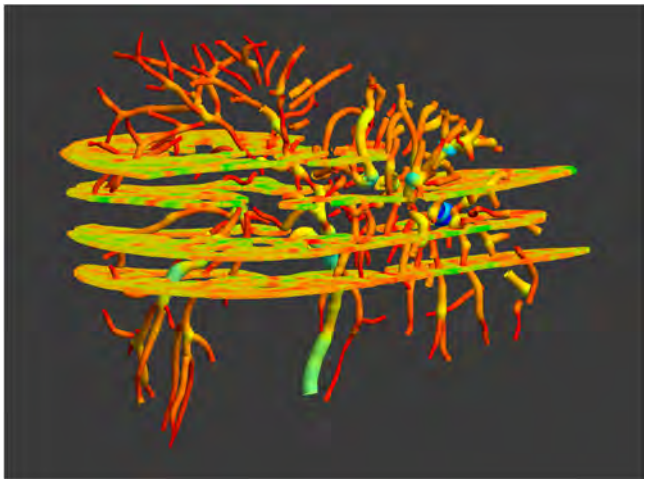


Figure 1: Co-registration of the biliary tree model to four axial liver cT1 maps in a patient with PSC for quantification of periductal cT1.

Results: Fifty eight patients (67% male) with median age of 47 years (range: 18–76) and median PSC duration of 8 years (range: 1–25) as well as ten healthy participants (70% male) with median age 33 years (range: 25–44) were recruited. There was a significant difference in mean cT1 over the three regions ($p < 0.0001$) in PSC but no difference was observed in healthy participants. Pairwise comparisons in PSC showed mean cT1 in ROI 1 (780 ms) was higher than ROI 2 (764 ms; $p < 0.0001$) and reference (765 ms; $p < 0.0001$) but there was no difference between ROI 2 and reference ($p = 0.15$). Importantly, the mean cT1 in ROI 1 was higher in PSC with advanced fibrosis on LSM (815 vs 770 ms, $p = 0.02$). A cut-off of 774 ms had an area under the receiver operating characteristics curve (AUROC) of 0.72 (95% CI 0.54–0.89, $p = 0.01$) to identify advanced fibrosis.
Conclusion: Periductal cT1 in the ring of tissue 2–5 mm around the bile ducts is significantly higher than regions further from the bile ducts in PSC and may represent a macroscopic finding that correlates to the histologic "onion skin" fibrosis. This demonstrates how quantitative MRI techniques can be used to assess features of disease that were previously seen only at histology. Follow-up data from this study will assess the ability of periductal cT1 to predict fibrosis progression and clinical endpoints.

AS123

Heterozygous carriers of ABCB4 mutations show a mild clinical course, but impaired quality of life and limited risk for cholangiocarcinoma – a cohort study

Marta Mazzetti[1], Elsemieke de Vries[2], Bart Takkenberg[2], Nahid Mostafavi[2], Henny Bikker[3], Marco Marzioni[1], Rozanne de Veer[4], Adriaan Van der Meer[4], Michael Doukas[5], Joanne Verheij[6], Ulrich Beuers[7]. Email: marta.mazzetti@virgilio.it

Background and Aims: Carriers of ATP binding cassette B4 (ABCB4) mutations may develop progressive familial intrahepatic cholestasis type 3 (PFIC3) with biliary cirrhosis, low-phospholipid-associated cholelithiasis (LPAC), intrahepatic cholestasis of pregnancy (ICP) and/or persistent hepatocellular secretory failure (PHSF) or may remain free of clinical complications. Here, the clinical long-term course, quality of life and histological re-evaluation according to Nakanuma were investigated in a cohort of heterozygous carriers of ABCB4 mutations.
Method: In this bicenter cohort study, adult individuals with a proven ABCB4 mutation were analyzed. Participants underwent history taking, physical examination, blood analysis, abdominal ultrasound (US) and elastography (Fibroscan®) and were asked to complete a 36 Item Short Form Health Survey (SF36) regarding quality of life and Visual Analogue Scale (VAS) for pruritus. Past clinical findings were collected from electronic patient files. All available liver biopsies were re-classified according to the Nakanuma staging system. Outcome of quality-of-life-data was compared to that published for patients with primary biliary cholangitis (PBC), primary sclerosing cholangitis (PSC) and the general population.
Results: Sixty-seven patients were identified of whom 64 (96%) were alive at inclusion into the study and 63 (94%) were treated with ursodeoxycholic acid. Two patients died of cholangiocarcinoma and one of decompensated biliary cirrhosis. Three more deaths of cholangiocarcinoma were reported in first degree relatives of participants without available genetic analysis. Overall transplant-free survival was 91% (average time from first presentation 16 years). Liver stiffness was normal (<6.3 kPa) in 75%, and microcalcifications were detected at ultrasound in 22% of cases. Quality of life (SF-36, n = 48) was lower than that of the general population especially in the energy/fatigue and general health domains and comparable to that reported for PSC patients. The Nakanuma scoring system applied in 15 available histological specimens reflected the clinical disease course.
Conclusion: Heterozygous carriers of an ABCB4 mutation have a mild clinical course, but impaired quality of life and limited risk of cholangiocarcinoma. Use of Nakanuma staging appears feasible for histological evaluation in ABCB4 deficiency.

AS124

The effect of chyme reinfusion on the bile salt/fibroblast growth factor 19 signaling axis in intestinal failure patients with a temporary jejunal double enterostomy

Xinwei Chang[1,2], Denis Picot[3], Kiran Koelfat[1,2], Sander M.J. van Kuijk[4], Sabrina Layec[3], Marie Carsin[3], Laurence Dussaulx[3], Eloi Seynhaeve[3], Florence Trivin[3], Laurence Lacaze[5], Ronan Thibault[5], Frank Schaap[2,6], Steven Olde Damink[1,2,6]. *[1]Department of Surgery, Maastricht University Medical Center, Maastricht, Netherlands; [2]Department of Surgery, NUTRIM School of Nutrition and Translational Research in Metabolism, Maastricht University, Maastricht, Netherlands; [3]Department of Nutritional and Digestive Rehabilitation, Clinique Saint Yves, Rennes, France; [4]Department of Clinical Epidemiology and Medical Technology Assessment, Maastricht University Medical Center, Maastricht, Netherlands; [5]Nutrition Unit, CHU Rennes, Univ de Rennes, NuMeCan Institute, INSERM, INRA, Univ Rennes, Rennes, France; [6]Department of General, Visceral and Transplantation Surgery, RWTH University Hospital Aachen, Aachen, Germany*
Email: steven.oldedamink@maastrichtuniversity.nl

Background and Aims: Temporary jejunal double enterostomies may result in intestinal failure (IF) and require parenteral nutrition (PN). Etiology of IF-associated liver disease (IFALD) is multifactorial, and involves PN and enterohepatic circulation (EHC) disruption. Chyme reinfusion (CR) improves IF and liver abnormalities and restores EHC. Bile salts are signaling molecules undergoing EHC and negatively regulate their own synthesis via endocrine FGF19 produced in the ileum. Here we tested the hypothesis that functional restoration of the EHC and attendant bile salt/FGF19 signaling contributes to the beneficial effects of CR.

Method: IF patients with a double jejunal enterostomy on PN were recruited for CR treatment in a tertiary referral center (RESCUE study: ClinicalTrial.gov NCT02990195). Blood samples were collected prior to, at start, and 1, 3, 5 and 7 weeks after CR initiation. Ileum biopsies were taken prior to and 3 weeks after start of CR. Plasma levels of FGF19, total bile salts (TBS), 7alpha-hydroxy-4-cholesten-3-one (C4, a plasma marker of bile salts synthesis), citrulline, bile salt composition, and serum liver injury and cholestasis markers were determined. A linear mixed model was used to evaluate the (temporal) relationship between citrulline, TBS and FGF19 and biochemical/clinical outcomes.

Results: Twelve patients (5 females, age 67.7 ± 14.6 y) were included. Elevated serum markers for cholestasis (GGT, ALP) (both $p < 0.01$) and liver injury (ALT, AST) normalized after CR, and hypoalbuminemia was corrected reflecting improved nutritional status ($p < 0.001$). CR resulted in improved intestinal function, as inferred from elevated plasma citrulline from week 1 onwards and enhanced mRNA expression of epithelium-specific genes (e.g. *FXR*, *OSTa/b*). Plasma FGF19 was increased after CR and peaked after 1 week (0.034 ± 0.030 ng/mL at baseline vs 0.141 ± 0.080 ng/mL at 1 week, $p < 0.01$). This was accompanied by normalization of plasma C4 which was elevated at baseline, and reduced circulating TBS levels (both $p < 0.05$). CR altered the composition of the circulating bile salts pool: the increased fractions of gut-microbiota derived unconjugated and secondary bile salts (both $p < 0.05$) reflected restored contact between bile and the gut microbiota.

Conclusion: CR treatment improves liver and intestinal function in IF patients with a jejunal enterostomy. The beneficial effect of CR is partly mediated by bile salt/FGF19 signaling, resulting in restored homeostatic regulation of bile salt synthesis.

AS125

Patients with autoimmune hepatitis and liver cirrhosis have disease activity despite normal transaminases

Alena Laschtowitz[1,2], Kalliopi Zachou[3], Vasiliki Lygoura[3], Simon Pape[4], Finn Derben[2,5], Munira Altarrah[6], Sören Alexander Weidemann[7], Sergio Oller-Moreno[8], Joost Ph Drenth[4], George Dalekos[3], Michael Heneghan[6], Richard Taubert[2,5], Ansgar W. Lohse[1,2], Christoph Schramm[1,2,9]. *[1]University Medical Centre Hamburg-Eppendorf, I. Department of Medicine, Germany; [2]European Reference Network for Hepatological Diseases; [3]University Hospital of Larissa, Department of Medicine and Research Laboratory of Internal Medicine, Larissa, Greece; [4]Radboud University Medical Centre, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands; [5]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [6]King's College Hospital, The Institute of Liver Studies, London, United Kingdom; [7]University Medical Centre Hamburg-Eppendorf, Department of Pathology, Hamburg, Germany; [8]University Medical Center Hamburg-Eppendorf, Institute of Medical Systems Biology, Hamburg, Germany; [9]Martin Zeitz Centre for Rare diseases, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany*
Email: laschtowitz@gmail.com

Background and Aims: In autoimmune hepatitis (AIH) serum aminotransferase and immunoglobulin G (IgG) levels within the normal ranges define biochemical remission and are considered as surrogate markers for histological remission. However, it remains unclear to what extent these parameters predict histological activity in patients with AIH and liver cirrhosis.

Method: In a European multicentre retrospective study we included 125 biopsies from 113 patients with AIH and histologically proven liver cirrhosis and with available biochemistry parameters at time of biopsy. (Hamburg: n = 69, Larissa: n = 26, Hannover: n = 19, Nijmegen: n = 10, London: n = 1). As control group we identified 71 biopsies of 69 patients from Medical University Centre Hamburg-Eppendorf with diagnosis of AIH but without liver cirrhosis. Data were assessed at time of biopsy and at last follow-up.

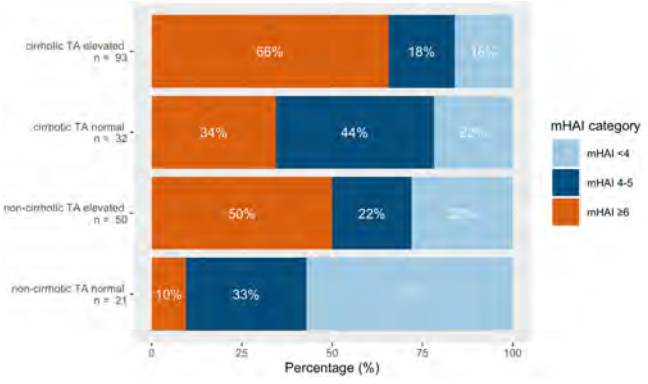

Figure 1: Histological activity scores subdivided as histological remission (mHAI <4), mild residual disease activity (mHAI 4–5) or moderate to high inflammatory activity (mHAI ≥ 6) in AIH patients with and without liver cirrhosis and serum aminotransferase levels within the normal range. TA, aminotransferases; mHAI, modified hepatitis activity index.

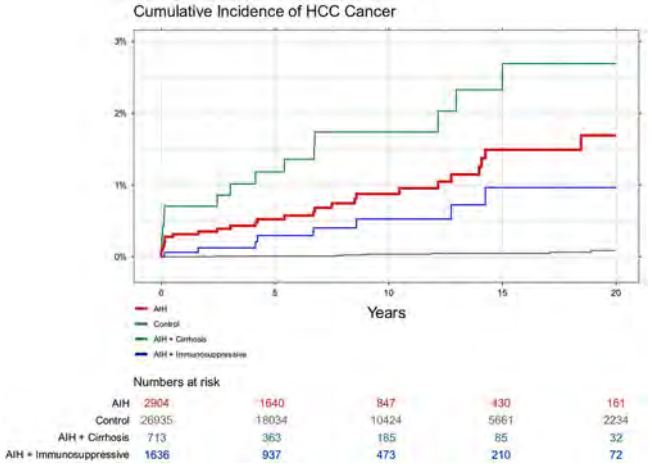
Results: In patients with AIH liver cirrhosis and elevated transaminases (n = 93) 66% presented with moderate to high histological activity (mHAI ≥ 6) (Fig. 1). Normal aminotransferases were seen in 26% (32/125) of patients with AIH and liver cirrhosis. Of these, only 22% (7/32) had histological remission (mHAI <4), 44% (14/32) presented with residual (mHAI 4–5) and 34% (11/32) with moderate to high inflammatory activity (mHAI ≥ 6). In contrast, in 43% (9/21) ($p = 0.019$) of AIH patients without cirrhosis and normal aminotransferase levels possessed histological activity of ≥ 4/18 points. The addition of IgG to define complete biochemical remission

(transaminases and IgG within normal ranges) improved the prediction of moderate to high histological activity in only 2/12 patients with AIH liver cirrhosis presenting with mHAI ≥ 6. However, 67% of patients with AIH and cirrhosis and complete biochemical remission had mHAI ≥ 4.
Conclusion: Patients with AIH cirrhosis and transaminases within the normal range may still have AIH activity that warrants intensified immunosuppressive therapy. The addition of serum IgG levels may improve the diagnostic performance of biochemistry. Our results indicate that biochemical parameters alone do not accurately predict AIH disease activity in cirrhosis.

AS126
Autoimmune hepatitis and cancer risk – a Danish nationwide cohort study

Morten Daniel Jensen[1], Lisbet Groenbaek[1], Hendrik Vilstrup[1], Peter Jepsen[1,2]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark;* [2]*Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus N, Denmark*
Email: mortenjensen_92@hotmail.com

Background and Aims: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease, and the chronic inflammation may cause cancer development. We examined cancer risk in a nationwide cohort of patients with AIH.
Method: We identified all Danish citizens diagnosed with AIH between 1994 and 2018 and followed them through Danish healthcare registries. For each of the 2,904 patients with AIH we included 10 population controls matched on gender, age, and year of birth. We examined absolute and relative risks of hepatocellular carcinoma (HCC) and other cancers (non-HCC-cancers) using the cumulative incidence function and Cox proportional hazards regression. Within the cohort of AIH patients, we assessed relative risks of HCC and non-HCC-cancers for patients with vs. without cirrhosis and on vs. off immunosuppressive treatment.
Results: The 20-year risk of HCC was 1.7% [95% confidence interval (CI): 1.1–2.6] for patients with AIH vs. 0.1% [95% CI: 0.0–0.2] for controls. For AIH patients with and without cirrhosis the 20-year risk of HCC was 2.7% [95% CI: 1.5–4.5] and 1.3% [95% CI: 0.6–2.4], respectively, while the risk was 1.0% [95% CI: 0.4–2.0] and 2.4% [95% CI: 1.4–3.9] for patients on vs. off immunosuppressive treatment (Figure). Among patients with AIH, cirrhosis was associated with HCC (hazard ratio = 7.6 [95% CI: 3.3–17.8]), but not with non-HCC-cancers (hazard ratio = 1.2 [95% CI: 1.0–1.5]). Immunosuppressive treatment exerted a protective effect against HCC development (hazard ratio = 0.3 [95% CI: 0.1–0.7]), but was associated to non-HCC-cancers (hazard ratio = 1.3 [95% CI: 1.0–1.6]).



Conclusion: AIH was associated with an increased 20-year risk of HCC in comparison with controls, but the absolute risk excess was small: 1.6% over a 20-year period. Among patients with AIH, cirrhosis was associated with an increased risk of HCC while immunosuppressive treatment, by contrast, reduced the risk.

The role of ferroptosis in chronic liver disease

Julia Piche[1], Tobias Otto[1], Antje Mohs[1], Marius Woitok[1], Christian Trautwein[1]. [1]*University Hospital RWTH Aachen, Department of Internal Medicine III, Aachen, Germany*
Email: jpiche@ukaachen.de

Background and Aims: The prevalence of non-alcoholic fatty liver disease, ranging from steatosis to non-alcoholic steatohepatitis (NASH), is increasing in developed countries. In some patients, progression towards cirrhosis and hepatocellular carcinoma (HCC) occurs. To present, the underlying mechanisms for disease progression remain incompletely understood. In NASH oxidative stress and lipid peroxidation constitute prominent features and may hence play a key role. Interestingly, accumulation of lipid peroxides can trigger ferroptosis, an iron-dependent mode of cell death. According to *in vitro* studies, acyl-CoA synthetase long-chain family member 4 (ACSL4) is an essential contributor to ferroptosis. In our study, we aimed to investigate the relevance of ferroptosis for disease progression using hepatocyte-specific ACSL4 inhibition in experimental models of chronic liver disease.
Method: Primary hepatocytes from either wild-type (WT) mice or mice with hepatocyte-specific deletion of ACSL4 ($ACSL4^{\Delta hepa}$) were treated with specific inducers (e.g., RSL3) and inhibitors (e.g., Liproxstatin-1) of ferroptosis. In addition, we compared disease development between WT and $ACSL4^{\Delta hepa}$ mice to investigate the role of ferroptosis. We used a high-fat diet (HFD) to trigger NASH and STZ (Streptozocin) with HFD as a NASH-HCC model.
Results: Treatment of primary hepatocytes with RSL3 leads to increased cell death, which could be rescued by adding Liproxstatin-1 or by using ACSL4-deficient hepatocytes.
In our HFD-based NASH model, we did not find significant differences between WT and $ACSL4^{\Delta hepa}$ mice. Specifically, liver-to-body weight ratio, serum transaminase levels, and immune cell infiltration were not altered. In contrast, in our NASH-HCC model, inhibition of ferroptosis in hepatocytes augments chronic liver disease resulting in increased serum transaminase levels in $ACSL4^{\Delta hepa}$ mice. Importantly, while the overall tumor burden was not affected in $ACSL4^{\Delta hepa}$ mice, the number of smaller tumors was significantly increased.
Conclusion: Our results demonstrate that primary mouse hepatocytes are susceptible to induction of ferroptosis and that this mode of cell death depends on functional ACSL4. Interestingly, ferroptosis seems to be a protective mechanism during tumor initiation, by regulating lipid accumulation and cell death in hepatocytes. Therefore, activation of ferroptosis or inhibiting key molecules regulating cell death, can be a possible therapeutic treatment for human disease.

AS128

The NADPH oxidase NOX4 regulates lipid metabolism, which contributes to its tumour suppressor actions in hepatocellular carcinoma

Irene Peñuelas-Haro[1], Esther Bertran[1], Eva Crosas-Molist[1], Fulvio Santacatterina[2], Silvia Marin[3], María Isabel Hernández-Álvarez[4], María Luz Martínez-Chantar[5], Marta Cascante[3], Ulla Knaus[6], Antonio Zorzano[4], Jose Manuel Cuezva[2], Isabel Fabregat[1]. *[1]Bellvitge Biomedical Research Institute (IDIBELL) and CIBEREHD and University of Barcelona, L'Hospitalet de Llobregat, Spain; [2]Centro de Biología Molecular Severo Ochoa (CSIC/UAM) and CIBERER, Madrid, Spain; [3]Universitat de Barcelona (UB) and Institut de Biomedicina de la Universitat de Barcelona (IBUB) and CIBEREHD, Barcelona, Spain; [4]Institute for Research in Biomedicine (IRB) and Barcelona Institute of Science and Technology (BIST) and CIBERDEM, Barcelona, Spain; [5]CIC Biogune and CIBEREHD, Derio, Bizkaia, Spain; [6]Conway Institute, School of Medicine, Dublin, Ireland*
Email: ifabregat@idibell.cat

Background and Aims: The NADPH oxidase (NOX) family has emerged in the last years as an important source of reactive oxygen species (ROS) in signal transduction. The isoform NOX4 has been implicated in a variety of physiological and pathological processes. In recent works, we found that stable knockdown of NOX4 expression in liver tumor cells increases their proliferative capacity in vitro and enhances their tumorigenic potential in xenografts in mice, resulting in earlier onset of tumor formation and increase in tumor size (Crosas-Molist et al., Free Radic Biol Med 2014). NOX4 could also regulate other cellular processes that occur later in progression and that favor tumor metastasis, such as migration and invasion (Crosas-Molist et al., Oncogene 2016). NOX4 gene deletions are frequent in HCC patients, correlating with higher tumour grade. Here we aim to determine the cellular and molecular mechanisms regulated by NOX4 in liver cells that could explain its tumor suppressor functions.
Method: Cell models: HCC cells (PLC/PRF/5 and SNU449) were NOX4 was either silenced (ShRNA) or overexpressed. Transcriptomics, Proteomic and Metabolomic analyses. Metabolomic profile through Seahorse technology. Analysis of mitochondria structure and function. Analysis at real time of cell adhesion, proliferation and migration through xCELLigence technology.
Results: A proteomic analysis, by comparing control cells with HCC cells where NOX4 had been silenced or overexpressed, allowed the identification of metabolism as one of the highest affected processes. Silencing NOX4 in PLC/PRF/5 cells increased both the glycolysis and oxidative phosphorylation pathways, while the overexpression of NOX4 in SNU449 cells showed opposite effects. A detailed transcriptomic and metabolomic analysis indicated that NOX4 could be regulating fatty acid metabolism. We found differences in gene expression related to fatty acid transport, oxidation and de novo synthesis, as well in the amount of monoacylglycerol, diacylglycerol and carnitine intermediates, which indicate an inverse correlation between the expression of NOX4 and the cell capacity to use fatty acids. Silencing NOX4 induced changes in the amount and dynamics of the mitochondria, increase in the protein levels of complex IV and V and higher ATP levels. Preliminary results indicate that NOX4 regulates c-Myc, which could mediate the changes observed.
Conclusion: The liver tumor suppressor functions of NOX4 could be explained through its effects on HCC cell lipid metabolism.

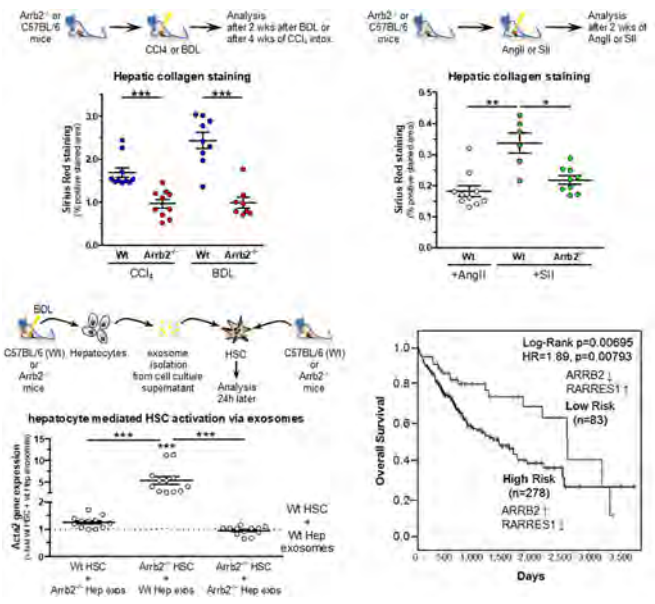
Email: robert.schierwagen@kgu.de

Background and Aims: Beta-arrestin-2 (ARRB2) is a regulator of the G protein-coupled receptors, such as the profibrotic Angiotensin II type 1 receptor (AGTR1), redirecting signalling to G protein-independent pathways. Their role in liver fibrosis, cancer and the transition from fibrosis to cancer are not fully understood and were investigated in this study.
Method: Fibrosis was induced in Arrb2-deficient and wildtype (Wt) mice using bile duct ligation (BDL) or carbon tetrachloride (CCl_4). AGTR1 was stimulated either G protein-dependent by angiotensin II administration or by the modified peptide [Ser(1), Ile(4), Ile(8)]-angiotensin II to selectively activate ARRB2 downstream of AGTR1. Fibrosis and HSC activation were investigated *in vivo* by gene and protein expression/histological staining. Crosstalk between primary murine hepatic stellate cells (HSC) and hepatocytes was analysed *in vitro*. Gene array analyses identified mediators of ARRB2-dependent signalling in primary human HSC. Findings in experimental liver fibrosis and cancer were confirmed in human tissue and hepatic cells (hepatocytes, HSC, HCC). Additionally, external validation was performed *in silico* using Geo-database, Oncomine and SurvExpress.
Results: ARRB2 is increased in human and experimental liver cirrhosis, mainly in activated HSC and injured hepatocytes. In turn, ARRB2-defiency decreases fibrosis and HSC activation *in vivo*. Interestingly, ARRB2-loaded exosomes released from injured Wt

hepatocytes are able to activate ARRB2-deficient HSC, while ARRB2-deficient exosomes had no effect in Wt HSC. Transcriptome analysis of human primary HSC revealed that ARRB2 induces retinoic acid receptor responder 1 (RARRES1). RARRES1 correlates with profibrotic factors, such as collagen 1, alpha-smooth muscle actin and transforming growth factor beta expression. On the other hand RARRES1 is a tumor suppressor. Release of ARRB2-positive exosomes from injured hepatocytes leads to RARRES1 downregulation in these hepatocytes. Decreased RARRES1 was also found in HCC cell lines and human tissue, while ARRB2 and RARRES1 were upregulated in surrounding cirrhotic peritumor tissue. In HCC, upregulation of ARRB2 and downregulation of RARRES1 could be confirmed in large human series using external validation.



Conclusion: Chronic liver injury leads to release pf ARRB2-loaded exosomes by hepatocytes. These exosomes are taken up by HSC and induce fibrosis. ARRB2 regulates RARRES1 and may induce pre-malignant transformation.

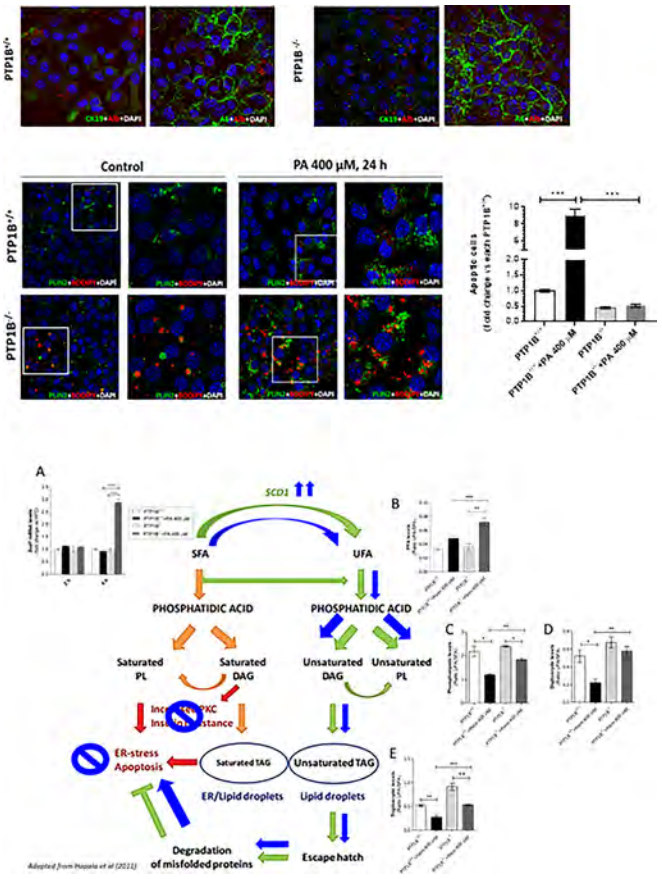
AS130

Inhibition of protein phosphatase 1b protects against lipotoxicity in liver progenitor oval cells

Ines Barahona[1], Pilar Valdecantos[1], Patricia Rada[1], Alma Astudillo[2], Jesus Balsinde[2], Aranzazu Sanchez[3], Angela Martinez Valverde[1]. *[1]IIB Alberto Sols (CSIC/UAM), Department of Metabolism and Cell Signaling, Madrid, Spain; [2]Biology and Molecular Genetic Institute, Innate Immunity and Inflamation, Valladolid, Spain; [3]University Complutense of Madrid, Biochemistry (Pharmacy School), Madrid, Spain*
Email: ibarahona@iib.uam.es

Background and Aims: Oval cells are progenitor cells with an emerging role in liver regenerative responses by their differentiation capacity. However, the characterization of their susceptibility to lipotoxicity in the context of obesity-associated non-alcoholic fatty liver disease is unknown. Inhibition of protein tyrosine phosphatase 1B (PTP1B) is a promising pharmacological strategy against insulin resistance and obesity. Also, PTP1B deficiency protects against acute and chronic hepatocyte damage. On that basis, we analyzed the susceptibility of oval cells with or without PTP1B to lipotoxicity and the molecular mechanisms involved.

Method: Oval cells from PTP1B$^{+/+}$ and PTP1B$^{-/-}$ mice were isolated, cultured and characterized. For lipotoxicity studies, oval cells were treated with palmitic acid (PA) for different time-periods, after which unfolded protein response (UPR) and autophagy/apoptosis markers were analyzed. A lipidomic study was conducted to characterize the accumulation of lipid species upon PA stimulation in PTP1B$^{+/+}$ and PTP1B$^{-/-}$ oval cells.



Results: Treatment with PA for 24 h induced apoptotic cell death in PTP1B$^{+/+}$ oval cells in parallel to a blockade of the autophagy flux. This lipotoxic effect was absent in PTP1B$^{-/-}$ cells that accumulated lipid droplets upon PA treatment and presented elevated levels of UPR-sensitive mediators, AMPK phosphorylation and sirtuin 1. These effects were also found in PTP1B silenced wild-type oval cells. Moreover, PA-treated PTP1B$^{-/-}$ oval cells showed an enhanced anti-oxidant response including nuclear factor erythroid 2-related factor nuclear translocation. Lipidomics revealed that upon PA treatment PTP1B$^{-/-}$ oval cells present elevations in stearoyl CoA desaturase 1 (Scd1) mRNA and higher unsaturated/saturated fatty acids after PA stimulation either free or incorporated into triacylglicerides, diacylglicerides and phospholipids. Blockade of autophagy flux in PTP1B$^{-/-}$ cells inhibited lipid droplet formation and restored lipoapoptosis.

Conclusion: Our results revealed that liver oval cells are susceptible to lipotoxicity, an effect mediated at least in part by the induction of oxidative stress. PTP1B deficiency protects against lipotoxic cell death by mechanisms including enhancement of antioxidant defence and a major capacity to generated unsaturated lipid species stored in lipid droplets, suggesting a potential benefit in cellular regenerative therapies against NAFLD. This effects are likely mediated by autophagy-derived energy suppliers.

AS131

The splicing regulator SLU7 is required for DNMT1 protein stability and DNA methylation maintenance

Miriam Recalde[1], María Gárate-Rascón[1], Maddalen Jimenez[1], María Elizalde[1], María Azkona[1], Marina Bárcena-Varela[1], Leticia Colyn[1], Maria U. Latasa[1], Iker Uriarte[1,2], Maite G. Fernandez-Barrena[1,2,3], Matías A. Avila[1,2,3], Maria Arechederra[1,3], Carmen Berasain[1,2,3]. [1]*Centre of Applied Medical Research (CIMA)-University of Navarra, Program of Hepatology, Pamplona, Spain;* [2]*CIBERehd, Instituto de Salud Carlos III, Madrid, Spain;* [3]*Instituto de Investigaciones Sanitarias de Navarra-IdiSNA, Pamplona, Spain*
Email: cberasain@unav.es

Background and Aims: We have recently demonstrated that the splicing regulator SLU7 is essential for the survival of transformed cells of different origin including human HCC cells. In addition, SLU7 is required for securing normal liver regeneration after partial hepatectomy. Common to both scenarios is the increased cell proliferation. Indeed, we have identified SLU7 as a key mediator of cell cycle progression and genome stability. DNA methyltransferase 1 (DNMT1) is responsible for the maintenance of DNA methylation during cell division. DNA methylation regulates tissue-specific gene transcription in collaboration with other epigenetic regulators, affecting numerous cellular processes. Moreover, recent advances demonstrate that DNA methylation can influence alternative splicing. Based on this background, we aim to study the crosstalk between the splicing factor SLU7 and DNA methylation.
Method: SLU7 and DNMT1 expression were knocked-down in a large panel of human cancer cell lines of different origin (HCC cell lines PLC/PRF/5 and HepG2, colorectal carcinoma cell line HCT-116 and non-small cell lung cancer cell line H358, among others) and their reciprocal expression was determined by both qPCR and Western blot analysis. Global DNA methylation, gene-specific promoter methylation and the mechanism involved in this crosstalk were determined by different approaches. Finally, studies were performed in wild-type and SLU7 knocked down mice.
Results: Knock-down of DNMT1 enhanced SLU7 expression. Strikingly, SLU7 knock-down led to reduced DNMT1 abundance in proliferating normal and cancer cells, but does not affects its gene transcription levels. This DNMT1 depletion in SLU7 silenced cells was associated with global DNA hypomethylation and the re-expression of methylation silenced genes. Mechanistically, co-immunoprecipitation assays revealed that SLU7 and DNMT1 directly interact. Importantly, we found that this regulation also occurred in vivo and that SLU7 was required for DNMT1 expression after partial hepatectomy.
Conclusion: Our results demonstrate an absolute SLU7 requirement for DNMT1 protein stability unraveling an unknown connection between a splicing factor and epigenetic regulation. Deciphering into the mechanisms that control cell proliferation may contribute to develop new therapeutic strategies.

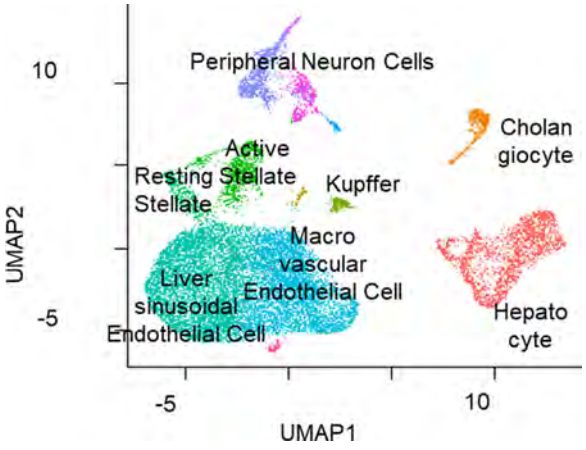
Email: sean.harrison@medisin.uio.no

Background and Aims: A major limitation of human pluripotent stem cell derived cell-based products is the inability to adequately recapitulate human development in a 2 dimensional (2D) in vitro context. The lack of physiologically relevant cell culture systems greatly hampers both the maturity and functional aspects of nearly all stem cell derived cell types. This is especially true for the hepatic lineage derived from human pluripotent stem cells. Recently, a number of groups have strove to move away from traditional 2D tissue culture paradigms to more physiologically relevant 3 dimensional (3D) systems. The formation of organoid based differentiation protocols have been reported for cell types representative of the three germ layers, including hepatic organoids. However currently available methods suffer from a number of drawbacks, including a high reliance on extracellular matrices (ECM), such as Matrigel, to support cystic organoid growth, and the use of costly growth factors both being a hurdle for scaling. Additionally, current 3D hepatic organoids are generally a single cell type, i.e. hepatocytes or cholangiocytes, thus rendering them less physiologically relevant as compared to native tissue.



Method: To address these shortcomings, we have translated our recently reported small molecule driven hepatocyte differentiation protocol from 2D to 3D. Importantly the present work requires no expensive infrastructure, is ECM independent and can be easily scaled to produce massive amounts of 3D "mini-liver" organoids.
Results: The organoids showed enhanced functional attributes when compared to 2D controls. Importantly, the organoids maintained key hepatic functions long term in culture as compared to their 2D counterparts. Single cell RNA sequencing (21,000 cells, figure 1), proteomics and extensive profiling via immunochemistry revealed the formation of liver organoids containing the major cell types of the native liver including parenchymal cells, hepatocytes and cholangiocytes, and non-parenchymal cell types including hepatic stellate cells, liver sinusoidal endothelial cells, vasculature structures, and kupffer cells.
Conclusion: This protocol serves as an inexpensive and simple method to produce massive quantities of liver like tissue with enhanced function and maturity a pre-requisite for a myriad of applications including cellular therapy, tissue engineering, pharmaceutical drug toxicity assessment, disease modelling, and basic developmental research.

NAFLD – Experimental

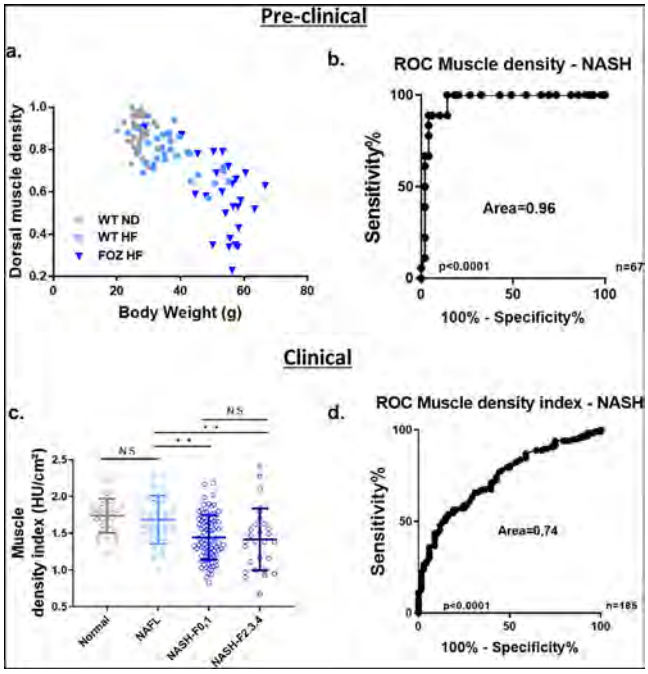
Email: isabelle.leclercq@uclouvain.be

Background and Aims: A substantial body of literature supports that a low muscle mass, low strength or a higher muscle fatty infiltration are associated with NAFLD presence and severity. Here, we investigated the muscle compartment in NAFLD models and a human cohort to evaluate muscle changes in correlation with liver disease progression.

Method: For over 34 weeks, we followed WT mice fed a standard chow as controls (Ctl), WT mice fed a high fat (HF) diet (60% fat) as a model of simple steatosis (WT HF) and foz/foz mice fed a HF diet as a model of progressive NASH (FOZ HF). We developed and validated a novel preclinical micro-Computed Tomography (micro-CT) based methodology to prospectively study skeletal muscle mass and fatty infiltration in muscle and liver in a high-throughput and non-invasive manner. We used CT to measure skeletal mass and fatty infiltration retrospectively in a large cohort of 197 morbidly obese patients with biopsy-based liver histology (62.4%, 19.7% and 17.2% had respectively NASH, NAFL and normal liver histology).

Results: In animals with NASH, muscle mass dissociated from body weight gain and relative decrease in muscle mass was associated with severe loss of muscle strength from 12 week on. Myosteatosis was the earliest muscular change as reflected by a significantly lower muscle density in FOZ HF as early as 4 week (0.79 ± 0.02) when compared to Ctl (0.91 ± 0.02). Myosteatosis severity was strongly correlated with NAS score ($r = -0.87$, $n = 67$, $p < 0.001$), irrespectively of the time point studied, and could not be explained by the higher body weight of foz/foz (Fig. 1a). Myosteatosis powerfully discriminated NASH from non NASH-NAFL or normal liver (AUROC = 0.96, $p < 0.001$) in this model (Fig. 1b). In a large population of 185 morbidly obese patients, CT-derived myosteatosis identified patients with biopsy proven NASH amongst those with uncomplicated steatosis and normal liver histology (Fig. 1-c,d), independently of possible confounding factors and outperforming classical biomarkers such as FIB4, NFS and CK18 (AUROC = 0.57, 0.52 and 0.55 respectively). Myosteatosis inclusion in a multivariate model returned an AUROC of 0.81 for NASH prediction ($p < 0.001$).



Conclusion: Taken together, our data support that myosteatosis, hepatocellular damage and inflammation develop synchronously with NASH onset, paving the way for the exploitation of myosteatosis as a non-invasive marker of NASH and suggesting a muscle-liver reciprocal cross-talk during liver disease progression.

AS134

Vitamin D3 up-regulated protein 1 attenuates non-alcoholic steatohepatitis by regulating AMPK/mTORC1/TFEB-mediated autophagy

Hyojung Kwon[1], Heeseon Park[1], Youngsuk Won[2]. *[1]Chungnam National University, Department of Veterinary Pathology, College of Veterinary Medicine, Daejeon, Korea, Rep. of South; [2]Korea Research Institute of Bioscience and Biotechnology, Laboratory Animal Resource Center, Chungbuk, Korea, Rep. of South*
Email: hyojung@cnu.ac.kr

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is caused by abnormal lipid metabolism and can progress to non-alcoholic steatohepatitis (NASH). Recent studies have demonstrated hepatic autophagy being impaired in NASH patients, but its underlying mechanisms remains unclear. Here, we investigated the role and regulatory mechanism of vitamin D3 up-regulated protein 1 (VDUP1), a key mediator of cellular stress responses, in the pathogenesis of NASH.

Method: Human liver biopsies from normal healthy donors and NASH patients were quantitatively evaluated by immunohistochemistry for VDUP1, LC3B, and p62/SQSTM1. A control diet or a methionine- and choline-deficient (MCD) diet was fed to wild-type (WT) and VDUP1 knockout (KO) mice to induce nutritional steatohepatitis for 4 weeks with or without rapamycin treatment (5 mg/kg/d). For *in vitro* experiment, isolated primary WT and VDUP1-KO hepatocytes were treated with AICAR (500 μM) for 6 hours and starved.

Results: Hepatic VDUP1 expression was dramatically up-regulated in NASH patients compared with healthy controls. VDUP1 expression was positively correlated with steatosis ($r = 0.6420$, $p = 0.0099$),

hepatocellular ballooning (r = 0.6624, p = 0.0071), lobular inflammation (r = 0.5160, p = 0.0492), and NAFLD activity score (NAS; r = 0.6894, p = 0.0045). The number of LC3B puncta, a well-known marker of autophagosomes, was significantly lower in NASH patients compared with normal controls, while the expression of p62/SQSTM1, a protein specifically degraded by autophagy, was increased. VDUP1 KO mice showed severe hepatic steatosis, inflammation, and fibrosis, accompanied by impaired autophagy compared to WT mice after MCD-diet feeding. VDUP1 directly interacted with phospho adenosine monophosphate-activated protein kinase (AMPK), leading to inactivation of mTOR complex 1 (mTORC1) and nuclear translocation of transcription factor EB (TFEB), which in turn promoted autophagy. AMPK activation with AICAR stimulated autophagy with mTORC1 inhibition and nuclear TFEB translocation in VDUP1-KO hepatocytes. Finally, inhibition of mTORC1 with rapamycin ameliorated MCD-diet induced steatosis, inflammation, and fibrosis with activation of TFEB and induced autophagy in VDUP1 KO mice.
Conclusion: This study suggests that up-regulation of hepatic VDUP1 serves as a protective mechanism that ameliorates NASH by promoting AMPK/mTORC1/TFEB-mediated autophagy. A possible therapeutic strategy for NASH may be to target VDUP1.

AS135

Inhibition of ? 24-dehydrocholesterol reductase ameliorates non-alcoholic steatohepatitis in mice

Hiroyuki Nakashima[1], Enchen Zhou[1], Patrick van der Zande[2], Zhuang Li[1], Evelyne Steenvoorden[3], Christoph Müller[4], Martin Giera[3], Bruno Guigas[2], Franz Bracher[4], Patrick Rensen[1], Yanan Wang[1]. *[1]Leiden University Medical Center, Department of Medicine, Division of Endocrinology, and Einthoven Laboratory for Experimental Vascular Medicine, Leiden, Netherlands; [2]Leiden University Medical Center, Department of Parasitology, Leiden, Netherlands; [3]Leiden University Medical Center, Center for Proteomics and Metabolomics, Leiden, Netherlands; [4]Ludwig-Maximilians-Universität München, Department of Pharmacy, Center for Drug Research, Munich, Germany*
Email: hiro1618@ndmc.ac.jp

Background and Aims: Δ24-Dehydrocholesterol reductase (DHCR24) is a crucial terminal enzyme in cholesterol biosynthesis converting the ultimate intermediate desmosterol into cholesterol. Desmosterol is an endogenous liver X receptor (LXR) ligand with anti-inflammatory properties and reduces cholesterol and fatty acid biosynthesis by suppressing signaling via sterol regulatory element binding protein 1c. We hypothesized that increasing desmosterol levels obtained via inhibiting DHCR24 reduces hepatic steatosis and inflammation, the two most important hallmarks of nonalcoholic steatohepatitis (NASH). Thus, by using the novel DHCR24 inhibitor SH42, characterized by high potency and selectivity, we aimed to investigate the therapeutic effects of DHCR24 inhibition on NASH development.
Method: *APOE*3-Leiden.CETP* mice, a well-established translational model for lipoprotein metabolism that develops diet-induced human-like NASH characteristics, were fed a high fat and cholesterol diet (HFCD) with or without simultaneous SH42 treatment. After 8 weeks, liver steatosis and inflammation were assessed. Lipidomics, lipid mediators and cholesterol biosynthesis analyses were carried out on plasma and liver.
Results: DHCR24 inhibition via SH42 treatment markedly increased plasma desmosterol levels (+5,600%), without influencing food intake nor affecting body weight and body composition during the whole time-frame of intervention. SH42 decreased plasma cholesterol esters (−24%) and fatty acid (−19%) levels whilst not affecting diacylglycerol (DAG) and triacylglycerol (TAG) levels. Notably, SH42 largely increased plasma 19,20-epoxydocosapentaenoic acid (19,20-EpDPA) levels (+210%), a well described and potent anti-inflammatory/pro-resolving lipid mediator. In the liver, SH42 reduced the neutral lipid content, namely DAG (−21%), TAG (−38%) and cholesteryl esters (−26%). Moreover, liver histological assessment showed that SH42 prevented HFCD-induced hepatic steatosis, inflammation, ballooning and crown-like structure formation. Flow cytometry analysis also showed that SH42 reduced the number of F4/80^{low} CD11b^{high} Ly6c^{high} infiltrating monocytes in the liver.
Conclusion: Inhibition of DHCR24 by SH42 increases plasma desmosterol, accompanied by reduction of hepatic steatosis, inflammation and damage. We anticipate that DHCR24 inhibition is a potential novel therapeutic strategy for the treatment of NASH by killing two birds with one stone, i.e. inflammation as well as hepatic fat accumulation.

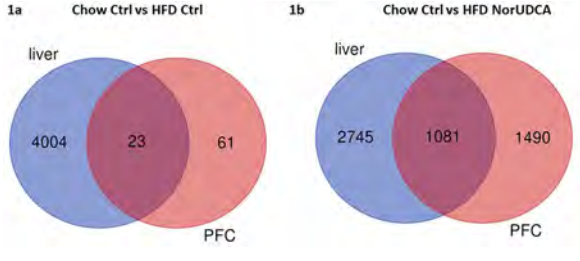
The bile acid derivative norursodeoxycholic acid affects fatty-liver associated anhedonia and anxiety in mice

Daniel Steinacher[1], Johannes Grießner[2], Claudia Fuchs[1], Lorenz Hinterleitner[1], Maximilian Baumgratner[1], Joanna Kaczanowska[2], Florian Grössl[2], Andreas Hess[3], Wulf Haubensak[2], Michael Trauner[1]. *[1]Medical University of Vienna, Wien, Austria; [2]Research Institute of Molecular Pathology (IMP), Wien, Austria; [3]Institute of Experimental and Clinical Pharmacology and Toxicology, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany*
Email: michael.trauner@meduniwien.ac.at

Background and Aims: Chronic liver diseases, such as non-alcoholic fatty liver disease, and metabolic conditions like obesity are associated with behavioral disorders like anxiety and depression, but the underlying pathophysiology is not well understood. We aimed to deepen the understanding of the interaction of high-fat diet induced liver disease and obesity with brain structures involved in emotion processing. To evaluate the potential of targeting a putative shared underlying disease mechanism, we tested the effect of chronic NorUrsodeoxycholic acid (NorUDCA) on anxiety and depression-like behavior in mice.
Method: Male C57BL/6J mice received either chow (A04, Safe Diets, France) or high-fat-diet (HFD, 36% fat from butter, HF260, Safe Diets, France) ±0.5% NorUDCA for 39 weeks. Starting at week 8, all groups were tested in standard behavioral assays while feeding continued. Functional magnetic resonance imaging (fMRI) of the brain was used in stressed and unstressed conditions with blood-oxigen-level-dependent (BOLD) imaging as a proxy for neuronal activity. We used liquid-chromatography based mass spectral analysis for the measurement of neurotransmitter and bile acid species. mRNA was extracted from livers and brains (n = 5 per group). A Tn5 enzyme based RNA-seq library prep was performed and underwent Ilumina seq. Genes were ranked by log2FC and a p-adjusted threshold of <0.05 was applied. Ingenuity Pathway Analysis (IPA, Quiagen) and PANTHER were used for further analysis.
Results: Chronic NorUDCA treatment in mice which received a high-fat diet reduced food consumption and body weight as well as anhedonia, fear and anxiety. Mass spectrometry showed that NorUDCA is present in the brain tissue of NorUDCA-treated mice, and that NorUDCA treatment also alters neurotransmitter makeup. Using transcriptome analysis, 23 differentially expressed (DE) genes were induced by HFD in both the liver and the prefrontal cortex (PFC) (Fig. 1a), and 1081 DE genes were induced in both the liver and PFC in the HFD NorUDCA group when compared to Chow Ctrl group (Fig. 1b).



Conclusion: This study shows for the first time an effect of a bile acid derivative on the brain to control HFD associated stress, anxiety and depression as well as ameliorating HFD induced- fatty liver disease in mice, deepening our understanding of the shared pathophysiology and treatment of these conditions.

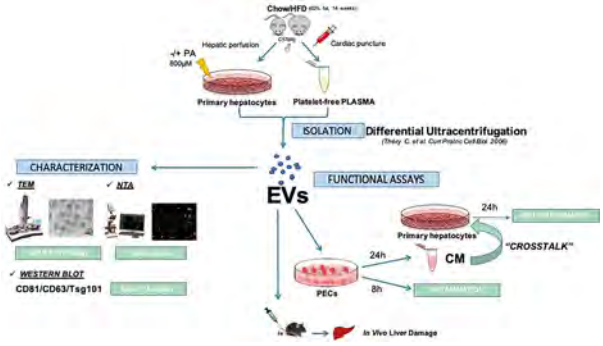
Effect of the hepatic extracellular vesicles in inflammation-associated insulin resistance in non-alcoholic fatty liver disease

Rosa Alén[1,2], Irma Garcia-Martinez[1,2], Manuel Izquierdo[1], Angela Martinez Valverde[1,2]. *[1]Instituto de Investigaciones Biomédicas Alberto Sols, CSIC-UAM, Madrid, Spain; [2]Centro de Investigación Biomédica En Red de Diabetes y Enfermedades Metabólicas (CIBERDEM), Madrid, Spain*
Email: avalverde@iib.uam.es

Background and Aims: Cell-to-cell communication by extracellular vesicles (EVs) is an emerging issue in non-alcoholic fatty liver disease (NAFLD). However, the EVs role in the interactome within liver cells remains uncertain. Thus, we aimed to analyze EVs secretion in hepatocytes under NAFLD conditions, their impact on macrophages inflammation and, ultimately, in hepatocytes insulin signaling.
Methods: C57Bl6j male mice were fed chow (control) or high-fat diet (HFD) for 14 weeks. Exosome-enriched fraction (Exos) was isolated by differential ultracentrifugation from: *1)* hepatocytes from chow-fed mice without (Exo^{Ch}) or with palmitic acid treatment (PA) (Exo^{PA}), *2)* hepatocytes from HFD-fed mice (Exo^{HFD}), *3)* plasma from chow- (Circ- Exo^{Ch}) or HFD-fed mice (Circ-Exo^{HFD}). Exos were characterized by Western-blot, Transmission Electron Microscopy and Nanoparticle Tracking Analysis. Mouse peritoneal macrophages (PECs) were stimulated for 8 hours with different Exos fractions and inflammatory responses were assessed by RT-qPCR and immunofluorescence. PKH67-stained Exos were added to PECs to monitor their internalization. Hepatocytes were incubated for 24 hours with conditioned medium (CM) from Exos-treated PECs to examine insulin signaling. C57Bl6j mice were injected intravenously with hepatocyte-derived Exos to analyze *in vivo* effects (**graphical abstract on Figure**).



Results: The release of Exo^{PA}, Exo^{HFD} and Circ-Exo^{HFD} was increased compared to Exo^{Ch} and Circ-Exo^{Ch}. Exos were internalized by PECs through the endosomal pathway and both Exo^{PA} and Exo^{HFD} triggered proinflammatory responses such as nuclear NF-kappaB translocation and elevations in Il6 and Il1beta mRNAs. Moreover, insulin resistance was induced in hepatocytes incubated with CM from PECs that received Exo^{PA}, Exo^{HFD} and Circ-Exo^{HFD}. Livers from mice injected with Exo^{PA} and $Exo^{HFD,}$ but not Exo^{Ch}, showed increased stress kinases signaling and NF-kappaB nuclear translocation at 1 h post-injection. Furthermore, hepatocyte insulin resistance was found when mice were treated for 24 hours with Exo^{PA} and $Exo^{HF}D$.
Conclusion: Our results identified a novel molecular mechanism in the interactome hepatocyte-macrophage-hepatocyte where both Exos from hepatocytes under NAFLD conditions and from plasma from HFD-fed mice induced insulin resistance through macrophages inflammatory responses. The study of the cargo from hepatocyte-derived Exos could provide new mechanistic insights on this interactome during NAFLD.

AS138

Alterations in bile acids and TGR5 activation in non-alcoholic steatohepatitis

Justine Gillard[1], Anne Tailleux[2], Laure-Alix Clerbaux[3], Bart Staels[2], Yves Horsmans[4], Laure Bindels[5], Isabelle Leclercq[1]. *[1]UCLouvain, Laboratory of Hepato-Gastroenterology, Brussels, Belgium; [2]University of Lille, Inserm, CHU Lille, Institut Pasteur de Lille, U1011, Lille, France; [3]University (Hospital) of Zurich, Institute of Molecular Cancer Research and Department of Molecular Pathology, Zurich, Switzerland; [4]Cliniques Universitaires Saint-Luc, Gastroenterology Unit, Brussels, Belgium; [5]UCLouvain, Metabolism and Nutrition Research Group, Brussels, Belgium*
Email: isabelle.leclercq@uclouvain.be

Background and Aims: Bile acids (BA) modulate lipid and glucose homeostasis, energy expenditure, inflammatory tone and fibrosis through Farnesoid X receptor (FXR) and G-protein-coupled receptor (TGR5) signaling. Altered BA sensing and signaling might thus contribute to NASH pathogenesis. In humans, BA analysis is restricted to systemic blood and feces and reflects BA that escaped hepatic uptake and intestinal reabsorption, respectively, and thereby does not reflect the enterohepatic BA pool. Studying BA in mice enables the assessment of BA profile in bile and portal blood. Here, we aimed to determine BA profile in a mouse model of NASH.
Method: We studied foz/foz mice (FOZ) and WT mice fed a HFD for 12 weeks as a model of NASH (NAS $\geq$ 6) and of simple steatosis (NAS $\leq$1), respectively. Portal blood, bile, feces and tissues were sampled after 12 h fasting and 4 h refeeding. BA profiling was established by LC-MS/MS. To test TGR5 activation, HEK293 T cells overexpressing TGR5 and a CRE luciferase reporter were exposed to portal plasma of FOZ and WT mice. Bile flow was assessed by cannulation of the gallbladder.
Results: Total BA concentration in bile was similar in both groups but the proportion of primary BA was higher and that of secondary BA was lower in FOZ (83%/17%) than in WT mice (62%/38%) (Figure, left). As supported by equal bile flow and BA concentration, the amount of BA secreted by the liver is similar in FOZ and WT mice. Increased expression of Cyp7a1 and Cyp8b1 in FOZ mice supports increased primary BA synthesis through the main classical pathway. Total BA concentration as well as the absolute and the relative concentration of secondary BA was lower in the portal blood of FOZ than in WT mice (Figure, right). This could be explained by a defective transformation of primary to secondary BA by the gut microbiota or by reduced intestinal BA reabsorption. However, similar fecal BA amount does not support the later hypothesis. Overall, altered BA profile in FOZ corresponded to low TGR5 agonist species in portal blood and in accordance, in a TGR5 reporter assay, the plasma of FOZ mice was 3.4-fold less effective in activating TGR5 than the plasma of WT mice.

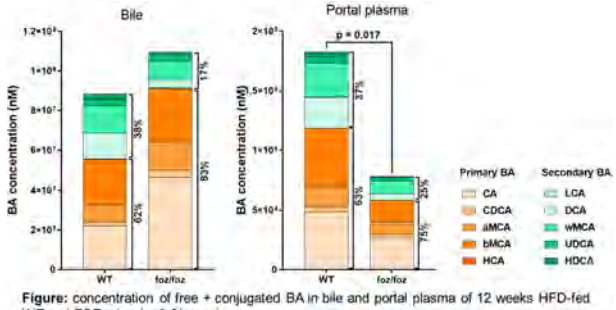


Figure: concentration of free + conjugated BA in bile and portal plasma of 12 weeks HFD-fed WT and FOZ mice (n=6-8/group).

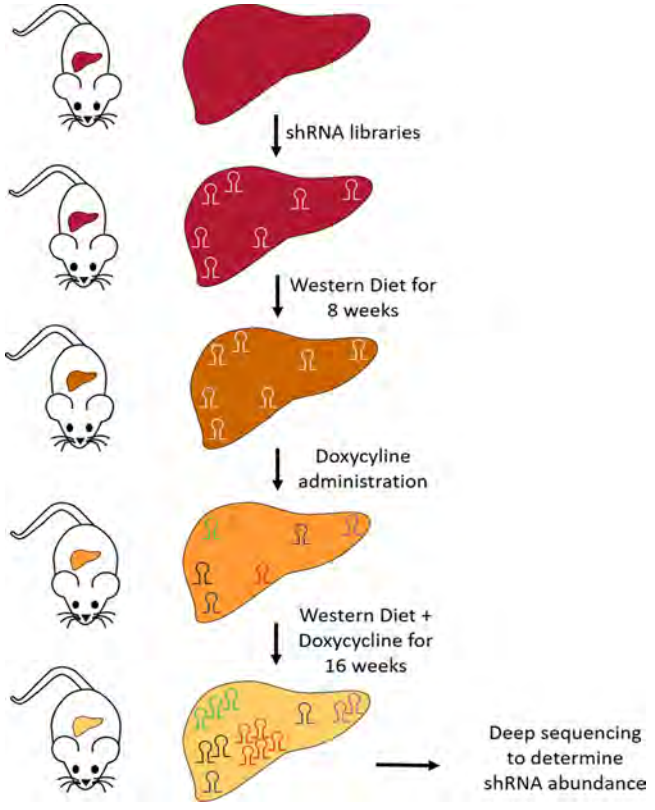
Conclusion: Deep alteration in BA pool, likely due to reduced transformation of primary to secondary BA by the gut microbiota, results in reduction of TGR5 ligands in the portal blood that could contribute to NASH pathogenesis in this experimental model.

SAT031

Genome-wide in vivo functional genetic screen to identify novel modulators of non-alcoholic fatty liver disease

Puja Khanna[1], Rong Gao[1], Viktoriia Iakovleva[1], Agnes Bee Leng Ong[1], Torsten Wuestefeld[1]. [1]*Genome Institute of Singapore, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore*
Email: wustefeldt@gis.a-star.edu.sg

Background and Aims: With a global prevalence of 25.2%, Non-Alcoholic Fatty Liver Disease (NAFLD) is the leading cause of chronic liver disease requiring transplantation worldwide. Despite this, NAFLD continues to be an underdiagnosed disease with no current approved treatment. This is primarily due to lack of understanding of the mechanisms underlying disease development and progression. To address this, we performed a genome-wide *in vivo* functional genetic screen to identify novel regulators of NAFLD. Our study aims to be the first-of-its kind to unravel the molecular basis of NAFLD with the hope of developing innovative therapeutics to address the imminent healthcare burden of this dreaded disease.



Method: RNA interference technology has transformed loss-of-function genetics. We adopted this technology to carry out a functional genetic screen to identify novel gene targets in NAFLD. shERWOOD-UltramiR shRNA library targeting the whole mouse genome was shuttled into the pT-T3GEPIR transposon-based plasmids to develop an inducible system. Hydrodynamic injection was used to stably deliver these along with sleeping beauty transposase to the hepatocytes of C57Bl6J mice. To recapitulate the fatty liver phenotype, mice were fed "Western Diet" supplemented with high fructose. Following 8 weeks of treatment, the first signs of fatty liver were observed and doxycycline was added to induce expression of the shRNA libraries. These mice were fed for another 16 weeks during which they mimicked slow disease progression similar to what is seen in humans, with patterns of obesity, steatosis, inflammation and fibrosis. The underlying idea of the screen is that shRNAs that give the hepatocyte an advantage in the detrimental environment, will increase in abundance over time. In contrast, if the knockdown is a disadvantage for the hepatocyte, the shRNA will deplete over time. If a shRNA has no influence, its abundance should not change in the pool. Illumina-based deep sequencing was used to determine the abundance of the shRNAs. Since this system includes several variables, only shRNAs that are reliably enriched or depleted (95% confidence interval with a 4-fold change) will be selected for further validation. Additionally, our results will be compared with clinical data from human NAFLD patient tissues as well as patient-derived organoids to ensure translation of our findings in human disease.

Results: Our preliminary results have identified several novel shRNAs that were enriched or depleted during the progression of NAFLD thereby conferring a negative or positive effect on the regenerative capacity of hepatocytes.

Conclusion: A genome-scale screen in a disease like NAFLD where there is limited understanding of the underlying molecular mechanism guarantees the uncovering of new insights that will prove useful in the development of novel therapeutics.

Liver fibrosis

Blocking MAIT cell activation accelerates liver fibrosis regression

Morgane Mabire[1], Hegde Pushpa[1], Manon Allaire[1,2], Al Sayegh Rola[1], JingHong Wan[1], Emmanuel Weiss[1,3], Richard Moreau[1], Hélène Gilgenkrantz[1], De La Grange Pierre[4], Sophie Lotersztajn[1]. [1]*INSERM CRI U1149, Faculté de Médecine Xavier Bichat, Paris, France;* [2]*AP-HP, Groupe Hospitalier Pitié-Salpêtrière - Charles Foix, Service d'hépatologie-gastroentérologie, PARIS, France;* [3]*AP-HP, Hôpital Beaujon, Service d'Anesthésie et Réanimation, Clichy, France;* [4]*GenoSplice, Hôpital La Pitié-Salpêtrière, Paris, France*
Email: morgane.mabire@inserm.fr

Background and Aims: Mucosal-Associated Invariant T (MAIT) cells are non-conventional T cells that are restricted by the non-classical MHC-1b molecule MR1 and display altered functions during chronic liver diseases. We have demonstrated the pro-inflammatory and profibrogenic properties of MAIT cells in the liver. Here, we investigated whether targeting MAIT cells to block their activation may impact on fibrosis regression and the mechanisms involved.

Method: Liver fibrosis was induced by repeated injection of carbon tetrachloride (CCl_4) in (i) C57BL6/J WT mice, (ii) MAIT cell-enriched *Mr1+* RORγt-Gfp^{TG}B6-MAIT^{CAST} (CastMr1^{+}) and (iii) MAIT cell-deficient *Mr1*-deficient B6-MAIT^{CAST} (Mr1$^{-/-}$) mice. For fibrosis regression, CCl_4 injections were discontinued and mice were daily administered with either Acetyl-6-formylpterin (Ac-6-FP), an inhibitor of MAIT cell activation or an anti-MR1 blocking antibody for 4 days. Frequency and phenotype of hepatic MAIT cells were analyzed by multi-color flow cytometry, defined as MR1:5-OP-RU tetramer-positive (MR1tet^{+}) cells. Pro-inflammatory (Ly-6C^{high}) and restorative (Ly-6C^{low}) macrophages were sorted from CCl_4-exposed mice treated with Ac-6-FP after the last injection of CCl_4, and their signature analyzed by RNA sequencing.

Results: Liver fibrosis was exacerbated in CastMr1^{+} as compared to Mr1$^{-/-}$ counterparts, and fibrosis remained elevated 4 days after the last CCl_4 injection. Compared to vehicle-treated animals, CCl_4-exposed CastMr1^{+} mice daily injected with Ac-6-FP showed accelerated fibrosis regression, as reflected by lower sirius red and α-SMA staining areas 4 day after the last CCl_4 injection. Similar findings were obtained when injecting an anti-MR1 antibody. Interestingly, acceleration of fibrosis regression by Ac-6-FP was no longer observed when macrophages were depleted using clodronate liposome. Flow cytometry analysis of hepatic leukocytes showed that Ac-6-FP promoted a decrease in Ly-6C^{high} and an increase in Ly-6C^{low} macrophage frequency. Furthermore, RNA sequencing analysis of

macrophage signature showed differential metabolic reprogramming of Ly-6C^{high} and Ly-6C^{low} by Ac-6-FP.
Conclusion: Blocking MAIT cell activation accelerates liver fibrosis regression, demonstrating that targeting MAIT cells may offer new perspectives for antifibrogenic therapy.

Clinical and Biological Sciences, Italy; [5]Senigallia Hospital, Department of Gastroenterology, Italy
Email: gsvegliati@gmail.com

Background and Aims: Liver fibrosis is the result of the wound healing response during chronic liver injury. HDL cholesterol (HDL) possesses anti-inflammatory and anti-oxidant effects in atherosclerotic plaque macrophages but its role in hepatic fibrosis is unknown. HDL metabolism is regulated by LXR but its hepatic activation is hampered by major side effects such as hepatic steatosis. Thus, aim of the present study was to evaluate whether selective intestinal activation of LXR could increase HDL levels and reduce hepatic fibrosis without the side effects on hepatic activation.
Method: Mice with intestinal constitutive LXRα activation (iVP16-LXRα) were exposed to intraperitoneal injection of carbon tetrachloride (CCl4) for 8 weeks.
Results: Compared to control iVP16 mice (iVP16), iVP16-LXRα showed reduced hepatic macrophage infiltration and a shift toward a M2 phenotype determined by arginine-1 (ARG1) expression and of the number of M2 macrophages co-stained with CD68 (pan-macrophage marker) and CD206 (M2 marker). In the liver of iVP16-LXRα, reduced gene expression of NF-kB was observed together with decreased p65 subunit immunostaining associated with lower expression of NF-kB downstream pro-inflammatory genes (TNFα, IL1β, IL6). Furthermore, gut LXRα activation decreased hepatic oxidative stress (by malonildialdehyde quantification and expression of the superoxide-generating NOX1 and 2) and increased mRNA levels of the defensive mechanism toward oxidative stress heme oxygenase-1 (HO-1). Decreased hepatic inflammation and oxidative stress lead to reduced fibrosis (by morphometry for Sirius Red and α-smooth muscle actin, and by hydroxyproline quantification), and fibrogenesis (by TGFβ and TIMP1 gene expression). Intestinal LXRα activation increased HDL synthesis in the gut, shown by gene expression of intestinal ATP-binding cassette transporter 1 (ABCA1), associated with higher levels of circulating HDL and of its hepatic receptor SIRB1. Correspondingly, in LPS-stimulated Kupffer cells (KC), HDL blocked the shift to M1 phenotype by ARG1 expression and decreased pro-inflammatory gene expression (TNFα, IL1β, IL6) by blocking LPS-induced NF-kB nuclear translocation. We thus hypothesized that activated macrophages could signal hepatocytes via TNFα. In fact, in TNFα–incubated hepatocytes, HDL again blocked NF-kB nuclear translocation together with expression of NOX1, IL1β, and IL6 expression while increasing HO-1 mRNA levels. These effects were not associated with hepatic steatosis development in vivo as shown by decreased hepatic SREBP1-c expression and triglyceride levels in iVP16-LXRα compared to iVP16.
Conclusion: Selective intestinal LXRα activation might represent a new target for the treatment of hepatic fibrosis, by increasing HDL circulating levels without the occurrence of the side effects related to hepatic LXR induction.

AS141
Toll-like receptor 4 signaling in bone marrow-derived macrophage promotes resolution of carbon tetrachloride-induced murine liver fibrosis
Yoichi Takimoto[1], Po-sung Chu[1], Nobuhiro Nakamoto[1], Takanori Kanai[1]. *[1]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*
Email: yoichi_tak2005@yahoo.co.jp

Background and Aims: Liver cirrhosis is the result of favoured fibrogenesis over ineffective fibrosis resolution. The pro-fibrotic roles of macrophage and its crosstalk between hepatic stellate cells through pattern-recognition receptors during the inflammatory phase of liver fibrosis have been extensively studied, however, these processes are relatively unclear during fibrosis resolution. By focusing on the gut-liver axis, we aimed to clarify the possible role of toll-like receptor 4 (TLR4) signaling pathway in macrophages during fibrosis resolution.
Method: Age-matched wild-type (WT) B6 mice were intraperitoneously injected repetitively with carbon tetrachloride (CCl_4, 0.6 ml/g) for 4 weeks to induce liver fibrosis. After the last injection, mice were observed or manipulated at specific time points until 7 days, known as the spontaneous fibrosis resolution phase of this model. Levels of liver fibrosis were evaluated by histology and protein contents. Hepatic and bone marrow mononuclear cells, total in vivo matrix metalloproteinase (MMP) activity were studied by flow cytometry. During the fibrosis resolution phase, multiple antibiotics per os for gut sterilization, TAK-242 iv for selective inhibition of intracellular signaling of TLR4, and bone-marrow transplantation (BMT) of TLR4-knockout mice were also used. In vitro phagocytosis assay was used to study the matrix-degrading phenotype of macrophages.
Results: During the fibrosis resolution phase, the whole liver demonstrated significantly elevated expression of TLR4, but not TLR2, TLR6 or TLR9. Total in vivo MMP activity study revealed that CD11b-posiive macrophages were the principal producer of MMPs. TAK-242 administration significantly retarded fibrosis regression histologically, and depressed whole liver MMP12 expression ($p < 0.01$). Gut sterilization during the fibrosis resolution phase also significantly demonstrated the same phenotype as TLR4-inhibition by TAK-242, which implicated gut-liver axis might play a possible pro-fibrolytic role through TLR4 signaling. In the BMT experiments, TAK-242 administration significantly retarded fibrosis regression in TLR4- knockout mice with WT-BM transplanted ($p < 0.05$), but not in WT mice with TLR4-/- BM transplanted, which implicated TLR4 signaling in the BM-derived cells, but not in hepatic parenchymal cells, is crucial for fibrosis resolution. In the in vitro phagocytosis assay, the matrix degrading phenotypes of BM-derived macrophages, including down-expression of Ly6C and MMP12 expression, were both significantly depressed by in vitro TAK-242 administration ($p < 0.05$).
Conclusion: In CCl_4-induced murine liver fibrosis, TLR4 signaling in bone marrow-derived macrophages promotes fibrosis resolution through MMP12 production. TLR4 signaling in macrophages may be a potential therapeutic target for accelerating liver fibrolysis.

Email: anna.moles.fernandez@gmail.com

Background and Aims: Changes in proteolytic activity are essential to liver fibrosis development. Proteases control not only matrix turnover but also, the activation and repression of growth factors and

chemokines influencing disease progression. Beyond metalloproteases, our knowledge of the proteolytic enzymes contributing to liver fibrosis is limited. The importance of lysosomal protease cathepsin D (CtsD) in kidney fibrosis has been recently demonstrated but its role in liver fibrosis remains elusive. Thus, the aim of this study was to analyse CtsD cells-specific role during liver fibrosis.

Method: To study the cell-specific role of CtsD we generated two novel knock-out mouse strains by breeding LysMCre (macrophages) or AlbuminCre (hepatocytes) mice with CtsD floxed mice. CtsD cell-specific deletion was confirmed in primary isolated hepatocytes and peritoneal macrophages by PCR and WB. Fibrosis was established chronically by CCl_4 (0.5 µl/g) in $CtsD^{AlbCre+/+}$ and $CtsD^{AlbCre-/-}$ or $CtsD^{LysMCre+/+}$ and $CtsD^{LysMCre-/-}$. Liver damage was determined by serum ALT and H&E staining. Fibrotic and inflammatory genes were determined by real-time-PCR in total liver. CtsB, CtsD and α-SMA were determined by immunohistochemistry or WB.

Results: First we determined CtsD expression in WT after chronic CCl_4 challenge, demonstrating CtsD presence in hepatocytes and macrophages. CtsD cell-specific deletion was validated by protein expression (WB) and floxed allele recombination (PCR), using primary mouse hepatocytes and peritoneal macrophages from $CtsD^{AlbCre+/+}$ and $CtsD^{LysMCre+/+}$ respectively and in comparison, with their floxed counterparts. To note, cathepsin B expression remained unaffected in hepatocytes or macrophages from $CtsD^{AlbCre+/+}$ or $CtsD^{LysMCre+/+}$ respectively. Neither CtsD deletion in macrophages nor in hepatocytes affected liver damage after chronic CCl_4 administration. CtsD cell-specific deletion in macrophages, but not in hepatocytes, increased liver fibrosis as shown by an increase in Sirius red staining, alpha-SMA protein expression and increased hepatic alpha-SMA, TGF-beta and Col1A1 mRNA. Furthermore, inflammation was affected only in macrophage-CtsD deficient mice showing significant increase in CCL2, CCL3 and CCL4. Finally, lack of CtsD in macrophages during liver fibrosis resulted in an upregulation of MMPs, such as MMP7 and MMP13.

Conclusion: Specific deletion of CtsD in macrophages, but no in hepatocytes, triggers upregulation of inflammation and matrix remodeling, leading to an amplification of the fibrotic response.

Background and Aims: Advanced liver fibrosis is a major risk factor for hepatocellular carcinoma (HCC). There are no approved anti-fibrotic therapies and compounds in clinical development only have shown unsatisfactory clinical efficacy. Applying a human cell-based model system for liver disease therapeutics discovery using a clinical prognostic liver signature as a read-out (cPLS system), we identified nizatidine, a histamine receptor H2 (HRH2) blocker, as a candidate compound for treatment of liver fibrosis and HCC chemoprevention.

Method: To decipher nizatidine's mechanism of action, we performed perturbation studies using the cPLS system followed by validation in two NASH-HCC animal models and patient-derived tissues. Using our recently developed single cell RNA-Seq (scRNA-Seq) pipeline (Aizarani et al. Nature 2019), we combined scRNA-Seq analyses of patient liver tissues with perturbation studies to uncover the liver cells targeted by nizatidine.

Results: Nizatidine markedly and significantly reduced liver fibrosis, inflammation and hepatocarcinogenesis in two complementary mouse and rat models for NASH-HCC, as shown by a decrease of the collagen proportionate area (CPA), α smooth muscle actin (αSMA) staining, quantitative analysis of hydroxyproline and expression of genes mediating fibrogenesis. Mechanistic studies uncovered the HRH2/cAMP/CREB pathway as a pan-etiology driver for progression of fibrotic liver disease and hepatocarcinogenesis. Single cell RNA-Seq of human liver tissue treated with nizatidine identified pro-inflammatory $HRH2^{+}$/$CLEC5A^{high}$/$MARCO^{low}$ liver macrophages as a nizatidine target. Gene-level analyses in patient liver-derived macrophages revealed that nizatidine decreases expression of chemoattractant and pro-inflammatory cytokines, corresponding to a decrease of neutrophil/monocyte infiltration and of liver inflammation observed in the NASH-HCC mouse model. Restoration of the expression of patient liver macrophage antigen presentation-related pathways combined with an increase of $CD8^{+}$ T cell recruitment in liver of nizatidine-treated animals suggest improvement of anti-cancer surveillance.

Conclusion: By improving liver fibrosis, inflammation and anti-cancer surveillance, HRH2 targeting compounds provide a therapeutic candidate approach for patients with advanced fibrosis at risk for HCC and will guide future optimization of refined HRH2-targeting liver disease therapies.

AS144

PLN-74809, a clinical-stage, dual alphaVbeta6/alphaVbeta1 integrin inhibitor, reduces fibrosis in a preclinical model of biliary fibrosis and precision-cut liver slices from primary sclerosing cholangitis and primary biliary cholangitis patients

Johanna Schaub[1], Chun Chen[1], Martin Decaris[1], Steve Ho[1], Gail Lee[1], Vikram Rao[1], Megan Marlow[1], Shamra Martin[1], Tony Chen[1], Jianfeng Wu[1], Christina Dooka[1], Jake Cha[1], Manuel Munoz[1], Katerina Leftheris[1], Eduard Gorina[1], Eric Lefebvre[1], Scott Turner[1]. *[1]Pliant Therapeutics, South San Francisco, United States*
Email: jschaub@pliantrx.com

Background and Aims: Integrins $\alpha_V\beta_6$ and $\alpha_V\beta_1$ are heterodimeric cell-surface proteins that bind to and activate latent transforming growth factor (TGF)-β, a key driver of fibrosis. In primary sclerosing cholangitis (PSC) and primary biliary cholangitis (PBC), integrins $\alpha_V\beta_6$ and $\alpha_V\beta_1$ are thought to play a role in the development and propagation of fibrosis through the activation of TGF-β by cholangiocytes and stellate cells, respectively. PLN-74809 is an investigational, oral, dual-selective inhibitor of $\alpha_V\beta_6$ and $\alpha_V\beta_1$ that is currently in clinical studies. The study aims were 1) to test the ability of PLN-74809 and PLN-75068, a related dual-selective inhibitor, to block biliary fibrosis through inhibition of integrin-mediated TGF-β activation and 2) to evaluate safety and pharmacokinetics of PLN-74809 in healthy volunteers.
Method: Immunohistochemistry (IHC) and enzyme-linked immunosorbent (ELISA)-based assays were used to evaluate expression of $\alpha_V\beta_6$ and $\alpha_V\beta_1$ in human tissue samples from PSC and PBC patients. Anti-fibrotic properties of PLN-74809 or PLN-75068 were evaluated *in vivo* in two mouse models of biliary fibrosis (Mdr2$^{-/-}$ and DDC diet) and in precision-cut liver tissue slices (PCLivS) from PSC and PBC patient tissue explants by IHC, hydroxyproline quantitation, and/or gene expression analysis. Phase 1 studies were conducted in healthy volunteers to evaluate safety and pharmacokinetics of PLN-74809.
Results: Integrins $\alpha_V\beta_6$ and $\alpha_V\beta_1$ were significantly elevated in fibrotic Mdr2$^{-/-}$ mice and DDC-fed mice, and in PSC and PBC patient liver tissue. PLN-74809 and PLN-75068 reduced both relative hepatic collagen levels and serum alkaline phosphatase levels in Mdr2$^{-/-}$ mice and DDC-fed mice, respectively. PLN-74809 reduced hepatic TGF-β signaling in Mdr2$^{-/-}$ mice and PLN-75068 reduced myofibroblasts in DDC-fed mice. PLN-74809 significantly reduced collagen gene expression in PCLivS from PSC and PBC patient tissue explants. Phase 1 studies of PLN-74809 demonstrated good oral bioavailability and tolerability, with the half-life supportive of once-daily dosing.
Conclusion: Dual inhibition of $\alpha_V\beta_6$ and $\alpha_V\beta_1$ with PLN-74809 or PLN-75068 reduced fibrosis in preclinical models of biliary fibrosis and in PCLivS from PSC and PBC patient tissue explants. Phase 2 evaluation of PLN-74809 in idiopathic pulmonary fibrosis and PSC patients is being planned.

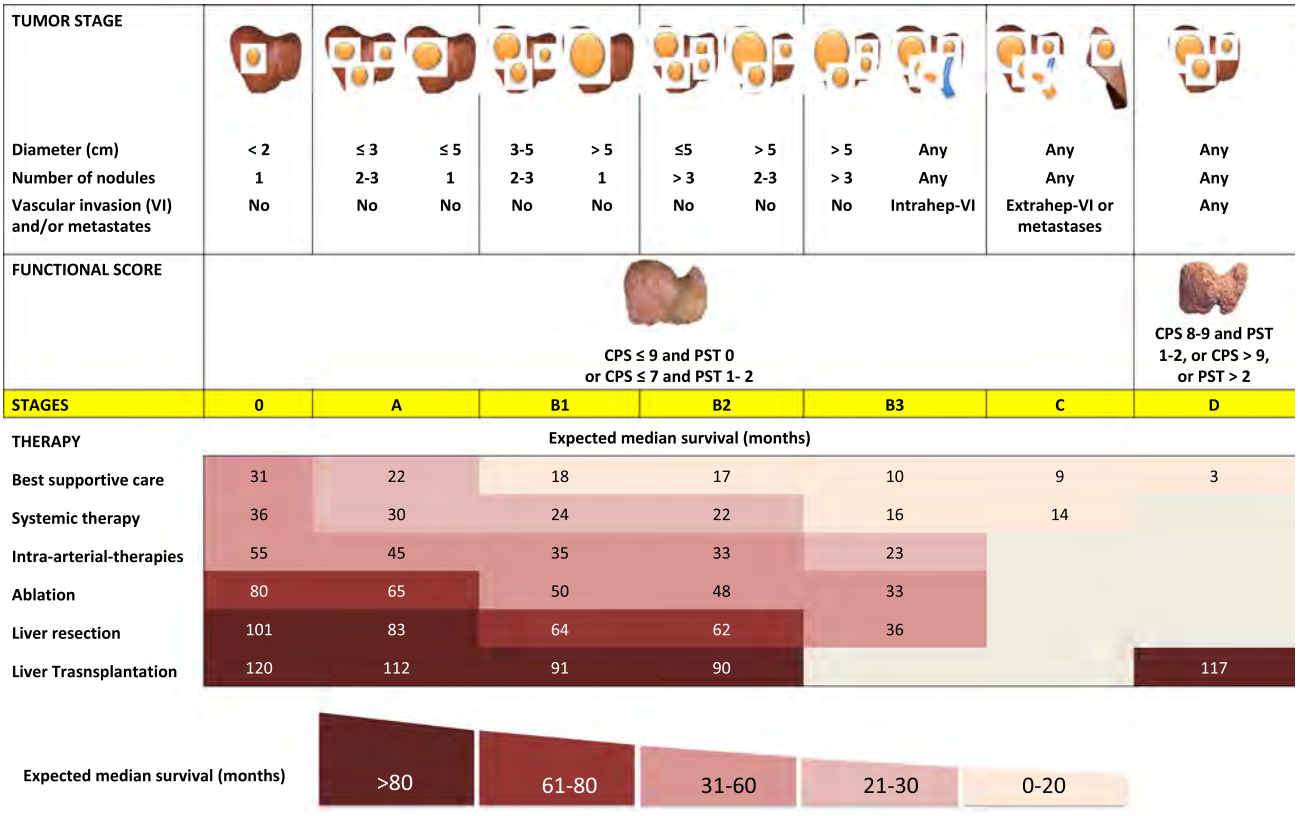
The concept of time-varying therapeutic hierarchy for patients with hepatocellular carcinoma: a multicenter cohort study. On behalf of the ITA.LI.CA study group

Alessandro Vitale[1], Fabio Farinati[1], Franco Trevisani[2], Umberto Cillo[1].
[1]*Padua University Hospital, Italy;* [2]*Alma Mater Studiorum – University of Bologna*
Email: alessandro.vitale@unipd.it

Background and Aims: While prognostic studies usually focus only on the first (or the main) treatment, the oncological history of patients with hepatocellular carcinoma (HCC) is characterized by a sequence of different treatment approaches. We sought to evaluate the survival benefit of sequential HCC therapies using a time varying multivariable survival model applied to a large cohort of HCC patients.

Method: We considered 6191 treatment strategies performed in 2800 HCC patients recorded in a prospectively collected multicenter Italian database from 2008 trough 2016.

We carried out a time-varying (TV) survival analysis where the total follow-up time for each patient was split into several observations accounting for each treatment procedure where appropriate. Before each treatment decision, patients were completely re-staged so that



Abbreviations. CPS, Child Pugh score; PST, performance status; VI, vascular invasion; Intrahep, intra-hepatic; Extrahep, extra-hepatic.

Figure 1: (abstract: AS145): The concept of "therapeutic hierarchy" is reported in association with the ITA.LI.CA simplified staging for treatment allocation derived from the last ITA.LI.CA study.
According to this approach, treatment choice is partially independent from the disease stage. In fact, for stages 0 to B2, all therapeutic solutions are available in a hierarchical order (from LT to BSC); for stage B3 only LT is contraindicated due to an unacceptable risk of HCC recurrence; for stage C, only systemic therapy and BSC are suggested; for stage D, LT and BSC are the only possible therapies.

ELSEVIER

all re-assessed variables (i.e. liver function, tumor characteristics, therapy) were studied as TV parameters. A TV multivariable survival model was then used to evaluate the survival benefit of each treatment strategy (liver transplantation = LT, liver resection = RES, ablation = ABL, intra-arterial therapy = IAT, Sorafenib = SOR) over best supportive care (BSC). The survival benefit of HCC treatment was described as hazard ratio (HR), 95% confidence interval (CI), using BSC as reference value.

Results: The 6191 treatment strategies were: LT = 155, RES = 589; ABL 1728; IAT = 2184; SOR = 708; BSC = 827.

In the TV multivariable survival model, treatment strategy showed an independent effect on survival. The TV survival benefit of different therapies over BSC was: LT = 0.29 (0.24–0.36); RES = 0.30 (0.25–0.36); ABL 0.38 (0.33–0.43); IAT = 0.51 (0.45–0.57); SOR = 0.78 (0.67–0.90). Other significant variables in the multivariable survival model resulted: female gender, lnAFP (TV variable), and Italian Liver Cancer (ITA.LI.CA) stage (TV variable).

Conclusion: We demonstrated a decreasing TV survival benefit from surgical to systemic therapies in a large Italian cohort of HCC patients. This TV therapeutic hierarchy was independent from patient, liver function, and tumor characteristics.

A novel tailored prognosis calculator for the individualized curative treatments allocation of HCC patients within the Mmilan criteria

Ningning Zhang[1,2], Wentao Jiang[3], Yamin Zhang[1], Tianqiang Song[2], Jiayu Lv[4], Jie Gu[4], Ying Wu[5], Jing Qian[6], Dazhi Tian[3], Qingjun Guo[3], Li Zhang[3], Jisan Sun[3], Yan Xie[3], Zhenglu Wang[3], Xin Sun[3], Zhongfang Yan[6], Yonghe Zhou[6], Yongjian Liu[6], Yibo Qiu[4], Bing Yang[4], Zhongyang Shen[3], Wei Lu[2,3]. *[1]Tianjin First Central Hospital, Hepatobiliary Surgery, Tianjin, China; [2]Tianjin Medical University Cancer Institute and Hospital, Liver Cancer Center, Tianjin, China; [3]Tianjin First Central Hospital, Liver Transplantation, Tianjin, China; [4]Tianjin Medical University, The First Central Clinical College, Tianjin, China; [5]Nankai University, School of Statistics and Data Science, Tianjin, China; [6]Tianjin Second People's Hospital, Interventional Radiology, Tianjin, China*

Email: mail4luwei@163.com

Background and Aims: Controversies always exist during multidisciplinary treatment (MDT) decision making for hepatocellular carcinoma (HCC) within the Milan criteria (MC) due to the lack of evidence-based studies of composite multi-parametric evaluations among three potential curative therapies: liver transplantation (LT), liver resection (LR) and local ablation (LA). However, the prognosis prediction algorithm for HCC within the MC has never been explored. We aimed to develop a prognosis calculator for the individualized curative treatments allocation and assist with MDT decision making for these patients.

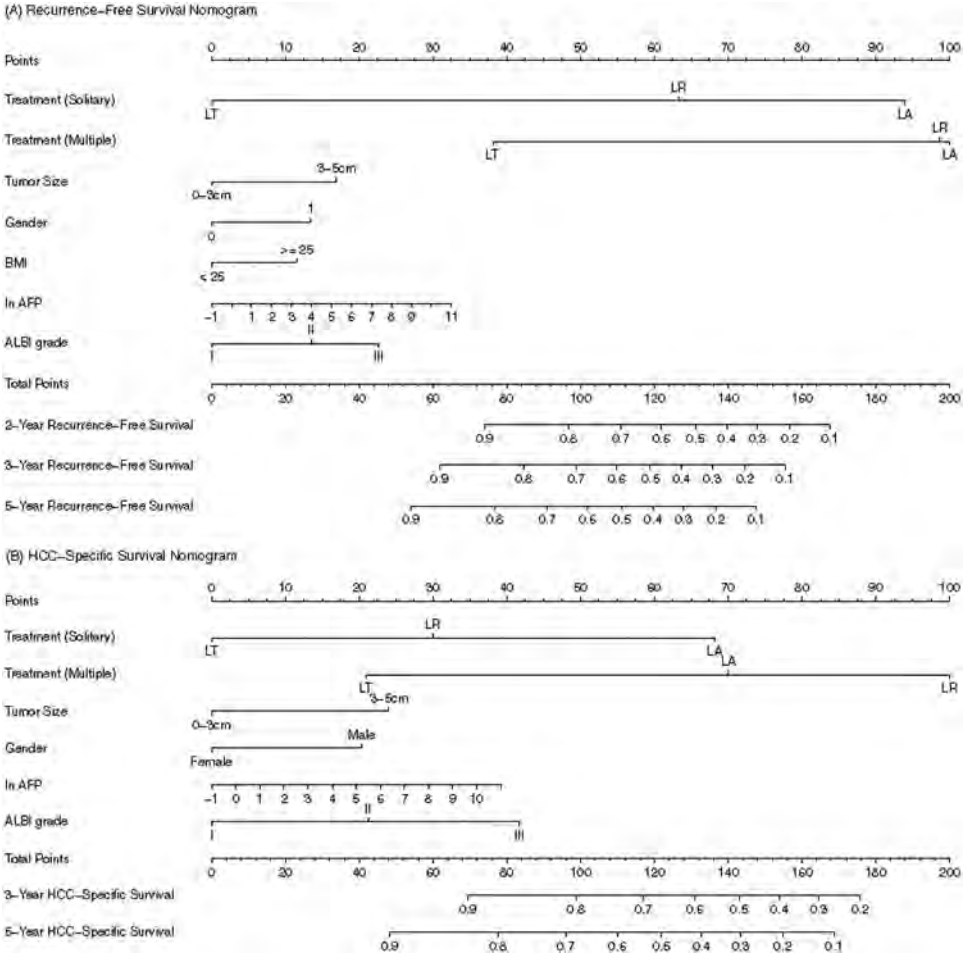

Figure: (abstract: AS146)

Method: Between July 2009 and May 2016, a total of 746 consecutive HCC patients within the MC underwent LT, LR and LA were enrolled and randomly divided into training (n = 501) and validation (n = 245) cohorts. Recurrence free survival (RFS), HCC-specific survival (HSS) and overall survival (OS) among the three treatment groups and subgroups were compared after inverse probability of treatment weighting (IPTW) to overcome treatment selection bias. Prediction models of RFS and HSS were developed and nomograms for RFS and HSS were derived and validated with the calibration, discrimination and risk stratifications.
Results: The median follow-up was 56.9 months. LT showed the best outcomes (LT vs. LR vs. LA: 86.8% vs. 50.7% vs. 26.0% for 5-year RFS and 85.2% vs. 72.6% vs. 47.1% for 5-year OS), and LA showed the highest proportion of recurrence within the MC. RFS and OS of LR and LA were similar in subgroup multiple tumours with 0–3 cm, but LA showed higher proportion of recurrence within the MC. Nomograms of RFS and HSS based on gender, body mass index (BMI), treatment allocation, tumour number (solitary or multiple), tumour size (3–5 cm vs. ≤3 cm), alpha-fetoprotein (AFP) and albumin-bilirubin (ALBI) grading were constructed and showed satisfactory performance in the validation cohort. The two models were validated with satisfactory discrimination abilities (c indexes for RFS: 0.80, 0.82, and 0.87 at 2, 3, and 5 years and c index for HSS: 0.79 and 0.86 at 3 and 5 years), calibration curves and risk stratifications of RFS and HSS. The online prognosis calculator for curative treatments allocation of HCC patients within the MC according to the two models was successfully established, please see the website: https://yingwu.shinyapps.io/Tianjin-PC-MDT/.
Conclusion: The prognosis calculator for HCC within the MC showed feasibility on individualized curative treatment allocation to assist with MDT decision making.

AS147

Refinining the post transplant outcomes prediction of Metroticket 2.0 through mRECIST criteria

Carlo Sposito[1,2], Matteo Serenari[3,4], Stefano Di Sandro[5], Rita Golfieri[3,6], Carlo Spreafico[7], Angelo Vanzulli[2,5], Vincenzo Mazzaferro[1,2], Luciano De Carlis[5], Matteo Cescon[3,4], Antonio Pinna[4], Alessandro Cucchetti[4,8]. *[1]Fondazione IRCCS Istituto Nazionale Tumori di Milano, GI Surgery and Liver Transplantation, Milan, Italy; [2]University of Milan, Department of Oncology, Milan, Italy; [3]S.Orsola – Malpighi Hospital, Bologna, Italy; [4]University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [5]University of Milano-Bicocca and Niguarda-Cà Granda Hospital, Milan, Italy; [6]University of Bologna, Department of Specialized, Diagnostic and Experimental Medicine, Bologna, Italy; [7]Fondazione IRCCS Istituto Nazionale Tumori di Milano, Radiology, Milan, Italy; [8]Morgagni – Pierantoni Hospital, Forlì, Italy*
Email: carlo.sposito@istitutotumori.mi.it

Background and Aims: The combination of morphology and biology represents the most useful approach to select candidates with hepatocellular carcinoma (HCC) for liver transplantation (LT) at acceptable risk of recurrence. However, the weight of response to neo-adjuvant therapies remains partially unsolved for most of post-LT prediction models. Aim of this study was to embed radiological response in the Metroticket 2.0 model for post-LT prediction of "*HCC-related death*" to provide more usefulness in the modern clinical scenario.
Method: Data from 988 transplanted patients (2000–2015) with adequate clinical and radiological information were included. The last radiological assessment before LT was reviewed according to the mRECIST criteria. Competing-risk analysis was applied. The added value of including radiological response into the Metroticket 2.0 was explored through the category-based Net Reclassification Improvement (NRI).
Results: At last radiological assessment prior to LT, complete response (CR) was diagnosed in 35.9%, partial response/stable disease (PR/SD) in 29.7% and progressive disease (PD) in 34.4%. Patients with CR had 5-year rates of "*HCC-related death*" of 2.9%, those with PR/SD had 8.0% and those with PD had 12.8% ($P < 0.001$). Log_{10}AFP ($p < 0.001$) and the sum of number and diameter of the tumour/s ($p = 0.001$) were determinants of "*HCC-related death*" for PR/SD and PD patients, with different hazards. To maintain the post-LT 5-year incidence of "*HCC-related death*" <30%, the Metroticket 2.0 criteria were restricted in presence of PD, correctly reclassifying 16.7% of patients who died from "*HCC-related death,*" at the expenditure of 7.0% of patients who did not have the event. The overall NRI was of 9.7.

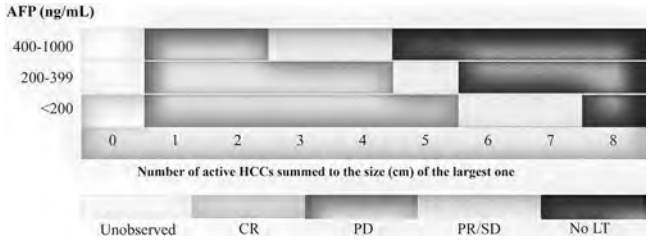

Figure 1: Identification of transplantable tumour on the basis of HCC morphology parameters (largest vital tumor size + number of vital tumor nodules) and biology (AFP and last radiological mRECIST assessment), determined at pre-LT radiology The darkest areas describe a 5-year "HCC-related death" above the safety threshold of 30%.

Conclusion: Inclusion of mRECIST criteria within the Metroticket 2.0 framework can provide further clinical information when judging eligibility for candidates to LT.

AS148

Clinical-radiomics analysis for preoperative prediction of objective response to transarterial chemoembolization in hepatocellular carcinoma

Mingyu Chen[1,2], Jiasheng Cao[1], Jiahao Hu[1], Win Topatana[1], Shijie Li[1], Sarun Juengpanich[1], Jian Lin[3], Jennifer Wu[4], Xiujun Cai[1,2]. *[1]Sir Run-Run Shaw Hospital, General Surgery, Hangzhou, China; [2]Engineering Research Center of Cognitive Healthcare of Zhejiang Province; [3]Longyou People's Hospital, General Surgery, China; [4]NYU Langone Health, Perlmutter Cancer Center, New York, United States*
Email: mychen@zju.edu.cn

Background and Aims: Preoperative decision-making for selecting patients who have an objective response to transarterial chemoembolization (TACE) remains challenging. Therefore, we aimed to develop and validate a clinical-radiomic model (CR-model) for preoperatively predicting the treatment response to TACE in intermediate-stage hepatocellular carcinoma (HCC) patients.
Method: A total of 595 patients with intermediate-stage HCC were retrospectively included. Treatment response-related radiomic signature (TRR-signature) was built on 3,404 radiomic features from 4 target volumes. The TRR-signature and 22 clinical factors were integrated into a predictive model, the CR-model, with multivariate logistic regression. The performance of this model was evaluated by the calibration curves and the area under the receiver operating characteristic curves (AUCs).
Results: Five independent predictors, including a TRR-signature-1 ($P < 0.001$) and 4 clinical factors, including AFP ($P = 0.004$), Barcelona Clinic Liver Cancer System (BCLC) stage B subclassification ($P = 0.01$), tumor location ($P = 0.039$), and arterial hyperenhancement ($P = 0.050$), were taken into the CR-model. The calibration curves for the probability of objective response showed optimal agreement between nomogram prediction and actual observation. The AUCs of this model in training, and the internal and external validation cohorts were 0.96, 0.94, and 0.90, respectively. As a prognostic factor,

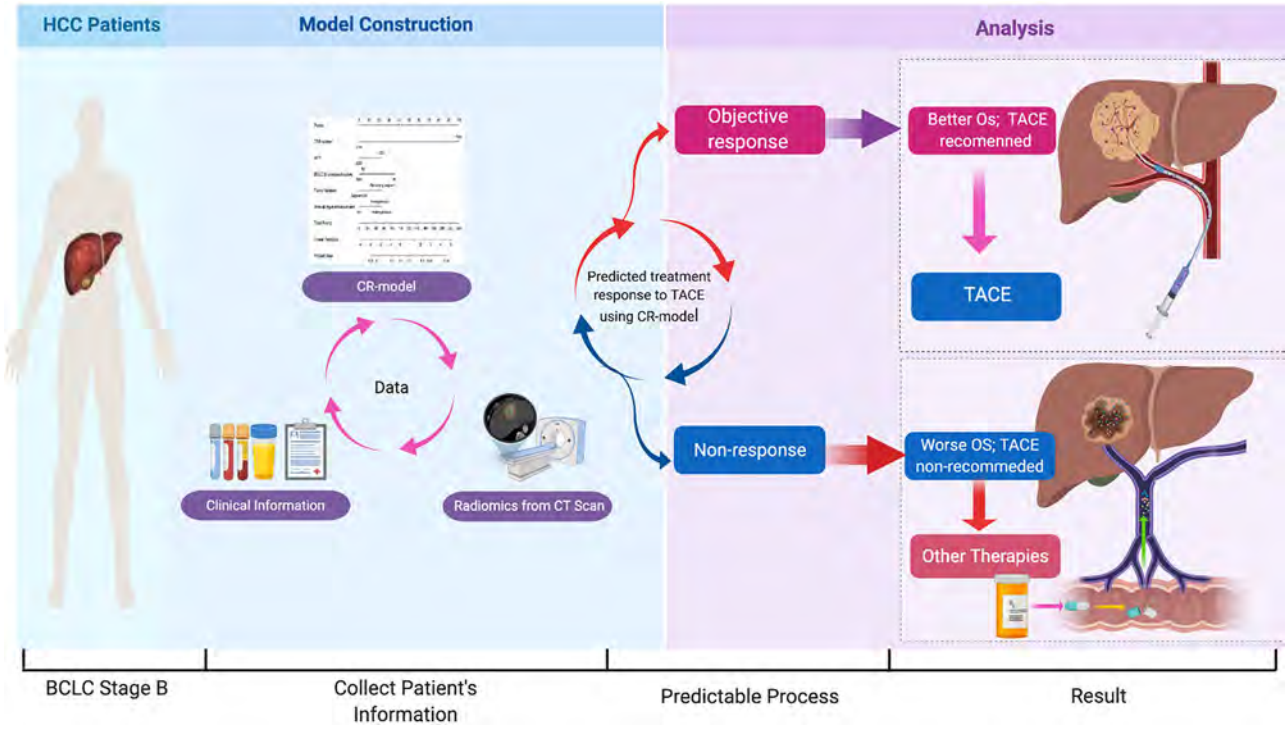

Figure: (abstract: AS148)

the treatment response (objective vs non-response) predicted by the CR-model showed significant differences of overall survival in the external validation cohort (HR, 2.41; 95%CI, 1.59 to 3.66; $P < 0.001$). Notably, it also allowed significant distinction between survival curves within each BCLC B subclassification.

Conclusion: The clinical-radiomic model demonstrates a good performance for predicting treatment response, and provides a powerful tool to assist the clinicians in patient selection.

AS149

Optimal time-point of response assessment for predicting survival is associated with tumor burden in hepatocellular carcinoma receiving repeated transarterial chemoembolization

Email: hangh@fmmu.edu.cn

Background and Aims: It's unknown that whether initial response or best response is used to predict overall survival (OS) in hepatocellular carcinoma (HCC) receiving repeated transarterial chemoembolization (TACE). We sought to investigate their prognostic value and practicality as potential surrogate of OS.

Method: We conducted a retrospective study of treatment-naïve patients with unresectable HCC, well-preserved liver function, and a performance status score of 0–1 undergoing TACE between 1/2010 and 5/2016. Time-dependent Cox regression analysis and Pearson's correlation coefficient were used to determine the predictor and surrogacy.

Results: We identified 1549 eligible patients from 17 academic hospitals and stratified them into strata of low, intermediate and high tumor burden, based on our previously proposed "Six-and-twelve" score. Significant interaction between tumor burden and initial as well as best response were observed (both $p_{interaction} < 0.001$). In stratification analyses, initial and best responses could effectively predict and strongly correlated with OS in low (adjusted hazard ratio (HR): 2.55 and 2.95, respectively, both $p < 0.001$; $r = 0.84$, $p = 0.035$

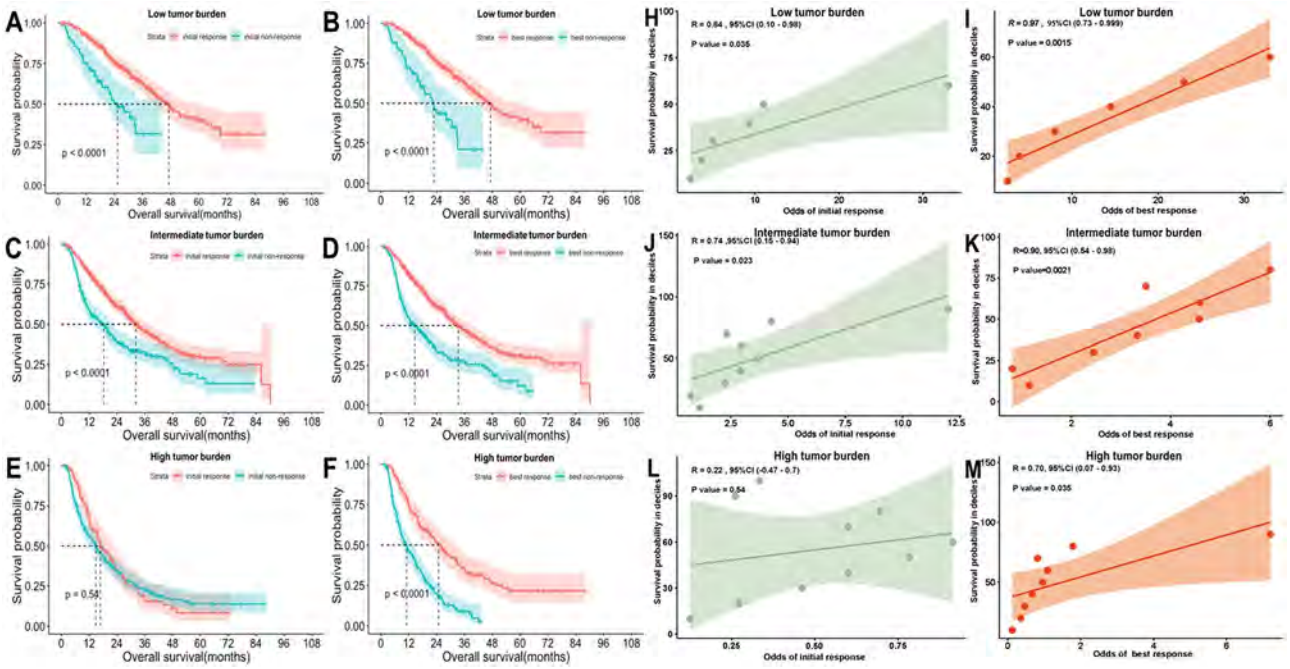

Figure: (abstract: PS-200)

and r = 0.97, p = 0.002, respectively) and intermediate strata (adjusted HR: 1.81 and 2.22, respectively, both p < 0.001; r = 0.74, p = 0.023, and r = 0.9, r = 0.002, respectively), with high concordance in these groups (kappa value: 0.92 and 0.88, respectively). Conversely, only best response but not initial response served to be predictable (adjusted HR: 2.61, p < 0.001, and adjusted HR: 1.08, p = 0.537, respectively) and significantly associated with OS (r = 0.70, p = 0.035, and r = 0.22, r = 0.54, respectively) in high strata.

Conclusion: Initial response conferred assessing efficacy at early time, making it preferred and pragmatic surrogate of OS among low and intermediate strata, however, it was impracticable to high strata, where best response provided modest correlation with OS. These findings have implications for prognosis, stratification and trial design.

AS150

Regorafenib improves survival after sorafenib treatment in patients with recurrent hepatocellular carcinoma after liver transplantation, compared to best supportive care

Email: mario.romero@salud.madrid.org

Background and Aims: Regorafenib (REGO) has been shown to be a safe second-line treatment for hepatocellular carcinoma (HCC) recurrence after liver transplantation (LT). The aim of this study was to compare the overall survival (OS) of REGO to best supportive care (BSC) after sorafenib (SOR)-discontinuation in LT patients.

Method: We conducted a retrospective, multicentre, international study, including all patients with HCC recurrence after LT who discontinued SOR. The REGO-group included patients treated with REGO after SOR-discontinuation, due to progression in tolerant patients, the control-group included all patients treated with BSC due to REGO unavailability, symptomatic progression or SOR-intolerance. The primary end-point was OS from SOR-discontinuation.

Results: Included were 96 LT-patients: 32 treated with REGO after HCC progression under SOR (group-A) and 64 patients receiving BSC after SOR-discontinuation 31 SOR-tolerant in progression (group-B), 20 SOR-intolerant and 13 discontinued SOR for other

reason (symptomatic progression, non-liver complications, patient's decision). The median survival for the whole cohort since SOR-start was 19.3 (13.4–25.1) months (mos). The comparative analyses were conducted between group-A and group-B, with similar clinical and demographic features [i.e. mTORi treatment 63% vs 81% (0.11); SOR 800 mg 41% vs 23% (p = 0.12); SOR treatment duration 11.1 (0.7–76.7) vs 7.8 (0.9–96.3) mos (p = 0.65); at SOR-discontinuation: ECOG-PS 0–1 100% vs 90% (p = 0.29); tumor burden: liver only 6% vs 10%, extra-hepatic only 44% vs 45%, both 50% vs 45% (p = 85); AFP: 134 (1–209,630) vs 1044 (1–88,950) ng/ml (p = 0.83)]. All the 32 patients treated with REGO [treatment duration 7.0 (5.5–8.4) mos] had at least 1 adverse event (grade 3/4: fatigue in 8 and dermatological reaction in 5). Median follow-up since SOR-discontinuation was 12.3 (0.6–42.2) mos for group-A and 4.5 (0.0–22.3) for group-B (p = 0.0006). At data-lock, 66% patients had died in group-A and 94% in group-B, symptomatic tumor progression being the main cause of death. The median OS from SOR-discontinuation was 14 mos (95%CI:10–18) for group-A and 4.5 mos (95%CI:24–66) for group-B (p < 0.005). The overall OS from SOR-start was 32.6 mos (95%CI:18–46) for the SOR-REGO group compared to 14.3 mos (95%CI:7–21) for the SOR-BSC sequence in the group-B (p = 0.001).

Conclusion: REGO is a safe and effective second line option after SOR-progression in patients with HCC recurrence after LT.

HCV Long-term management

The dynamics of FIB4 after sustained viral response predicts the risk of liver-related complication in HCV cirrhosis (ANRS CO12 Cirvir)

Jerome Boursier[1,2], Pierre Nahon[3], Maxime Guettier[1], Clémence Moreau[1], Jérémie Riou[4], Etienne Audureau[5], Marine Roux[1].
[1]Université d'Angers, Laboratoire HIFIH, Angers, France; [2]Centre Hospitalier Universitaire, Service d'Hépato-Gastroentérologie, Angers, France; [3]APHP Hôpital Jean Verdier, Service d'Hépatologie, Bondy, France; [4]Université d'Angers, Laboratoire MINT, Angers, France; [5]APHP Hôpital Henri Mondor, Santé Publique, Créteil, France
Email: jeboursier@chu-angers.fr

Background and Aims: Sustained viral response (SVR) significantly improves the prognosis in patients with cirrhosis due to hepatitis C virus (HCV), but does not totally eliminate further occurrence of liver-related complications (LRC). We aimed to evaluate whether the evolution of blood tests after SVR correlates with the residual risk of LRC and allows stratification of the prognosis in HCV cirrhotic patients.
Method: 695 patients with biopsy-proven HCV cirrhosis prospectively recruited in 35 French centres (ANRS CO12 CirVir cohort) who experienced SVR were included in the analysis. Data (clinics and biology) were collected at SVR (study baseline) and during the follow-up. The primary outcome was the first occurrence of LRC, a composite endpoint including cirrhosis complication (ascites, variceal bleeding, encephalopathy) and/or hepatocellular carcinoma (HCC). Time-dependent ROC curves were used to identify the best prognostic biomarker. Joint models accounting for the biomarker trajectory and LRC occurrence were developed to compute dynamic predictions. The predictive accuracy of these dynamic predictions was assessed using approximate cross-validated estimator (CVPOL) of expected prognostic observed cross-entropy. A web Shiny application was finally developed for clinical practice.
Results: A first LRC occurred in 50 patients (25 cirrhosis complications, 25 HCCs) during the median 3.7 [1.6–7.4] years follow-up following SVR. FIB4 provided the highest time-dependent ROC curve compared to the other biomarkers tested (APRI, AST, ALT, GGT, platelets), with values fluctuating around 0.8 at all horizons. Joint models identified four patient profiles using diabetes, baseline FIB4 and FIB4 evolution during the follow-up. CVPOL computed for a time at prediction from 1 to 5 years after SVR showed good predictive accuracy with results ranging from 0.08 to 0.46. Goodness of fit was assessed using predicted survival curves and observed weighted Kaplan Meier curves showed (Figure A). The web Shiny application developed for clinicians depicts the predicted risk of LRC after SVR based on the evolution of FIB4 results and diabetes status (Figure B).
Conclusion: The evolution of simple parameters (FIB4 and diabetes status) predicts the residual risk of liver-related complication after sustained viral response in patients with HCV cirrhosis. Such assessment could help to refine the patient management, especially for the most at-risk patients.

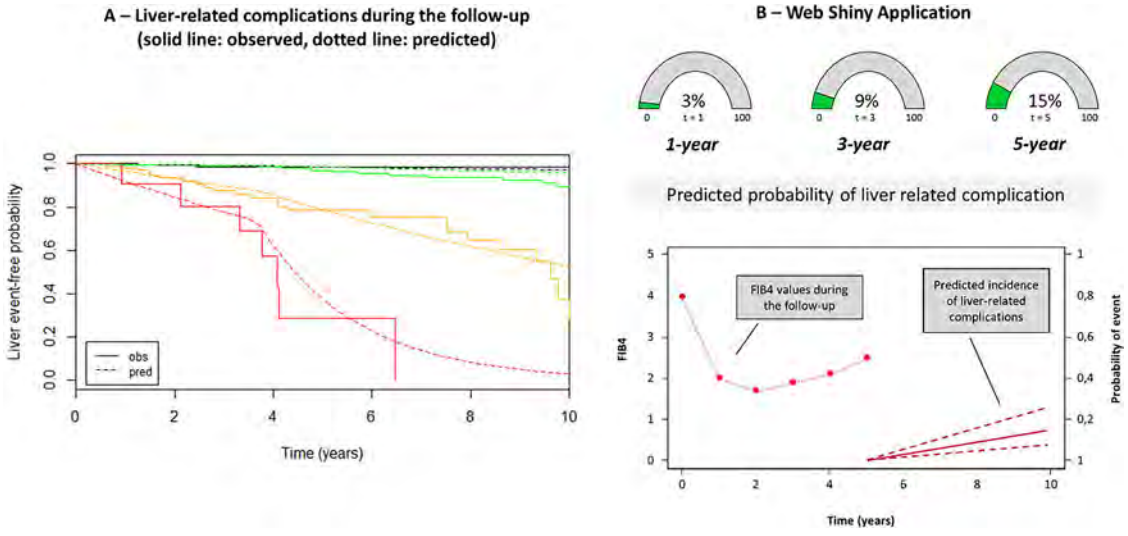

Figure: (abstract: AS151)

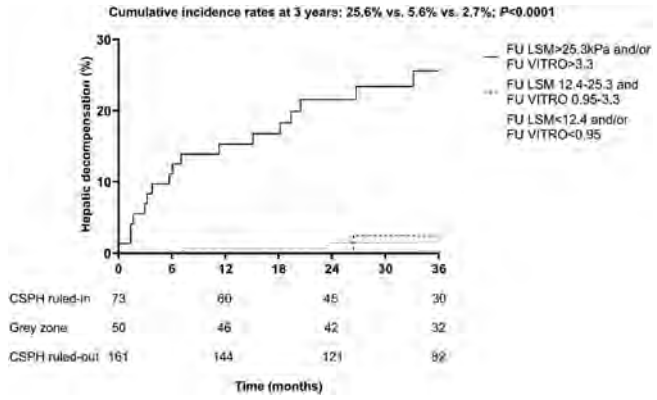
Non-invasive monitoring of liver disease regression in patients with advanced chronic liver disease after sustained virologic response to INF-free therapies

Georg Semmler[1,2], Teresa Binter[1], Karin Kozbial[1], Philipp Schwabl[1,2], David Chromy[1,2], David J.M. Bauer[1,2], Benedikt Simbrunner[1,2], Bernhard Scheiner[1,2], Theresa Bucsics[1,2], Albert Stättermayer[1,2], Matthias Pinter[1,2], Petra Munda[1], Michael Trauner[1], Peter Ferenci[1], Thomas Reiberger[1,2], Mattias Mandorfer[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory*
Email: georg.semmler@meduniwien.ac.at

Background and Aims: Hepatic venous pressure gradient (HVPG) predicts hepatic decompensation in patients with advanced chronic liver disease (ACLD) who achieved sustained virologic response (SVR) to interferon (IFN)-free therapies. However, non-invasive alternatives are needed for risk stratification after HCV cure.
Thus, we investigated the predictive value of non-invasive surrogates of portal hypertension (liver stiffness measurement [LSM] by transient elastography [TE] and VWF/platelet count ratio [VITRO]) for post-treatment hepatic decompensation in patients with pre-treatment ACLD who achieved SVR.
Method: Two hundred and eighty-four patients with information on paired pre- and post-treatment (follow-up [FU]) LSM and VITRO were followed after the end of antiviral therapy.
Results: Prior to IFN-free therapy, 258 (90.8%) patients had compensated, while 26 had (9.2%) decompensated ACLD. The mean pre-treatment MELD score was 8.6 ± 2.5points and the median LSM and VITRO values were of 17.1 (15.2)kPa and 1.66 (1.97), respectively. FU LSM (area under the curve [AUC]: 0.836 [95%CI: 0.745–0.907]) and FU VITRO score (0.853 [95%CI:0.778–0.928]) showed the best performance for predicting hepatic decompensation during FU. Both variables were independently predictive of hepatic decompensation in a Cox regression model (adjusted hazard ratio 1.031 [95%CI: 1.009–1.055] per LSM-kPa and 1.184 [95%CI: 1.033–1.358] per VITRO-point), even after adjusting for previous hepatic decompensation as well as post-treatment MELD and albumin levels.
A previously proposed combined approach (FU LSM<12.4 kPa and/or FU VITRO <0.95) was able to rule-out clinically significant portal hypertension (CSPH, HVPG ≥ 10 mmHg) at FU in the majority (56.3%) of patients – who had a negligible risk of hepatic decompensation after the end of antiviral therapy (2.7% at 3 years; Figure). In contrast, in patients in whom FU CSPH was ruled-in by non-invasive diagnostics (26% of the study population; FU LSM>25.3 kPa and/or FU VITRO >3.3), the risk of hepatic decompensation within 3 years post-treatment was high (25.6%). Patients within the diagnostic grey zone for FU CSPH (17.6% of the study population) had a numerically increased, but still a very low risk of hepatic decompensation during FU (5.6%).



Conclusion: FU LSM and FU VITRO score are strongly and independently predictive of post-treatment hepatic decompensation in ACLD patients who have achieved SVR to IFN-free therapies. An algorithm combining these non-invasive markers of portal hypertension that was developed to rule-in or rule-out FU CSPH identified populations at negligible versus high risk for hepatic decompensation. Accordingly, this algorithm enables risk stratification after SVR, and thus, facilitates personalized FU.

AS153

HIV co-infection and risk of morbidity and mortality in HCV patients treated by DAA

Mathieu Chalouni[1], Stanislas Pol[2], Philippe Sogni[3], Helene Fontaine[2], Karine Lacombe[4], Jean-Marc Lacombe[5], Laure Esterle[6], Camille Gilbert[6], Dorival Celine[5], Dominique Salmon-Ceron[2], Fabrice Carrat[5], Linda Wittkop[6]. *[1]INSERM, Bordeaux, France; [2]Assistance Publique - Hôpitaux de Paris, Paris, France; [3]Paris Descartes University, Paris, France; [4]Saint-Antoine Hospital, Paris, France; [5]Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France; [6]University of Bordeaux, Bordeaux, France*
Email: mathieu.chalouni@u-bordeaux.fr

Background and Aims: HIV co-infection leads to increased mortality, liver disease progression and extra-hepatic manifestations in HCV-infected patients. DAA lead to high SVR rates and decrease the risk of disease progression. We compared risks of liver-related events, liver-related mortality and non-liver-related mortality in HIV/HCV co-infected and HCV mono-infected patients treated by DAA.
Method: Four HCV mono-infected participants from the ANRS CO22 HEPATHER cohort were matched on age and sex to each HIV/HCV co-infected participant from the ANRS CO13 HEPAVIH cohort. All participants were treated by DAA between March 2014 and December 2017. Cox proportional Hazards models adjusted on age, sex, duration since HCV diagnosis, HCV contamination routes, HCV genotype, cirrhosis status, tobacco and alcohol consumption were used.
Results: 592 HIV/HCV co-infected and 2049 HCV mono-infected were included. Median age was 52.9 years [IQR: 49.6; 56.7] and 53.3 years [IQR: 49.6; 56.9]; 436 (73.6%) and 1498 (73.1%) were men; median duration since HCV diagnosis was 18.0 years [IQR: 12.4; 22.2] and 14.5 years [6.4; 20.8], and 159 (28.8%) and 793 (41.2%) were cirrhotic, respectively. Participants were predominantly treated by Sofosbuvir and Ledipasvir (48.8% and 34.5%, respectively) or Sofosbuvir and Daclatasvir (32.6% and 31.2%, respectively) and SVR was observed in 92.9% and 94.6% overall, respectively. After a median follow-up of 2.8 years, incidence of liver-related events was 12.4 per 1000 PY (95%CI: 7.7; 19.9) in HIV/HCV co-infected and 13.4 per 1000PY (95%CI: 10.5; 17.0) in HCV mono-infected ($p = 0.78$). Incidence of liver-related mortality was 5.6 per 1000 PY (95%CI: 2.8; 11.1) in HIV/HCV co-infected and 4.9 per 1000 PY (95%CI: 3.4; 7.1) in HCV mono-infected ($p = 0.76$). Incidence of non-liver-related mortality was 12.5 per 1000 PY (95%CI: 7.9; 19.8) in HIV/HCV co-infected and 4.9 per 1000 PY (95%CI: 3.4; 7.1) in HCV mono-infected ($p < 0.01$). After adjustment, HIV co-infection was not associated with a higher risk of liver-related events (HR = 0.67 95%CI: 0.27; 1.67) or liver-related-mortality (HR = 0.94 95%CI: 0.19; 4.67), but the risk of non-liver-related mortality (HR = 2.67 95%CI: 0.97; 7.37) tended to be higher in HIV/HCV co-infected.
Conclusion: After DAA treatment, the risk of liver-related events and liver-related mortality were similar between HIV/HCV co-infected and HCV mono-infected but HIV co-infection tended to increase the risk of non-liver-related mortality.

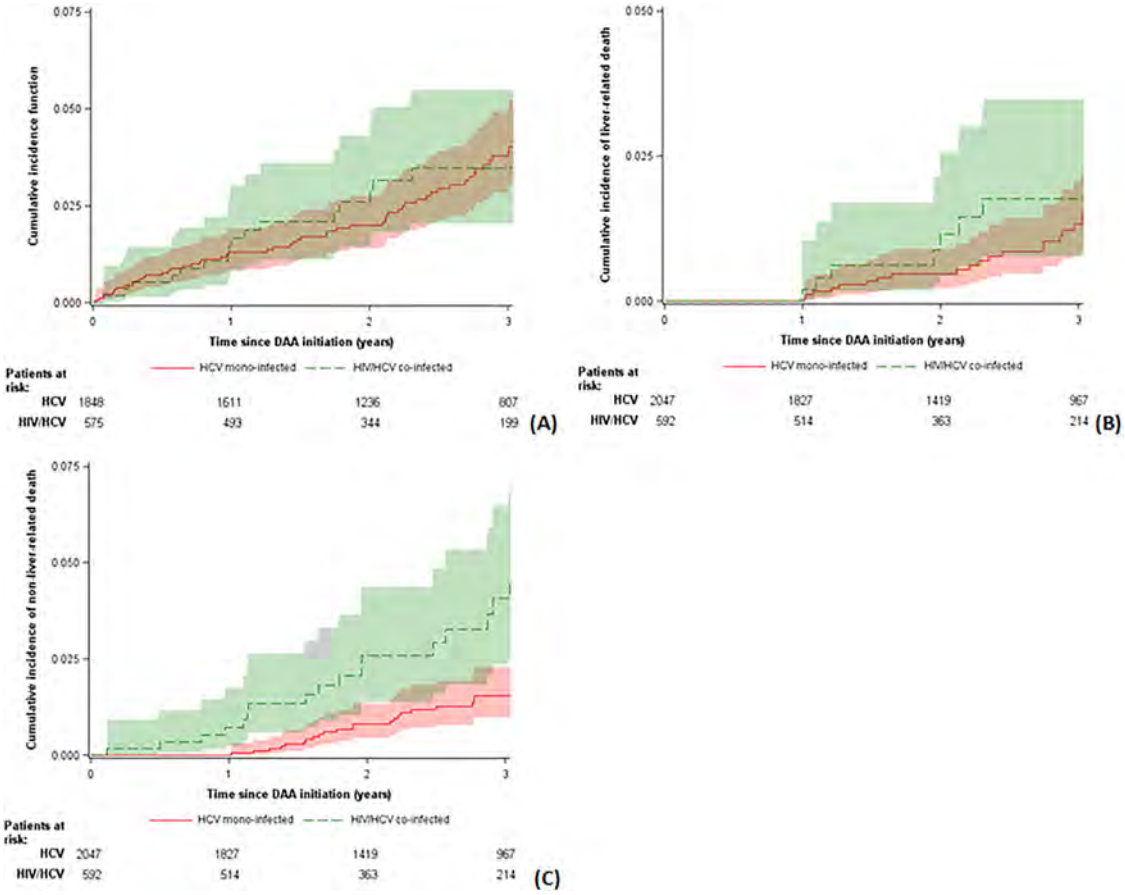


Figure 1: (abstract: AS153): Cumulative incidences (and 95% confidence intervals) of liver-related-events (A), liver-related death (B) and non-liver-related death (C), in HIV/HCV co-infected (in green) and HCV mono-infected (in red) from the ANRS CO13 HEPAVIH.

Predictive models for hepatocellular carcinoma (HCC) occurrence in patients with chronic hepatitis C and sustained virological response (SVR) achieved with direct acting anti-viral (DAA) included in the ANRS CO22 hepather cohort

Nathalie Ganne-Carrié[1], Azzi Jessica[2], Dorival Celine[2], Carole Cagnot[2], Helene Fontaine[2], Clovis Lusivka-Nzinga[2], Stanislas Pol[2], Fabrice Carrat[2]. *[1]Hôpitaux Universitaires Paris Seine Saint-Denis, APHP, et Université Paris 13, Bondy, France; [2]ANRS-AFEF HEPATHER Study Group, Paris, France*
Email: celine.dorival@iplesp.upmc.fr

Background and Aims: Despite viral eradication, patients with chronic hepatitis C have a residual risk of HCC especially in cases of pre-therapeutic advanced liver fibrosis. HCC risk factors and scores, well established before viral eradication, remain to be determined after SVR. For this purpose, we analyzed HCC predictive factors after SVR12 and developed a predictive score whose performance was compared to previous published scores.
Method: Among 12,324 HBsAg-negative patients with HCV chronic hepatitis enrolled in ANRS CO22 HEPATHER cohort, we selected those non-liver transplants, HCC-free and without missing values of interest who achieved SVR 12 weeks after DAA treatment. HCC predictive models were developed by Cox multivariate and validated in all included patients then specifically in those with cirrhosis. Calibration, discrimination and predicted risk classification of HCC were assessed and compared to the new published scores estimates. The primary endpoint was the area under the integrated time-dependent ROC curve (i-AUC).
Results: During follow-up (median 2.23 years –IQR 1.16–3.28; maximum 6.12), 220 (194 with cirrhosis) out of 7,752 selected patients developed an HCC. Eight independent variables were associated with HCC occurrence: male gender (HR 1.79 CI95%: 1.27–2.53), age at SVR >64 years (HR 2.45 CI95%: 1.46–4.12), advanced liver fibrosis (F3: HR 5.27, CI95%: 1.91–14.57; F4: HR 9.86, CI95%: 3.94–24.69), genotype 3 (HR 1.79 CI95%: 1.23–2.60), esophageal varices (HR 2.79, CI95%: 2.01–3.87, baseline serum AFP >5.5 ng/Ml (HR 1.36, CI95%: 1.02–1.80), ASAT to Platelets Ratio Index (APRI) >2 at end of treatment (HR 1.91, CI95%: 1.29–2.82) and past interferon-based regimen(s) with or without ribavirin (HR 1.71, CI95%: 1.20–2.44). An HCC risk score was established using these variables allowing the stratification of patients into three groups of risk level: high (n = 144, score ≥ 19/28), intermediate (n = 1677) and low (n = 5931, score < 11 /28) with 1 and 3-yrs HCC incidences of 7.08 and 18.00%, 3.00 and 8.34% and 0.37 and 1.13%, respectively. The performance of this score was higher than the published re-estimated scores in all selected patients with an i-AUC of 0.78 vs. 0.53–0.72. The models were well calibrated. Among patients with cirrhosis (n = 2836), beside liver fibrosis, all the 7 independent predictors were selected to establish a risk score of 14 points with iAUC of 0.71 vs 0.49–0.67.
Conclusion: The HEPATHER cohort HCC score has good short-term predictive performance in HCV- patients who achieved SVR12 after DAA treatment allowing to identify low-risk patients (HCC 3 years-incidence <1.5%, n = 5931 i.e 76.5%) in whom HCC screening may be superfluous in the first 3 years after SVR.

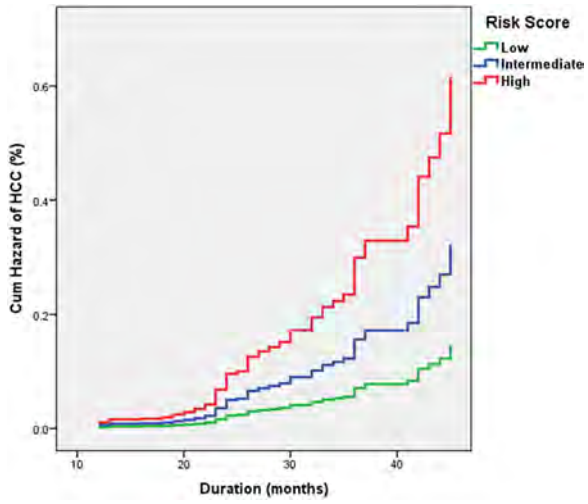
AS155

A simple score for HCC risk stratification in CHC patients with cirrhosis or advanced hepatic fibrosis who achieved SVR following DAA therapy

Gamal Shiha[1,2], Reham Soliman[2,3], Nabiel Mikhail[2,4], Ayman Hassan[2], Talal Amer[5], Mohammed Eslam[6]. *[1]Mansoura University, Internal Medicine [2]Egyptian Liver Research Institute and Hospital [3]Faculty of Medicine, Port Said University, Tropical Medicine [4]Faculty of Medicine, Assuit University [5]Faculty of Medicine, Mansoura University, Radiology [6]Westmead Hospital and University of Sydney, Storr Liver Centre, Westmead Institute for Medical Research*
Email: g_shiha@hotmail.com

Background and Aims: Patients with advanced fibrosis or cirrhosis before achieving a sustained virologic response (SVR) to direct-acting antiviral (DAA) treatment for hepatitis C virus (HCV) infection continue to have a risk for hepatocellular carcinoma (HCC) for several years. However, the heterogeneity and substantial intra-individual variation in this risk have encouraged the development of scoring system that predict risk of HCC occurrence. The aim of this work was to develop a model that offer individualized patient HCC risk prediction.

Method: This is a prospective study including chronic hepatitis C (CHC) patients with liver cirrhosis (F4) or advanced hepatic fibrosis (F3) who achieved SVR following DAAs from January 2015 until August 2017, conducted at the Egyptian Liver Research Institute and Hospital (ELRIAH). Clinically relevant baseline parameters were collected and patients were followed up every 6 months for up to 45 months. Factors associated with HCC were identified through multivariable Cox regression and used to develop a scoring model for prediction of HCC risk and the performance of the model was assessed by area under the Receiver operating characteristic (ROC) curve.



Results: 2326 CHC consecutive patients (1734 with F4 stage and 638 patients with F3) who achieved SVR were included. Follow up period was 23.51 ± 8.21 months (range 12–45 months). 109 patients (4.7%) developed HCC during the follow up period, out of them 101 patients had cirrhosis before initiation of DAA therapy and the remaining 8 patients had F3 liver fibrosis. Using multivariable Cox regression age, sex, serum albumin, α feto-protein (AFP) and pre-treatment fibrosis stage were identified as risk factors for HCC. To improve clinical utility, a simple predictive model (GS score) was constructed by assigning points for each covariate in proportion to the hazard ratios in the final multivariable model: age (≤54 vs. >54 years), sex (male vs. female), serum albumin (<3.8 vs. ≥ 3.8 g/dL), AFP (≤20 vs. >20 ng/ml) and pre-treatment fibrosis stage (F3 vs. F4). Using ROC analysis, patients were then stratified into three groups (low, medium and high risk) based on the score (AUROC = 0.824). The proposed model showed high predictive accuracy and the 2 year cumulative HCC incidence using Kaplan-Meier method was 2%, 4.5% and 10.3% in the low-risk, medium-risk and high-risk groups respectively.

Conclusion: GS score, using readily available parameters, has good predictive ability for occurrence of HCC after eradication of HCV. If validated, it may help to individualize HCC screening among CHC patients with liver cirrhosis and advanced hepatic fibrosis.

Email: fegarcia@ugr.es

Background and Aims: Treatment of chronic hepatitis C virus (HCV) infection with new regimens [Glecaprevir and Pibrentasvir (G/P) or Voxilaprevir/Velpatasvir/Sofosbuvir (VVS) results in high sustained virologic response (SVR) rates both in clinical trials and real world. Here we present real world data on the characteristics of G/P or VSS failure patients from the real world international SHARED collaboration.

Method: Virological and clinical Information were obtained from resistance databases within the SHARED collaboration. Population sequencing of NS3, NS5A and NSB5 was conducted and RASs conferring a >2-fold increased DAA susceptibility were analyzed. Clinical and virological data were collected retrospectively.
Results: Altogether 133 patients had a virologic treatment failure to G/P or VVS; 77% of patients were male, with a mean age of 56 years (IQR, 49–63). The majority of patients was infected with genotype (GT) 3a (n = 50, 38%), while 37 individuals had GT1a, 17 had GT1b, 17 had GT2c, 4 had GT2a, 5 had GT4d and 3 was infected with rare subtypes (GT3b, GT4k and GT6q). Cirrhosis was detected in 34 patients. Ninety-nine patients had a virologic failure to G/P: 33% failed without any NS3 or NS5A RAS, while 57% of patients developed RASs in NS5A and 14% in NS3. NS5A RAS presence was different according to HCV GT (>70% in GT1a and GT3, 40% in GT1b and 21% in GT2a/c). The most frequent RASs were Y93H in NS5A and D/Q168L in NS3. Interestingly, a combination of two or more RASs in NS5A was frequently detected in GT1a and GT3 (two n = 36; three n = 8). Thirty-four patients had a virologic failure to VVS retreatment (mainly with GT3, GT1a and GT1b). Prior to VVS initiation, 76% of patients harbored NS5A RASs with high frequencies (60%) of Y93 variants, whereas NS3 D168 RASs were uncommon (30%). After VVS failure, the NS5A resistance profile was identical compared to baseline in the majority of patients (65%) and NS3 D168 frequencies were reduced (16%). NS5B SOF RASs were uncommon.
Conclusion: After G/P failure, NS5A RASs were frequently observed as dual and triple combination patterns, especially in patients infected by genotypes 3 and 1a. Failure to VVS was mainly observed in patients infected with genotype 3a, with rare occurrence of NS3 and NS5B RASs and a resistance profile of RASs in NS5A that was maintained from previous treatments.

Email: blaise.kutala@aphp.fr

Background and Aims: In patients (pts) with NAFLD long-term liver outcomes and overall survival are incompletely characterized, particularly relative to the clinical phenotype and histological features.
Method: The HOTSURFR study, an international collaboration of 8 centers (France, Sweden, Germany, UK, Australia and Italy), included consecutive pts biopsied for suspected NAFLD between 2004 and 2011. Liver biopsy was read by a central pathologist and data on survival, liver-related events and cirrhosis occurrence were collected. Here we report the analysis of the first 473 pts (233 with centrally read biopsies) focusing on type 2 diabetes (T2D) status at baseline and follow-up and fibrosis stage according to the new EPoS 7-tier classification (no/mild fibrosis, stages 0–2; moderate advanced fibrosis, stages 3–4; cirrhosis stages 5–6).
Results: At baseline 66% of pts were men, median age was 53 years, 42% with BMI ≥ 30 kg/m^2, EPoS-F stage prevalence: 0–2, 73%; 3–4, 13%; 5–6, 14%. Median follow-up after biopsy was 9.5 yrs. 181 pts (38%) had T2D at baseline (Group A), 58 (12%) developed T2D (Group B) and 234 (49%) remained free of T2D (Group C). Death occurred in 48 pts, liver-related death in 16 pts, 52 pts developed cirrhosis and 48 pts liver-related events.
Overall 10 yr survival, liver-related death, and liver-related events were similar in Groups A/B and different from Group C (83%/87% vs 98%, p = 0.005; 7.6% /5.5% vs 0.9%, P = <0.001; 19%/11% vs 3.5%, p = 0.001, respectively). Annual incidence rate of liver-related events was 0.25% in EPoS-F0-1; 0.86% in EPoS-F2; 2.15% in EPoS-F3-4 and 6.66% in EPoS-F5-6. Baseline T2D and moderate fibrosis (EPoS-F3-4) independently predicted cirrhosis occurrence (HR 2.37 and HR 5.92, respectively). T2D and EPoS-F3-6) independently predicted liver-related events (HR 2.53 and HR 8.33, respectively). Group B had similar HRs as group A in all analyses for these outcomes.
Conclusion: In this ongoing, multicentric, consecutive, tertiary care, biopsied NAFLD population, the incidence of liver-related events ranged from 0.25 to 6.66%/yr depending on baseline fibrosis stage. Baseline or incident T2D is a major predictor of liver morbi-mortality. The new EPoS-F staging system has prognostic value for liver-related death and events.

Email: zobair.younossi@inova.org

Background and Aims: NAFLD is the most common cause of chronic liver disease (CLD) and among the top cause of liver-related mortality, cause of hepatocellular carcinoma and indication for liver transplantation. Since most of the data originates from tertiary care centers, comparable and consistent measures of cause of deaths among NAFLD at the population level have not been produced previously. Our aim is to quantify and describe all-cause deaths, liver-related and cancer deaths among NAFLD in the United States (U.S.) using a population-based mortality database.
Method: Mortality record from all death certificates filed in U.S. 2017 was utilized. Decedents with each CLD were classified by the International Classification of Diseases, 10th Revision (ICD-10) as an underlying or contributing cause of death. Cause-specific of deaths are based on the underlying cause of death. Liver-related deaths included liver cancer, cirrhosis and CLDs.
Results: For 2017, there were 2,776,829 decedent cases (20 years or older) in U.S. Of these, 83,154 (3.0%) were liver-related deaths (mean [SD] age, 64.6 [13.8] years) which ranked as the 8th leading cause of death. Alcoholic liver disease (ALD) was responsible for 27.9% of liver-related deaths; NAFLD, 26.3%; chronic hepatitis C (CHC) 12.1%; and chronic hepatitis B (CHB), 0.3%. Among decedents with NAFLD (n = 43,187), the four leading causes of death were liver-related (53.1%), cardiovascular disease (12.2%), non-liver cancer (6.6%) and diabetes-related (2.6%) deaths. The majority of cancer deaths among decedents with NAFLD came from solid cancers (79.6%). Although the leading cause of cancer death in decedents with NAFLD was liver cancer (42.6%), other solid cancers included lung cancer (8.5%), colorectal cancer (6.9%), pancreatic cancer (5.5%) and breast cancer (4.2%). Among decedents with NAFLD, causes of cancer death were different between males and females (Table).
Conclusion: NAFLD is the second leading cause of liver related mortality. Although liver cancer is the most common solid tumor in decedents with NAFLD, lung cancer, colorectal, pancreatic and breast cancer are also the other common causes of cancer-related deaths.

Email: olivier.govaere@newcastle.ac.uk

Background and Aims: Histological criteria used to diagnose and stage non-alcoholic fatty liver disease (NAFLD) have proven to be insufficient to predict time-dependent changes in fibrosis.[1] Only changes in disease activity have been reported to be associated with fibrosis progression in NAFLD. In this study we aim to explore predictors of NAFLD progression by combing histological, genetic and transcriptomics data in a large international cohort.
Method: The EuroDELTA cohort comprised patients from the European NAFLD Registry with two or more liver biopsies conducted at least one-year apart, without cirrhosis at baseline, that were identified at nine specialist centres across Europe. Samples were centrally read and histologically graded and staged using the NASH-CRN system. *PNPLA3* rs738409 and *TM6SF2* rs58542926 SNP genotypes were determined using TaqMan® probes on DNA from peripheral blood mononuclear cells. Targeted transcriptomics analysis was performed on mRNA isolated from a subset of formalin-fixed paraffin-embedded samples on the nanoString® nCounter analysis system using a custom-made assay panel. A selection of markers were validated on protein level using immunohistochemistry.
Results: A total of 517 patients with NAFLD were included with a mean age of 49 ± 12 years, a mean BMI of the cohort was 32.1 ± 6.0 Kg/m^2 and 63% were male. At baseline, 33% of the patients had T2DM and 47% had hypertension. During follow-up (median 4.8 (1–23.6) years), fibrosis progressed in 34% and regressed in 22%. Only the presence of type 2 diabetes at baseline was independently associated with fibrosis progression rate (OR 1.14). No single baseline histological feature, including ballooning, inflammation or NAFLD activity score, had sufficient precision to predict subsequent fibrosis progression. Carriage of the genetic variants *PNPLA3* rs738409 or *TM6SF2* rs58542926 did not confer to a significant predictive factor. In contrast, significant transcriptomic differences were observed at the mRNA level. At baseline, 117 differentially expressed genes predictive of subsequent disease progression were identified ($p < 0.05$): increased expression of genes correlating to "extracellular remodeling" (*LTBP2*, *COL1A1*, *COL4A2*, *ADAMTS2*, *LOXL4*, *STMN2*), "apoptosis" (*TP53I3*, *BCL2L1*) and cytokines/ligands (*GDF15*, *THY1*, *SPP1*/*OPN*). Interestingly, a reduction in expression of metabolism-related genes (*HSD17B13*, *ELOVL1*, *ACADSB*) and genes relating to coagulation (*F9*, *F10*) was observed. On protein level osteopontin (SPP1/OPN) positivity was observed in biliary epithelial cells, suggesting an immunoregulatory role.
Conclusion: This study provides novel insights into transcriptional changes during NAFLD evolution and fibrosis progression as well as proof of principle of a potential novel predictive transcriptomic "fingerprint" for disease progression.

AS160
A multidisciplinary approach to non-alcoholic fatty liver disease (NAFLD) improves cardiovascular risk factors

Anna Mantovani[1,2], Atul Goyale[3], Davide Roccarina[1], Laura Iogna Prat[1,2], Marta Guerrero[1], Roshni Patel[1], Jennifer Clancy[1], Devaki Nair[3], Emmanuel Tsochatzis[1]. *[1]Royal Free Hospital and UCL, UCL Institute for Liver and Digestive Health, London, United Kingdom; [2]University and Azienda Ospedaliera Universitaria Integrata of Verona, Department of Internal Medicine, Division of General Medicine and Hypertension, Liver Unit, Verona, Italy; [3]Royal Free London NHS Foundation Trust, Department of Clinical Biochemistry, London, United Kingdom*
Email: annamantovani4@gmail.com

Background and Aims: Cardiovascular (CV) disease is the leading cause of death in unselected patients with non-alcoholic fatty liver disease (NAFLD). Although the need of a multidisciplinary approach is highlighted in guidelines, there is lack of data to demonstrate its effectiveness. We assessed the efficacy of a multidisciplinary clinic through control of metabolic comorbidities and surrogate markers of liver involvement.
Method: Prospectively collected data of patients referred to a multidisciplinary NAFLD clinic, comprehensive of a hepatological consultation, cardiovascular risk assessment and dietetic counseling, were analyzed.
Results: 273 patients were enrolled (57% males) with a mean age of 56.4 ± 12.1 years. The median follow-up was 18 months. The prevalence of obesity, hypertension and diabetes was 60%, 67% and 50% respectively, while 13.2% had a positive history of CV events. At baseline, dyslipidaemia management was suboptimal in 64 patients (25.2%), while 57 (41.9%) patients with diabetes and 36 (19.6%) patients with hypertension needed modification of their treatment. During follow-up, there were statistically significant improvements in ALT ($p = 0.013$), AST ($p = 0.013$), systolic and diastolic blood pressure ($p = 0.002$ and 0.014 respectively), total cholesterol ($p < 0.001$) and glycated haemoglobin in diabetic patients (70.2 to 62.5 mmol/mol, $p = 0.04$). 142 patients (52%) achieved weight loss during the follow-up ($\geq 10\%$, $\geq 7\%$ and $\geq 5\%$ in 8.2%, 6% and 7.3% of the cohort respectively). The total number of patients with a QRISK3 score $\geq 10\%$ decreased from 156 (62.7%) to 97 (48.5%).
Conclusion: A multidisciplinary NAFLD approach was effective in improving liver-related and CV risk factors. A strong collaboration between primary and secondary care is essential to implement and maintain these improvements in the long term.

AS161
Active non-alcoholic steatohepatitis and severe fibrosis are associated to dysfunctional adipose tissue and worsen with adipose tissue insulin resistance independently of body mass index

Luisa Vonghia[1,2], Melania Gaggini[3], An Verrijken[2,4], Jonas Weyler[1,2], Fabrizia Carli[3], Bárbara Patrício[3], Wilhelmus Kwanten[1,2], Thomas Vanwolleghem[1,2], Eveline Dirinck[2,4], Ann Driessen[5], Luc Van Gaal[2,4], Sven Francque[1,2], Amalia Gastaldelli[3]. *[1]University Hospital Antwerp, Department of Gastroenterology and Hepatology, Edegem, Belgium; [2]University of Antwerp, Laboratory of Experimental Medicine and Pediatrics, Antwerpen, Belgium; [3]National Research Council, Cardiometabolic Risk Unit, Institute of Clinical Physiology, Pisa, Italy; [4]University Hospital Antwerp, Department of Endocrinology, Diabetology and Metabolism, Edegem, Belgium; [5]University Hospital Antwerp, Department of Pathology, Edegem, Belgium*
Email: luisa.vonghia@uza.be

Background and Aims: Adipose tissue act as an endocrine organ that influences the metabolism by releasing adipokines, proinflammatory factors and free fatty acids (FFA), which contribute to insulin resistance (IR). Non-alcoholic fatty liver disease (NAFLD) occurs in the setting of IR due to increased delivery of free fatty acids (FFA) from peripheral lipolysis and de novo lipogenesis while clearance of hepatic FFA is through mitochondrial beta-oxidation, the dominant oxidative pathway, or by triglycerides (TG) secretion in plasma. We explored whether adipose tissue insulin resistance (adipo-IR, which measures the impaired suppression of lipolysis in the presence of high insulin levels), plasma FFA, TG and beta-hydroxybutyrate (BOH) (that reflects liver FFA oxidation) concentrations were associated to the severity of Non-alcoholic steatohepatitis (NASH).
Method: A large cohort of consecutively recruited patients with liver biopsy (n = 211, Body Mass Index (BMI) 25–40 kg/m^2) were included in the study and characterised for presence of glucose intolerance (IGT) or diabetes (T2D) by oral glucose tolerance test. We measured plasma FFA, BOH, lipid profile, Adipo-IR (FFAxInsulin) and fat distribution by CT. Data were analysed by logistic multivariable analysis (LMA) adjusted for age, BMI, presence of IGT/T2D and odd ratios (OR) were calculated.

Results: Liver histology was as follows: 55 no NAFLD, 34 non-alcoholic fatty liver (NAFL) and 122 NASH. TG (128 ± 5 vs 141 ± 8 vs 176 ± 7 mg/dL) and Adipo-IR (9.0 ± 0.7 vs 10.6 ± 1,1 vs 13.5 ± 0.9 mmol/l*pmol/l) increased ($p < 0.008$) from noNAFL, NAFL to NASH. Visceral fat was increased similarly in NAFL (218 ± 15 cm^2) and NASH (196 ± 6 cm^2) compared to noNAFL (139 ± 8 cm^2, $p < 0.0001$), while BMI, subcutaneous fat, BOH and FFA were similar in the 3 groups. Presence of NASH was associated with increased Adipo-IR (OR = 2.5, CI 1.5–4.5, p = 0.0005) after adjusting for age, BMI, IGT/T2D. In case of increased necro-inflammation (ie "active NASH," the sum of ballooning and lobular inflammation ≥ 3) the OR was 2.6 (CI 1.4–4.7, p = 0.003). There was no independent association of FFA, BOH or TG. Moreover, NASH with severe fibrosis (F2-F4) had a much higher Adipo-IR (18.7 ± 4.1 mmol/l*pmol/l) *vs* NASH F0–1 (12.2+0.7 mmol/l*pmol/l), NAFL (10.6 ± 1.1 mmol/l*pmol/l) and noNAFL (8.6 ± 0.8 mmol/l*pmol/l, $p < 0.001$). In NASH with severe fibrosis (F2-4) the association with Adipo-IR had an OR = 3.3 (CI 1.4–8.0, p = 0.003) adjusted for age, BMI, IGT/T2D.

Conclusion: Increased adipo-IR was significantly associated to presence of active NASH and severe fibrosis independently of BMI, showing the importance of dysfunctional adipose tissue as a main target in this disease.

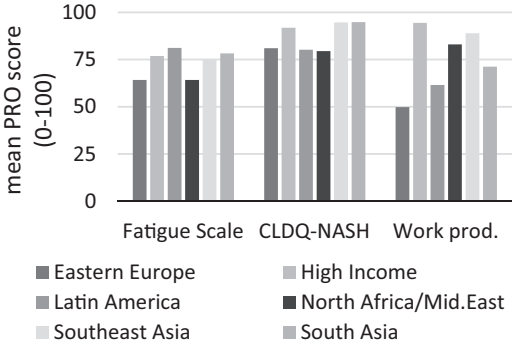
Email: zobair.younossi@inova.org

Background and Aims: NAFLD is a growing cause of chronic liver disease (CLD) worldwide. We assessed and compared clinical and PRO results in NAFLD patients enrolled in regions around the world to chronic viral hepatitis C (CVH).

Method: Global NAFLD/NASH Registry is enrolling NAFLD/NASH patients who are seen in real-world practices in 18 countries [6 Global Burden of Disease (GBD) super-regions]. Clinical and PRO data (CLDQ-NASH, FACIT-F, WPAI) are being collected. Similarly collected data from CVH patients were used for comparison.

Results: 7753 subjects (4250 NAFLD/NASH and 3503 CVH) were used for this analysis. In comparison to CVH, NAFLD/NASH patients were less likely males (44% vs. 52%), diabetics (37% vs. 13%) and have other components of metabolic syndrome (BMI 36 ± 10 vs. 27 ± 5, hypertension (HTN) 53% vs. 25%, hyperlipidemia (HL) 52% vs. 12%), with more depression and clinically overt fatigue (20% vs. 13% and 35% vs. 26%, respectively), but were less likely to have cirrhosis (8% vs. 14%) (all $p < 0.001$). Compared to CVH, PRO scores of patients with NAFLD/NASH were significantly impaired in all domains of FACIT-F and CLDQ (all $p < 0.05$, all but one $p < 0.01$); the greatest impairment was seen in Social Well-Being of FACIT-F, Activity/Energy, Abdominal Symptoms, Fatigue, and Systemic Symptoms of CLDQ (difference in group mean scores up to −8% of a PRO range size). Assessing geographic differences among NAFLD/NASH patients, 59% were enrolled from High-Income GBD super-region, followed by 14% in North Africa and Middle East, 12% in Southeast Asia, 8% in Latin America and the Caribbean, 4% in Eastern Europe, and 3% in South Asia. Clinical and PRO profile of NAFLD/NASH patients varied between the regions: patients were oldest in Eastern Europe (55 ± 11 years) and youngest in South Asia (44 ± 12), more likely males in Southeast Asia (62%) and less likely in Eastern Europe (26%). The highest BMI was in Eastern Europe (42 ± 9) and the lowest in South Asia (27 ± 4) along with the rates of type 2 diabetes (72% vs. 25%), HTN (90% vs. 27%), and HL (82% vs. 26%) in the same regions. The rates of psychiatric comorbidities (depression, anxiety) and fatigue were again the highest in Eastern Europe and the lowest in Southeast Asia (all $p < 0.0001$). Cirrhosis rate was the highest in South Asia (13%) and the lowest in Eastern Europe (1%) (all $p < 0.0001$). Assessment of PROs in NAFLD/NASH indicated the lowest CLDQ-NASH total scores were observed in Eastern Europe, Latin America, and North Africa/Middle East regions (4.9, 4.8, and 4.8 on a 1–7 scale, respectively); the highest were in Southeast and South Asia (5.7 in both regions). Similar trends were seen in PRO scores measured by FACIT-F and WPAI (all $p < 0.0001$) (Figure).



Conclusion: Patients with NAFLD/NASH have more comorbidities and PRO impairment than patients with CVH seen in real-world practices globally. Clinical and PRO presentations of NAFLD/NASH patients vary around the world.

Liver development and regeneration

Email: fotiss@yahoo.com

Background and Aims: The biliary tree is characterized by distinct populations with different susceptibility to disease. However, the characteristics and regenerative potential of these populations remain elusive. To address this challenge, we characterise the human intra- and extra-hepatic biliary epithelium using single-cell RNA sequencing (scRNAseq). We then explore which of these populations can be propagated as cholangiocyte organoids (COs) and interrogate the plasticity and the mechanisms controlling the identity of these organoids in vivo and in vitro.
Method: Biliary Epithelial Cells (BECs) from discarded donor livers and cholangiocyte organoids (COs) were characterized using droplet-encapsulation scRNAseq. (10 individuals, 14,003 primary cholangiocytes, 28,513 organoid cells, 12 lines). Pseudotime and Gene Ontology (GO) analysis was performed using Monocle and EnricR respectively. COs from different BEC populations were derived under the same culture conditions using our established technique. scRNAseq results were validated in human tissue though immunofluorescence. NOD-SCID mice were used for CO transplantation experiments.
Results: Our data identified transcriptional differences between intrahepatic (IHD), common bile duct (CBD) and gallbladder (GB) BECs. However, pseudotime analysis revealed a gradual transition in transcriptional signature between these populations. GO analysis identified differentially expressed genes as factors facilitating adaptation of cholangiocytes to their local microenvironment, such as bile modification genes. BECs cultured as COs assumed a similar profile, upregulated culture-condition associated genes and lost regional differences. IHD COs treated with gallbladder bile or Farnesoid X Receptor (FXR) agonists assumed a GB signature, while GB COs transplanted in the liver of immunocompromised mice assumed an IHD signature.
Conclusion: Our results provide the first transcriptional roadmap of the intra- and extrahepatic biliary tree; reveal the plasticity of BECs and COs and shed light into the mechanisms controlling their identity through FXR activation. These mechanisms could provide new insights into biliary regeneration and the effects of FXR agonists in cholestatic diseases.

AS164

Mapping origins of replication in a regenerating liver post partial hepatectomy

Giacomo Rossetti[1], Noëlle Dommann[2], Angeliki Karamichali[1], Vasilis Dionellis[1], Adrian Keogh[2], Daniel Candinas[2], Deborah Stroka[2], Thanos Halazonetis[1]. *[1]University of Geneva, Department of Molecular Biology, Geneva, Switzerland; [2]Bern University Hospital, University of Bern, Department of Biomedical Research, Visceral Surgery and Medicine, Bern, Switzerland*
Email: deborah.stroka@dbmr.unibe.ch

Background and Aims: DNA replication begins at thousands of individual origins of replication (ORI) that are tightly regulated both spatially and temporally. Timely execution of replication and transcription is important to avoid DNA replication stress and collisions which could lead to genomic instability and mutagenesis. The aim of this study is to monitor DNA replication and transcription to determine if collisions between replication and transcription occur during the proliferative phase in a regenerating liver.
Method: We synchronized hepatocyte proliferation using two-thirds partial hepatectomy (PH) in mice. To map early S-phase replication origins, nascent DNA was labelled in vivo with EdU every 2 hours from 24 to 44 hours post resection with and without hydroxyurea (HU), to limit fork progression after origin firing. Edu containing DNA was sequenced from isolated hepatocytes. To label newly transcribed mRNA, EU was injected into mice between 24 and 40 hours in two hours intervals for 30 minutes before harvesting. EUseq was performed to identify nascent mRNA in vivo.
Results: We were able to map and identify the temporal pattern of ORI in hepatocytes following PH. Origins were located outside transcribed genes.
Conclusion: For the first time, we could show that in a normal regenerating liver, transcription and translation are synchronized and with no collisions happening between them.

AS165

Single cell RNA -seq atlas of a regenerating liver in mice reveals early Kupffer cell proliferation

Daniel Sanchez-Taltavull[1], Tess Brodie[1], Zindel Joel[1], Noëlle Dommann[1], Bas Surewaard[2,3,4], Nicolas Melin[1], Adrian Keogh[1], Paul Kubes[2,3,4], Daniel Candinas[1], Guido Beldi[1], Deborah Stroka[1]. *[1]University of Bern, Visceral Surgery and Medicine, Department for BioMedical Research (DBMR), Bern University Hospital, University of Bern, Bern, Switzerland, Bern, Switzerland; [2]Snyder Institute for Chronic Diseases, Cumming School of Medicine, University of Calgary, Calgary, Canada; [3]Cumming School of Medicine, University of Calgary, Department of Microbiology, Immunology & Infectious Diseases, Calgary, Canada; [4]University of Calgary, Department of Pharmacology and Physiology, Calgary, Canada*
Email: deborah.stroka@dbmr.unibe.ch

Background and Aims: Liver regeneration is initiated by loss of hepatic tissue to restore homeostatic levels of liver mass and function. The main mechanism is proliferation of parenchymal cells, nevertheless this complex and orchestrated process requires the coordination of multiple cell types in a spatially and temporally regulated manner. Using single cell RNA-seq, we reveal the cell specific contribution to early events during liver regeneration.
Method: Liver regeneration was initiated using a standard two-thirds partial hepatectomy (PHx) model in C57Bl/6 mice. Hepatic cells were isolated by a two-stage collagenase in situ digestion. scRNA-seq libraries were prepared from 5000 cells from sham control, 3 hours, 6 hours and 24 hours after PHx in duplicate. Liver cells were further characterized by mass cytometry, Kupffer cells (KC) proliferation was assessed by EdU incorporation and flow cytometry as well by spinning disk confocal intravital microscopy.

Results: We profiled the transcriptome of 11896 individual cells of the parenchymal and non-parenchymal fraction. scRNA-seq revealed early time regulation for endothelial cells, hepatocytes, bone marrow-derived macrophages (BMDM) and KC. Mass Cytometry identified changes in the number of B cells, Granulocytes and BMDM after PHx. Pathway enrichment analysis showed proliferation of KC at 24 h. This finding was validated by FACS sorting EdU postive cells in KC at 24 h and by in vivo imaging.
Conclusion: Our results provide a genome wide picture of liver regeneration at a single cell level and reveal the regulated genes in each cell population after partial hepatectomy. Additionally, we have shown for the first time in vivo Kupffer cells proliferation as the first cell to proliferate in the regenerating mouse liver following PHx.

AS166

Myeloid cell-specific deletion of ERK5 regulates the response to liver regeneration after partial hepatectomy (PH) in mice

Giovanni Di Maira[1], Salvatore Sutti[2], Giacomo Vivona[1], Naresh Naik Ramawath[2], Emanuele Albano[2], Fabio Marra[1]. [1]*University of Florence;* [2]*Università del Piemonte Orientale*
Email: giovanni.dimaira@unifi.it

Background and Aims: The extracellular signal-regulated kinase 5 (ERK5) is a member of the Mitogen-Activated Protein Kinases family, and is involved in the modulation of proinflammatory mediators in endothelial cells and monocytes, and in the differentiation of monocytes to macrophages. In addition, signals derived from macrophages regulate liver regeneration after PH. We recently generated mice deletion of the ERK5 gene in cells of myeloid lineage (LysMCRE/ERK5KO).
This study was designed to investigate the phenotypic response of LysMCRE ERK5 KO mice subjected to PH.
Method: LysMCRE/ERK5KO mice were generated crossing ERK5 floxed mice (control mice) with mice expressing Cre-recombinase under the control of M-lysozyme promoter. Mice were subjected to a 65% partial hepatectomy (PH). Mice were sacrificed at 8, 24, 48 and 168 hours. Serum ALT and AST were measured using standard biochemical assays. Intrahepatic gene expression was assayed by quantitative real-time PCR.
Results: Measurement of liver-to body weight ratio showed that recovery of liver mass was slightly lower at 24 and 48 hours after PH in LysMCRE/ERK5KO mice, while no differences between the two experimental groups were observed at late time point (168 hours). Expression of the proliferation marker PCNA was decreased in LysMCRE/ERK5KO 48 hours after PH. Interestingly, although we did not observe a significant impairment of liver mass recovery in LysMCRE/ERK5KO mice, in these animals severe liver damage was evident at 24 and 48 hours after PH, as indicated by higher ALT and AST levels compared to the control group. Histological analysis confimed this result showing a higher degree of hepatic tissue damage in LysMCRE/ERK5KO mice subjected to PH. Analysis of M1/M2 markers in liver tissue showed a reduced expression of M2 markers (ARG1, MRC2), together with a parallel increase in M1 markers (CCL2, IL1β) in the LysMCRE/ERK5KO group 48 h after PH)+, compared to control mice.
Conclusion: This study suggests that ERK5 modulates the liver regeneration process regulating macrophage plasticity. Genetic loss of ERK5 in myeloid cells is associated with severe liver damage and reduced cell proliferation, a phenotype associated with enhanced M1 polarization of hepatic macrophage.

AS167

Ageing decreases the pool of newborn hepatocyte lineages, but does not impair their intrinsic proliferative response to partial hepatectomy in mice

Email: j.vaquero@iisgm.com

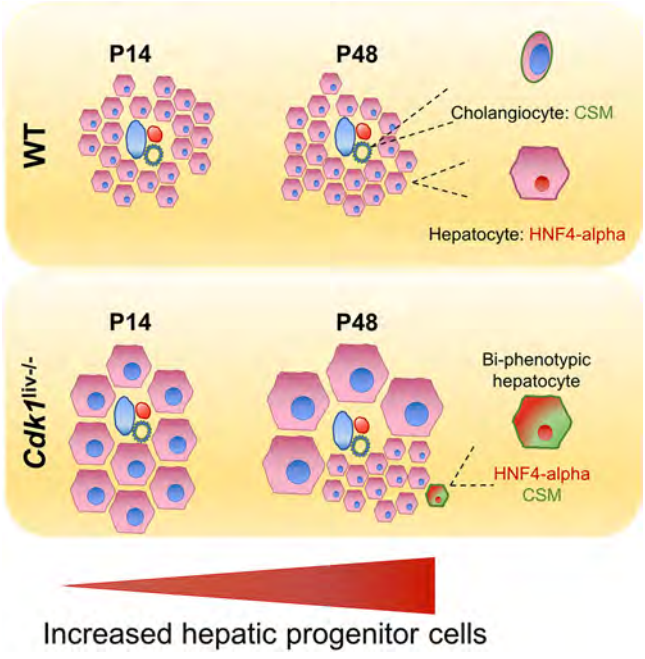
Background and Aims: Liver regeneration is known to decrease with age, but the operative mechanisms and the effects of aging on the sources of new hepatocytes are still unknown. Here, we evaluated the impact of aging on the contribution of newborn hepatocyte lineages to hepatocyte turn-over in the normal liver and after a partial hepatectomy (PH).
Method: The lineage reporter mT/mG mouse strain (Jackson Lab) was crossbred with mice expressing Cre-recombinase under the control of the Albumin promoter, generating litters (AlbCrexmT/mG mice) that expressed the Tomato-dye protein (mT+) in all cells, except in albumin-expressing cells which expressed EGFP (mG+) instead. Young adult (10–14 wk-o) and old (63–72 wk-o) male AlbCrexmT/mG mice underwent PH and were sacrificed 4 days later. Liver samples were formalin-fixed, sucrose-protected, and frozen in OCT. The contribution of intrahepatic albumin-naïve progenitor cells to the birth of *de novo* hepatocytes was evaluated by counting mT+ hepatocytes by confocal microscopy of thick liver tissue sections (300 micra) that had been made transparent using the CUBIC (Clear, Unobstructed Brain/Body Imaging Cocktails and Computational analysis) protocol. All counts were referred to the total number of hepatocytes evaluated in each mouse. A subset of mice underwent collagenase perfusions for hepatocyte isolation, and mT+ hepatocytes (negative for mG and F4/80, to correct for false positives) were counted by flow cytometry (FACS) and imaged after cell sorting.
Results: Compared with young adults, old mice showed a striking reduction of mT+ hepatocyte counts before (0.075% [0.023, 0.109] vs. 0.005% [0.001, 0.012], $p = 0.003$) as well as after PH (0.098% [0.051, 0.115] vs. 0.014% [0.002, 0.016], $p < 0.0001$). Such reductions resulted from a lower proportion of both isolated mT+ hepatocytes ($p < 0.0001$) and clusters of mT+ hepatocytes ($p < 0.01$). Despite these important differences, the fold-change increases of mT+ hepatocytes after PH was similar in both groups (Young: 1.378 [0.977, 1.378] vs. Old: 1.075 [0.941, 7.197], $p = 0.93$). Compared with baseline, PH increased the proportion of mT+ hepatocyte clusters (Young, $p = 0.0078$; Old, $p = 0.039$) and the percentage of mT+ hepatocytes localized in clusters (Young, $p = 0.008$; Old, $p = 0.039$) in both groups. The liver-to-body weight ratio tended to be lower in old mice after PH (3.15 [2.98, 3.57] vs. 2.95 [2.66, 3.29], $p = 0.11$). FACS and confocal microscopy of sorted mT+ hepatocytes confirmed the imaging counts.
Conclusion: Aging drastically decreases the birth of newborn hepatocyte lineages in mice. A considerable exhaustion of the pool of albumin-naïve intrahepatic progenitor cells rather than intrinsic defects of their proliferative capacity appeared to be the main operative mechanism. Increasing the endogenous pool of intrahepatic progenitors, therefore, could improve the liver regenerative capacity in advanced age.

AS168

Impaired hepatocyte cell division induces progenitor cell activation and emergence of bi-phenotypic hepatocytes

Gözde Zafer[1,2], Jin Rong Ow[1], Matthew Dewhurst[1], Noémi K. M. Van Hul[1,3], Matias Caldez[1,4], Christine Goh[1], Nai Yang Fu[5], Philipp Kaldis[1,6]. [1]*Institute of Molecular and Cell Biology (IMCB), A*STAR (Agency for Science, Technology and Research), Singapore;* [2]*National University of Singapore (NUS), Department of Biochemistry, Singapore;* [3]*Karolinska Institutet, Department of Biosciences and Nutrition, Huddinge, Sweden;* [4]*Osaka University, World Premier Immunology Frontier Research Center, Suita, Japan;* [5]*Duke-NUS Graduate Medical School, Singapore;* [6]*Lund University, Department of Clinical Sciences, Malmö, Sweden*
Email: philipp.kaldis@med.lu.se

Background and Aims: Recent studies suggest the involvement of other cell types in liver regeneration upon impaired hepatocyte cell division. However, more investigation is needed on the source of these cells. We previously showed that deletion of *Cdk1*, a critical component of cell cycle, in hepatocytes (*Cdk1*$^{liv-/-}$) does not affect the development and the regeneration of the liver. However, excessive inflammation and fibrosis were observed during postnatal liver development. We detected hypertrophied hepatocytes accompanied by the emergence of normal sized hepatocytes (NSHs) that express CDK1, despite *Cdk1* being completely deleted at 2 weeks postpartum. This indicates a contribution of non-parenchymal cells to liver regeneration and development. Thus, our aim is to identify other cell types contributing to the regeneration of the liver in the absence of hepatocyte cell division.
Method: Liver samples were collected at three-day intervals from postnatal mice to identify important time points for the emergence of NSHs. AAV8-TBG-GFP tail-vein injection was used to label and track the fate of hepatocytes to show that NSHs are not emerging from pre-existing ones. Samples were analyzed via IHC, IF, qPCR, and WB. Hepatocyte isolation and FACS analysis were used for GFP labelled hepatocytes to identify and analyze bi-phenotypic hepatocytes.
Results: P37 and P48 *Cdk1*$^{liv-/-}$ liver displayed substantial amount of NSH populations near hypertrophied hepatocytes and they were localized around zone 1. We labelled both *Cdk1*$^{liv-/-}$ and WT mice with AAV8-TBG-GFP, which specifically infects hepatocytes and causes GFP expression. Samples were injected at P28 and harvested at P42. IHC and IF analysis revealed that in WT samples, all the hepatocytes retained GFP labelling as there is nearly no cell division after P28. However, in *Cdk1*$^{liv-/-}$ samples, only hypertrophied hepatocytes retained GFP labelling, while all the NSH populations were GFP negative. Additionally, IHC staining and WB analysis revealed that some of these NSHs were able to express CDK1. We identified a small number of normal sized HNF4-alpha^{+} hepatocytes that express a newly identified cholangiocyte specific marker (CSM) that also labels hepatic progenitor cells (HPCs). To analyze these bi-phenotypic hepatocytes, we labelled *Cdk1*$^{liv-/-}$ and WT mice with GFP and isolated hepatocytes three days later. FACS analysis of CSM and GFP revealed that 3.1% of the *Cdk1*$^{liv-/-}$ hepatocyte population display bi-phenotypic expression.



Conclusion: We demonstrated that compromised hepatocyte cell division activates HPCs during postnatal liver development. A small population of bi-phenotypic hepatocytes were identified, and further investigation is needed to elucidate the differentiation process and underlying signals that activate these bi-phenotypic cells.

Positive topline results from a 24-week, randomized, double-blind, placebo-controlled, multicenter, phase 2 study of the FGF19 analogue aldafermin (NGM282) in patients with non-alcoholic steatohepatitis

Stephen A. Harrison[1,2], Guy Neff[3], Cynthia Guy[4], Mustafa Bashir[4], Angelo Paredes[5], Juan Frias[6], Ziad H. Younes[7], James F. Trotter[8], Nadege T. Gunn[9], Sam Moussa[10], Anita Kohli[11], Kristen Nelson[12], Mildred Gottwald[12], William Chang[12], Andrew Yan[12], Alex Depaoli[12], Lei Ling[12], Hsiao Lieu[12]. *[1]Pinnacle Clinical Research, San Antonio, United States; [2]University of Oxford, Oxford, United Kingdom; [3] Florida Research Institute, Lakewood Ranch, United States; [4]Duke University, Durham, United States, [5]Brooke Army Medical Center, San Antonio, United States; [6]National Research Institute, Los Angeles, United States, [7]Gastro One, Memphis, United States; [8]Texas Digestive Consultants, Dallas, United States; [9]Pinnacle Clinical Research, Austin, United States; [10]Adobe Gastroenterology, Tucson, United States; [11]Institute for Liver Health, Chandler, United States; [12]NGM Biopharmaceuticals, South San Francisco, United States*
Email: lling94080@yahoo.com.

Background and aims: Aldafermin (NGM282), an engineered FGF19 analogue, significantly inhibited bile acid synthesis, reduced hepatic fibrosis, inflammation and steatosis in previous 12-week NASH trials. Here we report the primary and key results from the 24-week (W24) study with paired liver biopsy.
Method: 78 subjects were randomized 1:2 to receive PBO (n = 25) or aldafermin 1 mg (n = 53) SC QD at 9 US study sites. Key inclusion criteria included biopsy-proven NASH with NAS≥4, stage 2–3 fibrosis and absolute liver fat content (LFC) ≥8%. Subjects underwent MRI-PDFF and liver biopsies at baseline (BL) and W24. The primary endpoint was change from BL to W24 in LFC. Histological endpoints included improvement in liver fibrosis by ≥1 stage with no worsening of NASH and resolution of NASH with no worsening of fibrosis (NASH CRN criteria).
Results: At W24, treatment with aldafermin resulted in statistically significant reductions in LFC (Table 1). A greater proportion of subjects on aldafermin achieved fibrosis reduction of ≥1-stage without NASH worsening (38% [aldafermin] vs 18% [PBO]), and NASH resolution with no worsening of fibrosis (24% [aldafermin] vs 9% [PBO]). 22% (aldafermin) vs. 0% (PBO) of subjects achieved both histological endpoints (P = 0.015). ALT, AST and fibrogenesis biomarkers (Pro-C3 and ELF) declined rapidly and significantly from BL with aldafermin therapy. AEs were mostly mild and moderate in severity. No difference in gastrointestinal AE was observed between arms. Incidences of SAEs were 12% (PBO) vs 4% (aldafermin), and discontinuations due to AE 4% (PBO) vs 0% (aldafermin). All SAEs were unrelated to drug.

Table 1: Change from baseline to week 24 in key endpoints

	PBO (n = 25)	Aldafermin 1 mg (n = 52)
Primary Endpoint		
Δ Absolute MRI-PDFF, %	−2.7 (1.3)	−7.7 (0.8) P = 0.002 vs PBO
% subjects with ↓5% absolute	*24%*	*68%* P < 0.001 vs PBO
Δ Relative MRI-PDFF	−13.1%	−38.8% P = 0.008 vs PBO
% subjects with ↓30% relative	*29%*	*66%* P = 0.004 vs PBO
Secondary Endpoints		
% Subjects achieving fibrosis improvement (≥1-stage) with no worsening of NASH	*18%*	*38%*
% Subjects achieving resolution of NASH with no worsening of fibrosis	*9%*	*24%*
% Subjects achieving fibrosis improvement (≥1-stage) with no worsening of NASH AND resolution of NASH with no worsening of fibrosis	*0%*	*22%*
Δ Absolute ALT, U/L	−15.9 (3.5)	−36.6 (2.4)
Δ Absolute AST, U/L	−8.5 (3.6)	−19.0 (2.4)
Δ Pro-C3, ng/mL	−0.9 (1.1)	−5.5 (0.7)

Shown are LS mean (SE) or %subjects.

Conclusion: In patients with NASH, aldafermin therapy resulted in statistically significant reduction in LFC and robust improvement in fibrosis and NASH histology compared with PBO. A greater proportion of patients treated with aldafermin achieved both histological endpoints of fibrosis improvement and NASH resolution compared to PBO. Aldafermin 1 mg maintained a durable response for 24 weeks with a favorable tolerability and safety profile.

LBO02

ATTIRE: Albumin to prevent infection in chronic liver failure: an interventional randomised controlled trial

Louise China[1], Simon Skene[2,3], Nicholas Freemantle[3], Kate Bennett[2,3], Ekaterina Bordea[3], Natalia Becares[1], Andrew Portal[4], Yiannis Kallis[5], Gavin Wright[6], Derek Gilroy[1], Ewan Forrest[7], Alastair O'brien[1].
[1]University College London, Division of Medicine, London, United Kingdom; [2]University of Surrey, United Kingdom; [3]UCL Institute of Clinical Trials and Methodology, United Kingdom; [4]Bristol Royal Infirmary, United Kingdom; [5]QMUL, Barts Liver Centre, London; [6]Basildon University Hospital, United Kingdom; [7]Glasgow Royal Infirmary, United Kingdom
Email: louise.china@ucl.ac.uk.

Background and aims: Acutely decompensated cirrhosis patients are highly prone to infection. Multiple experimental studies support an anti-inflammatory role for Albumin in addition to its oncotic properties. Evidence supports the use of weight-based infusions of 20% Human Albumin Solution (HAS) for Spontaneous Bacterial Peritonitis and Hepato-renal syndrome, but albumin is also widely used for other indications where there is an absence of trial data. Recent albumin trials in outpatients with ascites support the notion that regimens that aim to normalise serum albumin concentrations might improve mortality. The ATTIRE trial aimed to determine if targeting a serum albumin level ≥35 g/L in decompensated cirrhosis inpatients using repeated daily HAS infusions reduced incidence of infection, renal dysfunction and mortality compared to standard care.
Method: ATTIRE was a multicentre, open label trial in hospitalised decompensated cirrhosis patients with serum albumin <30 g/L at enrollment at 35 UK sites (January 2016–June 2019). Treatment commenced within 3 days of admission with patients randomised to targeted 20% HAS for up to 14 days (or discharge) or standard care. The composite primary endpoint was new infection, renal dysfunction or mortality from day 3–15 of treatment.
Results: 828 patients were recruited with no baseline differences between groups with respect to median(IQR): creatinine 68(54–90) μmol/L, bilirubin 94(46–171) μmol/L, INR 2(1–2) and albumin 23(4) g/L. 70% were male, 79% reported alcohol misuse, 28% had infection and 53% were prescribed antibiotics. The median(IQR) volume of HAS infused to patients in the treatment versus standard care arm was 1000(700–1500) ml vs 100(0–600) ml (p < 0.0001). There was no difference in composite primary endpoint between targeted albumin (n = 125/414; 30.2%) and standard care (n = 128/414, 30.9%, OR 0.968 (95%CI 0.716–1.307, p = 0.830). There was no difference when the endpoint window was extended to day 1, in individual components, length of stay or mortality at 3/6 months. There was no treatment effect in subgroup analyses that included baseline organ dysfunction, infection, MELD score, albumin level or reason for admission. The mean increase in cost associated with intervention was £573.26 (95% CI −1,247.54–101.01). There were more serious adverse events in the HAS arm (95 vs 74).
Conclusion: The ATTIRE trial does not support targeted HAS over current UK standard care for hospitalised decompensated cirrhosis patients.

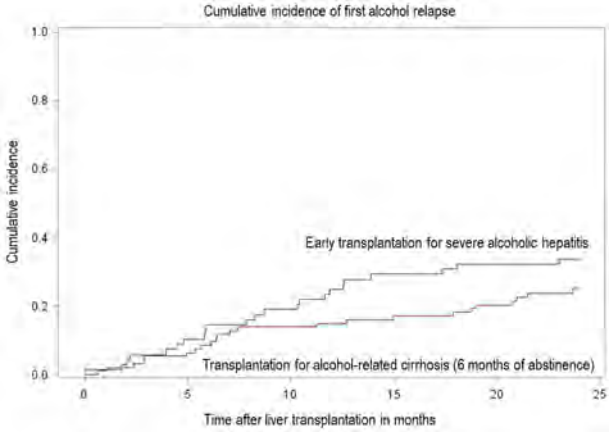
Background and aims: Early liver transplantation (eLT) for severe alcoholic hepatitis (SAH) is an emerging therapy that must be evaluated in prospective controlled studies with a rigorous study design to bring reliable data to experts.
Method: this prospective controlled trial (NCT01756794) compared 3 groups: A: patients with SAH not responding to medical treatment selected for eLT using a dedicated score (≥220/250), based on social and addiction parameters; B: patients candidates for transplantation for alcohol-related cirrhosis with at least 6 months of abstinence; C: patients with SAH not responding to medical treatment denied for eLT (score <220). Primary analysis was restricted to transplanted patients, to assess the non-inferiority of A versus B on 2-year alcohol relapse after LT using the alcohol timeline follow back (ATLFB) method and a pre-specified margin of 10%. Secondary outcomes were pattern of alcohol relapse and survival after LT. A secondary analysis was restricted to all patients of groups A and C to assess the benefit of eLT in SAH on 2-year survival.
Results: We included 155 patients with SAH: 78 selected for eLT (group A, median Lille score = 0.86), 77 denied for eLT (group C, median Lille score = 0.81). 129 patients were included in group B. Primary analysis: 68 (A) and 93 patients (B) were transplanted and included. MELD score at inclusion in groups A and B were 30.6 vs. 22.3, p < 0.001. The non-inferiority of A versus B was not demonstrated with a 2-year alcohol relapse of 33.8 (A) and 24.7% (B, figure), absolute difference of 9.1, one-sided 95% confidence interval, −∞ to 21.1%. Regarding secondary outcomes, 2-year heaving drinking relapse rate was higher in group A (22.1 vs. 5.4%, p < 0.001). In heavy drinking relapsers, median percentage of time spent to drink during the follow-up was 10 (A) vs. 5.9% (B). Two-year survival in groups A and B was similar (89.7 vs. 88.1%). Secondary analysis: 2-year survival was higher in group A (patients transplanted or not, n = 78) than in group C (n = 77): 82.8 vs. 28.2%, p < 0.001.



Conclusion: In the first controlled study in this field, relapse rate is of 33.8% in patients early transplanted for SAH as compared to 24.7% in patients with alcohol-related cirrhosis. Using a pre-specified non-inferiority margin of 10%, we cannot conclude to non-inferiority. Heavy drinking is more frequently seen after eLT. Early liver transplantation induces a drastic improvement of survival in patients with SAH not responding to medical therapy.

Email: ryan.huss@gilead.com.

Background and aims: Patients with advanced fibrosis due to NASH are at increased risk of end-stage liver disease, hepatocellular carcinoma, and mortality. We evaluated the safety and efficacy of an ACC inhibitor, FXR agonist, and ASK1 inhibitor, as monotherapy and in combination, in patients with advanced fibrosis due to NASH.
Method: In this phase 2b trial, 392 patients with advanced fibrosis (F3-F4) due to NASH were randomized to receive placebo, selonsertib 18 mg (SEL), cilofexor 30 mg (CILO), or firsocostat 20 mg (FIR), alone or in two-drug combinations, once daily for 48 weeks (W48). Biopsies from baseline (BL) and W48 were read by a central reader and digital images of biopsies were evaluated using a machine learning (ML) approach (PathAI, Boston, MA). The primary endpoint was the proportion of patients with a ≥1-stage improvement in fibrosis without worsening of NASH. Secondary endpoints included changes in NAFLD Activity Score (NAS), liver biochemistry, and noninvasive fibrosis markers.
Results: The majority of patients had cirrhosis (56%), diabetes (72%), and NAS ≥5 (83%). More patients treated with combination therapy achieved a ≥1-stage improvement in fibrosis without worsening of NASH compared to placebo: CILO/FIR (21%, p = 0.17), CILO/SEL (19%, p = 0.26), FIR/SEL (15%, p = 0.62), FIR (12%, p = 0.94), CILO (12%, p = 0.96), and placebo (11%). Based on a ML approach, CILO/FIR led to a significant decrease in NASH CRN fibrosis score (difference in LSmeans from BL to W48: −0.42 vs. −0.16 for placebo; p = 0.040) and a shift in biopsy proportionate area from F3-F4 to ≤F2 fibrosis. Compared to placebo, CILO/FIR led to significantly increased proportions of patients with a ≥2-pt reduction in NAS and ≥1-grade improvements in steatosis, lobular inflammation, and ballooning (all p < 0.05; Figure). Fibrosis improvement without worsening of NASH with CILO/FIR was more frequent in patients with ≥2-pt NAS response (35% vs 14%, p = 0.060). CILO/FIR also led to significant improvements

in serum ALT, AST, bilirubin, total bile acids, CK18, insulin, estimated glomerular filtration rate (eGFR), and ELF score (all $p \leq 0.05$), and an increase in the proportion of patients with ≥25% reduction in liver stiffness by transient elastography (45% vs 20% with placebo, p = 0.016). All regimens were well tolerated. Pruritus occurred in 28% of patients treated with CILO/FIR (73% mild; no Grade 3 or discontinuations) vs 15% with placebo. LSmean changes in lipids vs placebo in patients treated with CILO/FIR were: total cholesterol (+17 mg/dL, p = 0.005), LDL (+9 mg/dL, p = 0.080), HDL (−4 mg/dL, p = 0.012), and triglycerides (+45 mg/dL, p < 0.001).

Conclusion: In patients with bridging fibrosis and cirrhosis, treatment with CILO/FIR for 48 weeks was well tolerated and led to improvements in fibrosis and NASH activity. This combination offers the potential for fibrosis regression in patients with advanced fibrosis due to NASH.

Email: hamish.innes@gcu.ac.uk.

Background and aims: The host genetics underpinning the development of alcohol-related liver cirrhosis is beginning to emerge, but is still incompletely understood. Better insight would improve risk-stratification of patients, help delineate its pathophysiology, and support the development of new treatments. The UK Biobank (UKB) study integrates host genotyping and health behavior data for a cohort of half a million individuals in UK aged 40–69 years, with available data for a wide range of biochemistry variables. The aim of this study was to use this resource to undertake a Genome-Wide Association Study (GWAS) for alcohol-related liver disease.

Method: UKB participants consuming >25 units/week of alcohol if female and >36 units/week if male, were included in a discovery GWAS against indirect markers of hepatic fibrosis and hepatocellular injury; *viz*. APRI, FIB-4, the Forn's score, serum alanine and aspartate transaminase.

Loci identified in the discovery analysis were then tested for association with alcohol-related cirrhosis status in a previously generated European GWAS data-set, together with a nested alcohol-related cirrhosis case-control study derived from within UKB (Phase 1 validation). Variants associated with alcohol-related cirrhosis in Phase 1 validation at a False Discovery Rate (FDR) <20%, were then

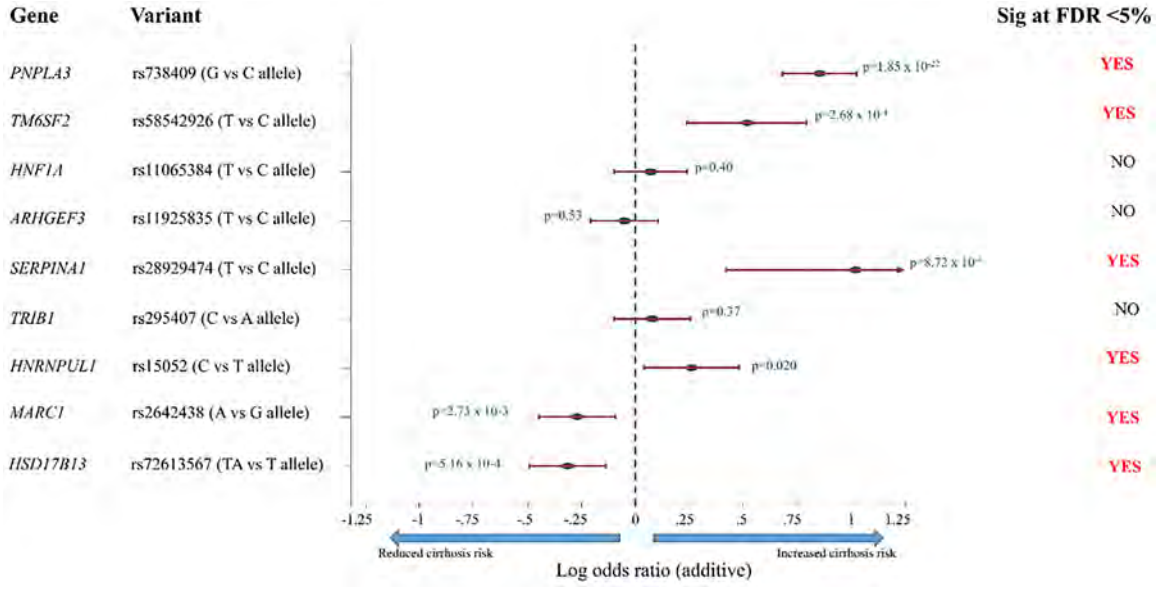

Figure: (abstract: LBO05): Results of phase 2 replication analysis. Association are adjusted for age, sex, type 2 diabetes and BMI.

directly genotyped in two European validation cohorts comprising 1536 cases with alcohol-related cirrhosis and 771 alcohol misusers without liver disease (Phase 2 validation). A FDR <5% was used to judge statistical significance in phase 2 validation, adjusting for age, sex, type 2 diabetes and BMI.

Results: The discovery GWAS, which included 35,839 UKB participants, identified 50 independent risk loci with genome-wide significance (p-value $<5 \times 10^{-8}$). Nine of these loci were significantly associated with risk of developing alcohol-related cirrhosis in the Phase 1 validation; six of the nine loci were significantly associated with risk of developing alcohol-related cirrhosis in the Phase 2 validation (see Figure). These six included four known risk variants in *PNPLA3*; *TM6SF2*; *HSD17B13*; and *SERPINA1*, plus two novel risk variants in *mitochondrial amidoxime reducing component 1* (*MARC1)* and *heterogeneous nuclear ribonucleoprotein U like 1 (HNRNPUL1)*. The minor "A" allele of *MARC1*:rs2642438 was associated with a reduced risk of cirrhosis (adjusted OR: 0.76; p = 0.0027); conversely the minor "C" allele of *HNRNPUL1*:rs15052 was associated with an increased risk (adjusted OR:1.30; p = 0.020).

Conclusion: This new GWAS has identified two novel single nucleotide polymorphisms (SNPs) – *MARC1*:rs2642438 and *HNRNPUL1:*rs15052 – that modulate the risk of alcohol-related cirrhosis in opposite directions. Both variants warrant further investigation.

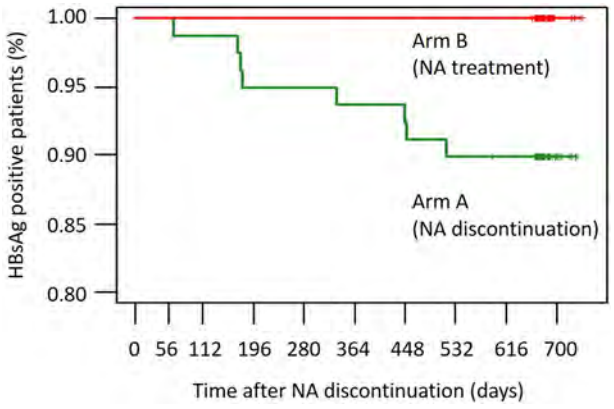
Background and aims: Disc Discontinuation of long-term suppression of HBV replication with nucleos(t)ide analogues (NUCs) can result in durable immune control of hepatitis B virus (HBV) replication in HBeAg negative patients. We have assessed the effect of NUC discontinuation in HBeAg negative patients in a prospective, multicenter, randomized trial (the Stop-NUC study).

Method: HBeAg-negative patients without cirrhosis who had achieved suppressed HBV DNA for ≥4 years during NUC therapy were randomly assigned to either stop (Arm A) or continue (Arm B) treatment. The primary endpoint was sustained HBsAg loss at week 96. Secondary end points included HBsAg seroconversion, virologic response (HBV DNA ≤20 IU/mL), biochemical response (alanine aminotransferase (ALT) < upper level normal (ULN)) as well as number of ALT flares (ALT >3 ULN) and time to re-therapy in the non-treatment arm. All patients were observed for 96 weeks, with visits including standard laboratory tests including HBV DNA levels, quantitative HBsAg, alanine aminotransferase (ALT) and bilirubin measurements, and adverse event reporting. In each arm 83 patients were randomized. The full analysis set comprised 158 patients (79 vs 79), excluding eight patients who dropped out immediately after randomization.

Results: At week 96 after NUC discontinuation, HBsAg loss or seroconversion were achieved in 8/79 (10%) and 6/79 (8%) patients in Arm A and in no patient in Arm B, respectively (p = 0.006 and p = 0.028). After NUC discontinuation, all patients in Arm A and no patient in Arm B experienced an HBV DNA flare >20 IU/mL, however, at week 96 HBV DNA were levels ≤20 IU/mL in 24/79 (31%) patients in Arm A and in all patients in Arm B (p < 0.001). ALT flare occurred in 28/79 (35%) patients in Arm A and in no patient in Arm B, and ALT levels were within normal ranges in 69/79 (88%) patients in Arm A and in 77/79 (97%) patients in Arm B at week 96 (p = 0.032). At week 96, NUC treatment had to be re-installed in 11/79 (14%) in Arm A while 54/79 (68%) patients had no indication for treatment according to current EASL recommendations. No patient in Arm A suffered serious adverse event possibly related to NUC discontinuation.



Conclusion: This first large-scale randomized study demonstrates the potential of discontinuation of long-term NUC treatment for induction of durable immune control and functional cure in patients with HBeAg negative chronic hepatitis B (EudraCT-Nr.: 2013-004882-15).

LBO07

Proton beam radiotherapy versus radiofrequency ablation treatment in patients with recurrent hepatocellular carcinoma: a randomized controlled phase 3 non-inferiority APROH trial

Joong-Won Park[1], Tae Hyun Kim[1,2], Young-Hwan Koh[1,3], Bo Hyun Kim[1], Min Ju Kim[3], Ju Hee Lee[3], Boram Park[4]. *[1]National Cancer Center, Center for Liver and Pancreatobiliary Cancer, Goyang-si, Korea, Rep. of South; [2]National Cancer Center, Center for Proton Therapy, Goyang-si, Korea, Rep. of South; [3]National Cancer Center, Department of Radiology, Goyang-si, Korea, Rep. of South; [4]National Cancer Center, Biostatistics Collaboration Team, Goyang-si, Korea, Rep. of South*
Email: jwpark@ncc.re.kr.

Background and aims: Radiofrequency ablation (RFA) is the standard of care for patients (pts) with Barcelona Clinic for Liver Cancer stage 0 and A hepatocellular carcinoma (HCC) not suitable for surgery. The role of external proton beam radiotherapy (PBT) is under investigation and a phase 2 study of PBT showed promising local control and safety. Herein, we conducted an investigator-initiated phase 3 non-inferiority trial to evaluate the effects of PBT on recurrent or residual HCC (rHCC).

Method: Patients (pts) with rHCC (size <3 cm, number ≤2) were randomly assigned (1:1) to receive PBT (Arm P) or RFA (Arm R) according to the Child-Pugh score and initial tumour stage. If the randomly assigned method was not technically feasible, pts were allowed to enroll in the other arm. Eligible pts of Arm P received a total of 66 Gray equivalent in 10 fractions and those of Arm R received RFA with a monopolar electrode. The primary endpoint was 2-year (y) local progression-free survival (LPFS) rate with a non-inferiority margin of 15%; secondary endpoints included overall survival, progression-free survival, tumour response rate and safety profile. (NCT01963429).

Results: Between December 2013 and December 2017, 144 pts in Arm P (n = 72) and Arm R (n = 72) comprised the intention-to-treat (ITT) population and the trial was concluded on January 2020. The baseline characteristics of pts were well balanced. In Arm P, six pts switched to Arm R and five pts received another treatment, while in Arm R, 19 pts switched to Arm P and three pts received another treatment. Thus, the per-protocol (PP) population comprised 80 pts in Arm P and 56 pts in Arm R. In the ITT population, the 2-y LPFS rate with PBT vs. RFA was 92.8% vs. 83.2% (90% confidence interval [CI], 0.7–18.4%; p < 0.001), meeting criteria for non-inferiority. In the PP population, 2-y LPFS rate with PBT vs. RFA was 94.8% vs. 83.9% (90% CI, 1.8–20.0%; p < 0.001). The 3- and 4-y LPFS rate with PBT were also significantly non-inferior to those with RFA. Efficacy outcomes are shown in the figure. The most common any-grade adverse events (AEs) were radiation pneumonitis (32.5%), and decrease in leukocyte counts (23.8%) in Arm P; and increase in alanine aminotransferase level (96.4%), abdominal pain (30.4%) in Arm R. No Grade 4 AEs or mortality were noted.

Conclusion: PBT was non-inferior to RFA in terms of LPFS in pts with rHCC, and PBT was tolerable and safe, consistent with the known profile.

Email: richard.j.thompson@kcl.ac.uk.

Background and aims: Children with progressive familial intrahepatic cholestasis (PFIC) due to bile salt export pump (BSEP) deficiency often present with debilitating pruritus, short stature, and progressive liver disease. The NAPPED study (NCT03930810) shows that ~50% of patients receive a liver transplant by age 10, but those who achieve serum bile acid (sBA) levels of <100 μmol/L after partial external biliary diversion show improved native liver survival and reductions in aspartate aminotransferase (AST), alanine aminotransferase (ALT), and bilirubin. Maralixibat (MRX) is an apical sodium-dependent bile acid transport inhibitor that interrupts the enterohepatic recirculation, reducing pruritus and cholestasis, and improving growth at Week 72 in an open-label, long-term study (INDIGO; NCT02057718). Here, we describe >4.5 years of treatment with MRX.
Method: MRX was dosed at 280 micrograms/kg daily for 48 weeks, increasing to 280 micrograms/kg twice daily in the extension. The NAPPED sBA threshold (≤100 micromol/L) was applied to patients remaining on-study >4.5 years. Transaminases, bilirubin, and growth were assessed to Week 237.
Results: Of the enrolled patients (n = 19) with nontruncated BSEP mutation (median age 4.1 years, range 1–13; 32% male), 7 achieved sBA control and remained on-study as of Week 237. Mean (standard error) sBA reduction was 234.4 (80.5) micromol/L ($p < 0.05$) with a mean value of 44.2 (38.8) micromol/L (*vs.* 299.6 micromol/L at baseline [BL]). Mean reductions in AST and ALT were 35.4 (11.5) and 41.1 (14.3) U/L with mean values of 26.7 (*vs.* 62.1 at BL) and 16.7 (*vs.* 57.9 at BL), respectively (both $p < 0.05$). Mean reductions in total and direct bilirubin were 0.1 (0.3) and 0.4 (0.2) mg/dL with mean values of 0.7 (*vs.* 0.8 at BL) and 0.1 (*vs.* 0.6 at BL), respectively ($p = 0.8$ and 0.13). Those with abnormal bilirubin, normalized. No ongoing patients were listed for liver transplant after >4.5 years of MRX. Growth (height z-score; $p < 0.01$) and pruritus ($p < 0.001$) improved significantly. Long-term MRX was safe and well tolerated; the most frequent treatment-emergent adverse events were mild to moderate in severity.
Conclusion: Patients who achieved control of sBA during MRX treatment had native liver survival beyond 4.5 years, improved liver biochemistry and improved growth, suggesting the disease-modifying potential of MRX. These data support MRX as a potential alternative to surgery for children with PFIC due to nontruncating BSEP deficiency.

Background and aims: Lenvatinib (LEN), a multikinase inhibitor of vascular endothelial growth factor receptors 1–3, fibroblast growth factor receptors 1–4, platelet-derived growth factor receptor alpha, RET, and KIT, is approved for first-line (1L) treatment of unresectable hepatocellular carcinoma (uHCC). The US FDA granted accelerated approval to pembrolizumab (PEMBRO), an antiprogrammed death receptor-1 monoclonal antibody, for patients (pts) with HCC after sorafenib therapy. We assessed the safety and efficacy of LEN + PEMBRO in the first 80 pts with uHCC enrolled in the 1L setting.
Method: In this phase 1b trial (NCT03006926), pts received LEN 12 mg/day (bodyweight [BW] ≥60 kg) or 8 mg/day (BW <60 kg) orally + PEMBRO 200 mg intravenously on day 1 of a 21-day cycle. Primary endpoints were safety and tolerability for Part 1, and objective response rate (ORR) and duration of response (DOR) by modified Response Evaluation Criteria In Solid Tumors (mRECIST), and RECIST version 1.1 per independent imaging review in the 1L setting for Part 2.
Results: No dose-limiting toxicities were found in Part 1 (6 pts). At data cutoff (October 31, 2019), the first 80 pts enrolled in the 1L setting had a median follow-up of 11.5 months; the median duration of treatment was 8.5 months (LEN, 8.3 months; PEMBRO, 7.7 months), and 26 pts continued treatment (LEN only, n = 2; both drugs, n = 24). Median overall survival was 22.0 months (95% CI 14.6–not estimable). Tumor responses assessed by mRECIST per investigator assessment are reported herein. Median progression-free survival was 8.6 months (95% CI 6.9–9.7) and ORR was 43.8% (95% CI 32.7–55.3); 5.0% of pts had a complete response and 38.8% of pts had a partial response. Median DOR was 12.6 months (95% CI 6.5–18.7), median time to response was 2.4 months (range: 1.2–11.8) and disease control rate (complete response + partial response + stable disease [≥5 weeks]) was 83.8% (95% CI 73.8–91.1). 21.3% of pts discontinued LEN + PEMBRO due to an adverse event (AE). Treatment-related AEs (TRAEs) occurred in 95% of pts (grade ≥3,

68%; grade ≥4, 5%). 35% of pts had serious TRAEs and 3 pts died from a TRAE (1 each for: acute respiratory failure/acute respiratory distress syndrome, intestinal perforation, abnormal hepatic function).
Conclusion: LEN + PEMBRO has promising antitumor activity with a tolerable safety profile. An ongoing phase 3 trial (NCT03713593) is assessing LEN + PEMBRO vs LEN alone as 1L therapy for uHCC.

Email: michel.ducreux@gustaveroussy.fr.

Background and aims: In IMbrave150, atezolizumab (atezo)+bevacizumab (bev) demonstrated a statistically significant and clinically meaningful improvement over sorafenib (sor) for the co-primary endpoints of overall survival (OS; HR 0.58 [95% CI, 0.42–0.79; p = 0.0006]) and independent review facility-assessed progression-free survival (PFS) per RECIST 1.1 (HR 0.59 [95% CI, 0.47–0.76; p < 0.0001]) in 501 patients (pts) with unresectable hepatocellular carcinoma (HCC) who had not received prior systemic therapy (tx) (Cheng ESMO Asia 2019). Here, we report safety data from IMbrave150 (NCT03434379).
Methods: In this open-label study, pts with systemic-tx naïve, unresectable HCC were randomised 2:1 to receive either atezo 1200 mg intravenously (IV) every 3 weeks (q3w) + bev 15 mg/kg IV q3w or sor 400 mg twice daily until unacceptable toxicity or loss of clinical benefit per investigator. Adverse events (AEs) were assessed per CTCAE version 4.0. AEs of special interest (AESI) were sponsor-defined based on the immune-mediated risks of atezo and other drugs in its class.
Results: In the safety population, 329 pts received atezo+bev and 156 received sor. Median tx duration was 7.4 mo for atezo, 6.9 mo for bev and 2.8 mo for sor (all ranges, 0–16 mo). Grade (Gr) 3–4 AEs occurred in 57% of pts receiving atezo+bev and 55% of pts receiving sor. Gr 5 AEs occurred in 5% and 6% of pts, respectively. AEs led to discontinuation of both atezo+bev in 7% of pts and of sor in 10% of pts. In both arms, most AESIs were Gr 1–2. Gr 3–4 atezo AESIs occurred in 26% and 30% of the atezo+bev and sor arms, respectively. More pts receiving atezo+bev (12%) required corticosteroid treatment than with sor (3%). The rate of immune-mediated hepatitis was comparable between the atezo+bev and sor arms (43% vs 40%, respectively).
Conclusions: Atezo+bev was generally well-tolerated in pts with HCC, and potential immune-mediated AESIs, a toxicity concern with checkpoint inhibitors, were manageable. The safety profile was consistent with the known risks of the individual study tx and underlying disease. The positive efficacy and patient-reported outcomes from IMbrave150 and these safety findings suggest that atezo +bev should be considered a practice-changing tx for pts with unresectable HCC who have not received prior systemic tx.

Nivolumab + ipilimumab combination therapy in patients with advanced hepatocellular carcinoma: subgroup analyses from CheckMate 040

Bruno Sangro[1,2], Aiwu Ruth He[3], Thomas Yau[4], Chiun Hsu[5], Yoon-Koo Kang[6,7], Tae-You Kim[8], Armando Santoro[9], Ignacio Melero[10], Masatoshi Kudo[11], Ming-Mo Ho[12], Ana Matilla[13,14], Francesco Tovoli[15], Jennifer Knox[16], Bassel El-Rayes[17], Mirelis Rivera Acosta[18], Jaclyn Neely[19], Yun Shen[19], Marina Tschaika[19], Anthony El-Khoureiry[20]. *[1]Clinica Universidad de Navarra, Pamplona, Spain; [2]CIBEREHD, Pamplona, Spain; [3]Georgetown University Hospital, Washington DC, United States; [4]University of Hong Kong, Hong Kong, China; [5]National Taiwan University Hospital, Taipei, Taiwan; [6]Asan Medical Center, Seoul, Korea, Rep. of South; [7]University of Ulsan, Seoul, Korea, Rep. of South; [8]Seoul National University, Seoul, Korea, Rep. of South; [9]Istituto Clinico Humanitas, Rozzano, Italy; [10]Universidad de Navarra, Pamplona, Spain; [11]Kindai University Faculty of Medicine, Osaka, Japan; [12]Chang Gung Memorial Hospital, Taipei, Taiwan; [13]Servicio de Digestivo, Hospital General Universitario Gregorio Marañón, Madrid, Spain; [14]CIBEREHD, Madrid, Spain; [15]University of Bologna, Department of Medical & Surgical Sciences, Bologna, Italy; [16]Princess Margaret Cancer Centre, Toronto, Canada; [17]Emory University Winship Center, Atlanta, United States; [18]Fundacion de Investigacion, San Juan, Puerto Rico; [19]Bristol-Myers Squibb, Princeton, United States; [20]USC Norris Comprehensive Cancer Center, Los Angeles, United States*
Email: bsangro@unav.es.

Background and aims: Nivolumab (NIVO) monotherapy is approved in the United States and other countries for patients with hepatocellular carcinoma (HCC) treated with sorafenib (SOR) based on CheckMate 040 (NCT01658878), which reported 14% objective response rate (ORR) and 16-month median overall survival (mOS; El-Khoueiry et al. Lancet 2017). Primary efficacy and safety of NIVO + ipilimumab (IPI) in patients with advanced HCC previously treated with SOR were presented recently (Yau et al. J Clin Oncol 2019). We will present subgroup analyses from this study.
Method: Patients were randomized to 3 arms: [A] NIVO 1 mg/kg + IPI 3 mg/kg Q3W (4 doses) or [B] NIVO 3 mg/kg + IPI 1 mg/kg Q3W (4 doses), each followed by NIVO 240 mg Q2W, or [C] NIVO 3 mg/kg Q2W + IPI 1 mg/kg Q6W. Treatment continued until intolerable toxicity or disease progression. Primary endpoints were safety/tolerability, ORR, and duration of response (DOR; investigator assessment per RECIST v1.1). Key secondary endpoints included disease control rate (DCR), OS, and progression-free survival (blinded independent central review [BICR] per RECIST v1.1); key exploratory endpoints included ORR (BICR per RECIST v1.1). Data cutoff was January 2019.
Results: A total of 148 patients were randomized. Minimum OS follow-up from last patient randomization date to data cutoff was 28 months. At baseline, 34% of all patients had vascular invasion, 82% had extrahepatic spread, and 91% had Barcelona Clinic Liver Cancer stage C; 84% discontinued SOR because of disease progression and 14% because of toxicity. For all treated patients, ORR was 31% (7 had complete response), with median DOR of 17 months; DCR was 49%; the 30-month OS rate was 37%. NIVO + IPI was well tolerated; 38% of patients had grade 3–4 treatment-related adverse events (TRAEs; most common any grade: pruritus and rash; most common grade 3–4: aspartate aminotransferase increase and lipase increase); 5% had grade 3–4 TRAEs leading to discontinuation. Subgroup analyses based on duration of prior SOR therapy and other patient characteristics will be presented.

Conclusion: NIVO + IPI led to clinically meaningful benefits, with a manageable safety profile in patients previously treated with SOR. NIVO + IPI may provide a new treatment option for these patients.

Background and aims: ADP-A2AFP specific peptide enhanced affinity receptor (SPEAR) T-cells are genetically engineered to target AFP+ tumors in the context of HLA-A*02, which are being evaluated in an ongoing Phase 1 trial in patients with hepatocellular carcinoma (HCC; NCT03132792). Here we describe late-breaking data from the 3rd dose cohort of this trial.

Method: First-in-human study in HCC, patients (pts) must be HLA-A*02:01$^+$ or 02:642$^+$ and have AFP expression by immunohistochemistry (IHC) at ≥1+ in ≥20% HCC cells or serum AFP ≥400 ng/ml (recently amended to ≥100 ng/ml), and ≤5% AFP expression by IHC in non-cancerous liver tissue. Up to 35 pts with HCC with modified 3+3 design. For Cohort 3, lymphodepletion is fludarabine 30 mg/m^2 QD for 4 days and cyclophosphamide 600 mg/m^2 QD for 3 days. Following lymphodepletion, target transduced cell dose for Cohort 3 was 5×10^9 (range: 1.2 to 6.0×10^9). Cohort expansion may occur allowing for doses up to 10×10^9 transduced cells.

Results: As of Feb 10, 2020, 3 pts (1 M, 2 F) were treated in Cohort 3 with 5.6, 5.0 and 5.1×10^9 transduced cells. Pts experienced cytopenias (up to G4 leukopenia, lymphopenia, and neutropenia) as well as febrile neutropenia related to lymphodepleting chemotherapy followed by recovery. There were no reports of T-cell related hepatic toxicity, although one pt had abnormal liver chemistries considered possibly related to ADP-A2AFP with evaluation ongoing. There have been no DLTs reported to date. High peak levels of peripheral SPEAR T-cells were observed up to 4 wks post-infusion.
The first pt in Cohort 3 had a confirmed partial response (cPR) with 100% reduction in target lesions; one non-target lesion remained at Wk 8. This was associated with rapid and sustained decrease in serum AFP levels from 6531 ng/mL at baseline to 14 ng/mL at Wk 12. The second pt had PD at Wk 4 with new liver lesions, and an increase in a single liver target lesion by 5% in SLD from baseline. This 2nd pt experienced a transient reduction from 2283 ng/mL at baseline to 1788 ng/mL at Wk 2 (22% reduction), with a subsequent increase to 2759 ng/mL at Wk 8. The third pt had PD at Wk 4 based on increased SLD from baseline. Serum AFP initially decreased at Wk 2 with a return toward baseline by Wk 4.

Conclusion: There have been no clear reports of T-cell related on-target or off-target toxicity, and no protocol-defined DLTs. There is promising early evidence of efficacy and these data support continued investigation.

Email: mchakravarthy@axcellahealth.com.

Background and aims: Effective and sustainable treatments for nonalcoholic steatohepatitis (NASH) will likely require simultaneously addressing metabolism, inflammation, and fibrogenesis. AXA1125 and AXA1957 are novel oral endogenous metabolic modulator (EMM) compositions of primarily amino acids. AXA1125-003 (NCT04073368) investigated the safety, tolerability, and physiologic effects of AXA1125 and AXA1957.
Methods: This multicenter, randomized, placebo (PBO)-controlled study enrolled 102 adult NAFLD subjects ±T2D, with proton density fat fraction (PDFF) ≥10% and corrected T1 [cT1] ≥830 msec by multiparametric MRI. Subjects received twice-daily administration of either AXA1125 24 g, AXA1957 13.5 g or 20.3 g, or PBO for 16 weeks. Safety and tolerability were assessed by laboratory measures and adverse events (AEs). Physiologic assessments included change from baseline in key markers of metabolism (MRI-PDFF and homeostasis model assessment of insulin resistance [HOMA-IR]) and fibroinflammation (alanine aminotransferase [ALT], cT1, cytokeratin-18 [CK-18], N-terminal type III collagen propeptide [pro-C3]). Here, we report interim analysis (IA) data for subjects who completed ≥ 1 postbaseline MRI.
Results: Baseline characteristics were suggestive of NASH (average MRI-PDFF >20%, cT1 >900 msec, FibroScan >10 kPa, and pro-C3 >16 ng/mL). Among 62 subjects evaluable for this IA, those receiving AXA1125 and AXA1957 showed improved MRI-PDFF, ALT, cT1, and CK-18 relative to PBO as early as Week 8 and sustained at Week 16. Roughly 50% and 30% of subjects receiving AXA1125 and AXA1957, respectively, had ≥30% relative reduction from baseline MRI-PDFF. Fifty percent of subjects dosed with either composition had ≥40 msec absolute reduction in cT1. AXA1125 treatment led to marked absolute reductions in HOMA-IR. Subjects showed improvements in ALT, especially in those with a decrease >17 IU/L. Differential changes in CK-18 and pro-C3 were noted. Both compositions were safe and well tolerated, with stable lipid profiles. Overall, product-related AE rates were low, mostly mild, with minimal discontinuation and no product-related serious AEs. Top-line results from the complete data set will be shown.
Conclusion: AXA1125 and AXA1957 were safe, well tolerated, and led to clinically relevant multifactorial effects. These EMM compositions represent a novel mode of action with the potential to simultaneously address NASH and key comorbidities, including insulin sensitivity.

LBP02

Lack of reliability of liver biopsies in non-alcoholic steatohepatitis (NASH) clinical trials - potential implications for developing new therapies for NASH

Beth Davison[1], Stephen A. Harrison[2], Gad Cotter[1], Naim Alkhouri[3], Arun Sanyal[4], Chris Edwards[1], Jerry Colca[5], Julie Iwashita[5], Gary Koch[6], Howard Dittrich[5]. *[1]Momentum Research, Inc.; [2]University of Oxford Medical Science Division, Radcliff Department of Medicine; [3]Texas Liver Institute; [4]Virginia Commonwealth University, Hepatology; [5]Cirius Therapeutics; [6]University of North Carolina at Chapel Hill, Gillings School of Public Health*
Email: bethdavison@momentum-research.com.

Background and aims: Liver biopsies are a critical component of pivotal studies in nonalcoholic steatohepatitis (NASH) constituting main inclusion criteria, risk stratification factors and endpoints.
Method: We evaluated data from the EMMINENCE study examining a novel insulin sensitizer (MSDC-0602 K) in NASH. Digitized slides from 678 biopsies (baseline and 1 year follow up) for 339 patients were read independently by three hepatopathologists blinded to treatment code and scored using the NASH CRN Histological Scoring System. Inter-reader reliability was examined by comparing all possible pairs of the three hepatopathologists with respect to NASH CRN scores (ballooning, inflammation, steatosis, fibrosis); NAS, the sum of the ballooning, inflammation, and steatosis scores; and NASH diagnosis; as well as dichotomous derived endpoints at 12 months of NAS improvement with no concurrent worsening of fibrosis of ≥1 stage, and improvement of fibrosis by at ≥1 stage with no worsening of NASH. Reliability was assessed using unweighted and weighted kappa coefficients.
Results: Inter-reader linearly weighted kappas were 0.609, 0.484, 0.328, and 0.517 for steatosis, fibrosis, lobular inflammation, and ballooning, respectively. Inter-reader kappas were especially poor for the diagnosis of NASH (0.400), and also for the two currently approvable endpoints-NASH resolution without worsening of fibrosis (0.396), and fibrosis improvement without worsening of NASH (0.366) (Table).
Almost half of the patients enrolled were deemed not to have met the inclusion criteria by at least one hepatopathologist; all three hepatopathologists agreed that eligibility criteria were met for only 53.7% of these patients.
The average effect of MSDC-0602 K 125/250 mg combined versus placebo on 12-month changes in noninvasive markers of fibrosis and liver injury was almost double in terms of standard deviations (0.33 SDs) as compared to histologic endpoints (0.18 SDs), suggesting that the significant lack of reliability in hepatic histology interpretation may have reduced the apparent treatment effect of MSDC-0602 K. Indeed, the observed effect of MSDC-0602 K 125/250 mg combined versus placebo tended to be larger for NASH CRN features with higher reliability (r = −0.54).

Inter-reader reliability regarding endpoints derived from NASH CRN Scores for 339 patients with Paired Biopsies

Endpoint	Inter-reader Comparison	% Agreement*	% Agreement Expected by Chance*	Unweighted Kappa (95% CI)
Hepatic histological improvement in NAS	Original v. H1	71.68	54.62	0.376 (0.276, 0.476)
	Original v. H2	74.04	58.93	0.368 (0.264, 0.472)
	H1 v. H2	74.93	57.36	0.412 (0.310, 0.514)
	Average	73.55	57.17	0.382 (0.308, 0.456)
Resolution of NASH with no worsening of fibrosis	Original v. H1	79.65	60.09	0.490 (0.389, 0.590)
	Original v. H2	81.12	69.45	0.382 (0.268, 0.497)
	H1 v. H2	76.99	65.91	0.325 (0.219, 0.432)
	Average	79.25	65.65	0.396 (0.315, 0.477)
Improvement of fibrosis with no worsening of NASH	Original v. H1	76.11	60.70	0.392 (0.286, 0.497)
	Original v. H2	75.81	65.49	0.299 (0.184, 0.413)
	H1 v. H2	78.76	63.94	0.411 (0.301, 0.521)
	Average	76.89	63.53	0.366 (0.289, 0.444)
Resolution of NASH with at least a 2-point improvement in NAS	Original v. H1	80.53	67.11	0.408 (0.293, 0.523)
	Original v. H2	84.66	75.10	0.384 (0.256, 0.513)
	H1 v. H2	79.35	72.65	0.245 (0.125, 0.365)
	Average	81.51	71.87	0.343 (0.256, 0.430)
* Unevaluable score considered as a response category.				

Figure: (abstract: LBP02)

Simulations show that the lack of reliability in liver histology interpretations' effect on both eligibility ascertainment and assessment of treatment effect may reduce the power of a well-designed NASH study form > 90% to 40%.
Conclusion: Reliability of hepatopathologists' liver biopsy evaluation using currently accepted criteria is poor. This lack of reliability may affect NASH pivotal studies by introducing patients who do not meet NASH study entry criteria, misclassifying fibrosis subgroups, and attenuating apparent treatment effects.

LBP03

HM15211, a novel GLP-1/GIP/Glucagon triple-receptor co-agonist significantly reduces liver fat and body weight in obese subjects with non-alcoholic fatty liver disease: A Phase 1b/2a, multi-center, randomized, placebo-controlled trial

Manal Abdelmalek[1], Jaeduk Choi[2], Youngmin Kim[2], Kyounghee Seo[2], Marcus Hompesch[3], Seungjae Baek[2]. *[1]Duke University, Gastroenterology, Durham, United States; [2]Hanmi Pharm. Co., Ltd., Korea, Rep. of South; [3]ProSciento, Inc., United States*
Email: seungjae.baek@hanmi.co.kr.

Background and aims: NASH is a disease with a complex multifaceted pathophysiology. HM15211 is a novel long-acting GLP-1/GIP/Glucagon triple-receptor co-agonist, targeting NASH via multiple modes of action. HM15211 has shown therapeutic potential in animal models of obesity, NASH (AS015) and safe profiles in a previous first-in-human study (FRI115).
Method: Non-diabetic obese subjects with non-alcoholic fatty liver disease (NAFLD) were enrolled (MRI-PDFF ≥10%) in a Phase 1b/2a single-blind, randomized, placebo-controlled study to investigate the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of multiple subcutaneous (SC) weekly doses of HM15211 for 12 weeks. In total 66 subjects were randomized, the baseline mean (SD) age of participants was 46 (11.4) years, 50.0% were women, BMI was 36 (4.96) kg/m^2 and liver fat by initial MRI-PDFF was 19.2 (6.5) %. The study was designed as a multiple ascending dose study, to test 5 different doses of HM15211 (0.01, 0.02, 0.04, 0.06, and 0.08 mg/kg), enrolling 12 subjects per cohort. Subjects were randomized to HM15211 or placebo in a ratio of 3:1 (9 on active, 3 on placebo). Week 12 MRI-PDFF data for final dosing (0.08 mg/kg) cohort will be presented at ILC.
Results: The mean (SD) relative changes from baseline in liver fat at week 8 were −14.9 (12.2) % for 0.01 mg/kg ($p = 0.13$), −43 (23.5) % for 0.02 mg/kg ($p < 0.0001$), −44.5 (46.6) for 0.04 mg/kg ($p = 0.0005$), −71 (23.8) % for 0.06 mg/kg ($p < 0.0001$), −80.3 (13.2) % for 0.08 mg/kg ($p < 0.0001$), vs. −1.2 (24.5) % for placebo group. The mean (SD) relative changes from baseline in liver fat at week 12 were −19.6 (12.2) % for 0.01 mg/kg ($p = 0.30$), −36 (28.1) % for 0.02 mg/kg ($p = 0.06$), −38 (53.5) % for 0.04 mg/kg ($p = 0.12$), −59.3 (27.6) % for 0.06 mg/kg ($p = 0.0020$), and −5.7 (37.8) % for placebo group. The liver fat reduction proportionally increased by escalating doses and the observed maximum liver fat reduction at week 12 was 88% by currently available data. HM15211 decreased body weight compared with placebo across all treatment groups. Placebo-corrected kg and % reduction of body weight were −1.3, −1.8*, −2.1*, −3.1*, and −4.3* kg (−1.2, −1.9*, −2.2*, −2.9*, and −4.4*%) at week 8 and −2.1, −3.1*, −1.9, −4*, and −5.3* kg (−1.9, −3.4*, −2.1, −3.8*, and −5.1* %) at week 12 in 0.01 to 0.08 mg/kg dose cohorts, respectively (*$p < 0.05$). HM15211 was shown to be well tolerated. The most common dose-dependent adverse events were mild gastrointestinal symptoms. Two subjects at different dosing cohorts developed hyperglycemia, but rapidly resolved with IP discontinuation. There were no deaths or serious adverse events related to HM15211 in any cohort.
Conclusion: HM15211 was safe and well tolerated during 12 weeks treatment in non-diabetic obese subjects with NAFLD.Treatment with HM15211 significantly decreased liver fat content and body weight in 8 and 12 weeks. Further development of HM15211 as a treatment for NASH is warranted.

Liver toxicity in the Phase 2 Catalyst 206 trial of Inarigivir 400 mg daily added to a nucleoside in HBV EAg negative patients

Kosh Agarwal[1], Nezam Afdhal[2], Carla Coffin[3], Scott Fung[4], Geoffrey Dusheiko[1], Graham Foster[5], Magdy Elkhashab[6], Edward Tam[7], Alnoor Ramji[8], Radhakrishnan Iyer[9], Patrick Kennedy[5]. *[1]Institute of Liver Studies, Kings College Hospital, London, United Kingdom; [2]Beth Israel Deaconess Medical Center, Boston, United States; [3]Liver Unit, University of Calgary, Calgary, Canada; [4]Toronto General Hospital, Toronto, Canada; [5]Blizard Institute, Queen Mary University of London, London, United Kingdom; [6]Toronto Liver Center, Toronto, Canada; [7]LAIR Centre, Vancouver, Canada; [8]GI Research Institute, Suite 770, Vancouver, Canada; [9]Springbank Pharmaceuticals Inc, Hopkinton, United States*
Email: kosh.agarwal@nhs.net.

Background and aim: Inarigivir, an orally administered dinucleotide, activates RIG-I and has secondary *in vitro* properties of a non-nucleoside reverse transcriptase inhibitor of HBV. Over 250 pts with HBV or HCV have received inarigivir from 25 to 900 mg daily for between 1 to 12 wks, alone or in combination with a nucleoside analogue (NUC). The CATALYST Phase 2 trials were designed to assess longer treatment with inarigivir 400 mg daily in HBV pts, either alone or in combination with a NUC.

Methods: CATALYST 206 evaluated inarigivir 400 mg daily for 24 wks in NUC treated suppressed HBV pts; ARM 1 in pts who stopped their NUC and received inarigivir alone; ARM 2 added inarigivir to pts who continued NUC therapy. In December 2019, an unexpected series of mainly hepatic adverse events occurred in 7 pts treated in ARM 2 of CATALYST 206 resulting in immediate cessation of all inarigivir trials.

Results: 42 HBeAg-negative pts with normal ALT and HBV DNA <1.3 $\log_{10}$ in 7 sites in the UK and Canada were randomized to treatment with inarigivir 400 mg daily in ARM 2. There were 29 Asians, 8 African and 5 Caucasian pts; 27 male and 15 female, mean age 47.8 years (range 25–66 yrs). 7 pts presented with an SAE after a mean of 16 wks treatment (range 13–21 wks). All 7 had elevated ALT (maximal elevation mean 212 IU/L; range 116–412), 4 had associated hyperbilirubinemia >2 × ULN and 3 had abdominal pain. 1 pt was hospitalised with an ALT of 109 IU/L, bilirubin 68 umol/L and within 24 hours developed lactic acidosis, severe necrotizing pancreatitis with progressive liver failure and died from multi-organ failure. Another 6 pts developed elevated ALT >200 IU/L with no changes in bilirubin or synthetic function after stopping inarigivir while still on NUC. There was no obvious difference in age, gender, ethnicity or NUC therapy in those developing liver injury *vs* those who did not. PK trough levels for SB 9200 and its metabolites at wk 4 and 12 were no different between those with and without liver injury. 5 pts underwent liver biopsy but in only 1 was significant inflammation evident, predominantly findings of mild hepato-cellular injury and steatosis were seen, with significant cholestasis in 2 pts. Electron microscopy showed no significant ultra structural evidence of mitochondrial injury. In some pts, liver injury only occurred up to 3 wks after stopping inarigivir although a pattern of resolution was seen in all by 6 wks. Treatment with steroids, NAC and URSO was of questionable benefit. The efficacy endpoint of HBsAg reduction > 0.3$\log_{10}$ was seen in 23 pts (55%) with a mean reduction of 1.13$\log_{10}$ (range 0.5–2$\log_{10}$) and occurring between wks 6–12.

Conclusion: We describe an unusual, heterogeneous DILI observed after a mean of 16 weeks of inarigivir (400 mg daily) added to a NUC. Further studies are ongoing to identify causality and mechanisms. These findings have implications for trial design in HBV 'cure' studies and liver safety parameter monitoring.

LBP05

Antiviral activity, pharmacokinetics and safety of the second-generation hepatitis B core inhibitor ABI-H2158 in Phase 1b study of patients with HBeAg-positive chronic hepatitis B infection

Kosh Agarwal[1], Junqi Niu[2], Yanhua Ding[2], Edward Gane[3], Tuan Nguyen[4], Katia Alves[5], Marc Evanchick[5], Hany Zayed[5], Qi Huang[5], Steven Knox[5], Luisa Stamm[5], Richard Colonno[5], Tarek Hassanein[6], Dong Joon Kim[7], Young-Suk Lim[8], Man-Fung Yuen[9] . *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]The First Hospital of Jilin University, Changchun, China; [3]Auckland Clinical Studies Limited, Auckland, New Zealand; [4]T. Nguyen Reseach and Education, San Diego, United States; [5]Assembly Biosciences, South San Francisco, United States; [6]Southern California Research Center, Coronado, United States; [7]Hallym University Chuncheon Sacred Heart Hospital, Chuncheon, Korea, Rep. of South; [8]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Rep. of South; [9]University of Hong Kong, Hong Kong, China*
Email: kosh.agarwal@nhs.net.

Background and aims: The HBV core protein plays an integral role in multiple steps of the HBV lifecycle. ABI-H2158 is a second-generation HBV core inhibitor in development for the treatment of chronic hepatitis B infection. Here we report the antiviral activity, pharmacokinetics (PK) and safety from a Phase 1b study in which patients (pts) were treated with ABI-H2158.

Method: In each cohort, 9 pts (7 active, 2 placebo [Pbo]) were randomized in a blinded manner to receive either ABI-H2158 100, 300 or 500 mg or Pbo once daily for 14 days. Eligible pts were males or females aged ≥18 and ≤65 years, HBV treatment naive, HBeAg positive with HBV DNA ≥2×10^5 IU/mL and Metavir F0-F2. HBV DNA, pgRNA, HBeAg, HBsAg and HBcrAg were measured on Days 1, 8 and 15. PK was assessed on Days 1 and 14. Safety was evaluated by treatment-emergent adverse events (AEs) and laboratory parameters.

Results: Across the cohorts, the mean (range) age of pts was 36 (19–51) years, with the majority being male (59%), Asian (96%) and HBV genotype C (59%). At baseline, the mean (range) HBV DNA was 8.0 $\log_{10}$ (4.7–9.1) IU/mL, pgRNA was 6.8 $\log_{10}$ (5.2–7.9) U/mL and ALT was 40 (14–124) U/L. Change in HBV DNA and pgRNA from baseline to Day 15 and PK data are shown in the Table 1. AEs were reported for 38% (8/21) of pts receiving ABI-H2158 and 50% (3/6) receiving PBO. The majority of AEs were Grade 1; none were Grade 3 or 4, serious or led to treatment discontinuation. Headache was the only AE reported by more than 1 pt receiving ABI-H2158 (2 pts). Graded laboratory abnormalities were observed in 71% (15/21) of pts receiving ABI-H2158 and 50% (3/6) receiving Pbo, the majority of which were Grade 1. Transient increases in ALT were observed in 24% (5/21) of pts receiving ABI-H2158 (all Grade 1) and in 33% (2/6) receiving Pbo (1 Grade 1; 1 Grade 3).

	ABI-H2158			
	100 mg (n = 7)	300 mg (n = 7)	500 mg (n = 7)	Placebo (n = 6)
HBV DNA change from Baseline ($\log_{10}$ IU/mL), mean (range)	−2.3 (−3.0 to −1.7)	−2.5 (−3.3 to −0.8)	−2.7 (−3.2 to −1.7)	−0.1 (−0.3 to 0.1)
pgRNA change from Baseline ($\log_{10}$ U/mL), mean (range)	−2.1 (−2.7 to −1.5)	−2.2 (−2.6 to −1.4)	−2.0 (−3.5 to −1.3)[a]	−0.1 (−0.2 to −0.1)
C_{max}, ng/mL	3,390	8,400	9,890[a]	–
AUC_{0-24}, hr*ng/mL	46,100	112,000	133,000[a]	–

[a]n = 6.

Conclusion: Results from this Phase 1b study demonstrate that ABI-H2158 has potent antiviral activity and a favourable safety profile when administered once daily for 14 days supporting further evaluation in combination with nucleos(t)ide analogues in Phase 2.

LBP06

Wide variations in liver transplantation (LT) policies across Europe for patients with acute-on-chronic liver failure (ACLF) despite excellent post-LT survival: Results of a CLIF/ELITA collaborative study

Email: luca.belli@ospedaleniguarda.it.

Background and aims: 28-day mortality of ACLF patients increases with its severity. LT has been shown to be an effective salvage therapy even for the sickest patients with ACLF, but most of the data are derived from retrospective single centre studies or from registries, which fail to provide granular information. The attitudes, clinical approach, outcomes of wait listed (WL) and LT patients in Europe is unknown. This study was designed to address these questions as a part of a collaboration between ELITA and EF-CLIF.
Method: 20 Centres from 8 European countries were involved. 2607 consecutive patients undergoing LT between January 2018 to June 2019 and 75 patients listed for ACLF, but dying on the waiting list during the same time frame were the subjects of this study. 223 ACLF patients on ICU but not wait-listed served as disease controls.
Results: Of these 2607 patients, 1188 (45.6%) received a LT for decompensated cirrhosis, 863 (33.1%) for HCC and 556 (21.3%) for other reasons. Of the 1188 LT candidates with decompensated cirrhosis, 228 (19.1%) had ACLF at LT; ACLF1: 57 (4.8%), ACLF2: 76 (6.4%) and ACLF3: 95 (8%). Wide variations were observed among countries, with France and Germany having high rates of ACLF2-3 at LT (25–40%); Italy, Switzerland, Poland and Netherlands medium rates (7–14%) and UK and Spain low rates (3–5%) ($p < 0.0001$). Patients with ACLF2-3 received an LT after a median of 6-days compared with ACLF1 patients who received an organ after 17-days ($p < 0.0001$). Overall 1-year survival after LT was 81% (95%CI: 74–87), independent of the ACLF grade (FIG). Bacterial infection (59%) and alcoholic hepatitis (19%) were the most prevalent precipitating factors. Pre LT arterial lactate levels higher than 4 (HR 3.49; 95% CI 1.12–10.85) and recent infection from multi-drug resistant organisms (HR 3.2; 95% CI 1.07–9.75) were independent predictors of post-LT mortality. When including in the analyses the 75 patients that were listed for ACLF, but died on the WL, the 1-yr survival from listing was only 51% (95%CI: 41–59) in those with ACLF3 with 36% dying on the WL (FIG). Mortality of contemporaneous controls not listed for LT was commensurate with expected high mortality.
Conclusion: The results reveal wide variations in attitudes to listing and transplanting patients with ACLF in Europe despite clear evidence of excellent post-LT survival and transplant benefit

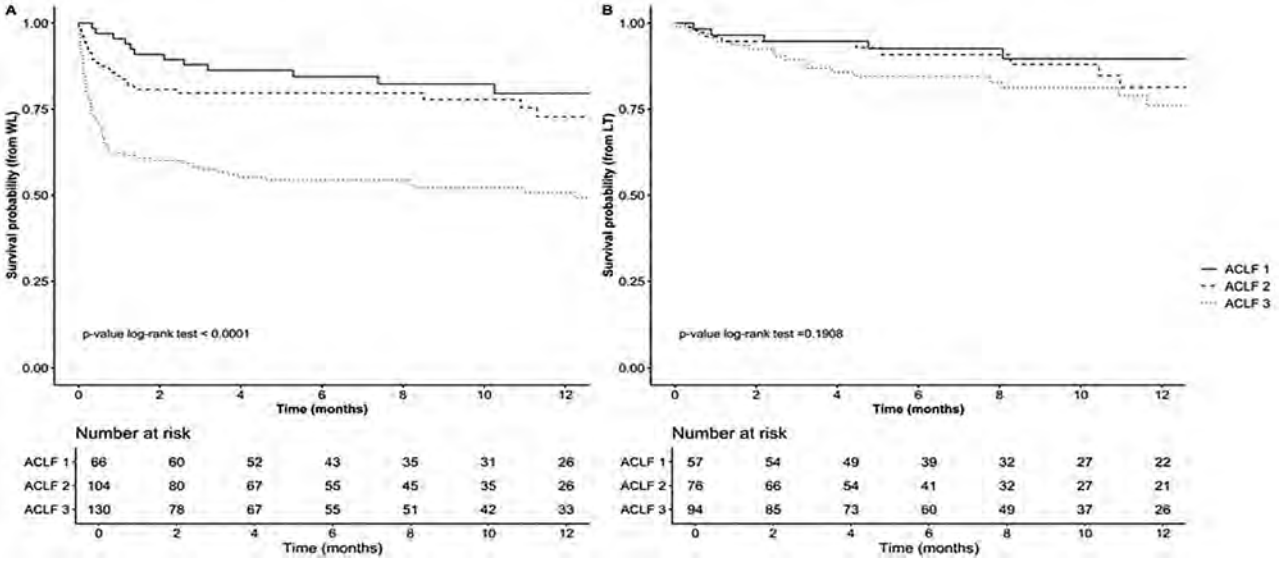

Figure: (abstract: LBP06): Survival after WL (panel A) and after LT (panel B).

emphasizing the need for harmonisation. The current allocation policies do not address the urgency for ACLF patients suggesting need for changing allocation policies.

LBP07

Declining HCV incidence following rapid HCV treatment scale-up in a prison network in Australia: Evidence of treatment as prevention from the SToP-C study

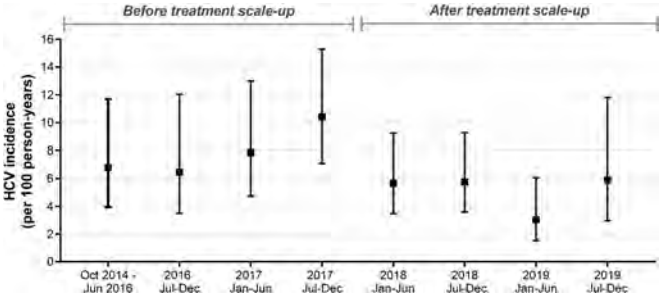
Gregory Dore[1], Behzad Hajarizadeh[1], Jason Grebely[1], Marianne Byrne[1], Pip Marks[1], Janaki Amin[1,2], Hamish Mcmanus[1], Tony Butler[1], Peter Vickerman[3], Natasha Martin[3,4], John Mchutchison[5], Diana Brainard[6], Carla Treloar[7], Andrew Lloyd[1].
[1]UNSW Sydney, The Kirby Institute, Sydney, Australia; [2]Macquarie University, Faculty of Medicine and Health Sciences, Sydney, Australia; [3]University of Bristol, School of Social and Community Medicine, Bristol, United Kingdom; [4]University of California San Diego, Division of Infectious Diseases & Global Public Health, San Diego, United States; [5]Assembly Biosciences, San Francisco, United States; [6]Gilead Sciences Inc., Foster City, United States; [7]UNSW Sydney, Centre for Social Research in Health, Sydney, Australia
Email: gdore@kirby.unsw.edu.au.

Background and aims: There are no large scale interventional trials supporting HCV treatment as prevention (TasP). The Surveillance and Treatment of Prisoners with hepatitis C (SToP-C) study assessed HCV TasP in four Australian prisons.

Method: SToP-C enrolled people incarcerated in two maximum (male) and two medium security prisons (one male, one female) where opioid agonist therapy (OAT) but not needle-syringe programs were available. Following HCV antibody (Ab) and RNA screening, participants were monitored six monthly for risk behaviors and HCV, with three sub-populations: (1) uninfected (Ab–); (2) previously infected (Ab+/RNA–); (3) infected (Ab+/RNA+). Uninfected and previously infected (at-risk) participants were followed for HCV primary and reinfection, while infected participants were assessed for treatment. Enrolment commenced October 2014 with final follow-up November 2019. HCV treatment was provided to small numbers by prison health service until mid-2017, when intensive DAA scale-up (12 weeks sofosbuvir/velpatasvir) through SToP-C was introduced. HCV incidence was compared between before and after treatment scale-up periods.

Results: Of 3,640 participants enrolled, 710 (19%) had detectable HCV RNA and 2,930 were at-risk of primary infection (n = 2,217) or reinfection (n = 713) at baseline. Enrollment coverage was 53–89% across prisons. DAA treatment was initiated in 324/397 (81%) RNA+ participants during scale-up period. The at-risk population with longitudinal follow-up (n = 1,637) had median age 33 years; and included 82% male; 47% history of injecting drug use (of whom 28% received OAT). Among at-risk population, 56/1,066 primary infection and 56/571 reinfection events were detected. During 1,764 person-years (py) follow-up, HCV incidence was 6.4/100 py (95%CI: 5.3, 7.7): primary infection 4.6/100 py (3.5, 5.9), and reinfection 10.6/100 py (8.2, 13.8). HCV incidence declined from 8.1/100 py (6.4, 10.4) prior to treatment scale-up to 5.0/100 py (3.8, 6.6) following (p = 0.032; Figure), including 49% reduction in primary infection from 6.5/100 py (4.7, 9.0) to 2.9/100 py (1.9, 4.6; p = 0.018), and non-significant 20% reduction in reinfection from 12.3/100 py (8.4, 17.9) to 9.4/100 py (6.5, 13.5; p = 0.42).

Conclusion: Rapid scale-up of DAA therapy was associated with HCV incidence reduction in prison, indicative of TasP. The findings support broad DAA scale-up among incarcerated populations, and enhanced harm reduction in this population, particularly for prevention of reinfection.



LBP08

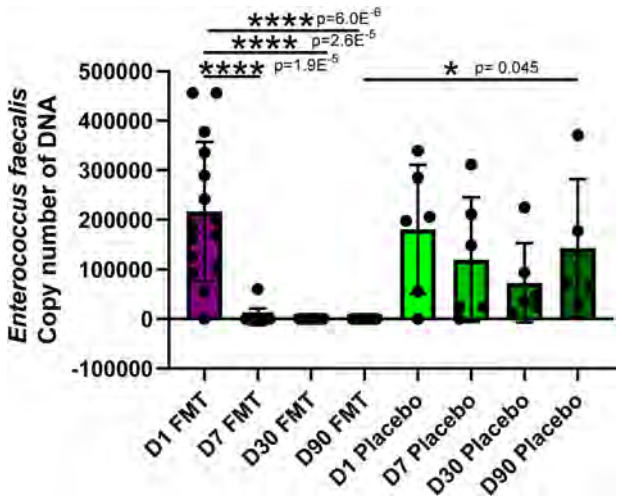
faecal microbiota transplantation reduces pathogenic burden and is anti-inflammatory in patients with advanced cirrhosis

Lindsey Edwards[1], Charlotte Woodhouse[1], Victoria Kronsten[1], Ane Zamalloa[1], Thomas Tranah[1], Vishal Patel[1], Alberto Sanchez-Fueyo[1], Simon Goldenberg[2], Debbie L. Shawcross[1].
[1]King's College London, Institute of Liver Studies, Inflammation Biology, London, United Kingdom; [2]Guy's & St Thomas' NHS Foundation Trust, Center for Clinical Infection and Diagnostic Research, Infectious Diseases, London, United Kingdom
Email: lindsey.edwards@kcl.ac.uk.

Background and aims: Patients with advanced cirrhosis have enteric dysbiosis with small bowel bacterial overgrowth and translocation of bacteria and their products across the gut epithelial barrier. This culminates in systemic inflammation and endotoxaemia, inducing innate immune dysfunction, which predisposes to infection, and multi-organ dysfunction. We hypothesised that modifying the gut microbiota with Faecal Microbiota Transplantation (FMT) may reduce the progression of chronic liver failure.

Method: The prospective, randomised, single-blinded, feasibility trial evaluating FMT (n = 15) against placebo (n = 6) [PROFIT Trial NCT02862249] was completed in late 2019. Patients were evaluated then administered FMT/placebo into the jejunum within 7 days of baseline. To assess the stability of transplanted gut microbiome and its efficacy in modulating the patient's own microbiome, disease and inflammatory status: urine, blood, saliva and stool were collected at days 0, 7, 30 and 90 post-FMT administration. To compare the composition of the faecal and oral microbiota with the donor microbiome, DNA was extracted from matched stool and saliva samples for metagenomic analyses and for qPCR of selected enteropathogens. Serum samples were analysed for immune function assays e.g. Tru-culture to assess the cytokine production after whole blood stimulation with stimulants such as LPS, heat-killed *E. coli* in comparison to null samples.

Results: FMT was associated with a reduction by day-90 in stool *Enterococcus faecalis* (p = 0.000006, Figure 1) and enteropathogenic (EPEC) *Escherichia coli* (p = 0.0033), but not in the placebo group. EPEC causes barrier damage and *E. faecalis* hydrolyses arginine to produce ammonia and produces a pore-forming toxin cytolysin that causes barrier damage. FMT eradicates cytolysin and reduces systemic inflammation with an increase in the production of the anti-inflammatory cytokines IL-10 and IP-10 at day-7 (p = 0.004 and p = 0.0002, respectively). TNFα is enhanced in the FMT group at day 7 (p = 0.0025) and maintained up to day 90. The antibacterial properties of TNFα may account for the loss of pathogenic bacterial species.



Conclusion: FMT reduces the pathogenic bacterial burden, removing enteric pathogens known to cause epithelial gut barrier disruption and modifies the systemic inflammatory profile in patients with cirrhosis. It may be possible to alter the microbiota to promote barrier repair and to restore immune tolerance in cirrhosis.

LBP09

The impact on mortality of a national hepatitis C elimination program, Georgia, 2015–2019

Lia Gvinjilia[1], Shaun Shadaker[2], Amiran Gamkrelidze[3], Tengiz Tsertsvadze[4,5], Nikoloz Chkhartishvili[4,6], Maia Butsashvili[7], David Metreveli[8], Maia Kereselidze[3], Vladimer Getia[3], Alexander Turdziladze[3], Irina Tskhomelidze[1], Tinatin Kuchuloria[1], Philip Spradling[9], Jian Xing[9], Muazzam Nasrullah[9], Francisco Averhoff[9]. *[1]TEPHINET for Hepatitis C Elimination Program in Georgia, Tbilisi, Georgia; [2]Centers for Disease Control and Prevention, Division of Viral Hepatitis, National Center for HIV/AIDS, Viral Hepatitis, STD and TB Prevention, Atlanta, United States; [3]National Center for Disease Control and Public Health of Georgia, Tbilisi, Georgia; [4]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia; [5]Hepatology Clinic HEPA, Tbilisi, Georgia; [6]Caucasus International University, Tbilisi, Georgia; [7]Clinic NeoLab, Tbilisi, Georgia; [8]Medical Center Mrcheveli, Tbilisi, Georgia; [9]Centers for Disease Control and Prevention, Atlanta, United States*
Email: lgvinjilia@gmail.com.

Background and aims: Georgia embarked on a national hepatitis C elimination program in April, 2015, which provided direct acting antiviral (DAA) medications free of charge to all hepatitis C virus (HCV) infected persons. We aimed to evaluate the impact of the program on all-cause mortality.

Method: We identified adults (≥18 years) registered in the national hepatitis C screening registry from April 2015 through May 2018 and linked these data to the national hepatitis C treatment database and national vital statistics using the 11-digit national personal identifier. We used vital statistics data to identify deaths through December 2018. Kaplan-Meier survival plots were generated to determine and compare survival among three groups: HCV-uninfected persons (screened negative for anti-HCV), persons HCV-infected (confirmed by viremia testing) who were not treated, and persons with HCV infection confirmed by viremia testing who were treated and cured (i.e. achieved sustained virologic response; SVR). We calculated adjusted hazard ratios (aHR) using Cox proportional hazards regression models for the three groups after controlling for sex, age, and hospitalization-regardless of the admission diagnosis.

Results: We identified 1,002,229 HCV-uninfected persons, 14,234 HCV-infected persons who were not treated, and 32,485 patients who were HCV infected and cured of their infection (achieved SVR). Untreated HCV-infected persons as well as those who were infected and achieved SVR were mostly men (73.4% and 79.8% respectively), while 57.7% of uninfected persons were females. Uninfected persons were slightly younger than those infected and not treated, and those who were cured (median ages: 43, 49 and 45, respectively) ($p < 0.0001$). The Kaplan-Meier analysis revealed that a greater proportion of untreated HCV-infected persons died during the study period compared to both uninfected and HCV cured persons (Figure). Overall, untreated persons had the highest proportion of deaths (8.0%; n = 1140), followed by uninfected (4.4%; n = 44, 047) and cured persons (1.8%; n = 575). In adjusted models, untreated HCV-infected persons were more likely to die compared with uninfected persons (aHR 2.34; 95%CI 2.20–2.48) and those who achieved SVR (aHR 3.12; 95%CI 2.82–3.45).

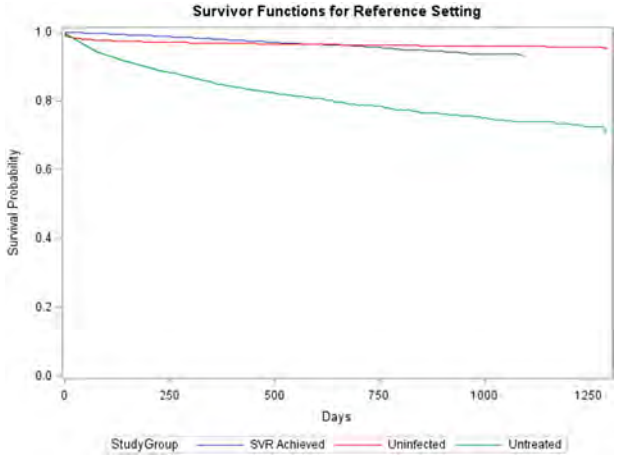


Figure: Comparison of Kaplan-Meier survival curves between study groups, adjusted for sex, age and hospitalization events.

Conclusion: Our findings demonstrate that persons with HCV infection who are cured with DAAs have an increased likelihood of survival, similar to persons never infected, when compared to HCV-infected persons who did not receive treatment.

LBP10

Bariatric surgery is not associated with a reduction in risk of severe liver disease in comparison to standard obesity treatment in 3,922 subjects

Hannes Hagström[1], Mattias Ekstedt[2], Torsten Olbers[2], Markku Peltonen[3], Lena Carlsson[4]. *[1]Karolinska Institutet, Department of Medicine, Huddinge, Stockholm, Sweden; [2]Linköping University, Sweden; [3]Finnish Institute for Health and Welfare, Helsinki, Finland; [4]Institute of Medicine, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden*
Email: hannes.hagstrom@ki.se.

Background and aims: Bariatric surgery is associated with a reduced overall mortality as well as improvement in histological features of non-alcoholic fatty liver disease (NAFLD). However, it is unclear if this translates to a reduced incidence of clinically relevant outcomes such as hepatocellular carcinoma (HCC) or decompensated cirrhosis.

Method: We used data from the Swedish Obese Subjects study, a matched controlled study comparing bariatric surgery (n = 2010) and conservative obesity treatment (n = 2037) with recruitment between 1987–2001. We excluded participants with any pre-existing liver disease except NAFLD at baseline (n = 125). The main outcome was a composite endpoint of ICD-based diagnoses including cirrhosis, decompensation events, HCC or death in liver disease, ascertained by linkage to Swedish national registers until the end of 2016. Patients were classified as having alcohol-related cirrhosis if there were any ICD-coding for alcohol use disorder or alcohol-related liver disease during follow-up. Cox regression was used to estimate hazard ratios

for severe liver disease, after adjustment for age, sex and baseline AST/ALT ratio.

Results: At baseline, mean age in the surgery group was 47.1 years, and 28.3% were males. Mean BMI was 42.4 kg/m^2, and 17.1% had type 2 diabetes. During a median follow-up of 21 years (interquartile range 17–24), there were 47 cases (2.2%) of severe liver disease in the surgery group, and 44 (2.3%) in the control group (p = 0.48). We found no increased risk of severe liver disease in the surgery group compared to the conservative obesity treatment group in the regression analysis (aHR = 0.94, 95%CI = 0.62–1.42, figure 1). Results were consistent across pre-defined sensitivity analyses. There was a non-significant trend of increased risk of alcohol-related cirrhosis in the surgery group (aHR 1.88, 95%CI = 0.75–4.73), but reduced risk for non-alcoholic cirrhosis (aHR 0.68, 95%CI = 0.42–1.09).

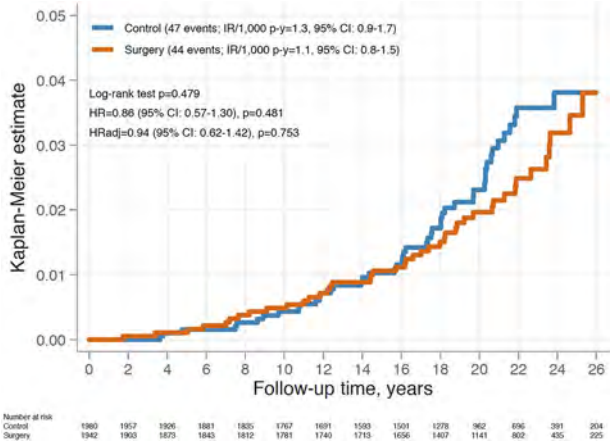

Figure 1. Kaplan-Meier failure curve of severe liver disease in surgery and control groups.

Conclusion: We found no association between bariatric surgery and reduced incidence of severe liver disease over long term in comparison to standard obesity care in this study. The result may, however, be a sum of a dual effect of an increased risk for alcohol-related cirrhosis but a reduced risk of cirrhosis attributed to NAFLD in the surgery group.

Email: harry.janssen@uhn.ca.

Background and aims: JNJ-56136379 (JNJ-6379) is a potent capsid assembly modulator producing normal empty capsids (CAM-N). We present wk 24 efficacy and safety from the ongoing Ph2 JADE study (NCT03361956) in chronic hepatitis (CHB) patients (pts).

Method: CHB not treated at study start (NT) and virologically suppressed (VS) HBeAg+ or HBeAg– pts were randomized to 75/250 mg JNJ-6379 qd or placebo (pbo) with a nucleos(t)ide analogue (NA; TDF/ETV) or received JNJ-6379 alone. As JNJ-6379 monotherapy will not be developed further, data from the combination arms are presented here. Primary endpoint was change from baseline (BL) in HBsAg at wk 24.

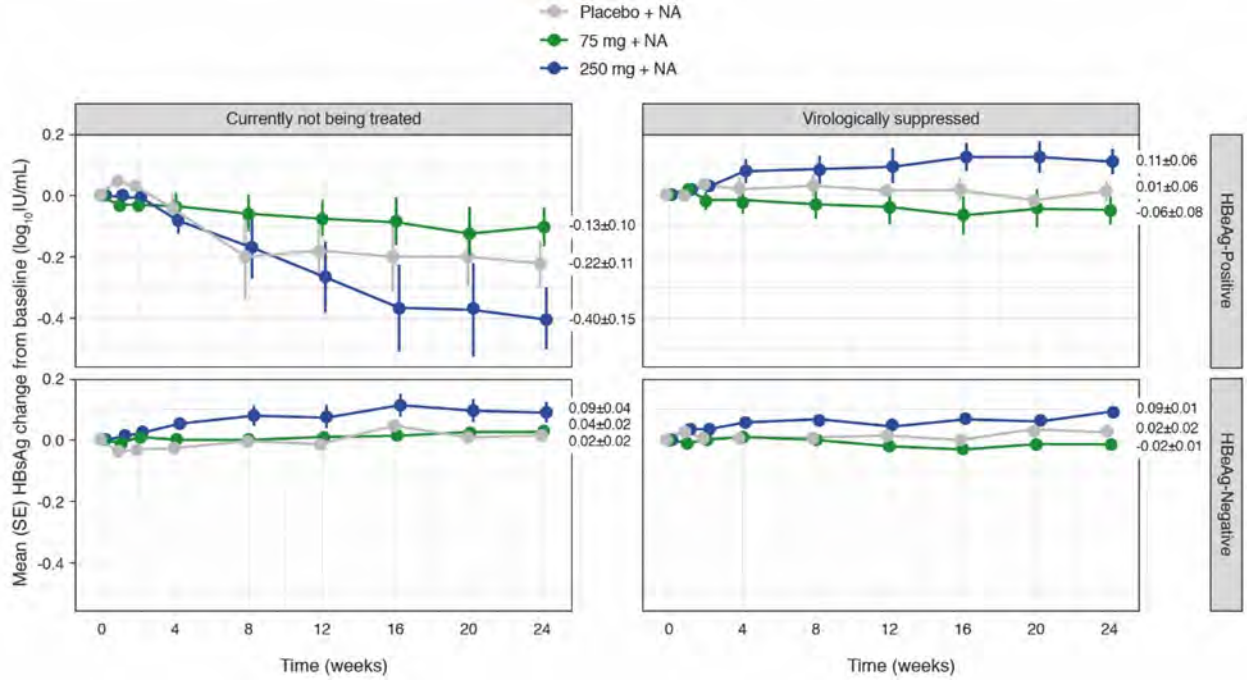

Figure: (abstract: LBP12): Mean (SE) change in HBsAg over 24 wks of treatment from baseline by population.

Results: Of 172 pts in the combination arms (88 NT; 84 VS), 48% were Asian and 34% HBeAg+.
In NT HBeAg+ pts, a more pronounced mean (SE) DNA decline from BL at wk 24 was observed for JNJ-6379 75 mg and 250 mg + NA [5.53 (0.23) and 5.88 (0.34) log_{10} IU/mL] over NA+pbo [5.21 (0.42)]; HBV DNA was <LLOQ in 0/12, 4/11 (36%) and 1/8 (13%) pts, respectively.
At wk 24 in NT HBeAg±pts, JNJ-6379 75 mg and 250 mg + NA showed an increased mean (SE) HBV RNA decline from BL [2.82 (0.25) and 3.13 (0.35) cp/mL] over NA+pbo [1.43 (0.32)]. HBV RNA was target not detected (TND) at wk 24 in 16/27 (59%), 19/25 (76%) and 9/20 (45%) NT HBeAg+/– pts, respectively. All JNJ-6379 VS pts with detectable HBV RNA at BL achieved HBV RNA TND at wk 24 vs 0% with NA+pbo.
JNJ-6379 250 mg+NA showed a mean (SE) HBsAg decline of 0.40 (0.15) log_{10} IU/mL in NT HBeAg+ pts at wk 24 (Figure). Pts with HBsAg decline also had HBeAg and HBcrAg declines and frequently early on treatment isolated ALT flares.
Maximal JNJ-6379+NA individual HBsAg and HBeAg reductions were 1.28 and 1.8 log_{10} IU/mL, respectively. Proportions of JNJ-6379+NA NT HBeAg+ pts with >0.3 log_{10} IU/mL reductions from BL in HBsAg and HBeAg were 8/23 (35%) and 19/23 (83%) vs 1/8 (13%) and 4/8 (50%) NA +pbo, respectively. Proportions of VS JNJ-6379+NA HBeAg+ pts with >0.3 log_{10} IU/mL reductions in HBeAg were 6/19 (32%) vs 1/5 (20%) NA +pbo.
No study treatment related serious adverse events or clinically significant changes in laboratory parameters occurred.
Conclusion: In not treated pts, JNJ-6379+NA increased HBV DNA suppression over NA alone. A mean 0.4 log_{10} IU/mL HBsAg decline with JNJ-6379 250 mg+NA was seen in NT HBeAg+ pts. JNJ-6379+NA was safe and well tolerated, supporting evaluation of JNJ-6379 in combination with an NA and the siRNA JNJ-73763989 in the ongoing Ph2 REEF-1 study (NCT03982186).

A Phase 2 Study of Peginterferon Lambda, Lonafarnib and Ritonavir for 24 Weeks: End-of-Treatment Results from the LIFT HDV Study

Christopher Koh[1], Julian Hercun[1], Farial Rahman[1], Amy Huang[1], Ben Da[1], Pallavi Surana[1], Devika Kapuria[1], Yaron Rotman[1], Anusha Vittal[1], Christy Ann Gilman[1], Gil Ben Yakov[1], Walter Lai[1], Harel Dahari[2], Jeffrey Glenn[3], Theo Heller[1]. *[1]NIDDK/NIH, Bethesda, United States; [2]Loyola University, Chicago, United States; [3]Stanford University School of Medicine, Stanford, United States*
Email: christopher.koh@nih.gov.

Background and aims: Hepatitis Delta Virus (HDV) infection, the most aggressive form of human chronic viral hepatitis, is still without an approved FDA therapy. Clinical trials have demonstrated anti-HDV activity with the prenylation inhibitor lonafarnib (LNF) boosted with ritonavir (RTV) and peginterferon lambda-1a (LMD) monotherapy. In a first-in-humans clinical trial, the Lambda InterFeron combination Therapy (LIFT) study evaluated the safety and antiviral effects of combination therapy with LMD/LNF/RTV in patients with chronic HDV infection.
Method: In this phase 2a open-label study, 26 adult patients with chronic HDV and quantifiable HDV RNA in serum (lower limit of quantitation <40 IU/mL) have completed treatment with subcutaneous LMD 180 mcg weekly and oral LNF 50 mg and RTV 100 mg twice daily for 24 weeks and are undergoing per-protocol post-therapy monitoring for 24 weeks. Tenofovir or Entecavir was started prior to therapy. Serial assessments of safety parameters, liver tests, pharmacokinetics, histology, and virologic (HDV RNA and HBV DNA) markers were obtained.
Results: In this ongoing study, patients were 62% male, median age of 40 years and included Asian (54%), White (31%) and African (15%) subjects. Median baseline evaluations included: ALT (62 IU/mL), AST (47 IU/mL), Ishak Fibrosis (3), modified HAI inflammation (9), HBV DNA (<21 IU/mL) and log HDV RNA (4.7 IU/mL). After 12 weeks of therapy, the median HDV RNA decline from baseline was 3.4 log IU/mL (IQR: 2.9–3.8, $p < 0.0001$) with 7 patients (27%) achieving undetectable HDV RNA and 6 patients (23%) with HDV RNA below the lower limit of quantification (BLOQ). At the end of therapy, the median HDV RNA decline was 3.4 log IU/mL (IQR: 2.9–4.5, $p < 0.0001$) with 11 patients (42%) achieving undetectable HDV RNA and 3 patients (11%) BLOQ. 25 of 26 patients (96%) achieved >2 log decline during 24 weeks of therapy. Adverse events were mostly mild to moderate and included GI related side effects, weight loss, hyperbilirubinemia, and anemia. Therapy was dose reduced in 3 patients and discontinued in 4 patients.
Conclusion: Triple combination therapy with LMD/LNF/RTV in chronic HDV patients appears to be safe and tolerable for up to 6 months in most patients. After 24 weeks, almost all achieve >2 log decline in HDV RNA during therapy with >50% achieving undetectable or BLOQ HDV RNA levels. These end-of-treatment results support continued exploration of this therapeutic combination in HDV.

LBP14

Proof-of-concept use of machine learning to predict tumor recurrence of early-stage hepatocellular carcinoma before therapy using baseline magnetic resonance imaging

Ahmet Said Kücükkaya[1,2], Tal Zeevi[1], Rajiv Raju[1], Nathan Chai[1], Stefan Haider[1], Mohamed Elbanan[3], Alexandra Petukhova[1,2], Mingde Lin[1,4], John Onofrey[1], Michal Nowak[1], Kirsten Cooper[1], Elizabeth Thomas[1], Bernhard Gebauer[2], David Madoff[1], Lawrence Staib[1], Ramesh Batra[5], Julius Chapiro[1]. *[1]Yale University School of Medicine, Department of Radiology and Biomedical Imaging, New Haven, United States; [2]Charité-Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität, and Berlin Institute of Health, Institute of Radiology, Berlin, Germany; [3]Yale New Haven Health System, Bridgeport Hospital, Department of Diagnostic Radiology, Bridgeport, United States; [4]Visage Imaging, Inc., San Diego, United States; [5]Yale University School of Medicine, Department of Surgery, Transplantation and Immunology, New Haven, United States*
Email: julius.chapiro@yale.edu.

Background and aims: Patients with early-stage hepatocellular carcinoma (HCC) are likely to experience tumor recurrence after initial therapy using thermal ablation, surgical resection or orthotopic liver transplantation (OLT), with some reports demonstrating recurrence rates up to 80% five years post-treatment depending on therapy option. Successful identification of patients who will likely recur could help optimize follow-up imaging, influence choice of adjuvant therapy, and could even improve transplant allocation. Currently, no biomarkers exist that can reliably predict recurrence. The combination of computational power and advanced machine learning-based algorithms allow in-depth exploration of imaging data to discover features predictive of recurrence. This study analyzed baseline magnetic resonance imaging (MRI) using state-of-the-art machine learning algorithms to predict HCC recurrence after first-line therapy with thermal ablation, surgical resection or OLT.
Method: This was a HIPAA-compliant, IRB-approved retrospective study with 120 patients who underwent either thermal ablation, surgical resection or OLT as first-line, stand-alone treatment for HCC between 2005 and 2018. Multiparametric contrast-enhanced MRI was analyzed by our machine learning model, which combined two readily available algorithms: VGG16 and XGBoost. The imaging dataset was labelled in six categories, with time-to-recurrence cutoffs at 1, 2, 3, 4, 5, or 6 years. Area under the receiver operating characteristic curves (AUC-ROC) was used to evaluate algorithm performance. Recurrence-free survival (RFS) was evaluated by Kaplan-Meier analysis, and survival curves were compared using the log-rank test.
Results: Of the 120 patients, 44 (36.7%) recurred at the time of analysis. Surgical resection (n = 32, 26.7%), thermal ablation (n = 29, 24.2%), and OLT (n = 59, 49.1%) were the treatment modalities. With 1, 2, 3, 4, 5 and 6 years as the time-to-recurrence cutoff, AUC-ROC values

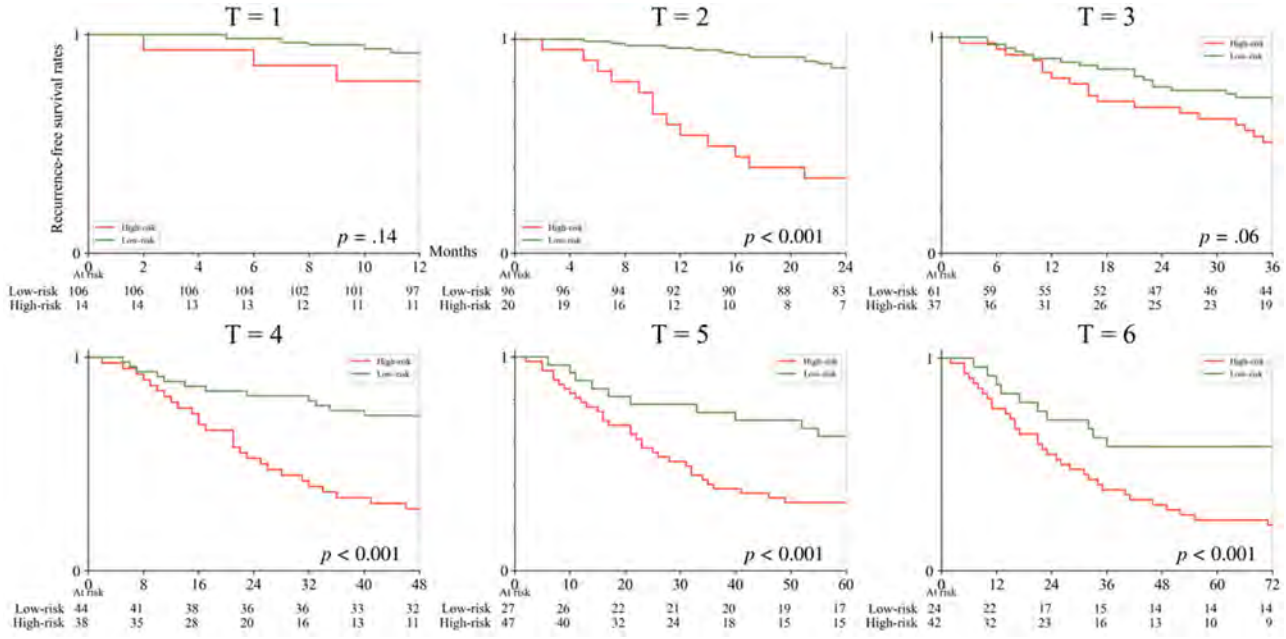

Figure: (abstract: LBP14): Kaplan-Meier analysis of Recurrence-free-survival (RFS) at each time-to-recurrence cutoff timepoints according to algorithm predictions. Each event on the green curve represents prediction inaccuracy (false-negative) and each event on the red curve represents an accurate prediction of recurrence (positive predictive value).

were, 0.74, 0.73, 0.71, 0.82, 0.71 and 0.79, respectively. Our algorithm was able to predict RFS with statistical significance at the 2, 4, 5, and 6-year time-to-recurrence cutoffs based on Kaplan-Meier analysis (log-rank p < 0.001).

Conclusion: Our study shows that machine learning-based algorithms can predict tumor recurrence of early-stage HCC prior to therapy using baseline MRI. Future developments could improve model sensitivity using larger (and external) patient cohorts and including clinical variables.

LBP15

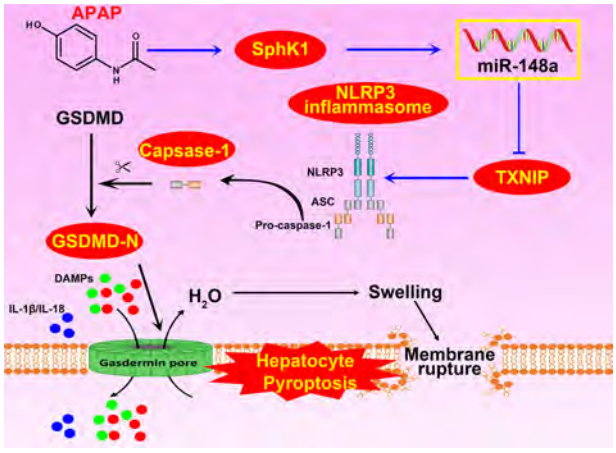
Hepatocyte-specific deficiency of sphingosine kinase 1 exacerbates acetaminophen-induced liver injury

Tian Lan[1], Jiale Dong[1], Yinghua Chen[2], Lihang Zhuang[1], Genshu Wang[3], Guruprasad Aithal[4], Jiao Guo[1]. [1]*Guangdong Pharmaceutical University, Institute of Chinese Medicine, Guangdong metabolic Diseases Research Center of Integrated Chinese and Western Medicine, Guangzhou, China;* [2]*The First Affiliated Hospital, Sun Yat-sen University, Organ Transplantation Center, Guangzhou, China;* [3]*The Third Affiliated Hospital, Sun Yat-sen University, Department of Hepatic Surgery and Liver Transplantation Center, Guangzhou, China;* [4]*University of Nottingham, National Institute for Health Research Nottingham Biomedical Research Centre, Nottingham, United Kingdom*
Email: lantian012345@163.com.

Background and aims: Sphingosine kinase 1 (SphK1) plays crucial roles in liver injury. Whether hepatocyte pyroptosis participates in the early stage of acetaminophen (APAP)-induced liver injury are not well understood. This study aims to investigate the role of hepatocellular SphK1 in APAP-induced hepatocyte pyroptosis and acute liver injury.

Method: Liver tissues from patients with DILI (DILI, n = 9) was obtained to examine the expression of SphK1. Hepatocyte-specific SphK1 conditional knockout (SphK1Hep−/−) and wild type (WT) mice (n = 6 for each group) were administrated with 250 mg/kg of APAP. Primary mouse hepatocytes isolated from WT and SphK1Hep −/− mice were treated with 5 mM APAP.

Results: SphK1 was strongly induced in patient and WT mice exposed to excess APAP. Surprisingly, SphK1Hep−/− mice had significantly higher mortality and elevated early hepatotoxicity compared to WT mice after APAP treatment. Conditional deletion of hepatocellular SphK1 increased hepatocyte pyroptosis and death. The enhanced hepatotoxicity in SphK1Hep−/− mice was associated with increased activation of NLRP3 inflammasome and Caspase 1 maturation and membrane rupture. Moreover, SphK1 deficiency in hepatocytes upregulated thioredoxin interacting protein (TXNIP) and downregulated miR-148a-3p. Furthermore, miR-148a-3p directly inhibited TXNIP expression. In contrast, APAP-induced NLRP3 activation and hepatocyte pyroptosis were reversed by miR-148a-3p mimic or TXNIP siRNA. Finally, the protective roles of SphK1 in hepatocyte damage was further strengthened by the results of adenovirus-mediated SphK1 overexpression in APAP-induced mice and correlation analysis of patients with AILI.



Conclusion: These data highlight a novel mechanism that the early stage of APAP-induced liver injury is characterized by hepatocyte pyroptosis, and demonstrate for the first time a protective role of hepatocellular SphK1 expression after APAP overdose via inhibition of NLRP3 inflammasome and pyroptosis.

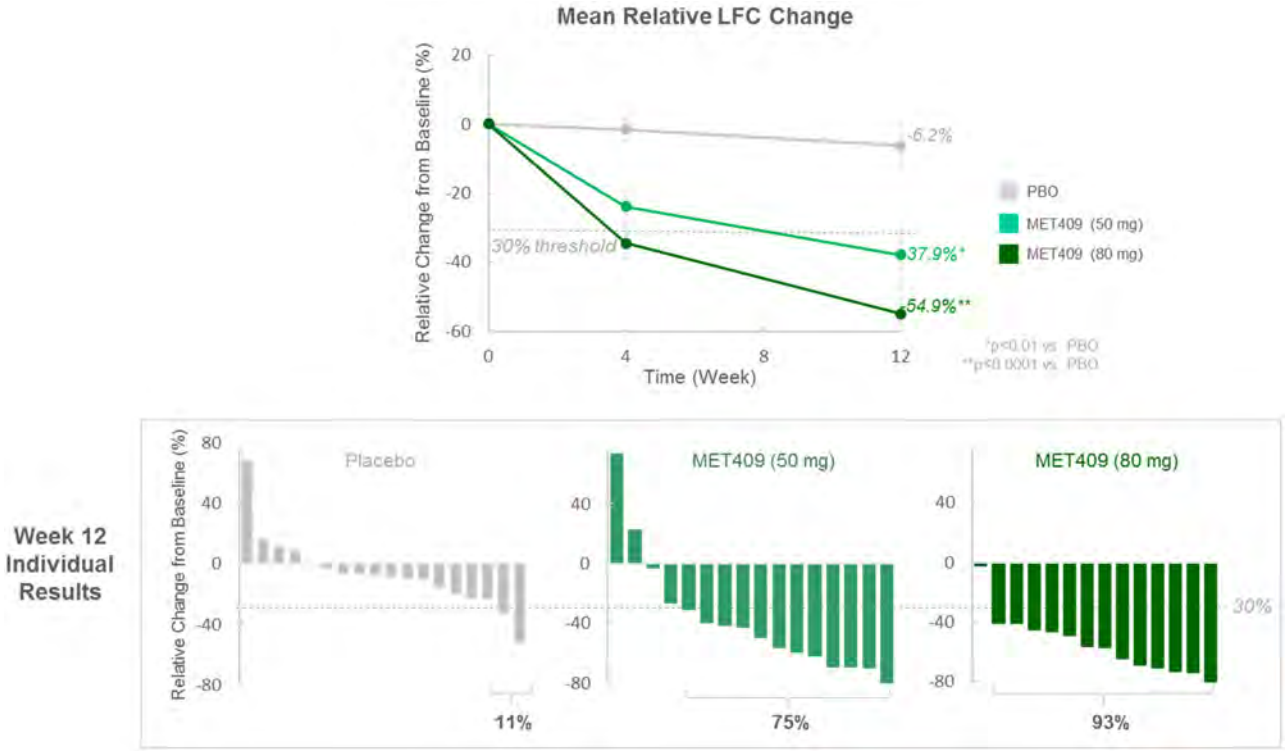


Figure: (abstract: **LBP16**)

LBP16

MET409, an optimized farnesoid X receptor agonist, decreased liver fat and improved liver enzymes in patients with non-alcoholic steatohepatitis: a 12-week, randomized, placebo-controlled study

Eric Lawitz[1,2], Mustafa Bashir[3], Jennifer Shim-Lopez[4], Jonathan Lee[4], Ken Song[4], Hubert Chen[4], Stephen Harrison[5]. *[1]Texas Liver Institute, San Antonio, United States; [2]University of Texas Health Science Center at San Antonio, San Antonio, United States; [3]Duke University Medical Center, Durham, United States; [4]Metacrine Inc., San Diego, United States; [5]Pinnacle Clinical Research, San Antonio, United States*
Email: hchen@metacrine.com.

Background and aims: Farnesoid X receptor (FXR) agonists have been validated to benefit patients with non-alcoholic steatohepatitis (NASH), although improvements in therapeutic index for the class remain elusive. MET409, a sustained agonist with a novel non-bile acid structure, demonstrated an encouraging profile after 14 days of dosing in healthy subjects and 28 days of dosing in an open-label study in 10 NASH patients. We now report the results of a 12-week, randomized, placebo (PBO)-controlled study.
Method: Men and women (18–75 years-old) with biopsy-confirmed NASH or liver stiffness ≥8.5 kPa on transient elastography (TE) were eligible. All subjects had ≥10% liver fat content (LFC) by magnetic resonance imaging-proton density fat fraction. Three cohorts were enrolled: 80 mg (n = 20), 50 mg (n = 19), and PBO (n = 19).
Results: At Week 12, MET409 significantly lowered LFC, with mean relative reductions of 55% (80 mg) and 38% (50 mg) vs 6% in PBO. MET409 achieved ≥30% relative LFC reduction in 93% (80 mg) and 75% (50 mg) of patients vs 11% in PBO, and normalized absolute LFC (≤5%) in 29% (80 mg) and 31% (50 mg) of patients vs 0% in PBO. MET409 resulted in ≥30% relative alanine aminotransferase (ALT) reduction in 50% (80 mg) and 31% (50 mg) of patients vs 17% in PBO, and ≥30% relative gamma-glutamyl transferase reduction in 64% (80 mg) and 81% (50 mg) of patients vs 0% in PBO. Despite a transient ALT increase in a subset of MET409 patients at both dose levels, a mean decrease (−24.9%) was seen for 80 mg at Week 12. Pruritus (mild-moderate only) was reported by 10% (50 mg) and 35% (80 mg) of patients. Only two pruritus-related early terminations occurred, both at 80 mg (10%). On-target increases in low-density lipoprotein cholesterol (LDL-C) were seen with MET409 (mean change; 80 mg: +23.7%, 50 mg: +7.8%, PBO: −1.5%). MET409 led to a slight body weight loss (mean change; 80 mg and 50 mg: −2.7 kg, PBO: −0.5 kg). There were no treatment-related serious or severe adverse events.
Conclusion: MET409 significantly decreased LFC and improved liver enzymes after 12 weeks of treatment in patients with biopsy-confirmed or phenotypic NASH based on TE. Additionally, MET409 at 50 mg delivered a differentiated, favorable pruritus and LDL-C profile. These results provide the first clinical evidence that the therapeutic index of FXR agonists can be enhanced through structural optimization. Further development of MET409 and structurally-related agonists should be evaluated.

LBP17

BMS-986263 (novel targeted lipid nanoparticle delivering HSP47 siRNA) safety and target engagement in patients with advanced hepatic fibrosis: week 36 results from a phase 2 randomized, double-blind, placebo-controlled trial

Eric Lawitz[1], Diane Shevell[2], Ratna Revankar[2], Sheng Gao[2], Samir Wadhawan[2], Warner Chen[2], Giridhar Tirucherai[2], Shuyan Du[2], Naim Alkhouri[1], Angie Coste[1], Fred Poordad[1], Edgar Charles[2]. *[1]The University of Texas at San Antonio, The Texas Liver Institute, San Antonio, United States; [2]Bristol-Myers Squibb, Princeton, United States*
Email: lawitz@txliver.com.

Background and aims: BMS-986263 is a lipid nanoparticle (LNP) containing a small interfering ribonucleic acid (siRNA) that degrades heat shock protein 47 (*HSP47*) mRNA, which encodes HSP47, a collagen chaperone. In the Phase 2 IM025-006 (NCT03420768) study, BMS-986263 weekly (QW) ×12 weeks (wks) was generally well tolerated and demonstrated METAVIR and Ishak improvements in patients (pts) with advanced liver fibrosis from chronic hepatitis C

who had achieved sustained virologic response (HCV-SVR). Here, we present HSP47 target engagement (TE) data (liver *HSP47* mRNA and protein), quantitative fibrosis measurement using dual-photon microscopy (qFIB), and safety through wk 36.

Method: This was a Phase 2, randomised, double-blind, placebo-(PBO) controlled study in pts with METAVIR F3-F4 fibrosis (local liver biopsy) at screening. BMS-986263 (45 or 90 mg) or PBO were IV infused QW ×12 wks; follow-up was until wk 36. Objectives included METAVIR (≥1 stage) and Ishak (≥2 stages) improvements (central-, pair-read liver biopsies); liver *HSP47* mRNA (EDGEseq) changes; HSP47 protein (IHC) and qFIB at wk12; safety and tolerability.

Results: Reduced liver *HSP47* mRNA levels were observed at wk 12 compared with baseline in 13% (2/15; PBO), 44% (8/18; 45 mg), and 71% (20/28; 90 mg) of pts. BMS-986263 45 and 90 mg groups showed a trend for decreased median liver HSP47 protein at wk 12. In IM025-006, 13% (2/15; PBO), 17% (3/18; 45 mg), and 21% (6/28; 90 mg) had METAVIR improvements; 0% (0/15; PBO), 0% (0/18), and 19% (5/27) of 90 mg pts had Ishak improvements. Of pts with METAVIR improvements at wk 12, 50% (1/2; PBO), 67% (2/3; 45 mg), and 100% (6/6; 90 mg) also showed qFIB improvement. All pts with Ishak improvement (5/5, all in the 90 mg group) had improved qFIB. qFIB improvements were observed for some METAVIR and Ishak non-responders. At wk 36, safety findings were consistent with wk 12. Most AEs were mild to moderate infusion-related reactions (IRRs); of all BMS-986263 infusions, IRRs occurred in 7% (15/216; 45 mg) and 11% (37/336; 90 mg) of pts. No meaningful bone biomarker changes occurred.

Conclusion: In this study of a limited number of pts with HCV-SVR and fibrosis, BMS-986263 IV QW ×12 wks demonstrated TE by reducing liver *HSP47* mRNA. The majority of METAVIR and Ishak responders had improved qFIB. BMS-986263 was generally well tolerated through wk 36. These data support further evaluation of BMS-986263 in pts with advanced liver fibrosis.

LBP18

JKB-122 in subjects with non-alcoholic fatty liver disease (NAFLD): a phase 2, randomized, multiple-dose, double-blind, placebo-controlled study

Kuo-Chin Huang[1], Ming-Yao Chen[2], Chih-Lin Lin[3], Sien-Sing Yang[4], Chao-Wei Hsu[5], Chia-Chi Wang[6,7], Yi-Hsiang Huang[8], Chun-Chao Chang[9,10], Ying-Chu Shih[11], Sheng-Hung Liu[11]. *[1]National Taiwan University Hospital, Department of Family Medicine, Taipei, Taiwan; [2]Shuang Ho Hospital, Department of Internal Medicine, New Taipei, Taiwan; [3]Taipei City Hospital-Renai Branch & Zhongxiao Branch, Division of Gastroenterology, Taipei, Taiwan; [4]Cathay General Hospital, Liver Center, Taipei, Taiwan; [5]Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan; [6]Taipei Tzu Chi Hospital, Department of Gastroenterology and Hepatology, Taipei, Taiwan; [7]Tzu Chi University, Buddhist Tzu Chi Medical Foundation and School of Medicine, Haulien, Taiwan; [8]Taipei Veterans General Hospital, Department of Medicine, Taipei, Taiwan; [9]Taipei Medical University Hospital, Department of Internal Medicine, Taipei, Taiwan; [10]Taipei Medical University, Department of Internal Medicine, School of Medicine, College of Medicine, Taipei, Taiwan; [11]TaiwanJ Pharmaceuticals, Hsinchu County, Taiwan*
Email: wallaceliu@taiwanj.com.

Background and aims: Non-alcoholic fatty liver (NAFLD) is a growing cause of chronic liver disease worldwide with 25% prevalence rate. NAFLD including nonalcoholic steatohepatitis (NASH), can progress to cirrhosis and hepatocellular carcinoma. These chronic liver diseases become a rapidly growing cause of liver transplantation. JKB-122 is a weak antagonist of the TLR-4, demonstrated to prevent steatosis, inflammation and hepatocellular ballooning in a NASH mouse model. The aim of this study was to assess the safety/tolerability and efficacy of JKB-122 in NAFLD patients with elevated ALT.

Method: This is a randomized (1:1:1), double-blind, placebo-controlled study in adults with NAFLD with an elevated ALT between 1.5× and 5× upper limit of normal. The NAFLD subjects were defined as the presence of hepatic steatosis, either by imaging or histology. Subjects received 5 or 35 mg of JKB-122 or placebo once daily for 3 months. The primary endpoint was reduction in hepatic steatosis by imaging studies and serum ALT at the end of 12-week treatment. The subject was considered as a responder if reduction of hepatic steatosis by image studies along with reduced serum ALT levels either a 30% or more decrease or the ALT value or within the normal range.

Results: 121 subjects were randomized (Mean age, 44 ± 11 years; man, 80%; mean BMI 28 ± 3.3 Kg/m^2; mean liver fat content (LFC) 20.8 ± 8.3%; and mean ALT 103.4 ± 32.7 U/L) and a total of 110 subjects completed all treatment visits and follow-up visit. For primary endpoint by image studies and ALT criteria after 12 weeks treatment, in the per protocol population 11 of 36 subjects, 8 of 37 subjects and 4 of 37 subjects met the definition of a responder in JKB-122 35 mg, 5 mg and placebo arm, respectively. The response rate of JKB-122 35 mg was significantly higher than that of placebo (30.6% vs. 10.8%, p-value = 0.0459). At the end of treatment, mean changes from baseline of fat percentage by magnetic resonance spectroscopy (MRS) were −3.5% ± 5.5%, −1.4% ± 3.3%, and −1.2% ± 4.1% in JKB-122 35 mg, 5 mg and placebo arm, respectively. JKB-122 35 mg and 5 mg arms both had a significant difference in mean change from baseline of fat percentage (p-values = 0.0005 and 0.0144). The LFC reduced >10% absolute rate of JKB-122 35 mg was higher than that of placebo (30.0% vs. 3.8%). JKB-122 35 mg also significantly improve BMI, LDL, HDL, total cholesterol or triglycerides compared to placebo. The most frequent AEs in 35 mg JKB-122-treated patients were dizziness (22% vs 5% in placebo), and most treatment emergent AEs were mild to moderate.

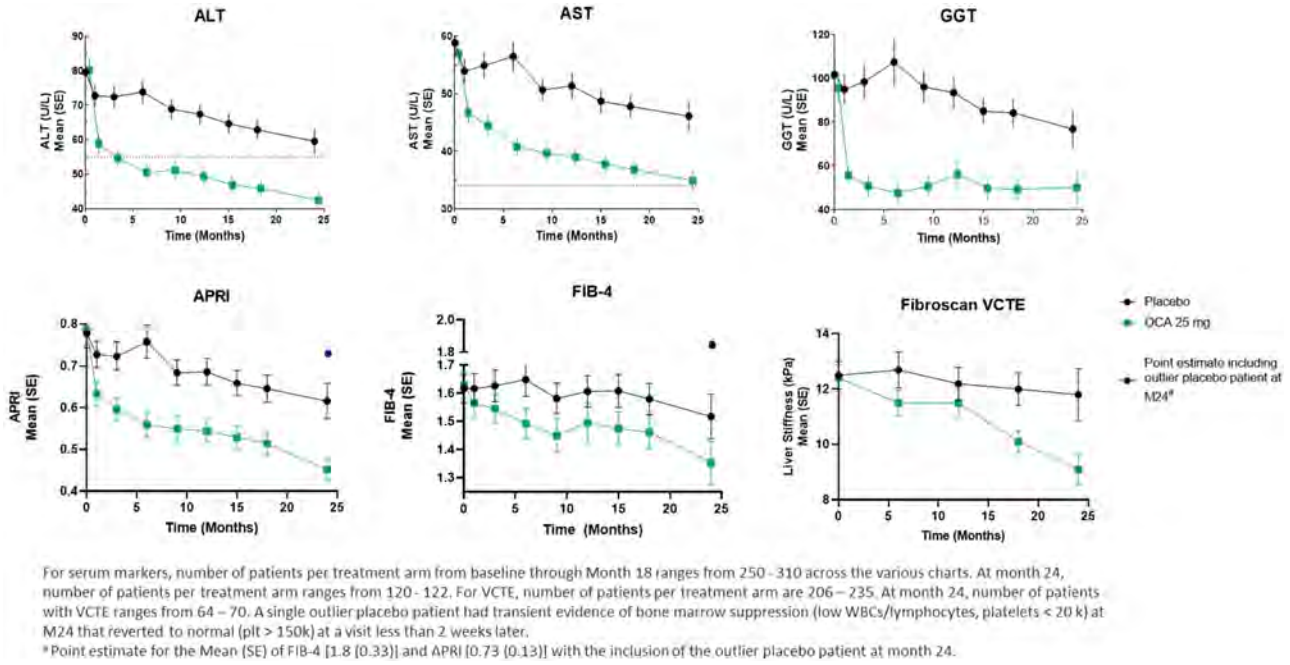
Conclusion: JKB-122 35 mg improves NAFLD in primary efficacy endpoint and some secondary efficacy endpoints, such as ALT, liver fat content in MRS image, cCK-18 level and Enhanced Liver Fibrosis (ELF) score, although no significant inter-group difference was observed compared to placebo. In term of safety profile, JKB-122 was well-tolerated.

LBP19

Obeticholic acid demonstrates sustained improvements at month 24 in transaminases and non-invasive markers of fibrosis: results of a post hoc analysis from the interim analysis of the REGENERATE study

Rohit Loomba[1], Vlad Ratziu[2], Quentin Anstee[3], Stephen Harrison[4], Arun Sanyal[5], Mary Rinella[6], Zobair Younossi[7], Zachary Goodman[7], Pierre Bedossa[8], Reshma Shringarpure[9], Huafeng Zhou[9], Aditya Venugopal[9], Mazen Noureddin[10]. *[1]University of California San Diego, La Jolla, United States; [2]Sorbonne Université, Paris, France; [3]Newcastle University, Translational & Clinical Research Institute, Faculty of Medical Sciences, Woolloongabba, United Kingdom; [4]Pinnacle Clinical Research, San Antonio, United States; [5]Virginia Commonwealth University, Richmond, United States; [6]Feinberg School of Medicine, Northwestern University, Chicago, United States; [7]Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; [8]Hôpital Beaujon, Assistance Publique-Hôpitaux de Paris, Service d'Anatomie Pathologique, Paris, France; [9]Intercept Pharmaceuticals, Inc., San Diego, United States; [10]Cedars-Sinai Medical Center, Los Angeles, United States*
Email: roloomba@health.ucsd.edu.

Background and aims: In the REGENERATE (NCT02548351) interim analysis, treatment with obeticholic acid (OCA) improved histologic liver fibrosis in patients with nonalcoholic steatohepatitis (NASH) and advanced fibrosis after treatment for 18 months. The REGENERATE study remains ongoing and will continue through clinical outcomes for verification and description of clinical benefit. To assess durability of response and the relationship between



For serum markers, number of patients per treatment arm from baseline through Month 18 ranges from 250 - 310 across the various charts. At month 24, number of patients per treatment arm ranges from 120 - 122. For VCTE, number of patients per treatment arm are 206 – 235. At month 24, number of patients with VCTE ranges from 64 – 70. A single outlier placebo patient had transient evidence of bone marrow suppression (low WBCs/lymphocytes, platelets < 20 k) at M24 that reverted to normal (plt > 150k) at a visit less than 2 weeks later.
*Point estimate for the Mean (SE) of FIB-4 [1.8 (0.33)] and APRI [0.73 (0.13)] with the inclusion of the outlier placebo patient at month 24.

Figure: (abstract: LBP19)

changes in non-invasive markers and histologic fibrosis improvement, transaminases and non-invasive markers were analyzed in patients with available 24-month data at the planned 18-month interim analysis.

Method: Patients from the interim analysis who had both evaluable month 18 biopsies (N = 250–310 per treatment arm) and month 24 data (N = 120–122 per arm) were included. Changes from baseline to month 24 in alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyl transferase (GGT), serum markers of fibrosis (FIB-4, AST to platelet ratio index [APRI]), and liver stiffness (FibroScan® vibration-controlled transient elastography [VCTE]; subset, N = 64–70 per arm) were analyzed. Descriptive summary statistics and percentage changes from baseline over time were evaluated by fibrosis improvement status (improved, stable, worsened) at month 18.

Results: Mean values of transaminases and other serum tests improved rapidly in patients treated with OCA. Improvements were sustained beyond 18 months of therapy compared with placebo (Figure). FibroScan VCTE also demonstrated improvement in liver stiffness over time, with a mean difference of 2.7 kPa between OCA 25 mg and placebo after 24 months on therapy (Figure). Changes in these markers were associated with changes in histologic fibrosis, with the greatest improvements observed in patients who had a ≥1 stage improvement in fibrosis stage at 18 months. Moreover, early changes in these markers were more pronounced in patients who had histologic fibrosis improvement at month 18.

Conclusion: OCA treatment elicited durable improvements in transaminases, other non-invasive serum markers of fibrosis, and liver stiffness by VCTE at month 24, suggesting continued improvement beyond the categorical histologic benefit seen at 18 months.

CX3CL1/CXCR1 axis recruits regulatory macrophages to promote tumor recurrence of intrahepatic cholangiocarcinoma after curative surgery

Ji Ye Zhu[1], Kwan Man[1]. [1]*The University of Hong Kong, Surgery, Hong Kong, China*
Email: kwanman@hku.hk

Background and aims: Background: Intragraft regional immunoregulation on tumor microenvironment may play a critical role in intrahepatic cholangiocarcinoma (iCCA) recurrence after curative surgery. Regulatory macrophages (Mregs) have promising potentials

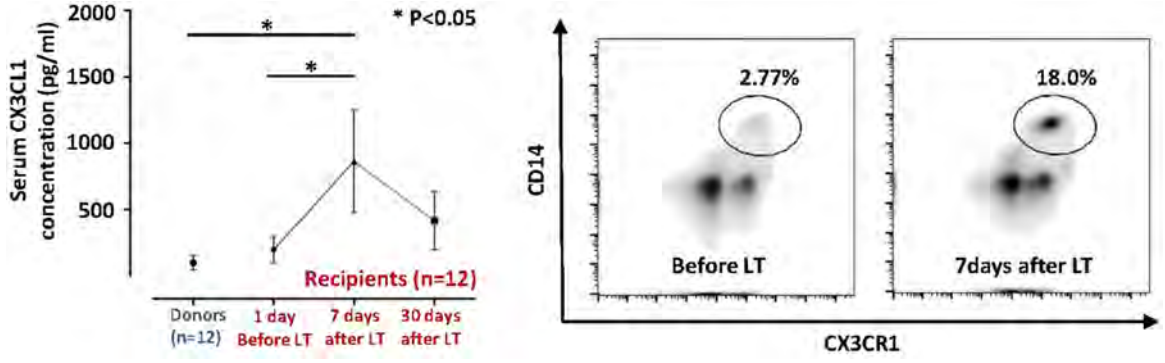

Figure 1: Serum CX3CL1 concentration and peripheral CX3CR1+ monocytes were elevated in LT patients.

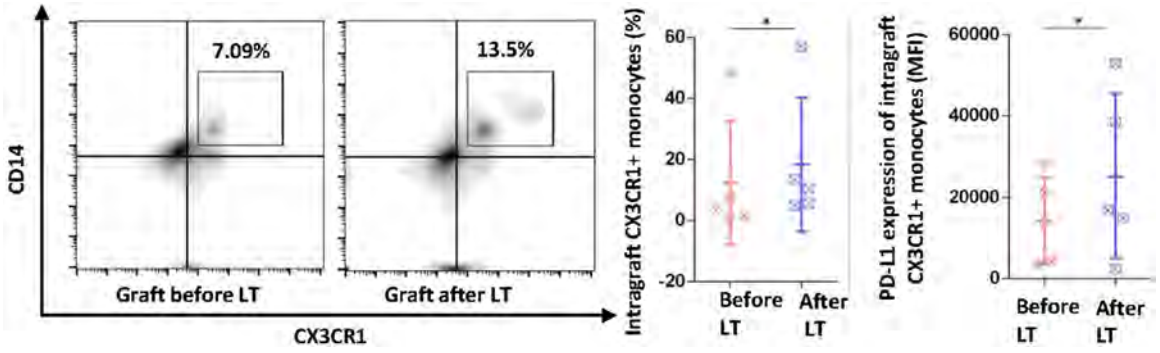

Figure 2: Increased immunosuppressive CX3CR1+ monocytes were detected in the graft of LT patients.

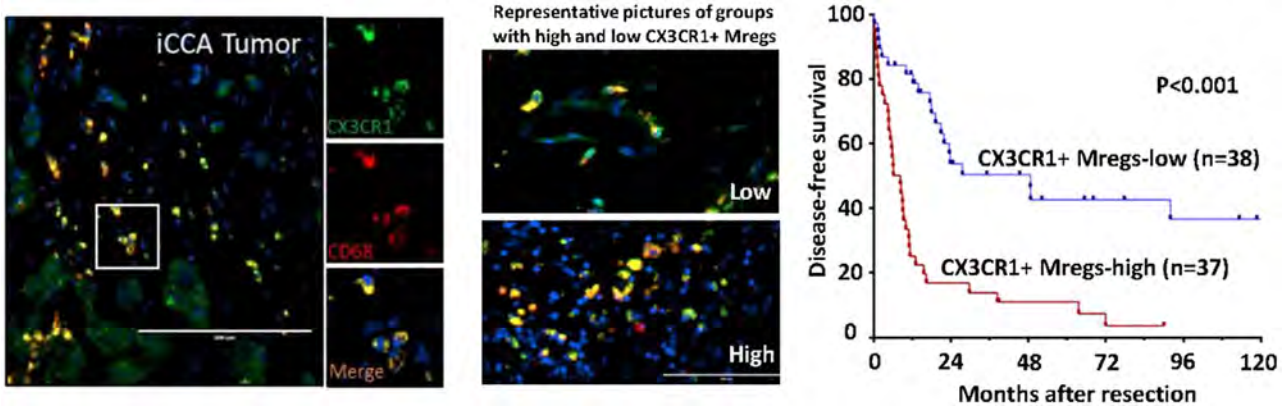

Figure 3: More CX3CR1+ macrophages were correlated with shorter DFS in iCCA.

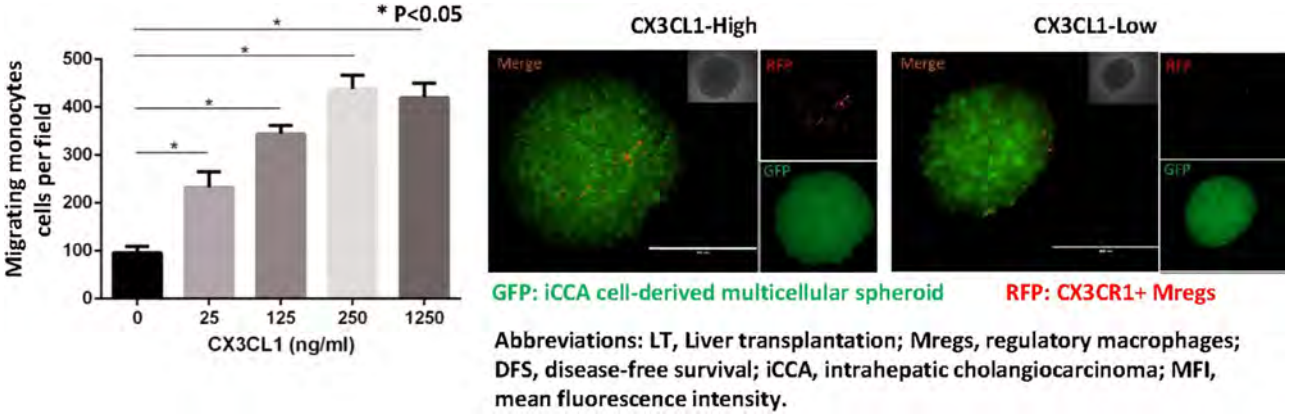

Figure 4: CX3CL1 facilitated the recruitment of monocytes and the infiltration of CX3CR1+ macrophages.

for the treatment of graft rejection due to the potent immunosuppressive function. However, Mregs in the tumor microenvironment were reported to promote tumor growth and immunoevasion. Here, we aim to investigate the role and mechanism of Mregs on iCCA recurrence after curative surgery.

Method: Gene expression profile from our institute and TCGA were analysed to explore the possible link between iCCA and monocytes. The serum CX3CL1 concentration, peripheral and intragraft CX3CR1+ monocytes were assessed in the liver transplant (LT) recipients. A total of 75 patients underwent resection for iCCA was included and prospectively followed-up since 2001 for survival analysis. The phenotypic analyses of Mregs from fresh iCCA tissue were conducted by flow cytometry. The effects of Mregs on iCCA were evaluated in vitro and in humanized NSG mice model.

Results: 1. Elevated serum CX3CL1 concentration and peripheral CX3CR1+ monocytes were detected in post-transplantation patients (Fig.1). 2. Compared with the graft before LT, intragraft CX3CR1+ monocytes and the PD-L1 expression on CX3CR1+ monocytes were increased in the graft after LT (Fig.2). 3. More infiltrated CX3CR1+ Mregs was detected in iCCA tumor tissue both after LT and resection (Fig.3). The higher number of CX3CR1+ Mregs in iCCA tissue was correlated with shorter disease-free survival (DFS) in iCCA patients

after curative surgery (Fig.3); 4. In the multivariate model, CX3CR1+ Mreg was identified as an independent prognostic factor for DFS (HR:3.400, 95%CI: 1.900-6.084, P < 0.001). 4. Elevated CX3CL1 facilitated recruitment and infiltration of Mregs (Fig.4).
Conclusion: Enhanced CX3CL1/CX3CR1 interaction facilitated intrahepatic Mreg infiltration, which subsequently promoted iCCA recurrence after curative surgery.

Email: mazen.noureddin@cshs.org.

Background and aims: The burden of non-alcoholic fatty liver disease (NAFLD) is increasing globally. The major priority is to identify patients with non-alcoholic steatohepatitis (NASH) who are at greater risk of progression to cirrhosis, and who will be candidates for clinical trials and emerging new therapies. We aimed to develop a highly specific serum-based score to identify patients with NASH, NAFLD activity score (NAS) ≥4, and significant fibrosis (F2-F3).
Methods: This study included a derivation cohort before validation in multiple international cohorts (n = 908). The derivation cohort was a cross-sectional, multicenter study of patients aged 18 years or older, who underwent liver biopsy for suspicion of NAFLD. To classify those patients with NASH at increased risk, a NAS score of ≥4 (with at least one point on each of steatosis, lobular inflammation and ballooning) and significant fibrosis (F2-F3) were used. The best fitting multivariable logistic regression model was identified and internally validated using boot-strapping. Score calibration and discrimination performance were determined in both the derivation and validation dataset.
Results: We performed serum metabolomic testing in an original cohort of 790 patients that was subsequently blind validated in a derivation cohort of 118 patients. From a total of 289 lipids analyzed, the final MASEF score included only12 lipids, body mass index (BMI), aspartate aminotransferase (AST) and alanine aminotransferase (ALT). Using logistic regression analysis, we could discriminate between NASH patients; NAS≥4 and F2-F3 compared to those without these features. The diagnostic performances of the MASEF score showed an area under the receiver operating characteristic curve (AUC), sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of 0.81 ± 0.02, 0.36, 0.96, 0.86 and 0.62 respectively, for the mentioned discrimination. While in the derivation cohort the AUC, sensitivity, specificity, PPV, and NPV were 0.82 ± 0.04,0.20, 0.95, 0.62 and 0.75, respectively.

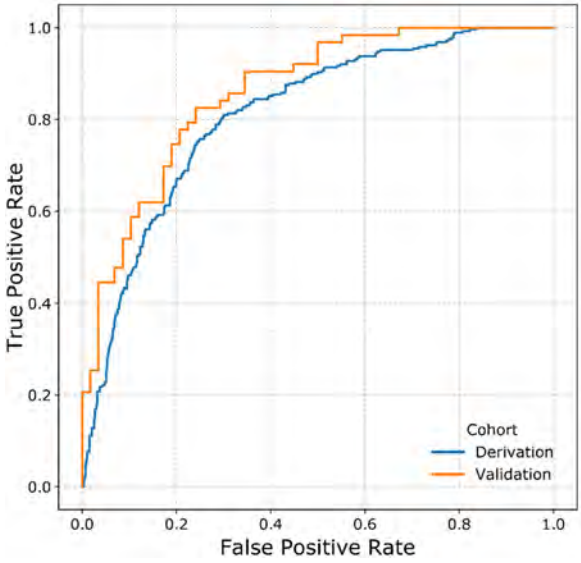

Figure: ROC Curves for the derivation cohort (blue) and validation cohort (orange).

Conclusion: The MASEF score provides an accurate, serum-based, easy to use test to non-invasively identify patients at risk of progressive NASH eligible for clinical trials or treatment.

LBP22

Screening for non-alcoholic fatty liver disease in persons with type 2 diabetes in the U.S. is cost effective: A comprehensive economical analysis

Mazen Noureddin[1], Calum Jones, Msc[2], Eduardo Vilar Gomez[3], Naim Alkhouri[4], George Therapondos[5], Parvez Mantry[6], Nigel Girgrah[5], Eric Mitchell[7], Kristen Shea, Mph[7], Norman L. Sussman[8], Michael Fuchs[9], Dr. Viviana Figueroa Diaz[10], Amreen Dinani[11], Douglas Dieterich[11], Mary Rinella[12]. *[1]Cedars Sinai, United States; [2]McCann Health; [3]Indiana University-Purdue University Indianapolis; [4]Texas Liver Institute; [5]Ochsner Health System; [6]The Liver institute at Methodist Dallas; [7]NASHNET; [8]Baylor College of Medicine; [9]Central Virginia VA Health Care System; [10]NYU Langone Health; [11]Mount Sinai Health System; [12]Northwestern Memorial Hospital*
Email: mazen.noureddin@cshs.org.

Background and aims: Globally, the prevalence of non-alcoholic fatty liver disease (NAFLD) is rising. It is imperative to identify high-risk patients whose disease may progress to significant liver fibrosis (≥F2). The American Association for the Study of Liver Diseases (AASLD) has no firm guidelines for non-alcoholic steatohepatitis (NASH) screening in high risk individuals due to inadequate data cost effective and treatment options.
Method: This cost-effectiveness analysis was developed to compare the value of screening in type 2 diabetes (T2D) patients for NASH against not screening. A Markov model was used to conduct a cost-utility analysis of 3 NAFLD screening methods consisting of combinations of ultrasound (US), alanine aminotransferase (ALT) determination followed by (1) liver biopsy alone, or (2) transient elastography for detection of patients more likely to have significant fibrosis (≥F2) followed by liver biopsy or (3) transient elastography alone. Post-detection, patients were hypothetically treated with weight reduction induced by intensive lifestyle intervention (ILI). Data provided by Vilar-Gomez et al. showed that 10% of patients who received the ILI were expected to lose over 10% of their body weight in 12 months. Costs (USD) and quality-adjusted life years (QALYs) were

discounted at 3%; the time horizon is lifetime. The threshold incremental cost-effectiveness ratio (≤$100,000 as well as ≤$50,000 per QALY) used is based on that favored by the Institute for Clinical and Economic Review.

Results: Screening ≥55-year-old patients with T2D/NAFLD using US and ALT, followed by transient elastography, to detect significant fibrosis (≥F2) is a cost-effective strategy versus no screening, when detected patients were immediately treated with a 1-year duration with ILI. Screening with liver biopsy was not cost-effective, because of disutility associated with biopsy.

Results for Screening Strategies with ILI Treatment in Patients with T2D/NASH (≥ F2)

Screening Strategy	Total			Incremental			ICER	
	Cost ($)	QALYs	LYs	Cost ($)	QALYs	LYs	($/QALY)	($/LY)
No screening	29,532	10.99	0.01	851.79	-0.14	0.55	-5,963 (Dominated)	1,556
Strategy 1	30,384	10.85	0.56					
No screening	29,532	10.99	0.01	468.01	-0.06	0.16	-7,222 (Dominated)	2,879
Strategy 2	30,000	10.93	0.17					
No screening	29,532	10.99	0.01	7.93	0.01	0.16	698 (Cost effective)	48
Strategy 3	29,540	11.00	0.18					

Conclusion: Non-invasive screening patients with T2D/NAFLD in the U.S. is cost effective and can be considered to decrease the burden of the disease.

LBP23

CHESS criteria for the screening of varices in patients with compensated advanced chronic liver disease: a multicenter study

Email: qixiaolong@vip.163.com.

Background and aims: The Expanded-Baveno VI criteria spare more endoscopies than the Baveno VI criteria with a minimal risk of missing varices needing treatment (VNT) in compensated advanced chronic liver disease (cACLD), mainly with hepatitis C virus, alcoholic and nonalcoholic steatohepatitis. This study aimed to validate and optimize the Expanded-Baveno VI criteria in cACLD with hepatitis B virus (HBV) as major etiology.

Method: We enrolled a real-world cohort with cACLD between December 2015 and July 2019 in one university hospital in China (Tianjin Second People's Hospital) to validate the Expanded-Baveno VI criteria. The cohort was also used to study the performance of different thresholds of platelets count and liver stiffness measurement (LSM) for identifying patients at very low risk (<5%) of having VNT to optimize the criteria. The new criteria were validated in an external multicentre cohort between August 2019 and December 2019 in 9 university hospitals in China (161 from The Sixth People's Hospital of Shenyang, 22 from Ankang Central Hospital, 17 from Guangdong Provincial Hospital of Chinese Medicine, 14 from Dalian Sixth People Hospital, 4 from Shanghai Tongji Hospital, 4 from The Fifth Affiliated Hospital of Zunyi Medical University, 2 from Ankang Hospital of Traditional Chinese Medicine, 2 from The People's Hospital of Guangxi Zhuang Autonomous Region, and 1 from The First Hospital of Lanzhou University).

Results: In the real-world cohort of 1085 cACLD with different etiologies (68.0% of HBV), the Expanded-Baveno VI criteria failed to identify patients of having VNT with 35/590 (5.9%) VNT missed. Therefore, the optimized criteria, CHESS criteria (platelet count >105 × 109 cells/L and LSM <19 kPa), were developed with a very low risk (<5%) of missing VNT. The CHESS criteria spared more unnecessary endoscopies than Baveno VI criteria (platelet count >150×109 cells/L and LSM <20 kPa) significantly (50.0% vs. 31.9%, p < 0.001). In addition, the CHESS criteria were validated in the external multicentre cohort of 227 patients with different etiologies (83.7% of HBV), and obviously spared more endoscopies than Baveno VI criteria (51.5% vs. 28.2%, p < 0.001) with 5/117 (4.3%) VNT missed.

	Real-world cohort (N = 1085)	Validation cohort (N = 227)
Age, years	49.83 (11.99)	53.91 (10.01)
Male, n (%)	654 (60.27%)	151 (66.52%)
HBV, n (%)	738 (68.01%)	190 (83.70)
Child-Pugh A, n (%)	974 (89.70%)	215 (94.71)
Platelet count, x10^9 cells/L	141.30 (60.45)	130.42 (57.74)
LSM, kPa	18.32 (13.61)	16.11 (12.29)
VNT, n (%)	139 (12.81%)	30 (13.22%)

Continuous data expressed as mean ± standard deviation. HBV, hepatitis B virus; LSM, liver stiffness measurement; VNT, varices needing treatment.

Conclusion: The CHESS criteria spare more unnecessary endoscopies than Baveno VI criteria with a very low risk of VNT missed in different etiologies (mainly HBV) of cACLD.

LBP24

Post-fecal microbiota transplant taxa correlate with 3-month survival in severe alcoholic hepatitis patients

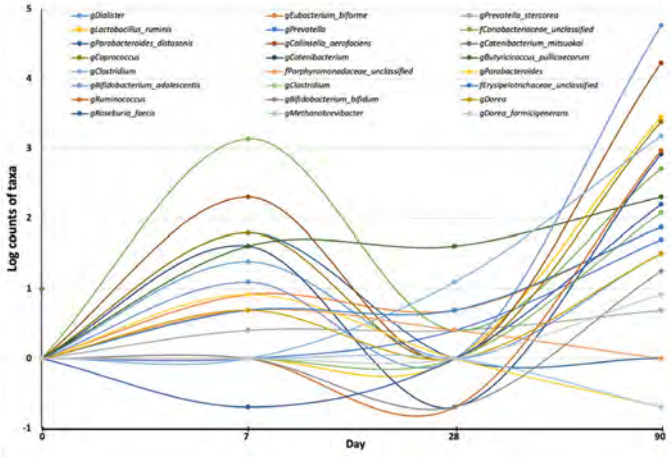
Shvetank Sharma[1], Apurva Pande[2], Vikas Khillan[3], Archana Rastogi[4], Vinod Arora[5], S. Muralikrishna Shasthry[5], Vijayraghavan Rajan[5], Guresh Kumar[6], Manoj Kumar[5], Stanislas Mondot[7], Jöel Doré[7], Shiv Kumar Sarin[5]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine; [2]Institutte of Liver and Biliary Sciences, Hepatolopgy; [3]Institute of Liver and Biliary Sciences, Microbiolgy; [4]Institute of Liver and Biliary Sciences, Pathology; [5]Institute of zLiver and Biliary Sciences, Hepatology; [6]Institute of Liver and Biliary Sciences, Clinical Research; [7]INRA*
Email: shvetanks@gmail.com.

Background and aims: Fecal microbiota transplant (FMT) has been received with mixed outcomes in different diseases. To understand the variations that microbiota has on event-free survival in SAH patients, a randomized controlled trial (NCT03091010) was undertaken comparing FMT with steroid therapy. Results of the microbiota changes are presented; clinical results would be reported separately.

Method: SAH patients (age 18–70 yr) with histological confirmation, DF score >32 and alcohol intake within last 30 days were randomized to receive steroids (n = 57) or FMT (n = 55). FMT was given as fresh preparation via naso-duodenal route for 7 days. Healthy first-degree relatives or those living in the same environment were screened for (but not limited to) *Clostridium difficile* toxin, *Helicobacter pylori* stool antigen (Ag), *Cryptosporidium* and *Isospora*, Rotavirus Ag, HBsAg, anti-HCV, HIV 1 and 2, VDRL and HLA A1. Microbiota was assessed by sequencing V3-V4 region of 16 s gene from DNA isolated from stool samples collected at baselines, days 7, 28, 90, on MiSeq system, using 2 × 300 bp paired-end mode.

Results: Patients in steroid and FMT groups were comparable at baseline (DF score 65 ± 16.2 and 68 ± 14, p = NS). FMT showed better outcome compared to steroid therapy for 90 days survival (p = 0.005).

Taxa like *Lactobacillus ruminis, Collinsella aerofaciens, Butyricicoccus pullicaecorum, Bifidobacterium adolescentis, Ruminococcus sp, Bifidobacterium bifidum, Roseburia faecis* and *Dorea formicigenerans* were not detected at baseline but were introduced by donors and took about 14–28 days to establish (Figure). In FMT arm, the Phylum Tenericutes was significantly associated with mortality (p = 0.003). Pathogenic genera like *Klebsiella*, *Salmonella*, and *Mycoplasma* showed significant increase (p = 0.075, 0.011, 0.037, 0.025 respectively) in non-survivors. Proteobacteria and Fusobacteria were significantly (p < 0.001, 0.019 respectively) associated with mortality. Phylum Firmicutes, family Lachnospiraceae, and genera *Veillonella* and *Prevotella*, favoured survival (p = 0.008, 0.051, 0.045, 0.033, respectively). There were no significant adverse events with FMT.



Conclusion: Healthy donor FMT is safe in SAH patients, establishes beneficial flora within 4 weeks and improves 90-day survival. However, in non-survivors pathogenic phyla persist. Taxa associated with mortality need to be studied and continuously screened for, to add FMT from new healthy donors, to improve survival.

LBP25

A novel immunoregulatory role for complement receptor C3AR1 in fibrosing cholangiopathies of biliary atresia and primary sclerosing cholangitis

Gabriela N. Matos Ortiz[1], Reena Mourya[2], Unmesha Thanekar[2], Pranavkumar Shivakumar[2,3]. [1]*University of Puerto Rico Mayaguez Campus, Department of Biology, Mayaguez, Puerto Rico;* [2]*Cincinnati Children's Hospital Medical Center, Division of Gastroenterology, Hepatology and Nutrition, Cincinnati, United States;* [3]*University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States*
Email: pranav.shivakumar@outlook.com.

Background and aims: The fibrosing cholangiopathies, biliary atresia (BA) and primary sclerosing cholangitis (PSC), are characterized by cholangiocyte injury, immune cell infiltrations and obstruction or stricturing of the biliary tree. The complement receptor, C3AR1 is implicated in negative regulation of immune cell mobilizations and suppression of *Tnfa* and *Il1b* in liver injury. Here, we investigated regulation of biliary disease pathogenesis by C3AR1 in the context of BA and PSC.

Method: Human and murine RNASeq mRNA expressions and proteomics data were analysed for plasma C3, C3a and C3adesArg. Experimental BA was induced in newborn wild-type (WT) and C3AR1$^{-/-}$ mice by *i.p.* injection of 1.0×10^6 ffu of rhesus rotavirus (RRV) and phenotyped for cholestasis. Double knockout mice were generated by superimposing C3AR1 deficiency on an MDR2$^{-/-}$ background. Homozygous MDR2$^{-/-}$C3AR1$^{-/-}$, WT and MDR2$^{-/-}$ mice were sacrificed on day 70 of life. Liver biochemistry was assessed by plasma bilirubin, ALT and AST levels. Histology of extrahepatic bile ducts (EHBDs) and livers was evaluated by H&E staining and cytokeratin (CK)$^+$ bile duct profiles. Liver immune cells were phenotyped using flow cytometry and gene expressions were determined by qRT-PCR.

Results: mRNA expressions of C3AR1, CXCR4 and CXCL12 were elevated in livers of human (2.5–7.3 fold above normals $P \leq 0.0003$) and EHBDs of experimental BA (RRV: 1.3–6.3 fold above controls, $P < 0.02$) reflecting homeostatic anti-inflammatory responses. Serum levels of C3, C3a and C3adesArg also increased in patients with BA (1.2–1.4 fold above controls, $P < 0.03$). RRV infection of C3AR1$^{-/-}$ mice resulted in severe EHBD atresia (Figure 1A), liver necroinflammation, early mortality by day 10 (77%) *vs* WT mice (0%, $P < 0.0001$) and elevated serum total bilirubin (25.7 ± 3.9; WT: 13.1 ± 1.9 mg/dL) and ALT (354 ± 158; WT: 128 ± 16 IU/L) levels ($P < 0.0001$). Hepatic mRNA expressions of *Tnfa*, *Il1b* and *Il6* and Nkg2d$^+$ CD4$^+$/CD8$^+$, NK, pDCs, macrophage and neutrophils were significantly elevated (2.6–6.3 fold, $P < 0.01$–<0.0001) in RRV–C3AR1$^{-/-}$ mice. Importantly, RRV infection suppressed C3AR1 expression on hepatic CD45$^+$Lin$^+$ and increased on CD45$^-$Lin$^-$ cells. MDR2 deficiency significantly suppressed hepatic C3AR–expressing CD3$^+$CD314$^+$CD4$^+$/CD8$^+$, CD11b$^+$Gr1$^+$, pDC and NKp46$^+$CD314$^+$ cells. C3AR1$^{-/-}$MDR2$^{-/-}$ mice showed enhanced onion skin fibrosis, dilatation of intrahepatic ducts resembling large-duct PSC and an inflamed and tortuous extrahepatic common duct (Figure 1B). Sirius red areas increased significantly in C3AR1$^{-/-}$MDR2$^{-/-}$($1.6^{E+05} \pm 4.4^{E+04}$) compared to MDR2$^{-/-}$ mice ($7.4^{E+04} \pm 3.3^{E+04}$).

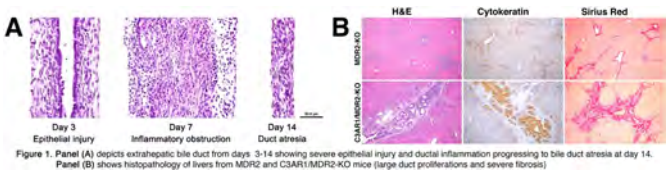


Figure 1. **Panel (A)** depicts extrahepatic bile duct from days 3-14 showing severe epithelial injury and ductal inflammation progressing to bile duct atresia at day 14. **Panel (B)** shows histopathology of livers from MDR2 and C3AR1/MDR2-KO mice (large duct proliferations and severe fibrosis)

Conclusion: C3AR1 regulates the fibroinflammatory and proliferative responses in biliary atresia and primary sclerosing cholangitis. C3AR1 agonism may therefore be a novel therapeutic intervention in pediatric and adult cholestatic liver diseases.

LBP26

Resolution of non-alcoholic steatohepatitis and hepatic fibrosis by sodium glucose transporter-2 inhibitor, ipragliflozin; a multicenter randomized controlled trial

Email: takahas2@cc.saga-u.ac.jp.

Background and aims: Sodium glucose transporter-2 inhibitors (SGLT2) are now widely approved treatment against diabetes, whereas the effect on hepatic outcome of nonalcoholic fatty liver disease (NAFLD) remains uncertain. We aimed to evaluate the SGLT2 effect on pathogenesis of NAFLD including pathological findings.
Method: Multicenter randomized controlled trial was conducted and diabetic patients with NAFLD were included. Liver biopsy was performed before randomization and 2nd liver biopsy was performed after the treatment for 72 weeks with ipragliflozin (50 mg/day, n = 21; IPR) or active control treatment, except SGLT2, pioglitazone, and/or glucagon-like peptide-1 analogs (n = 25; CTR). All liver biopsies were evaluated by two pathologists who were blind to group assignment and clinical parameters. Nonalcoholic steatohepatitis (NASH) was diagnosed using Matteoni's classification.
Results: There were no significant differences in basal bodyweight, hemoglobin A1c, frequency of concomitant diseases, or pathological NAFLD findings between the groups. Hepatic fibrosis was observed in 17 patients (81%) of IPR and 18 patients (72%) of CTR. After the treatment, IPR showed more significant decrease in body weight, BMI, visceral fat area evaluated by CT scan and hemoglobin A1c comparing with CTR. Liver fibrosis improved in 70.6% (12/17) of patients with liver fibrosis in the IPR group and 22.2% (4/18) of those in the CTR group ($p < 0.01$). Improvement in hepatocyte ballooning was greater in IPR than CTR (52.4% vs. 24%, $p < 0.05$). There was no significant difference between the groups in steatosis. NASH resolution was obtained in 66.7% of NASH patients of IPR and 27.3% of those of CTR. There was no patient with development to NASH from non-NASH in IPR whereas 33.3% of non-NASH patients developed to NASH in CTR.
Conclusion: Long term ipragliflozin treatment ameliorates hepatic fibrosis of NAFLD. Ipragliflozin brings NASH resolution and prevent aggravation of non-NASH, as well as improve glycemic control and obesity. SGLT2 inhibitor could be a therapeutic choice of diabetic patients with NAFLD.

LBP27

Novel markers to predict virological and clinical relapse onset following antiviral treatment discontinuation in chronic hepatitis B patients

Email: jaerssen@its.jnj.com.

Background and aims: This observational study aims to identify virological and host genetic predictive markers for relapse onset in chronic hepatitis B (CHB) patients discontinuing direct antiviral treatment.
Method: This multi-center, prospective study in Taiwan enrolled 186 CHB patients in their last year of a minimum 3-year treatment regimen with direct antivirals. Patients were followed for up to 2 years after treatment discontinuation. Virological relapse (VR) was defined as HBV DNA >2000 IU/mL. Clinical relapse (CR) was defined as ALT level >2× the upper limit of normal in addition to VR.
Blood samples were collected for DNA profiling by whole genome genotyping (Affymetrix Axiom™ Asia Precision Medicine Research Array).
Results: Of the cohort, 161 (86.6%) patients experienced VR of whom 110 (59.2%) also had a CR. HBeAg negativity prior to the start of treatment was associated with earlier VR. High HBsAg levels (≥100 IU/mL) at the end of the treatment (EoT) period was associated with earlier onset of VR and CR. Entecavir treatment was associated with delayed VR and CR compared to tenofovir.
A genome-wide association study revealed 33 independent genetic markers significantly associated with onset of VR and 9 markers significantly associated with onset of CR. Amongst those markers, SNPs in *CTLA4*, *HLA-DPB1* and *RBFOX1* (reported earlier as a recurrent site for HBV integration) were found to be associated with onset of CR, and SNPs in *SLC10A1* (encoding HBV receptor NTCP), *FUT8* (regulating NTCP expression) and several SNPs in the *HLA-C* region with onset of VR after treatment discontinuation.
Clearly improved sensitivity and specificity of the Cox proportional hazard regression models was observed when adding genetic markers to HBsAg level at EoT, antiviral treatment regimen, and HBeAg status at the beginning of the last treatment regimen. The Receiver Operating Characteristic (ROC) AUC increased from 0.67 to 0.86 to predict CR within 6 months after EoT, and from 0.82 to 0.95 to predict VR within 3 months after EoT.
Conclusion: The study revealed novel genetic markers predictive of relapse onset after treatment discontinuation. Several identified genes have previously been described already as key player in HBV replication but are now for the first time also shown to be associated with time to relapse in CHB. Host genetic markers can be useful contributors in predicting patient outcome when considering stopping suppressive treatment.

LBP28

Noninvasive point-of-care 13C-Methacetin Breath Test (MBT) predicts risk of clinical deterioration independently of currently used prognostic indicators in patients with decompensated NASH cirrhosis

John Vierling[1], Arun Sanyal[2], Scott Friedman[3], Mitchell Shiffman[4], Jean Chan[5], Raphael Werner[6], Jaime Bosch[7,8]. *[1]Baylor College of Medicine, Section of Gastroenterology and Hepatology and Division of Abdominal Transplantation, Houston, TX, United States; [2]Virginia Commonwealth University Medical Center, Division of Gastroenterology, Richmond, VA, United States; [3]Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, NY, United States; [4]Bon Secours Liver Institute of Virginia, Richmond, VA, United States; [5]Conatus Pharmaceuticals Inc, San Diego, CA, United States; [6]Exalenz Bioscience, Modi'in, Israel; [7]Hospital Clínic de Barcelona, IDIBAPS, CIBERehd, Barcelona, Spain; [8]Inselspital – Universitätsspital, Bern, Switzerland*
Email: raffiw@exalenz.com.

Background and aims: Patients with decompensated NASH cirrhosis are at risk for subsequent worsening of liver function and portal hypertension, resulting in decompensation events such as ascites (ASC), variceal hemorrhage (VH) and hepatic encephalopathy (HE). MBT quantitates hepatic CYP1A2 metabolism of orally ingested, non-radioactive ^{13}C-methacetin to $^{13}CO_2$ and acetaminophen by continuous monitoring of the $^{13}CO_2/^{12}CO_2$ ratio in expired breath. MBT provides composite results integrating the impacts of hepatic metabolic function and perfusion that quantifies the status of "liver health." The aim was to prospectively validate the independent association of MBT with the risk of developing a composite hepatic deterioration endpoint (Event) comprised of new ASC, VH, new HE, MELD score progression (MSP, defined as increase ≥4 points from baseline), and all-cause mortality (ACM) in patients with

decompensated NASH cirrhosis enrolled in a randomized, placebo-controlled trial of the caspase inhibitor emricasan.
Method: MBT was measured with the Exalenz BreathID® System using a cut-off value identified in a previous study. MBT results were collected at baseline from 138 patients enrolled in the study. Prospective monitoring for Events was performed for a median of 315 days. Results of MBT, expressed as the maximal ^{13}C-methacetin percent dose recovery rate (PDRpeak), reflect the peak hepatic capacity to metabolize methacetin.
Results: Average age was 61.1 (SD:8.5) years; average BMI was 33.9 (SD:6.2) kg/m^2; 52.2% were female. During the observation period, 38 patients (27.5%) met the composite endpoint (25 MSP, 1 HE, 1 ASC, 7 VH, 4 ACM). The previously identified cutoff of PDRpeak ≤5.5%/h identified 15.2% of all patients as having a high risk of Events and included 11/38 Events with a hazard ratio (HR) of 4.2 (95% CI: 1.75–10.07, p = 0.001) for Events (Figure). Multivariate analyses showed that the PDRpeak ≤5.5%/h had an independent predictive value superior to currently used predictors such as MELD or CTP scores (either separately or combined) or previous decompensation.

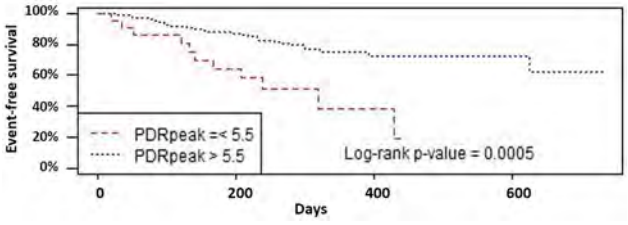

Figure: Event-free survival Kaplan Meier curve for MBT PDRpeak cutoff of 5.5%/h.

Conclusion: In patients with decompensated NASH cirrhosis, baseline MBT identified patients at high risk for additional clinical deterioration Events independently and more accurately than either MELD or CTP. The data indicate that MBT is a safe, operator-independent, in-office, non-invasive point-of-care tool to identify patients at increased risk for clinical deterioration.

LBP30

Antiviral activity and safety of the hepatitis B core inhibitor ABI-H0731 administered with a nucleos(t)ide reverse transcriptase inhibitor in patients with HBeAg-positive chronic hepatitis B infection in a long-term extension study

Email: mfyuen@hku.hk.

Background and aims: ABI-H0731 (731) is a first-generation HBV core inhibitor in development for the treatment of chronic hepatitis B infection (CHB). In the Phase 2a studies 202 and 201, treatment naïve (TN) and virally suppressed (VS) HBeAg-positive patients (pts) with CHB were randomized 1:1 to 731 or placebo (Pbo) with NrtI in a blinded manner for 24 weeks. The combination of 731+NrtI was well tolerated and demonstrated faster and greater reductions in HBV DNA and pgRNA than NrtI alone. Following study completion, eligible pts entering an open-label extension study 211 received 731+NrtI for up to an additional 76 weeks. Here we report the updated data from study 211 through the current last reported observation.
Method: For TN pts, HBV DNA was measured by COBAS TaqMan 2.0 (LLOQ = 20 IU/mL) and pgRNA by an in-house quantitative PCR assay (LLOQ = 135 U/mL). For VS pts, HBV DNA was measured by an in-house semi-quantitative PCR assay (LLOD = 5 IU/mL) and pgRNA by an in-house semi-quantitative RT-PCR assay (LLOD = 5 IU/mL). For all pts, quantitative HBeAg and HBsAg were measured by Abbott Architect (LLOQ = 0.11 IU/mL and 0.05 IU/mL, respectively) and HBcrAg by Lumipulse G (LLOD = 1 kU/mL). Safety was assessed by adverse events (AEs) and laboratory parameters.
Results: Of the 23 TN pts from study 202, median (range) treatment duration 57 (36–83) weeks, 21 pts have DNA declines to <100 IU/mL and 6 pts have pgRNA declines to <500 U/mL. Declines of ≥1 log or at <LLOQ in HBeAg, HBcrAg and HBsAg have been observed in 6, 8 and 3 pts, respectively. Of the 43 VS pts from study 201, median (range) treatment duration 58 (30–81) weeks, 34 and 21 pts have now achieved DNA and pgRNA <5 IU/mL, respectively. In addition, 29 pts have HBeAg <5 IU/mL, 27 pts have HBcrAg <500 kU/mL and 4 pts have HBsAg <1000 IU/mL. During the first 24 weeks of study 211, AEs were reported by 47% (31/66) pts, most of which were Grade 1 or 2. There were no SAEs or AEs leading to study drug discontinuation. The only AE reported by >5% was upper respiratory tract infection (4 pts, 6%). Most laboratory abnormalities were Grade 1 or 2. Transient or intermittent Grade 3 elevations in ALT were observed in 2 pts (3%), both of whom continue on study drug.
Conclusion: Results from the ongoing Phase 2a extension study demonstrate continued declines in HBV DNA, pgRNA and viral antigens in pts treated with 731+NrtI. 731 continues to exhibit a favorable safety and tolerability profile in pts treated for over 1 year. The data support the continued development of 731.

LBP31

Machine learning identifies histologic features associated with regression of cirrhosis in treatment for chronic hepatitis B

Dinkar Juyal[1], Chinmay Shukla[2], Harsha Pokkalla[2], Amaro Taylor[2], Oscar Zevallos[2], Murray Resnick[2], Michael Montalto[2], Andrew Beck[2], Ilan Wapinski[2], Patrick Marcellin[3], John F. Flaherty[4], Vithika Suri[4], Anuj Gaggar[4], Mani Subramanian[4], Ira Jacobson[5], Edward Gane[6], Maria Buti[7]. *[1]PathAI, Boston, MA, USA; [2]PathAI, Boston, MA, USA; [3]Department of Hepatology, AP-HP Hôpital Beaujon, Clichy, France; [4]Gilead Sciences Inc., Foster City, CA, USA; [5]Department of Medicine, NYU Langone Health, New York, New York; [6]Auckland Clinical Studies, Auckland, New Zealand; [7]Hospital General Universitario Valle Hebron and Ciberehd, Barcelona*
Email: vithika.suri@gilead.com.

Background and aims: Machine learning (ML) may facilitate interpretation of histologic changes associated with treatment of chronic hepatitis B virus (HBV) infection. We developed ML models

that identify and quantify histologic features in a clinical study of HBV patients receiving antiviral therapy.
Method: ML models were developed using H&E histology images from 330 patients enrolled in registrational studies for tenofovir disoproxil fumarate for HBV (GS-US-174-0102, GS-US-174-0103). Histological improvement and regression of cirrhosis were assessed by a central pathologist at baseline (BL) and weeks 48 and 240 according to the Ishak/Knodell necroinflammatory scoring and Ishak fibrosis staging systems. Images were split into training (N = 1090) and testing sets (N = 1061). Models were trained using the PathAI research platform (Boston, MA) to identify inflamed regions and immune cells (lymphocytes and plasma cells) using annotations from 40 board-certified pathologists. Additional annotations of steatosis and ballooning from previous models were included in training. Slide-level, quantitative ML features were computed and correlated with pathologist scores to assess accuracy. Regression analysis was performed to determine associations of ML features at BL and changes from BL with cirrhosis regression at week 240. Results were generated using the testing image set.
Results: ML % area of portal inflammation correlated strongly with Ishak portal inflammation scores ($\rho = 0.643$; $p < 0.001$) and ML % area of interface inflammation correlated strongly with Ishak periportal necrosis scores ($\rho = 0.716$; $p < 0.001$). Of the 48 patients in the testing set with cirrhosis at BL, 36 patients (75%) no longer had cirrhosis at week 240. Lower ML % area of steatosis (Figure) and greater ML % area of lobular inflammation at BL were predictive of cirrhosis regression ($p = 0.006$, $p = 0.047$, respectively), indicating the presence of underlying fatty liver in those who do not resolve cirrhosis. Change from baseline in ML % area of portal and lobular inflammation as well as change in lymphocyte density correlated with regression of cirrhosis at week 240 ($p = 0.010$, $p = 0.026$, $p = 0.031$ respectively).

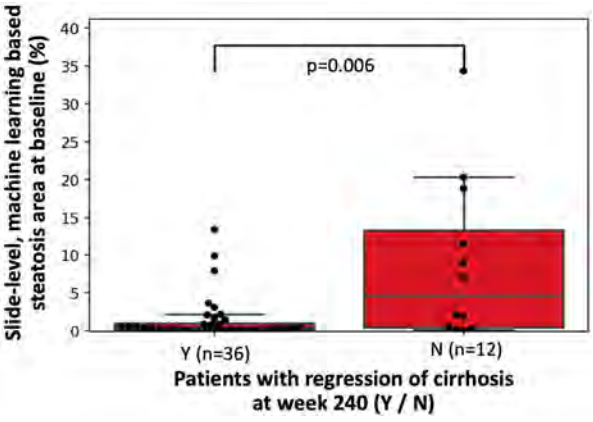

Figure: Steatosis area at baseline, determined by machine learning, was predictive of cirrhosis regression at week 240.

Conclusion: An ML approach accurately classified histopathologic features in H&E images from HBV clinical trial biopsies. ML features at BL and changes in ML features with treatment were significant associated with cirrhosis regression. An ML approach for evaluating liver histology in patients with HBV can provide mechanistic insight into both HBV disease pathogenesis and cirrhosis regression.

Email: zhongjianhong@gxmu.edu.cn.

Background and aims: The long-term survival of repeat hepatic resection (rHR) and radiofrequency ablation (RFA) for patients with recurrent hepatocellular carcinoma (HCC) is still unknown. We did a multicentric study to assess the long-term survival of rHR and RFA for patients with recurrent HCC.
Method: Between January 01, 2006, and December 31,2017, 940 patients with recurrent HCC received rHR orRFA. Only those with recurrent HCC within Milan criteria (with a solitary nodule diameter of ≤5 cm; 3 or fewer nodules, each ≤3 cm in diameter; and no macrovascular invasion or distant metastasis) after initial hepatic resection and had Child-Pugh liver function class A or B (7 score) werer included. The median (range) follow-up time was 65.6 (1.3–152.8) months.
Results: 847 patients from 9 centres in mainland China, Hongkong, and Italy were enrolled in the study. Of these, 307 patients received rHR while 540 received RFA. Median overall survival was 73.5 months in patients treated with rHR, compared with 66.3 months in those who received RFA (hazard ratio [HR] 0.99 [95% CI 0.80–1.24]; $p = 0.969$). The corresponding 10-years overall survival of the two groups were 34.8% and 28.3%. Median recurrence-free survival was significantly longer in rHR group when compared with the RFA group (24.1 months vs 15.2 months; HR 0.75 [0.63–0.88]; $p < 0.001$). The corresponding 10-years recurrence-free survival of the two groups were 13.1% and 6.0%. However, patients in the RFA group were with lower perioperative mortality and morbidity rates, and shorter hospital stay. Subgroup analyses based on each center and propensity score analysis found similar findings.

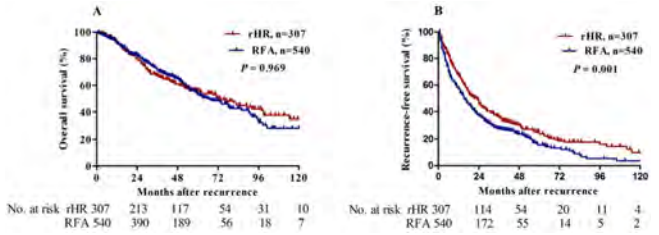

Figure 1. Overall survival (A) and recurrence-free survival (B) after repeat hepatic resection (rHR) or radiofrequency ablation (RFA) for recurrent HCC within Milan Criteria in total population.

Conclusion: rHR is associated with better recurrence-free survival for patients with recurrent HCC within Milan criteria. However, RFA is associated with lower mortality and morbidity rates with similar long-term overall survival. It could be considered as a reasonable alternative in patients with high risk for rHR.

LBP33

Analysis of HBsAg levels, HBsAg isoforms, HBsAg immune complexes, HBV pregenomic RNA and HBcrAg dynamics during and after NAP-based combination therapy in the REP 301-LTF and REP 401 studies

Michel Bazinet[1], Mark Anderson[2], Victor Pantea[3], Gheorghe Placinta[3], Iurie Moscalu[4], Valentin Cebotarescu[3], Lilia Cojuhari[3], Pavlina Jimbei[5], Liviu Iarovoi[3], Valentina Smesnoi[5], Tatiana Musteata[5], Alina Jucov[3,4], Jeff Gersch[2], Vera Holzmayer[2], Mary Kuhns[2], Gavin Cloherty[2], Andrew Vaillant[1]. *[1]Replicor Inc., Montreal, Canada; [2]Abbott Diagnostics, Illinois, United States; [3]Nicolae Testemițanu State University of Medicine and Pharmacy, Department of Infectious Diseases, Chișinău, Moldova; [4]ARENSIA Exploratory Medicine, Republican Clinical Hospital, Chișinău, Moldova; [5]Toma Ciorbă Infectious Clinical Hospital, Chișinău, Moldova*
Email: availlant@replicor.com.

Background and aims: After completion of NAP-based combination therapy with pegIFN and follow-up in the REP 301-LTF study (3.5 years) and REP 401 study (48 weeks), combined HBV outcomes were functional cure (HBsAg <0.05 IU/mL, HBV DNA target not detected, normal ALT [FC]) in 18/52 (35%), virologic control (HBV DNA ≤2000 IU/mL, normal ALT [VC]) in 19/52 (36%) and rebound (R) in 15/52 (29%) of participants. The goal of this study was to analyze the relationship between HBV outcome and experimental virologic markers of HBV infection.
Methods: Frozen serum samples (n = 1153) from all 52 participants in the REP 301/REP 301-LTF and REP 401 studies were analyzed by the following:

1. Abbott ARCHITECT HBsAg NEXT (analytical sensitivity 0.005 IU/mL).
2. Abbott research use only (RUO) assays for HBsAg isoforms (large, medium, small).
3. Abbott RUO assay for HBsAg/anti-HBs immune complexes (HBsAg IC).
4. Abbott RUO assay for pregenomic HBV RNA (pgRNA).
5. Fujirebio HBcrAg (LLOQ 3log$_{10}$ U/mL).

Results: All participants experiencing HBsAg loss (<0.05 IU/mL) during therapy (28/52) rapidly became negative with HBsAg Next. HBsAg <0.005 IU/mL was confirmed at the end of follow-up in 18/18 functional cure and 1/1 virologic control participants with previous HBsAg <0.05 IU/mL.
A more rapid reduction of S-HBsAg relative to the reduction of other HBsAg isoforms occurred in 39/40 participants with HBsAg decline >2 log$_{10}$ from baseline, consistent with targeting SVPs. At the end of follow-up, HBsAg isoforms were detectable in 0/18 (FC), 17/19 (VC) and 15/15 (R) participants. HBsAg IC (relative luminescence units or RLU) were in the positive range in 30/52 participants at baseline and at the end of follow-up in 0/18 (FC), 5/19 (VC) and 10/15 (R) participants.
At baseline, HBV RNA and HBcrAg were present in 42 and 34 participants. HBV RNA loss on therapy occurred in 5/ 14 (FC), 5/16 (VC) and 1/12 (R) participants. HBcrAg < LLOQ on therapy occurred in 5/9 (FC), 7/15 (VC) and 3/10 (R) participants. At the end of follow-up, both HBV RNA and HBcrAg were > LLOQ in 1/18 (FC), 15/19 (VC) and 13/15 (R) participants.
Conclusion: Functional cure of HBV infection following NAP-based combination therapy is profound, with HBsAg <0.005 IU/mL and both HBV RNA and HBcrAg < LLOQ. NEXT negativity and the absence of HBsAg IC RLUs in the positive range at the end of follow-up in FC participants suggests efficient reduction in integrated HBV DNA.

NAFLD: Clinical aspects except therapy

Adipose tissue insulin resistance and inflammation, but not reduced hepatic fat oxidation, are associated to active NASH and severe fibrosis

Amalia Gastaldelli[1], Melania Gaggini[1], Michael Allison[2,3], Ramy Younes[4], Chiara Rosso[4], Jörn M. Schattenberg[5], Vlad Ratziu[6,7], Elisabetta Bugianesi[4], Quentin Anstee[8]. *[1]Institute of Clinical Physiology, Cardiometabolic Risk Unit, Pisa, Italy; [2]Cambridge NIHR Biomedical Research Centre, Liver Unit, Department of Medicine, Cambridge, United Kingdom; [3]University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [4]University of Torino, Division of Gastroenterology, Department of Medical Sciences, Torino, Italy; [5]University Medical Center Mainz, Metabolic Liver Research Program, I. Email: Amalia@ifc.cnr.it

Background and Aims: The mechanisms that are involved in the progression of steatosis (NAFL) to NASH and to advanced liver disease are not completely elucidated. Reduced liver mitochondrial fat oxidation and VLDL secretion as consequences of increased fat overflow to the liver are implicated. Thus, we hypothesized that subjects with more severe NAFLD/NASH are those with increased adipose tissue (AT) insulin resistance (Adipo-IR, reflecting the impaired suppression of lipolysis), reduced beta hydroxybutyrate (BOH, reflecting hepatic mitochondrial fat oxidation) and reduced apolipoprotein B (ApoB), a rate limiting factor for VLDL secretion and thus implicated in the secretion of hepatic triglyceride (TG).
Method: In 318 histologically characterized NAFLD subjects (188 of which had NASH) in the EPoS European NAFLD Registry we measured circulating markers of AT dysfunction i.e., free fatty acid (FFA) and Adipo-IR = FFAxIns, AT inflammation (i.e. leptin, adiponectin, TNF-α and MCP-1), hepatic lipid oxidation (BOH) and secretion (TG and ApoB). Data were analysed by logistic multivariable analysis (LMA) adjusted for age, gender and BMI and odd ratios (OR) were calculated.
Results: Subjects with NASH had higher BMI (32.9 ± 0.4 vs 31.1 ± 0.6 Kg/m^2), Adipo-IR = FFAxIns (23.2 ± 1.5 vs 16.3 ± 1.6), TNF-α (4.9 ± 0.2 vs 3.3 ± 0.2 pg/ml), MCP-1 (112 ± 3 vs 92 ± 3 pg/ml), leptin (13.8 ± 1.0 vs 10.4 ± 1.0 ng/ml) and reduced adiponectin (11.0 ± 0.6 vs 13.5 ± 0.8 ug/ml), all p < 0.001 while TG (213 ± 37 mg/dl), ApoB (77 ± 2 mg/dl), BOH (99 ± 9 umol/l) and FFA (0.76 ± 0.02 mmol/l) were similar in the two groups.
Dysfunctional AT (showed by increased Adipo-IR) was independently associated with increased steatosis (OR = 8.3), presence of active NASH (OR = 3.1) and fibrosis F3-F4 (OR = 2.5), all p < 0.001.

Surprisingly, hepatic mitochondrial fat oxidation, reflected by BOH, was not reduced, but rather increased in subjects with F3-4 and associated with adipo-IR, ie with the overflow of fat from the adipose tissue to the liver ($p < 0.0001$). Adipo-IR was strongly positively correlated also with TG, leptin, TNF-α and MCP-1 concentration ($p < 0.0001$).
Conclusion: Severity of NAFLD is strongly associated with markers of AT dysfunction and inflammation while mitochondrial beta oxidation does not appear to be dysfunctional, indicating once again the importance of AT in the progression of NAFL to NASH.

Email: salva.augustin@gmail.com

Background and Aims: Most of the studies evaluating natural history of cirrhosis have been performed in patients with alcoholic liver disease or viral hepatitis. There is scarce information about natural history of patients with cirrhosis due to nonalcoholic steatohepatitis (NASH). The aim of the present study was to evaluate the natural history and prognostic factors in cirrhosis due to NASH.
Method: Retrospective study of patients with cirrhosis due to NASH in 9 hospitals from Catalonia. All patients diagnosed of NASH-cirrhosis between January 2010 and January 2019. The diagnosis of NASH cirrhosis was made according to clinical, analytical, imaging, elastographic and/or histologic criteria. Development of complications of cirrhosis, cardiovascular events, cancer or death were evaluated during follow-up.
Results: 446 patients with NASH-cirrhosis were identified. Among those, 382 were compensated at diagnosis and constitute the study population. Mean age at diagnosis was 65 ± 10 years, 51% were women and BMI was 32 ± 6 Kg/m^2. At diagnosis, 93% of patients had some metabolic risk factor, 65% had imaging signs of portal hypertension and 49% had esophageal varices. Mean liver stiffness value was 26 ± 16 kPa. The mean follow-up time was 3.6 ± 2.4 years. Ninety-two patients (24%) developed at least one complication of cirrhosis, being the most frequent ascites (18%), encephalopathy (9%), acute kidney injury (9%), gastrointestinal hemorrhage (8%) and spontaneous bacterial peritonitis (2%). Nine percent of patients developed hepatocellular carcinoma. During follow-up 37 patients died (10%). The most frequent cause of death was complications of cirrhosis (33%), followed by extrahepatic cancers (11%) and cardiovascular diseases (8%). Patients who died were older, had higher hepatic venous pressure gradient, higher liver stiffness, worse liver function and, interestingly, lower BMI compared to those who survived. The only parameters independently associated with mortality during follow-up were increased liver stiffness [OR 1.04 (1.02–1.07); $p = 0.002$] and lower BMI [OR 0.88 (0.78–0.99); $p = 0.03$].
Conclusion: Patients with NASH-cirrhosis in our cohort were diagnosed at advanced ages, had a similar distribution among genders and had a high prevalence of metabolic risk factors. Most common decompensation was ascites and the first cause of death was liver-related. High liver stiffness and low BMI were directly correlated with mortality.

THU003
Non-alcoholic fatty liver disease fibrosis score predicts cardiovascular mortality in post percutaneous coronary intervention patients: 5-year results from an observational registry
Dongyoung Lee[1,2]. *[1]Wonkwang University, San-Bon Hospital, Department of Internal Medicine, Gunpo, Korea, Rep. of South; [2]Sejong General Hospital, Department of Internal Medicine, Bucheon, Korea, Rep. of South*
Email: bestrong@naver.com

Background and Aims: The nonalcoholic fatty liver disease fibrosis score (NFS) is comprised of metabolic risk indicators that may accurately predict residual cardiovascular risk in patients with coronary artery disease (CAD) and metabolic dysfunction.

Table 1 Univariable and multivariable analysis for the association with LV dysfunction

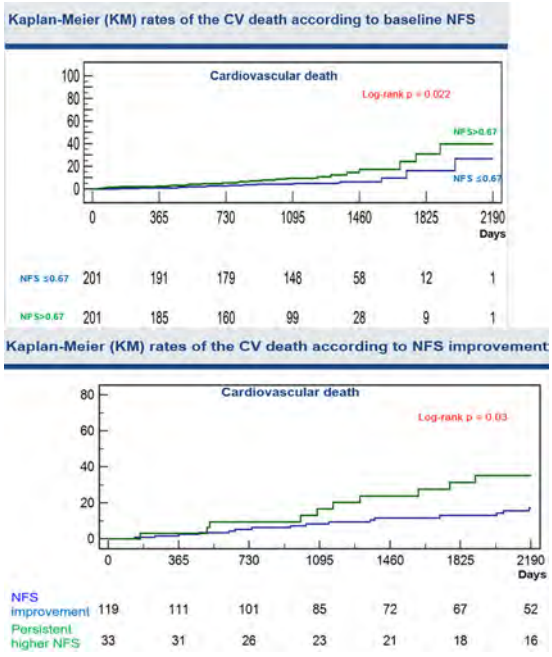
Variables	Unadjusted OR (95% CI)	p	Adjusted OR (95% CI)	p
Age	1.45 (1.03 to 1.94)	0.032	1.14 (1.04 to 2.04)	0.046
gender	0.71 (0.47 to 1.07)	0.104	1.18 (0.68 to 2.04)	0.558
diabetes	1.22 (1.96 to 1.51)	0.091	1.50 (0.90 to 2.50)	0.124
Hypertension	1.18 (0.68 to 2.04)	0.558		
Body Mass Index	1.50 (0.90 to 2.50)	0.124		
baseline high NFS>0.67	2.63 (1.64 to 4.21)	<0.001	1.86 (1.36 to 2.55)	< 0.001

Table 2 Multivariable Cox regression models for cardiovascular death

Models 1	Adjusted HR (95% CI)	p
Age	1.45 (1.03 to 1.94)	0.032
gender	0.71 (0.47 to 1.07)	0.104
diabetes	1.49 (1.09 to 2.04)	0.015
baseline LVEF<40%	2.20 (1.53 to 3.15)	<0.001
baseline high NFS>0.67	1.42 (1.03 to 1.95)	0.023
Model 2		
Age	1.33 (0.94 to 1.87)	0.108
gender	1.26 (0.90 to 1.76)	0.175
diabetes	1.80 (1.20 to 2.95)	0.02
LVEF imrpovement >20% after PCI	0.63 (0.42 to 0.94)	0.026
persistent high NFS>0.67 after PCI	1.52 (1.08 to 2.64)	0.033

Method: This is a nested case control study of the post PCI (percutaneous coronary intervention) registry from single tertiary hospital. Among 5589 patients who underwent PCI from 2010 through 2014, previously diagnosed 1510 NAFLD patients and 296 consecutive NAFLD patients who had undergone both PCI and ultrasonography of abdomen within 1 year between the tests were enrolled. (median age, 64 y (IQR 55–73)). We applied the NFS to the patients at baseline, using validated NFS cut-offs and 201 patients with higher NFS, defined as NFS > 0.67 at PCI, were 1:1 matched with controls, based on propensity scores for higher NFS > 0.67.
Results: Higher NFS (NFS > 0.67) was more prevalent in patients with left ventricle (LV) dysfuction (LV ejection fraction at PCI < 40%) than in those without (81.0% vs 33.6%, $p < 0.001$). Baseline higher NFS was

significantly associated with left ventricle dysfunction (adjusted OR 1.86, 95% CI 1.36 to 2.55, p < 0.001), and baseline higher NFS and persistent higher NFS at 1 year after PCI were independent predictor of a 5-years cardiovascular mortality, after adjustment for ejection fraction of left ventricle (adjusted HR 1.42, 95% CI 1.03 to 1.95, p = 0.023; adjusted HR 1.52, 95% CI 1.08 to 2.64, p = 0.033).



Conclusion: In this cohort study with a longitudinal assessment of the association between NAFLD status by NFS and the risk of cardiovascular mortality, we found post-PCI patients with persistent higher NFS were at higher risk of cardiovascular death compared with those without. An effort to reduce NFS could improve the long-term survival of post PCI patients, and NFS accurately identifies a unique group of post-PCI patients with significantly increased cardiovascular risk.

THU004

The association between liver fibrosis and cognitive impairment in type 2 diabetes: a cross-sectional sub-study of the south London diabetes cohort

Lisa Kuriakose[1], Calum Moulton[1], Anna Rokakis[1], Mussarat Rahim[2], Khalida Ismail[1], Michael Heneghan[2]. *[1]King's College London, Department of Psychological Medicine, United Kingdom; [2]King's College Hospital NHS Foundation Trust, London, United Kingdom*
Email: calum.moulton@kcl.ac.uk

Background and Aims: Type 2 diabetes (T2D) and fatty liver disease are respective risk factors for cognitive impairment, yet their comorbidity in relation to cognitive impairment is poorly studied. For the first time, we tested whether comorbid liver fibrosis is associated with cognitive impairment in people with T2D.
Method: The South London Diabetes (SOUL-D) cohort is a population-based, multi-ethnic cohort of 1735 people recruited at diagnosis of T2D from South London primary care centres between 2008–2012. Nine years after diagnosis of T2D, we recruited a subset of 101 people to undergo transient elastrography (Fibroscan) of the liver; significant (F2) fibrosis was estimated using a standard cut-off ≥ 7kPa. We assessed cognitive function using the Rey-Osterreith Complex Figure (ROCF) test, a neuropsychological assessment in which subjects reproduce a complicated line drawing under three conditions: 1) by copying; 2) by immediate recall without reference to the figure; and 3) by recall after a 30-minute delay. This assesses a range of cognitive domains including visuospatial ability, attention, concentration, executive function and visual memory. We used linear regression models to test the association between liver fibrosis and cognitive performance on each condition. Results were adjusted for demographic-, metabolic- and psychological confounders.
Results: Of 149 people invited, 101 (67.8%) consented. The mean age was 63.6 (10.0) years, mean HbA1c 60.0 (19.2) mmol/mol, mean BMI 31.0 (5.8) kg/m^2, mean T2D duration 9.0 (0.5) years, and 52 (51.5%) were female and 52 (51.5%) of non-white ethnicity. Twenty-seven patients (26.7%) had significant fibrosis. After adjustment for age, sex, ethnicity, current HbA1c, current body mass index and current depressive symptoms using the Patient Health Questionnaire-9, liver fibrosis was associated with impaired performance on the ROCF copy condition (β = −5.47 [95% CI −8.34 to −2.60], p < 0.001), ROCF immediate recall condition (β = −6.30 [95% CI −10.30 to −2.30], p = 0.003) and ROCF delayed recall condition (β = −4.51 [95% CI −8.27 to −0.74], p = 0.02).
Conclusion: In this primary care population with T2D, there is preliminary evidence of impaired cognitive performance across multiple domains in those with comorbid liver fibrosis. Longitudinal replication of these findings on a larger scale is needed, including the assessment of potentially modifiable targets such as insulin resistance.

THU005

A new vision of non-alcoholic fatty liver disease: a "cardiac" disease per se and a "vascular" disease only with hypertension

Andrea Dalbeni[1], Filippo Cattazzo[1], Anna Mantovani[1,2], Michele Bevilacqua[1], Davide Dell'Atti[1], Mirko Zoncapè[1], Veronica Paon[1], Donatella Ieluzzi[1], Laura Iogna Prat[1,3], Davide Roccarina[3], David Sacerdoti[4], Cristiano Fava[1], Emmanuel Tsochatzis[2]. *[1]University and Azienda Ospedaliera Universitaria Integrata of Verona, Department of Medicine, Verona, Italy; [2]Royal Free Hospital and UCL, UCL Institute for Liver and Digestive Health, London, United Kingdom; [3]Royal Free Hospital and UCL, UCL Institute for Liver and Digestive Health, London, Italy; [4]Royal Free Hospital and UCL, UCL Institute for Liver and Digestive Health, Verona, Italy*
Email: cattazzo.f@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is associated with an increased cardiovascular (CV) risk. However, it is still not clear whether NAFLD contributes independently to the development and progression of CV disease. This study aimed to assess the differences between NAFLD patients with or without hypertension (HT) and patients with HT but no NAFLD through markers of subclinical and clinical atherosclerosis, cardiac function and morphology and liver fibrosis.
Method: Eighty-seven participants (51,9 ± 9 y; males = 83,7%) were divided according to the presence of NAFLD and essential HT in three groups: only-NAFLD, only-HT and NAFLD+HT. Patients with BMI>35 and type II diabetes were excluded. Blood pressure (BP) measurement, carotid ultrasonography, echocardiography and transient elastography were performed. Carotid intima–media thickness (cIMT), Carotid Distensibility (CD) and Carotid-femoral pulse wave velocity (cf-PWV) were measured as markers of subclinical atherosclerosis and arterial stiffness.
Results: The prevalence of atherosclerotic plaques was significantly higher in NAFLD+HT group compared with only-NAFLD group (40% vs 5,7%; p < 0,001). Belonging to NAFLD+HT group, rather than other clinical variables, was independently associated with atherosclerotic plaques in stepwise multiple logistic regression analysis (beta ± SEM = 2.083 ± 0.958; p = 0,01; exp(B) = 15,88 [95%CI, 1,62–155,00]). No differences in cIMT, CD, cf-PWV, echocardiographic parameters and liver stiffness were found among the three groups; nevertheless, a significant prevalence of concentric cardiac remodeling (RWT>0,42) was detected in all groups (only-HT, NAFLD+HT and only-NAFLD group at 40,9%, 35,7% and 33,3%, respectively; p = not significant).

Conclusion: Overt atherosclerosis, rather than subclinical atherosclerosis and arterial stiffness, was more evident in NAFLD+HT patients. A surprising finding was the high prevalence of concentric cardiac remodelling in all groups, including in the only-NAFLD one, suggesting a possible direct involvement of NAFLD in cardiac structural changes. Therefore, the impact of NAFLD on vascular and cardiac structure could be different and partially dependent on the presence of HT.

THU006

NASH is emerging as a leading cause of hospitalisation for cirrhosis: results from a real-life, prospective, consecutive cohort

Christiane Stern[1], Ana Silva-Souza[1], Pascal Lebray[1], Marika Rudler[1], Dominique Thabut[1], Vlad Ratziu[1]. [1]*Hôpital Pitié-Salpêtrière, Service d'Hépato-gastroentérologie, Paris, France*
Email: christiane.stern@gmail.com

Background and Aims: There are no prospective, real-life driven estimates of the burden of NASH within the most severe end of spectrum of chronic liver disease, i.e. patients (pts) hospitalized for cirrhosis care.
Methods: All consecutive pts hospitalized in the Liver Unit during a 3-month time period starting on February 11th 2019 were included. The reason for hospitalisation was noted as cirrhosis-related or non-cirrhotic. Cirrhosis-related was further dichotomized in NASH alone or mixed NASH-another cause (based on long-term exposure to diabetes or obesity) and non-NASH causes (controls). Disease severity at entry, 6-month survival, readmission rate, diagnostic/therapeutic procedures performed during hospitalisation were captured.
Results: 173 pts were hospitalized, 85 for cirrhosis and 88 for other reasons. Among cirrhotics, 28 (33%) were NASH-related (NASH alone in 11, mixed cause in 17) while 13 (15%) were HCV, 8 (9%) HBV, 19 (22%) alcohol and 17 (20%) other causes. Overall, 58% were admitted for clinical decompensation and 42% for diagnostic/therapeutic procedures; 35% were Child-Pugh B and 24% Child-Pugh C. In NASH-related cirrhotics median MELD was 10 [7–34] vs 14 [6–32] in controls. Decompensation was the primary reason for hospitalisation in 39% NASH-cirrhosis vs 67% in controls, p = 0.016. NASH-related cirrhotics were Child-Pugh B in 33% and C in 11%; they had ascites (21%), jaundice (18%), encephalopathy (14%), gastrointestinal bleeding (11%), sepsis (4%), and/or SBP (4%) within 48 h of admission. Median hospital stay duration was 6 (1–21) days in NASH-cirrhosis and 7 (1–43) days in controls. 6-month readmission rate was 37% and 39%, respectively. During hospitalization, NASH-cirrhotic pts had endoscopy, variceal band ligation, paracentesis and HCC therapeutic procedures in 10, 4, 6, and 6 pts, respectively. 6-month mortality was 14% for NASH-related cirrhosis and 32% for controls (p = 0.133). Data on hospitalization costs will be provided.
Conclusion: In this first prospective real-life attempt to study, in a tertiary care center, the disease burden of NASH among hospitalized pts, NASH-related cirrhosis was the most prevalent cause for cirrhosis hospitalisation. Despite slightly lesser severity at entry, these pts had a high 6-month mortality, and similar duration of hospital stay and readmission rate as non-NASH cirrhotics. NASH-related cirrhosis is becoming a leading cause of decompensated cirrhosis requiring hospitalisation.

THU007

The paradigm of the two faced Janus: NAFLD and cardiovascular disease. An integrated and multidisciplinary new model to approach outpatients affected by diabetes type 2 and NAFLD

Diego Caroli[1], Erik Rosa-Rizzotto[1], Laura Scribano[1], Laura Peraro[1], Salvatore Lobello[1], Maria Grazia Dal Frà[2], Annunziata Lapolla[2], Franca De Lazzari[1]. [1]*St. Anthony Hospital, Gastroenterology, Padua, Italy;* [2]*St. Anthony Hospital, Diabetology, Padua, Italy*
Email: d.caroli@libero.it

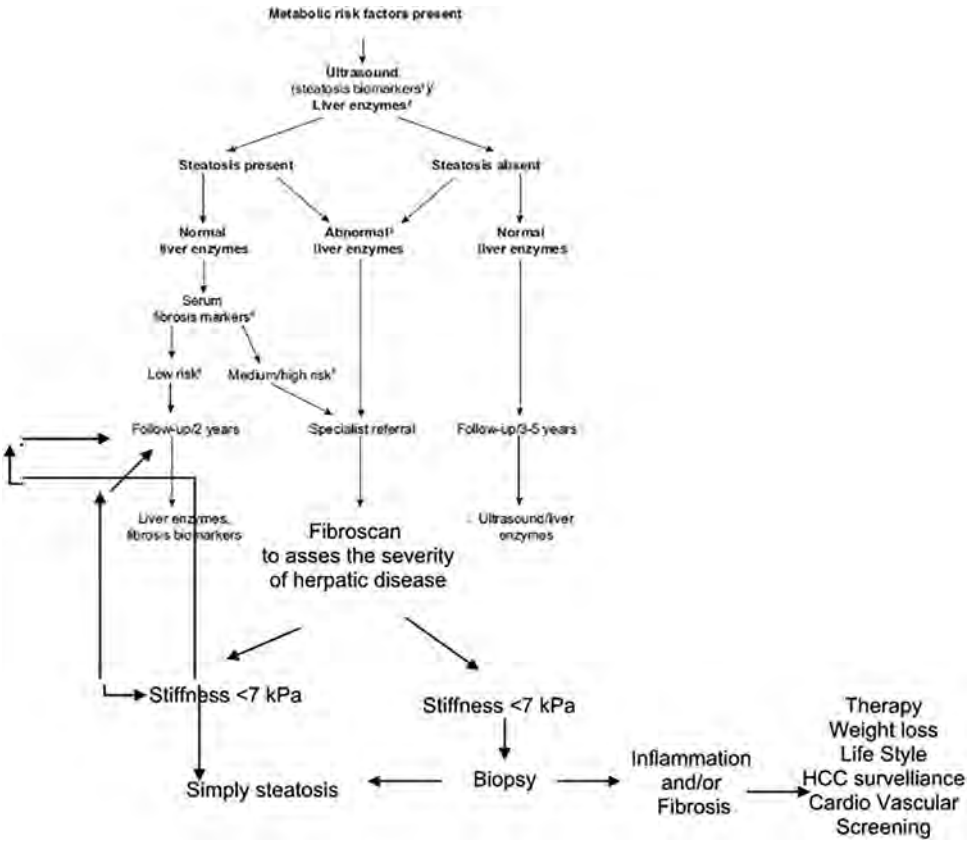


Figure: (abstract: THU007)

Background and Aims: Patients with NAFLD are at a higher risk of developing cardiovascular disease (CVD), infact CVD-related mortality is more common in patients with NAFLD in comparison to liver-related mortality. The aim of our study is to estimate the risk of CVD in adults DM2 patients with or without NAFLD. And also to present a new organizational model.
Method: We analyzed retrospectively a cohort of 6776 patients referraled from Diabetology Center of Padua that underwent to a regular follow up during the last two years. In collaboration to the Diabetologists and Cardiologists we start to evaluate the diabetic patients with suspicious of co-diagnosis of NAFLD trough the sequent algorithm (Fig. 1). In Day Service the patients perform: blood test with the elaboration of prognostic score: Fatty liver index, FIB-4 and Nafld fibrosis score, perform abdomen US and Fibroscan, Diabetologic and Hepatologic and Cardiological visit to asses the severity of disease. Patients with severe fibrosis (>7 kpa) underwent to Cardiovascular screening and recived medical therapies, life style suggestions, indication to lost weight and indication to follow up for surveliance for HCC.
Results: Among the 6776 diabetic patients, the incidence of NAFLD was 27.7% (NAFLD 1878 and NOT NAFLD 4898). NAFLD 1878 (M 1045 and F 833) and Cardiovascular Events in 560 (M 369 and F 191). NAFLD <65 years 803 (M 510 e F 293) and Cardiovascular Events in 213 (M152 and F 61). NOT NAFLD 4898 (M3027 and F 971) and Cardiovascular Events in 1305 (M940 and F465). NOT NAFLD <65 years 1324 (M889 and F435) and Cardiovascular Events in 256 (M191 and F65). CVD is dramatically associated to the diagnosis of diabetes type 2 (DM2) and also NAFLD in contrast to the esclusive diagnosis of DM2 and Not NAFLD ($p < 0.0001$ e Phi -0.09). CVD in patients >65 years is not different in NAFLD an NO NAFLD DM2 patients ($p = ns$). CVD in patients <65 years is significant associated to the diagnosis of NAFLD and DM2 (p0.0001 and Phi –0.08). Hepatocellular carcinoma is an anecdotal diagnosis in these patients in regular follow up and in treatment for diabetes.
Conclusion: Patients with NAFLD should be evaluated and managed accordingly in order to prevent further complications, in particular Cardiovascular Events. Possible management methods include innovative outpatients management with optimization of the time to asses the severity of disease and the subsequent right allocation of each case on specific follow up and indication.

THU009

Liver histopathology and extracellular matrix biomarkers in patients with advanced hepatic fibrosis from chronic hepatitis C who achieved a sustained virologic response

Diane Shevell[1], Eric Lawitz[2], Zachary Goodman[3,4], Morten Karsdal[5], Mette Juul Nielsen[5], Ratna Revankar[1], Shuyan Du[1], Joel Myers[1], Edgar Charles[1]. *[1]Bristol-Myers Squibb, Princeton, United States; [2]University of Texas Health San Antonio, Texas Liver Institute, San Antonio, United States; [3]Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States; [4]Fairfax Hospital, Center for Liver Diseases and Department of Medicine, Falls Church, United States; [5]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark*
Email: diane.shevell@bms.com

Background and Aims: The use of direct-acting antivirals has made hepatitis C virus (HCV) eradication (sustained virologic response [SVR]) possible for most patients, including those with cirrhosis. SVR has been associated with regression of fibrosis; however, fibrosis persists in a substantial proportion of patients. Little is known about liver collagen content and the degree of fibrogenesis several years after SVR. Here, we describe baseline liver pathology, imaging, and circulating biomarkers of fibrosis in patients enrolled in study IM025-006 (NCT03420768) who had advanced hepatic fibrosis secondary to HCV and had achieved SVR at least 1 year prior to screening.
Method: Patients with METAVIR F3-F4 fibrosis were identified based on local pathologist assessment of liver biopsies obtained within 8 weeks of screening. Fibrosis was subsequently reassessed by a central pathologist. Patients with a history of chronic liver disease not due to HCV, decompensation, BMI over 34, and ALT level over 2× the upper limit of normal were excluded. Additionally, patients were originally required to have a platelet count above the lower limit of normal; this was amended to over 100 × 109/L toward the end of enrollment. Exploratory objectives included baseline assessments of histological biomarkers of collagen morphology and immunohistochemistry (collagen proportionate area [CPA] and alpha-smooth muscle actin [SMA]), liver stiffness imaging biomarkers (magnetic resonance elastography [MRE] and transient elastography [TE]), and circulating biomarkers of fibrosis and extracellular matrix remodeling (PRO-C3, C3M, TIMP-1, HA, PIIINP).
Results: Of 61 enrolled patients, 34 (56%) were men, mean (SD) age was 60.4 (7.5) years, and the median (Q1, Q3) time since SVR was 37.9 (23.8, 50.3) months. In these patients, mean (SD) platelet count was 197.2 (45.2) × 109/L. Based on central liver pathologist assessment, METAVIR scores were as follows: F1 (n = 8), F2 (n = 24), F3 (n = 19), and F4 (n = 10). Mean (SD) CPA and alpha-SMA were 3.3 (2.1) % and 4.3 (4.0) %, respectively. Mean (SD) MRE and TE were 3.7 (1.3) kPa and 10.9 (5.8) kPa, respectively. Mean (SD) PRO-C3 was 12.1 (3.7) ng/mL.
Conclusion: Findings suggest that, several years after SVR, patients with advanced hepatic fibrosis from HCV had low levels of hepatic collagen and liver stiffness and low levels of active fibrogenesis.

THU010

PNPLA3 gene polymorphism and overall and cardiovascular mortality among non-alcoholic fatty liver disease in the United States

Karn Wijarnpreecha[1], Melissa Scribani[2], Pascale Raymond[3], Aijaz Ahmed[4], Donghee Kim[5], Denise Harnois[6]. *[1]Mayo Clinic, Gastroenterology, Jacksonville, United States; [2]Bassett Medical Center, Bassett Research Institute, Cooperstown, United States; [3]Bassett Medical Center, Internal Medicine, Cooperstown, United States; [4]Stanford University, Gastroenterology, Stanford, United States; [5]Stanford University, Gastroenterology, Stanford, United States; [6]Mayo Clinic, Transplant, Jacksonville, United States*
Email: dr.karn.wi@gmail.com

Background and Aims: The association between palatin-like phospholipase domain-containing 3 (*PNPLA3) I148M (rs738409)* polymorphism and mortality is not clearly understood. We determine the impact of *PNPLA3* polymorphism on overall and cardiovascular mortality among non-alcoholic fatty liver disease (NAFLD).
Method: The Third National Health and Nutrition Examination Survey (NHANES) from 1991 to 1994 and NHANES III-linked mortality data through 31 December 2015 were utilized. The primary outcome was the association between *PNPLA3* gene polymorphism and overall and cardiovascular mortality.
Results: NAFLD with *PNPLA3 GG* is more common in Hispanic, and had significantly higher liver chemistries and triglyceride than NAFLD with *PNPLA3 CC*. There was no association with overall or cardiovascular mortality among those with the *PNPLA3* G-allele. NAFLD with *PNPLA3* G-allele had lower overall mortality in age/sex-adjusted models (hazard ratio [HR] 0.57; 95% confidence interval [CI] 0.35–0.95). This association was marginally significant (HR 0.61 95% CI 0.37–1.00) adjusted with multiple metabolic risk factors include age, sex, race/ethnicity, smoking status, body mass index, presence of hypertension, presence of diabetes and total cholesterol. The *PNPLA3* G-allele was not associated with cardiovascular mortality.

Conclusion: *PNPLA3* polymorphism with G-allele in NAFLD was associated with lower overall mortality in a population-based US sample. While not statistically significant, the homozygous *PNPLA3* GG genotype showed a trend in decreased overall mortality in NAFLD.

Renal failure is associated with increased mortality, morbidity, and hospital charges in patients admitted with non-alcoholic steatohepatitis

Debashis Reja[1], Savan Kabaria[1], Augustine Tawadros[1], Lauren Pioppo[1], Michael Makar[1], Vinod Rustgi[2]. *[1]Robert Wood Johnson University Hospital, New Brunswick, United States; [2]Center for Liver Diseases and Masses at Robert Wood Johnson, Gastroenterology, New Brunswick, United States*
Email: dr845@rwjms.rutgers.edu

Background and Aims: NASH is a common medical condition associated with significant morbidity and mortality. There exists a paucity of data regarding impact of kidney injury (defined as Acute and Chronic kidney injury) on outcomes of NASH hospitalizations. Our aim was to investigate the outcomes of hospitalized NASH patients with and without kidney failure.

Method: All patients ≥ 18 years old with NASH-related hospitalizations identified from National Inpatient Sample in 2016 were included in this study. NASH Patients with kidney failure were identified as cases and the control group was matched by using propensity scoring method. The scoring was based on a multivariate logistic regression model accounting for age, gender, race, primary insurance payer, hospital type, hospital bed size, hospital region, and hospital teaching status. Using 8-to-1-digit match, we paired each admission in kidney failure group with one admissions in non – kidney failure group.

Continuous variables were reported as means ± SD and categorical variables were reported as number and percentages. Paired Student's t-test was used to compare the difference of mean age between patients with and without NASH. *Wilcoxon rank-sum test were used for variables that are not normally distributed.* Rao-Scott modified chi-square test was used to test the difference of distribution for categorical variables.

Results: The overall sample included 7,135,090 patients. Among 6,855 patients admitted for NASH, 8.7% had comorbid kidney injury. NASH with renal failure patients were older (66 vs 55.1 years, p < 0.0001), had more comorbidities (CCI Score >3 71.9% vs 18.1%, p < 0.0001) (Elixhauser Score >4 80.6% vs 37.3%, p < 0.0001), and were Medicare insured (66.1% vs 31.4%, p < 0.0001). After adjusting for confounders through multivariate regression, patients in the renal failure group had markedly higher mortality (OR 38.72, CI 8.00–91.73), Length of Stay (OR 3.02 p < 0.0001), and total hospital charges (OR $37,045, p < 0.0001).

Table 2: Outcomes of NASH patients with and without Kidney Failure

	NASH with Kidney Failure	NASH without Kidney Failure	Multivariate Beta/OR (95% CI)	p-value
Mortality (n, %)	18 (3.0%)	1 (0.2%)	28.72 (8.99, 91.73)	<0.0001
Mean Length of stay, days (Mean, SD)	6.4 (9.1)	3.1 (3.4)	3.02 (2.54, 3.5)	<0.0001
Mean Total Charge of Hospitalization (Mean, SD)	78022.7 (158580.8)	38024.8 (33476.0)	37045.9 (31756.18, 42335.62)	<0.0001

*Results were adjusted for age, gender,CCI Score, Elixhauser Score, insurance tye, hospital region, hospital location/teaching status, and hospital bed size.

Conclusion: Prevalence of kidney injury in hospitalizations for NASH is associated with markedly increased mortality, morbidity, length of stay, and hospital costs. As a result, clinicians should be hypervigilant in treating kidney injury in this population. Further studies should continue to investigate further approaches for treatment.

THU012

Cardiovascular and cerebrovascular co-morbidities in non-alcoholic steatohepatitis

Debashis Reja[1], Savan Kabaria[1], Augustine Tawadros[1], Lauren Pioppo[1], Michael Makar[1], Vinod Rustgi[2]. *[1]Robert Wood Johnson University Hospital, New Brunswick, United States; [2]Center for Liver Diseases and Masses at Robert Wood Johnson*
Email: dr845@rwjms.rutgers.edu

Background and Aims: NASH is a chronic liver disease associated with insulin resistance and metabolic syndrome that has progressed

from simple steatosis. This study uses the Nationwide Inpatient Sample (NIS) 2016 with ICD-10 coding to demonstrate its link with cardiac and cerebrovascular comorbidities, as well as their impact on mortality, length of stay, and costs.

Method: All patients ≥ 18 years old with NASH-related in NIS 2016 were included in this study. Propensity scoring method was used to select the control group (patients without NASH). The comorbidities of NASH were identified within the NASH and non-NASH patients.

The univariate and multivariate logistic regression were used to estimate the odds ratio of having NASH for patients with the comorbidity after adjusting for patient demographics. In addition, the odds ratio of in-hospital mortality, beta estimate of average change in length of stay and hospital charges were estimated by using multivariate logistic regression model and multivariate linear regression, respectively. Statistical significance was defined by the two-sided test with a p-value <0.05.

Results: The cohort consisted of 7,135,090 patients. 6,855 patients with NASH were compared to 6,855 patients without NASH after propensity match. NASH was significantly associated with Cardiac and Cerebrovascular comorbidities after adjusting for confounding factors. Significant cardiac factors were ischemic heart disease, CHF, Afib, PVD, HTN, HLD, DM, TIA, Ischemic Stroke (Table 1). In terms of mortality, CHF, HLD, DM were significant predictors. CHF, Afib, HTN, HLD, DM were significant predictors of LOS. For total charges, Ischemic Heart disease, CHF, Afib, DM significantly increased hospitalization charges.

Table 1: Association of comorbidity and NASH status

	Adjusted*	Mortality	Length of Stay	Total Charge of Hospitalization
Comorbidity	OR (95% CI)	OR (95% CI)	Beta (95% CI)	Beta
Chronic Ischemic Heart Disease	1.99 (1.8, 2.19)	*	*	4452.57
CHF	7.19 (6.15, 8.4)	3.37 (1.11, 10.28)	2.36 (1.62, 3.11)	10971.68
Afib	3.15 (2.75, 3.61)	*	0.76 (0.17, 1.35)	7525.42
PVD	2.64 (2.1, 3.33)	*	*	*
HTN	1.12 (1.03, 1.2)	*	−0.49 (−0.76, −0.22)	−3086.64 (−6100.77, −72.51)
HLD	0.84 (0.78, 0.9)	0.21 (0.07, 0.62)	−0.55 (−0.82, −0.28)	*
DM	2.31 (2.07, 2.58)	2.76 (1.01, 7.52)	1.5 (1.03, 1.97)	21551.57 (16355.54, 26747.59)
TIA	2.63 (1.48, 4.68)	*	*	*
Ischemic Stroke	8.06 (4.03, 16.11)	*	*	*

*not significant.

Conclusion: In this study we demonstrate significant cardiac and neurologic risk factors of NASH that lead to advanced disease. We also demonstrate that they are linked to increased mortality, length of stay, and costs. Targeting these risk factors early would decrease morbidity and mortality in NASH and decrease hospital costs.

THU013

Extra-hepatic gastrointestinal malignancies in NAFLD: nationwide inpatient sample 2016

Debashis Reja[1], Savan Kabaria[1], Augustine Tawadros[1], Lauren Pioppo[1], Michael Makar[1], Vinod Rustgi[2]. *[1]Robert Wood Johnson University Hospital, New Brunswick, United States; [2]Center for Liver Diseases and Masses at Robert Wood Johnson*
Email: dr845@rwjms.rutgers.edu

Background and Aims: Malignancy is a common cause of mortality NAFLD. In this study we seek to examine extrahepatic gastrointestinal malignancies in NAFLD. We used the Nationwide Inpatient Sample (NIS 2016).

Method: All patients ≥ 18 years old with and without NAFLD in NIS 2016 were included. Propensity scoring method was used to select the control group (patients without NAFLD). Malignancies were identified within the NAFLD and non-NAFLD patients. NAFLD was defined as Fatty Liver (ICD 10 K76.0) and NASH (ICD 10 K 75.81). Esophageal malignancy (ICD10 C15.9), gastric malignancy (ICD 10C16.9), large intestinal malignancy (ICD 10 C18.9) were used.

The univariate and multivariate logistic regression were used to estimate the odds ratio of having NAFLD after adjusting for patient demographics. In addition, the odds ratio of in-hospital mortality, beta estimate of average change in length of stay and hospital charges were estimated by using multivariate logistic regression model and multivariate linear regression, respectively. Statistical significance was defined by the two-sided test with a p-value <0.05.

Results: The study sample consisted of 7,135,090 patients. 6,855 NAFLD patients were matched with 6,855 non-NAFLD patients. Esophageal malignancy was found in .2%, gastric malignancy in .3%, large intestinal malignancy in .9%. Esophageal and gastric malignancies were significantly correlated with NAFLD on multivariate logistic regression analysis. Esophageal malignancy, OR 6.98 (95% CI 1.59, 30.7), Gastric Malignancy, OR 5.55 (95% CI 1.91–16.13). Malignancy of large intestine was not significantly correlated on univariate or multivariate analysis, OR .83 (95% CI .57–1.21). No significant correlation of length of stay, mortality, or hospital costs was seen with malignancy.

	Patients with NAFLD (n = 6855)	Patients without NAFLD (n = 6855)	Crude OR		Adjusted OR	
Malignancy			OR (95% CI)	p-value	OR (95% CI)	p-value
Esophageal Cancer	14 (0.2%)	2 (0.0%)	7 (1.59, 30.8)	0.0100	6.98 (1.59, 30.7)	0.0102
Gastric Cancer	22 (0.3%)	4 (0.1%)	5.51 (1.9, 16)	0.0017	5.55 (1.91, 16.13)	0.0016
Large Intestinal cancer	50 (0.7%)	60 (0.9%)	0.83 (0.57, 1.21)	0.3404	0.83 (0.57, 1.21)	0.3292

Conclusion: We demonstrate a significant link between esophageal and gastric malignancy in NAFLD. Previous studies have shown an increased risk of HCC, colorectal, and breast cancer. Obesity is thought to be the primary driver, but insulin resistance and metabolic syndrome may also contribute. Further studies are needed to stratify specific cancer subtypes.

THU016

Prevalence of non-alcoholic fatty liver in the Netherlands: the Netherlands Epidemiology of Obesity study

Gabrielle Alblas[1], Hildo Lamb[2], Frits Rosendaal[3], Bart Van Hoek[4], Minneke Coenraad[4], Renée Mutsert[3]. *[1]Leiden University Medical Center (LUMC), Internal Medicine, Leiden, Netherlands; [2]Leiden University Medical Center (LUMC), Radiology, Leiden, Netherlands; [3]Leiden University Medical Center (LUMC), Epidemiology, Leiden, Netherlands; [4]Leiden University Medical Center (LUMC), Gastroenterology and Hepatology, Leiden, Netherlands*
Email: g.alblas@lumc.nl

Background and Aims: Non-alcoholic liver disease (NAFLD), defined as a hepatic triglyceride content of more than 5.56% not due to excessive alcohol consumption. NAFLD covers a wide clinical spectrum, ranging from steatosis to non-alcoholic steatohepatitis, and increases the risk of end-stage liver disease and mortality. It is strongly associated with obesity, and with increased risks of type 2 diabetes, and cardiovascular diseases. Recent studies suggest an increased prevalence of NAFLD in Europe, but the prevalence of NAFLD in The Netherlands is currently unknown. We aim to determine the overall prevalence of NAFLD in a large Dutch population-based study, and in different subgroups with well-known risk factors of NAFLD.
Method: The Netherlands Epidemiology of Obesity (NEO) study is a population-based prospective cohort study in 6671 participants. Participants completed several questionnaires and underwent an extensive physical examination including blood sampling. Hepatic triglycerides content was assessed using proton magnetic resonance spectroscopy in a random subgroup of 2083 participants.
Results: Mean age of the population was 55.5 years, mean BMI 25.8 kg/m^2 and 47% were men. The prevalence of steatosis was 27%. The prevalence of steatosis was increased in elderly (55–65 years) participants (33%), men (36%), participants with a BMI >30 kg/m^2 (63%), diabetes (72%) and PNPLA3 CG and GG allele polymorphism (33%). Steatosis prevalence was even higher in subgroups with combined risk factors, e.g. in participants who had combined presence of high triglycerides and impaired glucose metabolism the prevalence of steatosis was 93%. Although less frequent, steatosis was also present in 13% of participants without overweight.
Conclusion: This study shows that hepatic steatosis, as assessed by proton magnetic resonance spectroscopy, is present in over a quarter of the general population in The Netherlands. The prevalence is higher is subgroups with well-known risk factors for NAFLD and especially if more than one risk factor is present.

THU017

Association between non-alcoholic fatty liver disease and nut consumption

Georg Semmler[1], Sebastian Bachmayer[1], Sarah Wernly[1], Eva-Maria Weilnböck[1], Bernhard Wernly[2], David Niederseer[3], Elmar Aigner[4], Christian Datz[1]. *[1]General Hospital Oberndorf, Teaching Hospital of the Paracelsus Medical University Salzburg, Department of Internal Medicine, Austria; [2]Paracelsus Medical University of Salzburg, Clinic of Internal Medicine II, Department of Cardiology, Austria; [3]University Hospital Zurich, Department of Cardiology, Switzerland; [4]Paracelsus Medical University Salzburg, Department of Internal Medicine I, Austria*
Email: georg.semmler@meduniwien.ac.at

Background and Aims: Nut consumption has been associated with reduced inflammation, insulin resistance, and oxidative stress. Therefore, we aimed to investigate the influence of nut consumption on prevalence and severity of NAFLD and the metabolic syndrome.
Method: 1362 asymptomatic subjects were included as part of a colorectal carcinoma colonoscopy screening program (SAKKOPI). Patients were characterized using biochemical and metabolic parameters and food frequency questionnaire. The diagnosis of NAFLD was established by transient elastography-based controlled attenuation parameter (CAP) >248 dB/m after exclusion of other liver diseases, excess alcohol consumption and viral hepatitis. Steatosis was graded as >248/>268/>280 dB/m for any, moderate and severe steatosis. Significant fibrosis was defined by a liver stiffness ≥ 8 kPa. Consumption of nuts was graded as: no consumption or <1 time/week; 1–3 times/week; 1 time/day and ≥ 2 times/day.
Results: Mean age was 58.7 ± 8.7years with a mean BMI of 26.7 ± 4.7 and a 28.3% prevalence (n = 394) of diabetes. Mean CAP value was 257 ± 75 dB/m with 707 patients (56.4%) having NAFLD. Median liver stiffness was 4.5 (interquartile range [IQR]:3.7–5.7)kPa while 94 patients (7.5%) had significant fibrosis. When comparing patients with and without daily nut intake, significant differences were observed for BMI (27.0 ± 4.7 vs 25.2 ± 4.2, p < 0.001), prevalence of diabetes (335 [29.7%] vs 45 [19.2%], p = 0.001), Homeostatic Model Assessment of Insulin Resistance (HOMA-IR; 1.63 [0.90–2.36] vs 1.33 [0.82–1.84], p < 0.001), triglycerides (101 [68–134] vs 89 [63–115]mg/dl, p = 0.001) and ALT (21 [14–28] vs 19 [13–24]U/l, p = 0.001) as well as liver stiffness (4.6 [3.6–5.6] vs 4.2 [3.3–5.1]kPa, p < 0.001) and CAP value (261 ± 75 vs 239 ± 73 dB/m p < 0.001). Moreover, distribution of steatosis stages was significantly different with 426 (41.1%) vs 59 (27.2%) showing severe steatosis (p < 0.001). A consecutive decrease among subgroups of nut consumption was observed for liver stiffness (4.6 [3.8–5.8] vs 4.6 [3.7–5.8] vs 4.2 [3.4–5.2] vs 4.1 [3.3–5.2], p < 0.001), CAP (264 ± 76 vs 257 ± 73 vs 239 ± 72 vs 240 ± 80 dB/m, p = 0.001), BMI (27.4 ± 4.9 vs 26.5 ± 4.5 vs 25.1 ± 4.1 vs 25.4 ± 4.5, p < 0.001) and HOMA-IR (1.72 [1.11–2.62] vs 1.53 [1.02–2.42] vs 1.37 [0.92–2.08] vs 1.31 [0.78–1.59], p < 0.001).
On multivariate binary logistic regression analysis investigating factors independently associated with the presence of hepatic steatosis, nut intake (odds ratio [OR]: 0.854 [95% confidence interval (CI): 0.733–0.995], p = 0.044) was significantly associated with hepatic steatosis correcting for BMI, age, HOMA-IR, liver stiffness and low/moderate alcohol intake.
Conclusion: Nut intake is inversely associated with hepatic steatosis and shows a trend towards less liver fibrosis. Additionally, nut consumption shows beneficial effects on other factors of the metabolic syndrome.

THU018

Myosteatosis and sarcopenia are prevalent in patients with NAFLD even in the absence of advanced fibrosis

Giada Pallini[1], Laura Iogna Prat[1], Davide Roccarina[1], Francesco Arico'[1], Anna Mantovani[1], Edoardo Vespa[1], Emmanuel Tsochatzis[1]. *[1]UCL Institute for Liver and Digestive Health, Royal Free Hospital and UCL, London, United Kingdom*
Email: giada.pallini@gmail.com

Background and Aims: Muscle fat infiltration, termed myosteatosis, is reported in patients with NAFLD, however its prevalence in non-cirrhotic patients is unknown. The same is true for sarcopenia and sarcopenic obesity. We analysed the presence of sarcopenia and fat infiltration in the muscular mass in a cohort of NAFLD patients with different disease severity.
Method: Patients with NAFLD and different stages of liver fibrosis who underwent a CT scan for any reason within 365 days from a liver biopsy or transient elastography with Fibroscan were included and divided into groups of mild-moderate (F0-F2) and advanced fibrosis (F3-F4). We also included patients with decompensated NASH cirrhosis who had a CT scan performed during the assessment for liver transplantation. Cross-sectional area index (CSMI), erector spinae fat-free muscle area (FFMA) and attenuation indexes measured at L3 level section of the CT scan were used to measure the muscle mass and presence of fat infiltration in muscles. Sarcopenia$^{L3\text{-}CSMI}$ was defined as L3-CSMI below 39 cm^2/m^2 in women and 50 cm^2/m^2 in men and myosteatosis was defined as <41HU in patients with a BMI up to 24.9, and <33 in those with a BMI ≥ 25 kg/m^2.
Results: We included 149 patients, 38.3% females, mean age 57.8 ± 10.5 years, BMI 31.7 ± 6.1 kg/m^2. Population was divided in F0-F2 n = 63 (42%), F3-F4 n = 43 (29%) and F4 decompensated (F4d) n = 43 (29%). Patients with sarcopenia were equally distributed in all fibrosis stages: F0-F2 21%, F3-F4 21% and F4d 28% (p = 0.64) despite a mean BMI >25 kg/m^2.
The fatty tissue infiltration of the erector spinae was 15% of the total muscular area and the proportion was equal throughout the groups. Eighty-nine patients (60%) had myosteatosis: 43 (48%) in F0-F2, 24 (27%) in F3-F4 and 22 (25%) in F4d (p = 0.175). Comparing patients with and without myosteatosis, CSMI was significantly higher in the myosteatosis group in F0-F2 and F3-F4 (by 10 cm2/m2 in both groups,

p < 0.001 and p = 0.003, respectively), but not in F4d CSMI. No predictors of sarcopenia were found in multivariable analysis.
Conclusion: A significant proportion of patients with NAFLD have sarcopenia, even in the absence of advanced fibrosis. Fat infiltration defined as fatty area of ES and myosteatosis, might confound the definition of sarcopenia leading to underestimation of its true prevalence. Therefore, further studies with larger populations are needed to define validated sarcopenia cut-off values for these patients.

THU019

A cholestatic pattern predicts liver outcomes in patients with non-alcoholic fatty liver disease

Grazia Pennisi[1], Rosaria Maria Pipitone[1], Stefania Grimaudo[1], Federica Spatola[1], Vincenzo Di Martino[1], Vincenza Calvaruso[1], Calogero Camma[1], Vito Di Marco[1], Antonio Craxi[1], Salvatore Petta[1]. [1]*Sezione di Gastroenterologia e Epatologia, Promise, University of Palermo, Italy*
Email: salvatore.petta@unipa.it

Background and Aims: The expression of NAFLD (non-alcoholic fatty liver disease) in liver biochemistry has usually a "cytolitic" pattern (raised ALT, normal ALP), but a "cholestatic" pattern (low ALT, raised ALP), can also be observed. We aimed to assess the prevalence of the "cholestatic" pattern in subjects with NAFLD at different stage of fibrosis and its impact on development of liver events and death.
Method: A cohort of consecutive NAFLD patients diagnosed by biopsy or, in the case of patients with compensated cirrhosis, by transient elastography and/or evidence of portal hypertension. Patients were divided into 3 groups based on the pattern of elevated liver enzymes as follows: predominantly cholestatic pattern (C pattern), predominantly hepatocellular pattern (H pattern), and mixed (M) pattern by using the formula (ALT/ALTULN)/(ALP/ALPULN). C pattern group included patients with a ratio of less than 2, whereas the H pattern group included patients with a ratio of more than 5. The M pattern group consisted of patients with a ratio between 2 and 5. Liver outcomes (decompensation –ascites, encephalopathy, variceal bleeding, jaundice- and hepatocellular carcinoma, HCC), as well as total and liver deaths were recorded during follow-up.
Results: 529 patients (62.4% males, mean age 49.8 years, mean BMI 30.3 Kg/m2, 46% with diabetes, 34.8% with F3-F4 fibrosis, 21.4% with cirrhosis) with a mean follow-up time of 68.3 months were enrolled. H, M and C patterns were found in 159 (30.1%), 258 (48.8%) and 112 (21.1%) patients, respectively. The prevalence of the C pattern was significantly higher in patients with cirrhosis when compared to all the other (17.7% in F0-F1, 8.4% in F2, 12.7% in F3 and 46% in cirrhosis, respectively, p < 0.001). 27 (5.1%) hepatic decompensation, 16 (3%) HCC, 17 (3.2%) total deaths and 14 (2.6%) and liver deaths were recorded, all occurring in patients with F3-F4 fibrosis. In the entire cohort, at multivariate Cox regression analysis adjusted for age, IFG/diabetes (not for overall mortality), PLT, albumin and F3-F4 fibrosis, C versus M versus H pattern was independently associated with a higher risk of hepatic decompensation (HR 2.42, 95% C.I. 1.02–5.74, p = 0.04), HCC (HR 2.90, 95% C.I. 1.01–8.34, p = 0.04), and liver deaths (HR 3.98, 95% C.I. 1.09–14.4, p = 0.03). Comparable results were observed in patients with F3-F4 fibrosis for liver decompensation (HR 2.63, 95% C.I. 1.11–6.23, p = 0.02), HCC (HR 2.94, 95% C.I. 1.03–8.41, p = 0.04), and liver deaths (HR 3.98, 95% C.I. 1.09–14.4, p = 0.03).
Conclusion: Patients with NAFLD cirrhosis have frequently a cholestatic pattern This is associated to a higher risk of decompensation, HCC and liver death.

Impact of non-alcoholic fatty liver disease on cardiovascular risk in a general population

Grazia Pennisi[1], Carola Buscemi[2], Silvio Buscemi[3], Vito Di Marco[1], Cristiana Randazzo[3], Federica Spatola[1], Antonio Craxì[1], Salvatore Petta[1]. [1]*Policlinico Paolo Giaccone, University of Palermo, Sezione di Gastroenterologia, Promise, Italy;* [2]*Unit of Geriatrics, Garibaldi Nesima Hospital, Postgraduate School of Geriatrics, University of Catania;* [3]*University Hospital Policlinico Paolo Giaccone, Unit of Endocrinology, Metabolic Nutrition Diseases, University of Palermo*
Email: graziapennisi901@gmail.com

Background and Aims: Non-alcoholic fatty liver (NAFL) is a major cause of liver disease worldwide leading also to a higher risk of cardiovascular events. We aimed to evaluate the impact of fatty liver and fibrosis on cardiovascular risk in a general population.
Method: 542 subjects included in the community-based ABCD (Alimentazione, Benessere Cardiovascolare e Diabete) study were recruited. Steatosis (CAP >288 dB/m) and severe fibrosis (Low risk, LSM <7.9 KPa with M probe and <5.7 KP with XL probe; intermediate risk, LSM 7.9–9.5 KPa with M probe and 5.7–9.2 KPa with XL probe; high risk, LSM ≥ 9.6 KPa with M probe and ≥ 9.3 KPa with XL probe) were assessed with FibroScan. Intima-media thickness (IMT) was measured with ultrasound (US). Multivariate linear, ordinal and logistic regression analyses were used to identify predictors of CV risk and IMT. Cardiovascular risk was evaluated by the Atherosclerotic Cardiovascular Disease (ASCVD) risk estimator and defined low if <5%, borderline if 5%–7.4%, intermediate if 7.5%–19.9% and high if ≥ 20%.
Results: Prevalence of steatosis and of severe fibrosis in this cohort were 31.7% and 6.8%, respectively. Subjects with NAFL, when compared to those without did not differ for IMT (0.75 vs 0.72 mm; p = 0.11) and IMT ≥ 1 mm (15.6% vs 12.1%; p = 0.24). Patients with high versus intermediate and low risk of severe fibrosis had a trend for higher IMT (0.72 ± 0.21 vs 0.79 ± 0.19 vs 0.79 ± 0.21 mm respectively; p = 0.08) and significant higher prevalence of IMT ≥ 1 mm (12.1% vs 28.6% vs 24% respectively; p = 0.03) and these association were maintained after adjusting for confounders (p = 0.04 for IMT; OR 2.73,95%C.I. 1.03–2.89, p = 0.03 for IMT ≥ 1 mm). ASCVD score was evaluated in patients with and without steatosis (Table 1) and according to the risk of severe fibrosis (Table 2). Notably, by ordinal regression analysis, both steatosis (OR 1.74, 95% C.I. 1.22–2.50, p = 0.002) and high versus intermediate and low risk of severe fibrosis (OR 1.78, 95% C.I.1.26-2.50, p = 0.001) were independent risk factors for a higher ASCVD risk after adjusting for obesity.

Table 1: Evaluation of ASCVD score in subjects with and without steatosis

	ATHEROSCLEROTIC CARDIOVASCULAR DISEASE SCORE (ASCVD)				
	Low	Borderline	Intermediate	High	p value
Steatosis (%)	30.3	11	30.3	28.4	<0.001
No steatosis (%)	49.4	10.5	20.5	19.6	

Table 2: Evaluation of ASCVD score in subjects with low, intermediate and high risk of fibrosis

	ATHEROSCLEROTIC CARDIOVASCULAR DISEASE SCORE (ASCVD)				
	Low	Borderline	Intermediate	High	p value
Low risk of fibrosis (%)	46	8.3	23.2	20.5	<0.001
Intermediate risk of fibrosis (%)	20.7	24.1	27.6	27.6	
High risk of fibrosis (%)	19.2	3.9	26.9	50	

Conclusion: In the setting of a general adult population the presence of NAFL and of severe fibrosis is linked to a high rate of cardiovascular risk factors, pointing towards the need for specific preventive measures.

THU021

Serum zinc level and liver fibrosis in male patients with non-alcoholic fatty liver disease

Won Sohn[1], Jung Hee Kim[2], Ju-Yeon Cho[3], Jae Yoon Jeong[4], Hong Joo Kim[1], Yong Kyun Cho[1], Byung Ik Kim[1]. *[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Internal Medicine, Seoul, Korea, Rep. of South; [2]Hallym University Dongtan Sacred Heart Hospital; [3]Chosun University Hospital, Internal Medicine, Gwang-Ju, Korea, Rep. of South; [4]National Medical Center, Seoul, Korea, Rep. of South*
Email: hand0827@naver.com

Background and Aims: The role of zinc in non-alcoholic fatty liver disease (NAFLD) is not clear. This study aimed to investigate the relationship between serum zinc level and liver fibrosis in patients with NAFLD.
Method: A cross-sectional study was conducted using nationally representative samples from the Korean National Health and Nutrition Examination Survey 2010. A total of 658 male adults were enrolled in the study. Liver fibrosis was assessed using Fibrosis-4 (FIB-4) index. The significant liver fibrosis was defined as FIB-4 index was more than 1.3. Zinc was measured using inductively coupled plasma mass spectrometry using PerkinElmer ICP-MS (PerkinElmer, MA, USA). Pearson correlation analysis was used to evaluate the relationship between serum zinc level and FIB-4 index. Univariable and multivariable logistic regression analyses were done to assess the risk factors including serum zinc level for significant liver fibrosis in patients with NAFLD.
Results: Of 658 male adults, a total of 197 patients with NAFLD were finally analyzed. The mean level of serum zinc was 144.3 ± 30.3 μg/dL. FIB-4 index was significantly increased as the serum zinc level decreased (Pearson correlation coefficient = –0.166, $p = 0.019$). The significant liver fibrosis (FIB-4 index ≥ 1.3) was observed in 48 patients (24%). The multivariable analysis showed that the significant liver fibrosis in patients with NAFLD was associated with age ≥ 50 years (hazard ratio [HR] 9.22 with 95% confidence interval [CI]: 3.54–24.51, $p < 0.001$), serum zinc level <140 μg/dL (HR 3.05 with 95% CI: 1.38–6.79, $p = 0.006$), and diabetes mellitus (HR 2.43 with 95% CI: 1.09–5.41, $p = 0.033$).
Conclusion: There was an inverse relationship between serum zinc level and FIB-4 index in patients with NAFLD. Low level of serum zinc was an independent risk factor for significant liver fibrosis in NAFLD. Further studies are needed to clarity the effect of zinc on liver fibrosis in NAFLD.

THU022

Identification of factors associated with engagement and adherence to a very low calorie diet to achieve significant weight loss in patients with advanced non-alcoholic fatty liver disease: a qualitative evaluation

Jadine Scragg[1], Kate Hallsworth[1,2], Sophie Cassidy[1], Steven Masson[2,3], Laura Haigh[2,3], Marie Boyle[2,3], Quentin Anstee[2,3], Stuart McPherson[2,3], Leah Avery[4]. *[1]Newcastle University, Population Health Sciences Institute, Newcastle upon Tyne, United Kingdom; [2]Newcastle Upon Tyne Hospitals NHS Foundation Trust, Liver Unit, Newcastle upon Tyne, United Kingdom; [3]Newcastle University, Institute of Clinical & Translational Research, Newcastle upon Tyne, United Kingdom; [4]Teesside University, School of Health & Life Sciences, Middlesbrough, United Kingdom*
Email: j.h.scragg@ncl.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is associated with excessive calorie consumption, insufficient physical activity and subsequent obesity. The recommended therapy for NAFLD is lifestyle modification to achieve weight-loss. Patients with advanced NAFLD may not have been successful in engaging with, or have undertaken, lifestyle interventions to initiate weight-loss. This qualitative study aimed to identify factors associated with engagement and adherence of patients with advanced NAFLD to an 8–12 week very low calorie diet (VLCD).
Method: 30 patients with advanced NAFLD were recruited to an 8–12 week VLCD (~800 kcal/day), using meal replacement products (Optifast, Nestlè Health Science). Following completion of the VLCD intervention, patients took part in a semi-structured face-to-face interview. Interviews were audio recorded, transcribed verbatim and thematically analysed to identify common themes associated with uptake and adherence.
Results: 27/30 patients completed the VLCD and 23 took part in an interview. The VLCD was reported by patients as an acceptable and feasible method of achieving significant weight loss to achieve improved liver health. The primary motivator for uptake was a "desire to achieve rapid weight loss (3–39 kg) to improve liver and diabetes-related health"; a significant factor to continued engagement was "accountability to the healthcare professionals providing support and guidance"; key facilitators to adherence were "ease of following the VLCD," "regular visits with feedback and praise from a medical professional" and "practical and emotional support from friends, colleagues and family members." Motivation, and subsequent adherence, was maintained by early weight-loss. Perceived barriers were highly individual, however "shift work" was commonly reported by those who struggled to adhere.
Conclusion: Findings suggest that use of the VLCD as a management option for NAFLD relies on frequent visits to clinic, personalised feedback provision, practical and social support, positive reinforcing feedback from healthcare professionals and practical and emotional support from friends, colleagues and family members. Moreover, early weight loss mediated intervention completion.

Email: javi.ampuero@gmail.com

Background and Aims: Rates of screening failure in NAFLD randomized clinical trials (RCT) are unacceptably high, being the lack of a complete histological definition of NASH one of the leading causes in patients with advanced fibrosis and cirrhosis. FDA allows including patients with one metabolic risk factor, ALT>40 IU/mL and F > 1 by elastography in the absence of liver biopsy in early RCT (Siddiqui, Hepatology 2018). We assessed the prevalence of histological steatohepatitis features in patients with advanced fibrosis and cirrhosis.

Method: Spanish multicenter study including 2249 biopsy-proven NAFLD patients from HEPAmet registry. NASH was diagnosed by NAS and SAF scores (including steatosis, ballooning, and lobular inflammation), and fibrosis by Kleiner score.

Results: Fibrosis was: F0 38.2% (858/2249), F1 26.1% (588/2249), F2 15% (337/2249), F3 13.7% (307/2249) and F4 7.1% (159/2249). NASH was: NAS 44.2% (994/2249) and SAF score 49.6% (1116/2249). Table shows percentage of steatosis, ballooning, lobular inflammation, and NASH across the fibrosis stages. According to NAS, 57.3% (267/466) of F3 and 45.9% (73/159) of F4 patients would have NASH, while these percentages would be F3 61.1% (285/466) and F4 52.8% (84/159) using SAF score (p = ns). Defining NASH by the presence of one of NAS or SAF score, it would be F3 67.8% (316/466) (p = 0.03) and F4 58.5% (93/159) (p = 0.02). Taking into account FDA criteria (at least, one metabolic factor together with ALT>40 IU/mL), the percentage of NASH would increase to F3 81.1% (378/466) and F4 74.2% (118/159) (p < 0.0001 over NAS and SAF for both F3 and F4).

Steatosis*						
	F0	F1	F2	F3	F4	P value
Patients (%)	75.6	86.9	92.6	92.5	86.2	<0.0001
Ballooning*						
	F0	F1	F2	F3	F4	P value
Patients (%)	43.7	70.7	78.9	76.5	63.5	<0.0001
Lobular inflammation*						
	F0	F1	F2	F3	F4	P value
Patients (%)	50.7	77.6	87.5	85.3	76.7	<0.0001
NAS score*						
	F0	F1	F2	F3	F4	P value
Mean ± SD	2.4 ± 1.7	3.5 ± 1.7	4.2 ± 1.7	3.9 ± 1.5	3.4 ± 1.7	<0.0001
NASH (NAS score ≥ 4)*						
	F0	F1	F2	F3	F4	P value
Patients (%)	25.8	49.1	64.4	63.2	45.9	<0.0001
NASH (SAF score)*						
	F0	F1	F2	F3	F4	P value
Patients (%)	31	56.5	69.1	65.5	52.8	<0.0001

*p < 0.05 between F4 *versus* F3 and F2.

Conclusion: Steatohepatitis histological criteria disappeared progressively with the fibrosis stage, so about half of the patients could be screening failure in RCT. To add NAFLD-related clinical criteria (such as metabolic risk factors and ALT) to the uncomplete NASH histological diagnosis in advanced fibrosis and/or cirrhosis could benefit patients whose main aim is to prevent cirrhosis complications, liver transplant, and death.

THU024

Risk factors associated to NAFLD-related advanced fibrosis in patients with normal ALT levels

Javier Ampuero[1,2], Rocío Aller[3], Rocío Gallego-Durán[1,2], Javier Crespo[4], José Luis Calleja Panero[5], Carmelo García-Monzón[6], Judith Gómez-Camarero[7], Juan Caballería[2,8], Oreste Lo Iacono[9], Rafael Bañares[2,10], Francisco Javier Garcia-Samaniego Rey[2,11], Agustin Albillos[2,12], Rubén Francés[2,13], Conrado Fernández-Rodríguez[14], Moises Diago[15], German Soriano[16], Raul J. Email: javi.ampuero@gmail.com

Background and Aims: The risk of advanced NAFLD in subjects with ALT<40 IU/mL is unclear. We aimed to know the prevalence and risk factors of NAFLD-related advanced fibrosis in patients with strictly normal transaminase levels.

Method: Spanish multicenter study including 2414 biopsy-proven NAFLD patients from HEPAmet registry. Definition of strictly normal ALT: male sex <30 IU/mL; female sex <19 IU/mL. Advanced fibrosis was F3-F4 *vs.* F0-F2.

Results: The 46.4% (1121/2414) of patients showed NASH and 20% (482/2414) advanced fibrosis. AST increased progressively across fibrosis stages (F0 36 ± 46; F1 39 ± 29; F2 47 ± 37; F3 50 ± 31; F4 55 ± 43 IU/mL; p < 0.0001), while ALT increased from F0 to F2 and decreased in F3 and F4 (F0 54 ± 59; F1 58 ± 47; F2 66 ± 59; F3 63 ± 43; F4 58 ± 73 IU/mL; p = 0.005). Normal ALT levels were shown in 20% patients (482/2414), and they showed a lower percentage of NASH (36.6% (160/437) *vs.* 51.8% (954/1841); p < 0.0001) and advanced fibrosis (14.8% (68/458) *vs.* 22% (408/1855); p = 0.001), but not cirrhosis (5.9% (27/458) *vs.* 7.4% (137/1855); p = 0.266). Age

[OR 1.04 (IC95% 1.01–1.08); p = 0.016], diabetes [OR 3.08 (IC95% 1.49–6.39); p = 0.002], platelets [OR 0.98 (IC95% 0.98–0.99); p = 0.0001], AST [OR 1.10 (IC95% 1.04–1.16); p = 0.001], and GGT [OR 1.01 (IC95% 1.00–1.01); p = 0.015] were associated with advanced fibrosis in presence of normal ALT (Table). ROC analysis was 0.89 (IC95% 0.85–0.93; p < 0.0001) and the best cut-off (Se 81.5%, Sp 83.1%; NPV 96.1%, PPV 46.9%; LR+ 4.82, LR- 0.22) separated adequately the risk of advanced fibrosis (46.9% (53/113) *vs.* 3.9% (12/307); p < 0.0001).

Characteristic	Unadjusted OR (95%CI) Advanced Fibrosis	Adjusted OR (95%CI) Advanced Fibrosis
Male sex	2.53 (1.46–4.40); p = 0.001	
Age; years ± SD	1.07 (1.04–1.10); p = 0.0001	1.04 (1.01–1.08); p = 0.016
BMI ± SD (kg/m^2)	0.95 (0.92–0.98); p = 0.002	
Arterial Hypertension	1.77 (1.05–3.00); p = 0.033	
Type 2 diabetes mellitus	4.88 (2.84–8.38); p = 0.0001	3.08 (1.49–6.39); p = 0.002
Glucose ± SD (mg/dL)	1.01 (1.00–1.02); p = 0.002	
Total cholesterol ± SD (mg/dL)	0.99 (0.99–1.00); p = 0.013	
Triglycerides ± SD (mg/dL)	1.00 (1.00–1.00); p = 0.888	
Hypertriglyceridemia	1.54 (0.92–2.60); p = 0.104	
Albumin ± SD (g/dL)	0.71 (0.39–1.31); p = 0.279	
Bilirubin ± SD (mg/dL)	1.96 (1.03–3.73); p = 0.039	
Platelet count ± SD (×10^9/L)	0.98 (0.98–0.99); p = 0.0001	0.98 (0.98–0.99); p = 0.0001
AST ± SD (IU/mL)	1.15 (1.11–1.21); p = 0.0001	1.10 (1.04–1.16); p = 0.001
ALT ± SD (IU/mL)	1.09 (1.04–1.14); p = 0.001	
GGT ± SD (IU/mL)	1.01 (1.01–1.02); p = 0.0001	1.01 (1.00–1.01); p = 0.015
Transient elastography (kPa)	1.08 (1.03–1.15); p = 0.005	

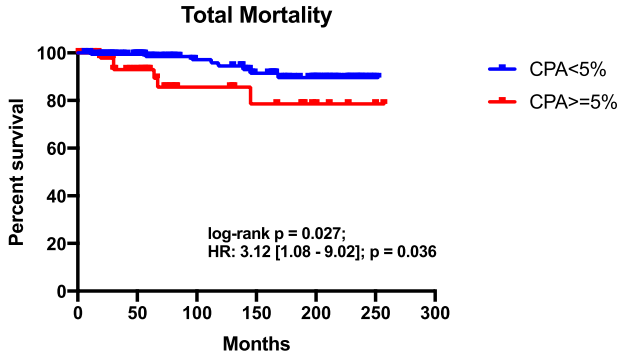
Conclusion: ALT had not good predicting accuracy for NAFLD severity since it decreased in advanced fibrosis in a U-shaped relationship. Age, diabetes, AST, GGT, and platelets were essential to detect patients with advanced fibrosis in patients with strictly normal ALT levels.

THU025

Fibrosis quantification by image morphometry of liver fibrosis predicts clinical outcomes in patients with non-alcoholic fatty liver disease

Zhengyi Wang[1,2], Gary Jeffrey[1,2], Yi Huang[1,2], Bastiaan Deboer[3], Luis Bertot[1,2], Leon Adams[1,2]. *[1]The University of Western Australia, Medical School, Perth, Australia; [2]Sir Charles Gairdner Hospital, Department of Hepatology, Perth, Australia; [3]PathWest Laboratory Medicine, Perth, Australia*
Email: leon.adams@uwa.edu.au

Background and Aims: Liver fibrosis predicts adverse clinical outcomes such as decompensation and liver-related death (LRD) in patients with nonalcoholic fatty liver disease (NAFLD). Pathologist staging of liver biopsy is the current gold-standard however it may suffer from observer variability. We aimed to investigate the accuracy of the collagen proportionate area (CPA) as an objective and reproducible method of predicting adverse outcomes in patients with NAFLD.
Method: Patients who attended a tertiary centre Hepatology Department from 1992 to 2015 with biopsy proven NAFLD were included. Computerized image morphometry was performed on biopsy slides stained by Sirius Red with CPA analyses performed by ImageScope v12.3.3. Fibrosis was staged according to the NASH-CRN scoring system. Clinical outcomes were determined by medical records and population-based data-linkage. Statistical analyses were performed by SPSS.
Results: A total of 208 patients (47% male, mean age 49 years) were followed for a median (interquartile range, IQR) of 6.0 (4.0–15.0) years totalling 1801 person-years. Death or liver transplantation occurred in 14 patients among which 5 had LRD and 7 patients developed liver decompensation. The median CPA value at baseline biopsy was 3.09% (IQR: 1.72–4.99%). CPA correlated significantly with pathologist fibrosis stage (Spearman rho 0.479, p < 0.001). Patients with higher CPA (> = 5.00%) had higher risks for total mortality [hazard ratio (HR): 3.12 (1.08–9.02); p = 0.036], liver related death [HR 14.48 (1.62–129.67); p = 0.017], and liver decompensation [HR 9.22 (1.79–47.63); p = 0.008]. CPA and pathologist fibrosis staging (FS) showed similar accuracy (AUROC) for the prediction of outcomes; total mortality, CPA: 0.623 (95% CI: 0.446–0.799), FS: 0.676 (0.509–0.837); LRD, CPA: 0.872 (0.691–1.000), FS: 0.917 (0.788–1.000); decompensation, CPA: 0.774 (0.555–0.993), FS: 0.823 (0.621–1.000); all p > 0.05]. In the sub-group of patients with cirrhosis (n = 9), a CPA cut-off of 10.0% was able to further stratify patients with higher and lower future risk of death or liver transplant (86% vs. 0%), LRD (86% vs. 0%), and decompensation (86% vs. 0%).



Conclusion: Liver fibrosis quantified by CPA analysis is an accurate predictor of clinical outcomes in patients with NAFLD and may further stratify risk in patients with cirrhosis.

THU026

Non-alcoholic fatty liver disease phenotype and prevalence across the menopause spectrum in women living with HIV

Jovana Milic[1], Adriana Cervo[2], Andrea Malagoli[1], Denise Morini[1], Valentina Menozzi[1], Federica Carli[1], Marianna Menozzi[1], Iacopo Franconi[1], Cristina Mussini[1], Giada Sebastiani[3,4], Giovanni Guaraldi[1]. *[1]University of Modena and Reggio Emilia, Modena, Italy; [2]University Hospital of Palermo; [3]Chronic Viral Illness Service, McGill University Health Centre (MUHC), Montreal, QC, Canada; [4]Division of Gastroenterology and Hepatology, MUHC, Montreal, QC, Canada*
Email: jovana.milic@gmail.com

Background and Aims: Both menopause and non-alcoholic fatty liver disease (NAFLD) are major metabolic events with potential systemic effects. The objective of the study was to describe natural history of NAFLD during menopause transition and the interplay between these two conditions in women living with HIV (WLWH).
Method: This was a cross-sectional study of consecutive WLWH attending Modena HIV Metabolic Clinic in 2018–2019. Women with hazardous alcohol intake and hepatitis B or hepatitis C virus co-infection were excluded. NAFLD and significant liver fibrosis were assessed with transient elastography and defined as controlled attenuation parameter (CAP) >248 dB/m and as liver stiffness measurement > = 7.1 kPa respectively. Menopause was determined according to STRAW criteria including 4 periods: reproductive, transitional, early and late menopause. Due to low absolute number of NAFLD cases, these criteria were further simplified dividing WLWH as “pre-menopause” if being in the first two periods and “post-

menopause" if being in the last two periods. Two logistic regression models were built to explore predictors associated with NAFLD in pre-menopause and post-menopause periods, using as covariates metabolic and anthropometric variables.

Results: We analyzed 296 WLWH with mean age = 54.3 (+−7.9) years, current median CD4 = 710 μL (IQR = 543–896) and HIV RNA undetectability in 98.3% of cases. Overall, NAFLD and significant fibrosis prevalence in WLWH were 33.8% and 11.8% respectively. NAFLD and significant fibrosis were observed in 33.3% and 7.4% in reproductive, 29.4% and 11.8% in menopause transition, 32.6% and 12.9% in early menopause and 56.3% and 12.5% in late menopause respectively (p = 0.07 and p = 0.66). Table shows characteristics between WLWH with NAFLD in reproductive and menopause period. In two multivariate logistic models, HIV duration, lipoatrophy, CD4/CD8 ratio and obesity were not associated with an increased risk of NAFLD in pre-menopause and post-menopause, while the HOMA was the only co-variate to predict NAFLD in post-menopausal WLWH (OR = 0.38, 0.15–0.8; p = 0.03).

Variable	Pre-menopause NAFLD	Post-menopause NAFLD	p
	32 (34.4%)	61 (65.6%)	
Age, years, mean (±SD)	49.5 (±6.6)	57.8 (±6.6)	
BMI, kg/m², mean (±SD)	26.9 (±5.9)	26.3 (±7.1)	0.56
Waist circumference, cm, mean (±SD)	94.1 (±13.6)	91.3 (±10.3)	0.44
Obesity (%)	8 (25%)	11 (18.3%)	0.63
HIV duration, years, median (IQR)	23.8 (14.8-27.6)	26.3 (23.9-30.3)	0.03
Nadir CD4, median, c/μL, median (IQR)	251 (145-385)	199 (100-277)	0.11
Current CD4, median, c/μL, (IQR)	727 (533-931)	716 (575-923)	0.75
CD4/CD8 ratio, mean (±SD)	1.1 (±0.5)	1.2 (±0.6)	0.67
Type 2 diabetes (%)	4 (12.5%)	16 (16.2%)	0.21
Multimorbidity (%)	5 (15.6%)	46 (75.4)	<0.001
FIB 4, mean (±SD)	1.2 (±0.9)	1.5 (±0.7)	0.09
LDL cholesterol, mg/dl, mean (±SD)	129 (±41.5)	125 (±41.2)	0.67
HDL cholesterol, mg/dl, mean (±SD)	62.6 (±16.3)	57.7 (±13.7)	0.21
Triglycerides, mg/dl, mean (±SD)	103.7 (±40.7)	143.1 (±77)	0.01
HOMA, mean	2.4 (±1.2)	3 (±1.9)	0.54

Conclusion: Prevalence and phenotype of NAFLD and liver fibrosis did not differ across the menopause in WLWH, suggesting that more complex immune-metabolic pathways, not captured by STRAW criteria, are involved in NAFLD natural history in aging WLWH.

THU028

The association with low skeletal muscle mass and carotid atherosclerosis in patients with non-alcoholic fatty liver disease

Min Kyu Kang[1], Jung Gil Park[1], Soo Young Park[2], Won Young Tak[2], Young Oh Kweon[2], Se Young Jang[2], Yu Rim Lee[3], Keun Hur[3].
[1]Yeungnam University, College of Medicine, Internal Medicine, Korea, Rep. of South; [2]Kyungpook National University, School of Medicine, Internal Medicine, Korea, Rep. of South; [3]Kyungpook National University, School of Medicine, Biochemistry and Cell Biology, Korea, Rep. of South
Email: kmggood111@naver.com

Background and Aims: Although low skeletal muscle mass (LSMM) and carotid atherosclerosis are associated with non-alcoholic fatty liver disease (NAFLD), respectively, associated with LSMM and subclinical atherosclerosis in patients with NAFLD has not been established. We investigated whether LSMM was associated with carotid atherosclerosis in patients with NAFLD.

Method: From January 2010 to November 2019, a total 683 ultrasound-confirmed NAFLD patients who performed carotid ultrasound from health promotion center of Yeungnam University Hospital were included in the analysis. LSMM was defined as Appendicular skeletal muscle (ASM) using bioelectrical impedance analysis divided by body mass index (ASM/BMI). Using carotid ultrasound and Doppler, elevated carotid intima media thickness (IMT) (>1 cm) and presence of carotid plaque were measured, which are defined as indicators of early atherosclerosis.

Results: Of 683 patients with NAFLD, 75 (11.0%) were diagnosed with LSMM. The LSMM group were older (52.9 vs. 49.2 years, p = 0.011), had higher BMI (29.0 vs. 26.3 kg/m², p = 0.001), proportion in presence of insulin resistance (53.3 vs. 33.2%, p = 0.001), proportion of elevated IMT (33.3 vs. 14.5%, p = 0.001) compared to non-LSMM group. In patients with NAFLD, the presence of LSMM was associated with elevated IMT (odd ratios [OR] = 2.26 to 2.95, p < 0.05) and carotid plaque (OR = 2.05 to 2.90, p < 0.05) using adjusted models for age, sex, diabetes, hypertension obesity, waist circumference, hyperuricemia, lipid profile, aminotransferase, gamma-glutamyl transferase, homeostatic model assessment-insulin resistance, and high sensitivity C-reactive protein (Figure). In patients with obese NAFLD as a subgroup, the presence of LSMM was associated with elevated IMT (odd ratios [OR] = 2.44 to 3.30, p < 0.05) and carotid plaque (OR = 2.56 to 3.54, p < 0.05) using adjusted model.

Conclusion: LSMM may be associated with elevated IMT and presence of carotid plaque in patients with NAFLD, independently classic metabolic factors and insulin resistance.

THU029

Gender difference and hepatocellular carcinoma incidence in non-alcoholic steatohepatitis patients with advanced liver fibrosis

Kanokwan Pinyopornpanish[1,2], Arthur McCullough[1], Carlos Romero-Marrero[1].
[1]Cleveland Clinic Foundation, Digestive Disease and Surgery Institute, Cleveland, United States; [2]Chiang Mai University, Internal Medicine, Chiang Mai, Thailand
Email: kpinyopornpanish@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is known to be more common in males than females. However, there are limited data regarding the effect of gender difference on the incidence of HCC in non-alcoholic steatohepatitis (NASH) patients. The study aimed to evaluate the effect of gender difference on the risk of developing HCC in NASH patients with advanced fibrosis.

Method: We conducted a single-center retrospective cohort study, including patients with biopsy-proven NASH with F3/F4 fibrosis and NASH or cryptogenic cirrhosis who were evaluated at our institution between 2007–2016. The date of diagnosis (biopsy date or clinical evidence of cirrhosis) and the date of last abdominal imaging, liver transplantation or HCC diagnosed were used to assess follow-up time. Kaplan-Meier analysis was used to estimate the cumulative incidence. The incidence rate was calculated and multivariate cox-regression analysis were used to evaluate the association of risk factors and HCC occurrence.

Results: 1,197 patients were included. There were 131 patients with F3 fibrosis and 1,066 patients with cirrhosis. Among NASH cirrhosis patients, 452 were male and 614 were female. Median follow-up was 3.84 years (IQR 2.16, 6.27). There were no differences in baseline age, race, body mass index or metabolic risk factors. However, male patients had fewer follow-up years (3.39 VS 4.13 years, p < 0.001) and more decompensated cirrhosis at presentation (48.4 VS 41.0%, p < 0.001). HCC developed in 102 patients. The incidence rates in all

	Elevated IMT		Carotid plaque	
	OR (95% CI)	*P*-value	OR (95% CI)	*P*-value
LSMM_BMI in NAFLD patients (yes vs. no)				
Unadjusted	2.95 (1.74-5.02)	<0.001	2.85 (1.51-5.39)	0.001
Age, sex adjusted	2.26 (1.26-4.04)	0.006	2.05 (1.03-4.08)	0.004
Model 1	2.28 (1.27-4.08)	0.005	2.20 (1.10-4.40)	0.026
Model 2	2.28 (1.27-4.08)	0.005	2.90 (1.40-6.04)	0.004
Model 3	2.26 (1.26-4.04)	0.006	2.74 (1.30-5.78)	0.008

LSMM, low skeletal muscle mass; OR, odds ratio; BW, body weight; BMI, body mass index; CI, confidence interval; NAFLD, non-alcoholic fatty liver disease; ASM: appendicular skeletal muscle mass.

Model 1: Age, sex, presence of diabetes, and hypertension

Model 2: Further adjusted for presence of obesity, waist circumference, and hyperuricemia

Model 3: Further adjusted for total cholesterol, triglyceride, and high-density lipoprotein, alanine aminotransferase, aspartate aminotransferase, gamma-glutamyl transferase, homeostatic model assessment-insulin resistance, and high sensitivity C-reactive protein

Figure: (abstract: THU028)

cirrhotic patients (both male and female), male with cirrhosis and female with cirrhosis were 2.07/100 person-year, 3.51/100 person-year and 1.19/100 person-year, respectively. Multivariable analysis showed that male gender (IRR 3.60; 95%CI 2.35–5.50, p < 0.001), clinical decompensation at presentation (IRR 1.63; 95%CI 1.08–2.46, p = 0.021) and older age (IRR 1.04; 95% CI 1.02–1.06, p < 0.001) were independent variables associated with HCC development. Among patients with F3 fibrosis, no HCC development was observed during the total of 674 follow-up years.

Conclusion: Gender has a significant impact on HCC development among patients with NASH-related cirrhosis. Further longitudinal studies are needed to better elucidate the reasons for these differences.

THU030

Advanced liver fibrosis predicts poor cardiovascular outcomes in patients with type 2 diabetes

Ho Soo Chun[1,2], Hye Yeon Chon[1,2], Jae Seung Lee[1,2,3], Hye Won Lee[1,2,3], Beom Kyung Kim[1,2,3], Jun Yong Park[1,2,3], Do Young Kim[1,2,3], Sang Hoon Ahn[1,2,3], Kwang-Hyub Han[1,2,3], Seung Up Kim[1,2,3].

[1]Department of Internal Medicine; [2]Institute of Gastroenterology, Yonsei University College of Medicine, Seoul, South Korea; [3]Yonsei Liver Center, Severance Hospital, Seoul, Korea

Email: ksukorea@yuhs.ac

Background and Aims: Atherosclerotic cardiovascular disease (ASCVD) is the principal cause of death in patients with type 2 diabetes (T2D). T2D is closely associated with non-alcoholic fatty liver disease (NAFLD); liver fibrosis is poorly prognostic in NAFLD patients. Thus, we explored whether liver fibrosis predicted the risk of ASCVD in patients with T2D.

Method: A total of 1,604 patients who had commenced oral anti-diabetic drugs to treat newly diagnosed T2D between 2006 and 2010 were recruited. NAFLD was defined as a hepatic steatosis index (HSI) >36. Liver fibrosis was assessed using the fibrosis-4 index (FIB-4) and the NAFLD fibrosis score (NFS). Advanced liver fibrosis was defined as an FIB-4 score >3.25 and an NFS >0.676. The predicted ASCVD risk was calculated using the 10-year ASCVD risk prediction model of the 2013 ACC/AHA (American College of Cardiology / American Heart Association) guideline.

Results: NAFLD and advanced liver fibrosis were identified in 920 (57.4%) and 39 (2.4%) patients respectively. During the follow-up period (median 80.1 [interquartile range 40.2–115.2] months), ASCVD developed in 199 (12.4%) patients. The predicted and observed ASCVD risks were significantly higher in patients with than without advanced liver fibrosis (28.0 vs. 18.1%, p = 0.001 and 23.1 vs. 12.1%, p = 0.041). Advanced liver fibrosis, as revealed by the NFS, independently predicted an increased risk of ASCVD (hazard ratio = 1.232, 95% confidence interval 1.071–1.418, p = 0.004) as did older age and hypertension. The cumulative incidence of ASCVD was significantly higher in patients with than without advanced liver fibrosis (p = 0.031, log-rank test). Among patients with NAFLD, the cumulative

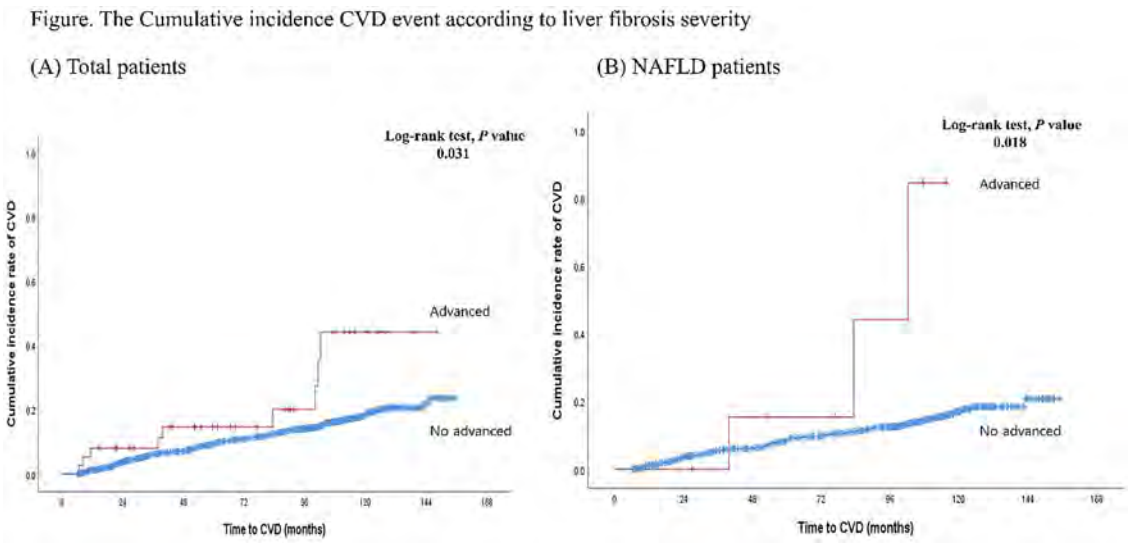

Figure: (abstract: THU030)

incidence of ASCVD was also significantly higher in patients with than without advanced liver fibrosis (p = 0.018, log-rank test).
Conclusion: Advanced liver fibrosis independently predicted an increased risk of ASCVD in patients who had commenced anti-diabetic drugs to treat newly diagnosed T2D. Thus, assessment of liver fibrosis might allow physicians to optimize the timing of appropriate preventative or diagnostic cardiovascular interventions in such patients.

THU031

Histological renal damage and eligibility for kidney donation are worse in patients with biopsy-proven non-alcoholic steatohepatitis compared with simple steatosis

Lorenzo Mulazzani[1], Davide Capelli[1], Manuel Labanti[2], Chiara Zanfi[3], Gabriela Sangiorgi[2], Fabio Piscaglia[1]. [1]*Policlinico di S. Orsola, University of Bologna, Unit of Internal Medicine, Department of Medical and Surgical Sciences, Bologna, Italy;* [2]*Policlinico di S. Orsola, Reference Center for Transplantation of Emilia-Romagna (CRT-ER), Bologna, Italy;* [3]*Policlinico di S. Orsola, Liver and Multiorgan Transplant Unit, Bologna, Italy*
Email: lorenzo.mulazzani2@studio.unibo.it

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) has been related with multi-organ comorbidities. Nevertheless, the relationship with kidney disease has been poorly investigated.
The aim of this study was to verify whether patients with NAFLD have higher risk of kidney disease evaluated during the process of eligibility for kidney donation and histological scores of damage.
Method: This study is based on the register of Reference Center for Organ Transplantation of Emilia-Romagna, which contains data collected during the work-up for the determination of eligibility of potential donors.
After having excluded patients with incomplete work-up (771), with non-NAFLD liver diseases (153) and whose liver was utilized for transplantation without a preliminary biopsy (414), 722 consecutive subjects ≥ 18 y submitted to liver biopsy from 2008 to 2018 were enrolled (mean age 62y, range 18–89). Patients were divided in three groups based on the review of histological reports: healthy liver (n = 166: no steatosis, fibrosis or inflammation), simple steatosis (n = 358: micro or macrovescicular steatosis involving >5% of the parenchyma, no fibrosis and inflammation), and non-alcoholic steatohepatitis (NASH, n = 198: fibrosis or inflammation). The risk of having kidneys not eligible for donation was assessed in these groups.
Finally, 403 of these 722 had been submitted to both liver and kidney biopsy (62y, range 18–89). The risk of kidney damage (assessed with Karpinski score) was verified in this population.
Results: Distributions of age, diabetes and hypertension were similar in the study groups.
NASH showed higher risk of having kidneys not eligible for donation than healthy liver. Odds ratios (OR) were: left kidney 1.9, p = 0.005; right kidney 1.7, p = 0.017. No increased risk was found in simple steatosis (p = 0.259 and p = 0.258).
A higher risk of histological kidney damage (Karpinski score ≥ 3, Figure 1) was found in NASH group (OR: left kidney 2, p = 0.022; right kidney 2.6, p = 0.002) but not in simple steatosis (p = 0.763 and 0.200).
Risk of vascular damage involving >20% of the glomeruli (Karpinski vascular score ≥ 2) was found in NASH (right kidney OR 1.9, p = 0.029) but not in simple steatosis (p = 0.405).
Conclusion: This study shows that NASH is associated with an increased risk of biopsy-proven kidney damage, not present in simple steatosis. These findings might indirectly suggest the presence of generalized inflammatory and fibrotic pathways in the subset of patients developing NASH.

THU032

Evolution of hepatic fibrosis and steatosis during long-term use of metformin in patients with type 2 diabetes

Hye Won Lee[1], Seung Up Kim[1], Jae Seung Lee[1], Beom Kyung Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1], Kwang-Hyub Han[1]. [1]*Yonsei University College of Medicine, Department of Internal Medicine*
Email: ksukorea@yuhs.ac

Background and Aims: The main therapeutic aim in patients with type 2 diabetes (T2D) is control of the serum glucose level. Metformin is widely used as a first-line antidiabetic agent. The prevalence of chronic liver diseases, such as non-alcoholic fatty liver disease, is high in patients with T2D. However, few studies have investigated the evolution of liver fibrosis and steatosis during long-term use of metformin in patients with T2D.
Method: From 2006 and August 2010, patients newly diagnosed T2D who received metformin were recruited. Patients were excluded if they had chronic liver diseases other than non-alcoholic fatty liver diseases, an insufficient follow-up period (<2 years), or insufficient laboratory information for calculation of noninvasive liver fibrosis and steatosis indices (i.e., fibrosis-4 index [FIB-4] and hepatic steatosis index [HSI]) at enrollment and at 2 years. Significant liver

	simple steatosis	NASH
Significance vs healthy liver	p=0.816	p=0.060

	simple steatosis	NASH
Significance vs healthy liver	p=0.270	**p=0.012**

Figure 1. Distribution of Karpinski classes (Karpinski score <3, 3-6 and ≥7) in patients with healthy liver, simple steatosis and NASH.

Figure: (abstract: THU031)

fibrosis was defined as FIB-4 score of >2.67 and fatty liver was defined as HSI score>36.0.

Results: In total, 1,292 patients were finally enrolled. The mean age of the study population (732 men and 560 women) was 60.8 years. The mean body mass index and mean serum glucose, hemoglobin A1c, and aspartate and alanine aminotransferase levels were 25.1 kg/m^2, 143 mg/mL, 7.3%, 26.5 IU/L, and 30.1 IU/L, respectively. The mean FIB-4 and HSI scores were 1.38 and 27.3, respectively. At enrollment, 83 (6.4%) patients had significant liver fibrosis, while 429 (33.2%) patients had fatty liver. After 2 years of metformin treatment, the mean FIB-4 score was significantly increased (1.38 to 1.51, $p < 0.001$), whereas the mean HSI was decreased (27.3 to 26.5, $p < 0.001$). In addition, significant liver fibrosis was developed in 52 (4.0%) patients, whereas the proportion of patients with fatty liver was stable or reduced (33.2% to 27.9% [n = 335], $p < 0.001$). The HbA1c levels were not significantly different between patients with and without significant liver fibrosis at baseline (7.3% vs. 7.4%, $p = 0.368$) and 2 years (7.0% vs. 6.8%, $p = 0.101$). Only age (odds ratio [OR] = 1.094, 95% CI, 1.038–1.153, $p = 0.001$) was independently associated with the risk of developing significant liver fibrosis after 2 years of metformin treatment. In the subgroup of 712 (55.1%) patients who were followed up for 5 years, the FIB-4 score tended to increase (mean 1.80 at 5 years), whereas the HSI score remained stable (mean 26.4 at 5 years). During the study period (median 97.1 months), 2 (0.3%) and 118 (19.1%) patients developed hepatocellular carcinoma and cardiovascular events, respectively.

Conclusion: During long-term metformin treatment, female patients with T2D had a significantly threefold higher risk of liver fibrosis progression. Therefore, early recognition of liver fibrosis progression and the use of appropriate medical interventions should be considered for female patients with T2DM.

THU033

Incidence and risk factors for cardiovascular events in patients with advanced fibrosis due to non-alcoholic steatohepatitis: data from the phase 3 STELLAR trials

Email: marianne.camargo2@gilead.com

Background and Aims: Nonalcoholic steatohepatitis (NASH) is associated with an increased risk of cardiovascular (CV) disease, but the impact of advanced fibrosis is unclear. Our objective was to describe the incidence and risk factors for major adverse CV events (MACE) in patients with NASH and advanced fibrosis enrolled in two phase 3 trials.

Method: Patients with advanced fibrosis (F3-F4) due to NASH (NAS ≥ 3) were enrolled in two placebo-controlled trials of selonsertib (STELLAR). The trials were discontinued after 48 weeks due to lack of

efficacy; hence treatment groups were combined. The incidence of adjudicated MACE was assessed via Poisson regression and associations between baseline demographic and clinical parameters (eg. fibrosis stage, NAS, ELF, ALT, history of CV disease, diabetes mellitus [DM], smoking, hypertension, lipids, hsCRP, and use of statins or GLP-1 receptor agonists) were determined via Cox regression.

Results: 1679 patients with bridging fibrosis (n = 802) or cirrhosis (n = 877) were included (median age 59 yrs, 60% female, 74% DM, 68% BMI ≥ 30 kg/m^2). During a median follow-up of 15.8 months (IQR 13.8, 18.2), 16 patients (1.0%; n = 2 with F3 [0.2%], n = 14 with F4 [1.6%]) had a total of 18 MACE (stroke [n = 5], coronary revascularization [n = 6], myocardial infarction [n = 4], and hospitalization for cardiac failure [n = 2] or unstable angina [n = 1]). The overall incidence (95% CI) of a first MACE was 0.72 per 100 person-years (pyrs) of follow-up (0.41, 1.17); the incidence was significantly higher in patients with cirrhosis (1.22 per 100 pyrs [0.67, 2.05] than those with F3 fibrosis (0.19 per 100 pyrs [0.02, 0.67]; hazard ratio [HR] 6.45 [95% CI 1.46, 28.36]; p = 0.0137). Additional risk factors for MACE in univariate analysis included older age (≥ vs <65 years: HR 2.87 [95% CI 1.08, 7.64]), baseline ELF score (HR per 0.5 units: 1.30 [1.03, 1.63]), and prior history of CV disease (HR 3.17 [1.10, 9.13]), but not sex, DM, smoking, hypertension, obesity, use of statins or GLP-1 receptor agonists, or baseline ALT, NAS, platelets, INR, FIB-4, total or LDL cholesterol, triglycerides, or hsCRP.

Conclusion: In this clinical trial population of patients with advanced fibrosis due to NASH, the incidence of adjudicated MACE was ~7 per 1,000 person-years. Patients with greater fibrosis burden at baseline – measured by biopsy or ELF – those ≥ 65 years of age, and patients with a prior history of CV disease, are at the greatest risk of adverse CV outcomes.

THU034

A substantial number of patients with non-alcoholic fatty liver disease and type 2 diabetes have advanced liver fibrosis with a normal serum alanine transaminase

Michael Patrick Johnston[1], Erica Jennison[2], Charlotte Cook[1,3], Rayyan Jamal[4], Chris Byrne[5,6], Janisha Patel[1]. *[1]University Hospital Southampton NHS Foundation Trust, Department of Hepatology, Southampton, United Kingdom; [2]University Hospital Southampton NHS Foundation Trust, Chemical Pathology, Southampton, United Kingdom; [3]University of Southampton, Primary Care and Population Sciences, Southampton, United Kingdom; [4]University of Southampton, Faculty of Medicine, Southampton, United Kingdom; [5]University of Southampton, Human Development and Health, Faculty of Medicine, Southampton, United Kingdom; [6]University Hospital Southampton NHS Foundation Trust, National Institute for Health Research Southampton Biomedical Research Centre, Southampton, United Kingdom*
Email: michael.johnston1@nhs.net

Background and Aims: Type 2 diabetes mellitus (T2DM) is the strongest risk factor for developing non-alcoholic fatty liver disease (NAFLD). NICE does not recommend screening for NAFLD in T2DM. NICE does recommend assessment of fibrosis in NAFLD. Over half of patients with NAFLD and a normal alanine transaminase (ALT) have non-alcoholic steatohepatitis, which is associated with fibrosis, cirrhosis and hepatocellular carcinoma. Our aim was: (1) establish the association between T2DM and advanced fibrosis in the liver clinic; (2) describe the proportion of individuals with advanced fibrosis and normal ALT.

Method: We generated a dataset of patients with NAFLD who had a FibroScan® in the liver clinic in 2018. We used a cross-sectional study design to analyse baseline characteristics of all patients including sex, age, body mass index (BMI), presence of T2DM, ALT and LSM.

Results: 277 patients attended the clinic with a diagnosis of NAFLD. Mean age (±SD) was 56.6 years (±12.9). 156/277 (56.3%) patients were male. 111/277 (40%) patients had T2DM. 69/111 (62%) patients with T2DM had advanced fibrosis (LSM ≥ 8.7 kPa). 41/166 (25%) patients without diabetes had advanced fibrosis. T2DM was positively associated with advanced fibrosis, crude odds ratio (OR) 5.01 [95% CI 2.97–8.43]. We performed multinomial logistic regression with age and sex as covariants. T2DM remained positively associated with advanced fibrosis after adjustment for age and sex (adjusted OR 5.02 [95% CI 2.96–8.54]). 30/111 (27.0%) patients with T2DM had a normal ALT (reference range 10–40 U/L) with advanced fibrosis.

Table: Baseline characteristics in patients with NAFLD grouped by presence/absence of T2DM

	All patients n = 277	
	T2DM	No T2DM
Total number	111	166
Male sex (%)	56 (50)	100 (60.0)
Age (years)	59.2 (57.2–61.3)	54.5 (52.3–56.7)
BMI (kg/m^2)	33.5 (32.3–34.6)	31.8 (30.9–32.6)
LSM (kPa)	13.5 (10.4–16.6)	9.0 (6.2–11.8)
Patients with advanced fibrosis ≥ 8.7 kPa (%)	69 (62.0)	41 (25.0)
Patients with normal ALT (%)	52 (46.8)	71 (42.8)
Normal ALT and advanced fibrosis (≥ 8.7 kPa) (%)	30 (27.0)	16 (9.6)

Conclusion: Advanced liver fibrosis occurred more than twice as frequently in patients with T2DM than those without T2DM. There was a strong association between T2DM and advanced fibrosis. A considerable proportion of patients with T2DM had advanced fibrosis and normal ALT. This result has significant implications for health care professionals managing patients with T2DM who may not test for liver disease when ALT levels are normal.

THU035

Unlike HbA1c level and the amount of visceral adipose tissue, the presence and severity of NAFLD do not predict the occurrence of major adverse cardiovascular events in an obese Belgian population

Mikhail Van Herck[1,2], Christophe Conrad[1], Simon Kleevens[1], Christophe De Block[3,4], Eveline Dirinck[3,4], Luc Van Gaal[3,4], An Verrijken[3,4], Vincent Segers[5,6], Emeline Van Craenenbroeck[5], Ann Driessen[7], Peter Michielsen[1,2], Toon Steinhauser[2], Thomas Vanwolleghem[1,2], Jonas Weyler[1,2], Luisa Vonghia[1,2], Sven Francque[1,2]. *[1]University of Antwerp, TWI²N, LEMP, Gastroenterology and Hepatology, Antwerpen, Belgium; [2]Antwerp University Hospital, Gastroenterology and Hepatology, Edegem, Belgium; [3]University of Antwerp, TWI²N, LEMP, Endocrinology, Antwerpen, Belgium; [4]Antwerp University Hospital, Endocrinology, Diabetology and Metabolism, Edegem, Belgium; [5]Antwerp University Hospital, Cardiology, Edegem, Belgium; [6]University of Antwerp, Laboratory of Physiopharmacology, Antwerpen, Belgium; [7]Antwerp University Hospital, Pathology, Edegem, Belgium*
Email: mikhail.vanherck@uantwerpen.be.

Background and Aims: Cardiovascular disease is the most important cause of morbidity and mortality in non-alcoholic fatty liver disease (NAFLD) patients. This study aimed at determining the predictive value of NAFLD grade at baseline, as well as other clinical parameters, with respect to the occurrence of major adverse cardiovascular events (MACE) during follow-up.

Method: Patients who consulted the metabolic unit of the Antwerp University Hospital between 2006–2012 and underwent a liver biopsy because of a clinical suspicion of NAFLD, were included consecutively with informed consent. The FLIP algorithm was used to define NAFLD grade: no NAFLD, non-alcoholic fatty liver (NAFL), non-fibrotic non-alcoholic steatohepatitis (NASH, <F2) and fibrotic NASH (≥ F2). MACE were defined as the occurrence of stroke, (non) ST elevation myocardial infarction [(N)STEMI)] or unstable angina. The occurrence of MACE was examined by reviewing the in-hospital and

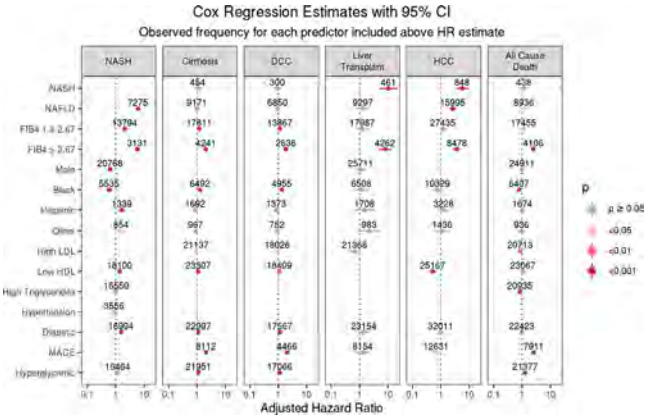
the nation-wide accessible electronic patient files. Statistical analysis was performed by Cox regression.
Results: 323 patients (M:F 99:224) were included with a mean age of 44 ± 12 y and a mean BMI of 39.5 ± 6.4 kg/m^2. Liver biopsy showed no NAFLD in 69, NAFL in 93, non-fibrotic NASH in 126 and fibrotic NASH in 35 patients. Glucose tolerance testing was normal in 187, impaired in 109 and showed a new diagnosis of type 2 diabetes in 27 patients. Mean blood pressure was 128 ± 14/76 ± 9 mmHg and 31% of patients were treated for hypertension. Cholesterol, HDL and triglyceride levels were 204 ± 41, 49 ± 14 and 153 ± 80 mg/dL resp. and 10% of patients were on a statin, while 47% had an active smoking habit.
Over a mean follow-up period of 4.6 ± 3.6 y, MACE were registered in 10 patients (2 no NAFLD, 2 NAFL, 4 non-fibrotic NASH and 2 fibrotic NASH). NAFLD grade did not show predictive value with respect to the occurrence of MACE (p = 0.799). In contrast, baseline HbA1c level and the amount of visceral adipose tissue, as assessed by computed tomography, were found to be strong predictors [resp. HR 4.741 per % (95% CI 1.515–14.651), p = 0.007 and HR 1.010 per cm^2 (95% CI 1.003–1.017), p = 0.003]. Conversely, no predictive value was shown for cholesterol, HDL or triglyceride levels, nor for sex or smoking habit. Concerning the systolic blood pressure, although no significant predictive value was demonstrated with respect to MACE, significance was reached with respect to the subgroup of acute coronary syndrome patients (n = 7), comprising unstable angina and (N)STEMI [HR 1.058 per mmHg (95% CI 1.015–1.103), p = 0.008].
Conclusion: In this population of obese patients, NAFLD grade wasn't shown to be a significant predictor of the occurrence of MACE during a mean follow-up period of 4.6 y. Conversely, HbA1c level and the amount of visceral adipose tissue were strong predictors, underlining the importance of insulin resistance and central obesity in the development of cardiovascular disease.

THU036

Association of FIB-4 score with disease progression in real-world populations diagnosed with NAFLD/NASH or at risk of NASH in US clinical practice

Michelle Lai[1], Jeremy Broestl[2], Andrew Frick[2], Richard Haubrich[3], Bruce Koch[3], Scott Milligan[2], Macky Natha[3], Zobair Younossi[4,5], Nezam Afdhal[1]. *[1]Beth Israel Deaconess Medical Center (BIDMC), Boston, United States; [2]Trio Health Analytics, San Diego, United States; [3]Gilead Sciences, Inc., Foster City, United States; [4]Inova Fairfax Hospital, Center for Liver Diseases, Department of Medicine, Falls Church, United States; [5]Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States*
Email: scott.milligan@triohealth.com.

Background and Aims: Patients with NAFLD are at increased risk of developing advanced liver disease. Using data from clinical practices in the US, we assessed the risk of NASH, cirrhosis, decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), and liver transplant (LTX) in populations with diagnosed NAFLD or NASH or at risk of NASH based upon clinical criteria.
Method: Data obtained from a proprietary EMR database were limited to adult patients with diagnosed NAFLD without NASH (ICD10 K76 and ICD9 equivalent without evidence of NASH) or NASH (ICD10 K75.81) and without viral hepatitis or alcohol abuse. Index date was the first calculable FIB4 between Jul 2015 to Jun 2017 with >1 y history and >2 y follow-up or to death. Cox proportional models were used to determine hazard ratios (HR) between groups, stratified by age and BMI group status at index. All multiple regression models used complete-case analysis and included diagnosis group, FIB4, race/ethnicity, and all covariates with p < 0.200 by individual models.
Results: Of 30 million adult patients, 81108 met all study criteria with 22% (17582) NAFLD without NASH, 1% (914) NASH, and 77% (62612) RISK (without NAFLD or NASH diagnosis) at index. Mean follow up was 34.8 months (32.3 NASH, 32.4 NAFLD without NASH, 34.9 RISK). Significant differences were observed between 2+ diagnosis groups for age, gender, race, BMI, comorbidities, and laboratory measures HDL and LDL cholesterol, triglycerides, blood glucose, platelets, and FIB4 at index. The proportion of patients with FIB4 ≥ 2.67 was significantly higher for NASH (31%, 283) compared to NAFLD without NASH (12%, 2107, p < 0.001) which was significantly higher than RISK (11%, 6820, p < 0.001). Results from Cox regression models indicated FIB4 ≥ 2.67 had the highest or 2nd highest HR for all evaluated outcomes [Figure]. Other variables associated with high HR were: index NAFLD without NASH for NASH outcome, major cardiovascular events (MACE) for cirrhosis and DCC outcomes, index NASH for LTX outcome, index NASH and index NAFLD without NASH for HCC outcome, and MACE for all-cause death. HR for cirrhosis and DCC outcomes were not significantly different between NASH, NAFLD without NASH, and RISK covariates.



Conclusion: In this real-world study of patients with diagnosed NAFLD/NASH or at risk of NASH, FIB4 ≥ 2.67 was singularly associated with the development of advanced liver disease by all outcomes evaluated.

THU037

Association of FIB-4 score with major cardiovascular events (MACE) in real-world populations diagnosed with NASH or NAFLD in US clinical practice

Michelle Lai[1], Jeremy Broestl[2], Andrew Frick[2], Richard Haubrich[3], Bruce Koch[3], Scott Milligan[2], Macky Natha[3], Zobair Younossi[4,5], Nezam Afdhal[1]. *[1]Beth Israel Deaconess Medical Center (BIDMC), Boston, United States; [2]Trio Health Analytics, San Diego, United States; [3]Gilead Sciences, Inc., Foster City, United States; [4]Inova Fairfax Hospital, Center for Liver Diseases, Department of Medicine, Falls Church, United States; [5]Inova Health System, Betty and Guy Beatty Center for Integrated Research, Falls Church, United States*
Email: scott.milligan@triohealth.com.

Background and Aims: Patients with NAFLD have higher incidence of cardiovascular disease (CVD) which is considered the most common cause of mortality in these patients. Using data from US clinical practices, we assessed incidence of MACE as indicated by coronary artery bypass grafting, coronary revascularization, heart failure (HF), myocardial infarction (MI), stroke, and unstable angina in populations with diagnosed NAFLD or NASH.
Method: Data obtained from a proprietary EMR database were limited to adult patients with diagnosed NAFLD without NASH (ICD10 K76 and ICD9 equivalent without evidence of NASH) or NASH (ICD10 K75.81) and without viral hepatitis or alcohol abuse. Index date was the first calculable FIB4 between Jul 2015 to Jun 2017 with >1 y history and >2 y follow-up or to death. MACE assignments were based upon ICD, CPT, and HCPCS codes. Cox proportional models were used to determine hazard ratios (HR) between groups, stratified by age at index. All multiple regression models used complete-case analysis and included diagnosis group, FIB4, race/ethnicity, obesity, and all covariates with p < 0.200 by individual models.

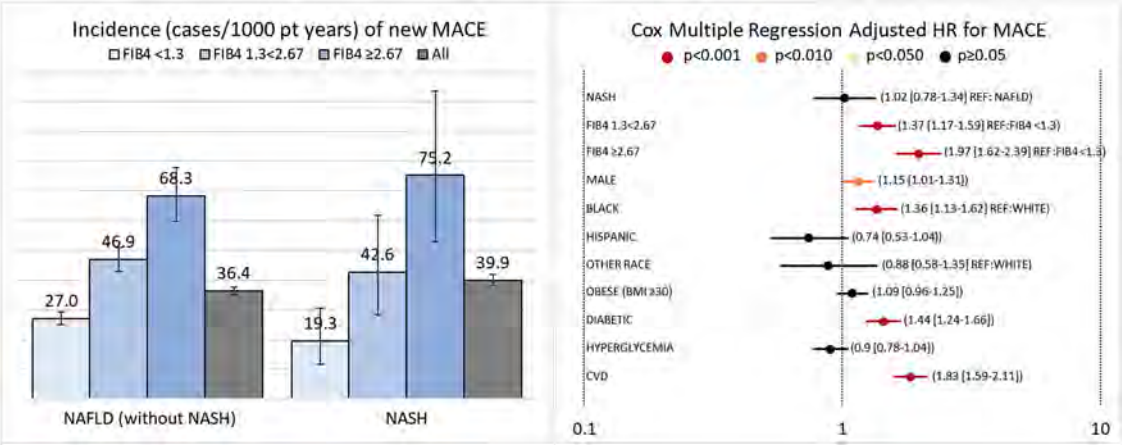


Figure: MACE incidence rates and 95% CI (left) and Cox multiple regression adjusted hazard ratios (right).

Results: Of 30 million patients, 18496 met all study criteria with 95% (17582) NAFLD without NASH and 5% (914) NASH at index. Mean follow up was 32.4 months. MACE prior to index was significantly higher for NAFLD without NASH (15%, 2620) vs NASH (13%, 118, $p < 0.001$). The most common MACE prior to index were HF (10%, 1785 NAFLD without NASH; 10%, 88 NASH) and MI (7%, 1258, NAFLD without NASH; 5%, 49 NASH). In 15758 patients without MACE prior to index, incidence rates (cases/1000 person-years) of any MACE were not significantly different between NAFLD without NASH (36.4) and NASH (39.9, $p = 0.430$). Within each diagnosis group, MACE incidence increased with increasing fibrosis. [Figure Left] Results from Cox multiple regression analysis indicated FIB4 ≥ 2.67 had the highest HR for MACE incidence followed by history of CVD, type II diabetes, and black. [Figure Right].
Conclusion: In this real-world study of patients with diagnosed NAFLD or NASH, the incidence of MACE increased with increasing fibrosis and FIB4 ≥ 2.67 was associated with the highest HR by Cox multiple regression.

THU038

Relevance of social support and severity of liver disease in biopsychosocial profiles of patients with non-alcoholic fatty liver disease

Jesús Funuyet-Salas[1], Agustín Martín-Rodríguez[1], María Ángeles Pérez-San-Gregorio[1], Manuel Romero Gomez[2,3].
[1]University of Seville, Personality, Assessment, and Psychological Treatments, Seville, Spain; [2]Virgen del Rocío University Hospital, Digestive Diseases Unit, Seville, Spain; [3]Institute of Biomedicine of Seville. University of Seville, SeLiver group, Seville, Spain
Email: jfunuyet1@us.es.

Background and Aims: It is unknown how social support and the progression of liver damage influence the biopsychosocial profile of patients with non-alcoholic fatty liver disease (NAFLD). Therefore, the objectives of this study were to: 1) Analyse whether there are differences between patients with absence and presence of non-alcoholic steatohepatitis (NASH) in quality of life, mental health and coping strategies, based on high or low perceived social support, 2) Analyse the influence of liver severity levels on these variables: NAFLD and NASH patients, with and without significant fibrosis (SF), considering the data on the general Spanish population for quality of life.
Method: Four hundred and ninety-two biopsy-proven NAFLD patients (290 men and 202 women, mean age 54.90 ± 11.74) were evaluated using the *SF-12, CLDQ-NAFLD, HADS, BDI-II, COPE-28* and *MSPSS* instruments. To respond to the first objective, four groups (G_1, n = 201, absence of NASH; G_2, n = 291, presence of NASH; G_3, n = 245, high social support; G_4, n = 247, low social support) were formed and a 2 × 2 factorial ANOVA was performed. To respond to the second objective, four groups were set up by severity, classified according to the steatosis, activity and fibrosis score (SAF score; G_a, n = 70, NAFLD without SF; G_b, n = 66, NASH with SF; G_c, n = 87, NAFLD with SF; G_d, n = 33, NASH without SF), which were compared using the Snedecor *F* test (post hoc comparisons: Tukey) and Welch *U* test (post hoc comparisons: Games-Howell), depending on whether homoscedasticity was met or not. The *t* test for independent samples was also applied to compare the quality of life (*SF-12*) with the general Spanish population. Cohen's *d* (for continuous variables) and *w* (for categorical variables) were used as indices of effect size.
Results: Interactive effects were found in vitality ($p = 0.047$), activity ($p = 0.005$), anxiety ($p = 0.044$) and denial ($p = 0.042$). Specifically, NASH patients (G_2) showed a higher-risk biopsychosocial profile when they perceived less social support. Furthermore, regardless of NASH, patients with low social support (G_4) had a lower quality of life, worse mental health and more maladaptive coping than those with high social support (G_3). NAFLD (G_c) and NASH (G_b) patients with SF showed lower quality of life than NAFLD (G_a) and NASH (G_d) patients without SF, or the general Spanish population. Patients with SF (G_b) also had worse mental health and coping than those without SF (G_a and G_d).
Conclusion: Regardless of the presence or absence of NASH, low perceived social support and SF were associated with a higher-risk biopsychosocial profile in NAFLD: worse quality of life and mental health, and more maladaptive coping. These findings suggest the relevance of integrating the psychological evaluation and intervention in protocols for following up on these patients.

THU040

NAFLD is a rising cause of HCC in women in a prospective populational cohort spanning 24 years (1990–2014)

Shuna Myers[1], Konstantinos Gkouvatsos[2], Laurent Spahr[2], Emiliano Giostra[2], Francesco Negro[2,3], Jean-Louis Frossard[2], Evelyne Fournier[4], Marie-Eve Bascaron[5], Isabelle Neyroud[4], Nicolas Goossens[2]. *[1]Université de Genève/Centre Médical Universitaire, Genève, Switzerland; [2]Hôpitaux Universitaires de Genève (HUG), Gastroenterology and Hepatology, Genève, Switzerland; [3]Hôpitaux Universitaires de Genève (HUG), Clinical Pathology, Genève, Switzerland; [4]Université de Genève/Centre Médical Universitaire, Geneva Cancer Registry, Genève, Switzerland; [5]Hôpitaux Universitaires de Genève (HUG), Division of Palliative Medicine, Genève, Switzerland*
Email: nicolas.goossens@hcuge.ch.

Background and Aims: There is conflicting data regarding the epidemiology and natural history of hepatocellular carcinoma (HCC) arising on the background of non-alcoholic fatty liver disease

(NAFLD-HCC). We aimed to assess the natural history and epidemiology of all patients with NAFLD-HCC between 1990 and 2014 in a well-defined population.

Method: All HCC cases resident in the canton of Geneva, Switzerland, diagnosed between 1990–2014 were identified from the prospective Geneva cancer registry and all data was manually checked and completed using Geneva university hospital electronic health records. NAFLD-HCC was diagnosed when specifically stated or when other causes of liver disease were excluded in the presence of type 2 diabetes, metabolic syndrome or obesity.

Results: 920 patients were diagnosed with HCC in the canton of Geneva between 1990–2014. Major aetiologies of underlying liver disease were alcohol (43.2%), hepatitis C and B viruses (20.7% and 9.1% respectively), and NAFLD (8.3%). The 76 NAFLD-HCC subjects were significantly older, had higher rates of obesity (46.6% vs 13.4%, $p < 0.001$), diabetes (73.0% vs 39.6%, $p < 0.001$) and were more commonly female (31.6% vs 18.6%, $p = 0.006$). The age-standardized incidence (ASI) of HCC increased between 1990–94 to 2010–14 from 11.6 to 12.8/100,000 in men and 1.8 to 3.3/100,000 in women. The proportion of NAFLD-HCC increased significantly in both sexes, but in particular in women from 0% in 1990–94 to 30% in 2010–14 (Figure).

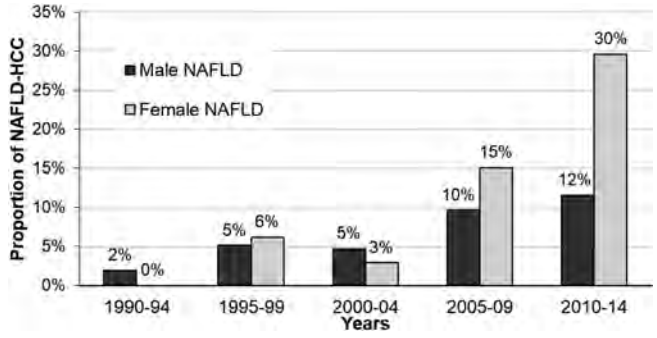

Figure: Proportion of NAFLD-HCC by sex between 1990–2014.

Conclusion: In a prospective populational cohort of HCC subjects spanning 24 years, NAFLD-HCC accounted for 8% of all HCCs. Compared to non-NAFLD-HCC, NAFLD-HCC patients were older, more comorbid and more frequently female. NAFLD is a rising cause of HCC, in particular in women. This study underlines the specific clinical characteristics of NAFLD-HCC, which will help to guide future recommendations and research.

THU041

Muscle fat infiltration in obese patients is associated with NAFLD related fibrosis severity - results from a prospective imaging study

Nicolas Lanthier[1,2], Sophie Hiel[3], Maxime Nachit[2], Rodriguez Julie[3], Jean-Paul Thissen[4], Pierre Trefois[5], Nathalie Delzenne[3]. *[1]Cliniques universitaires Saint-Luc, Service d'Hépato-Gastroentérologie, Brussels, Belgium; [2]Institut de Recherche Expérimentale et Clinique, UCLouvain, Laboratory of Gastroenterology and Hepatology, Brussels, Belgium; [3]Louvain Drug Research Institute, UCLouvain, Metabolism and Nutrition Research Group, Brussels, Belgium; [4]Institut de Recherche Expérimentale et Clinique, UCLouvain, Endocrinology, Diabetology, and Nutrition Department, Brussels, Belgium; [5]Cliniques universitaires Saint-Luc, Medical Imaging Department, Brussels, Belgium*
Email: nicolas.lanthier@uclouvain.be

Background and Aims: The association between NAFLD and visceral adipose tissue or sarcopenia has been reported, although results are discordant. The goal of this study is to analyze the spectrum of NAFLD among obese patients recruited prospectively and to detect clinical, biological and imaging data associated with steatosis or fibrosis.

Method: Baseline data of obese patients (BMI ≥ 30) randomized in a single center (Food4Gut study) were recorded. Transient elastography (TE) was done to quantify both liver steatosis by controlled attenuation parameter (CAP) measurement and liver fibrosis by liver stiffness measurement (LSM). Body composition was evaluated using bioelectrical impedance analysis. Subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT), muscle areas and muscle fat infiltration (MFI) were measured on CT-scan images at the third lumbar level.

Results: Fifty-two Caucasian patients (mean age: 50 years, 50% male, mean BMI 35.8) were included. TE was successful in 49 patients (94%). XL probe was used in 20 patients (38%). Mean LSM was low (6.5 kPa). Mean CAP result was high (324 dB/m) with the majority of the patients (73%) presenting severe steatosis (CAP ≥ 296 dB/m). 12 patients (24%) had advanced fibrosis defined by LSM ≥ 7.8 kPa (M probe) or ≥ 6.4 kPa (XL probe). Factors associated with severe steatosis and advanced fibrosis are summarized in the table. Interestingly, severe steatosis was associated with higher muscle quantity and severe fibrosis with a lower muscle density index, compatible with MFI. In a multivariate logistic regression analysis, MFI index was the strongest predictor of advanced liver fibrosis.

Conclusion: In summary, among obese patients, a high proportion of severe steatosis was diagnosed and advanced liver fibrosis was suspected in 24% of the patients. MFI provides a robust, skeletal muscle-specific characteristic linked to advanced fibrosis in NAFLD,

Table: (abstract: THU041)

	Parameter	Light-moderate steatosis	Severe steatosis	p-value	No fibrosis	Advanced fibrosis	p-value
Clinical parameters	Age (years)	49.2	50.1	NS	49.8	50.0	NS
	Weight (kg)	97.5	108.1	0.035	101.0	119.2	0.0035
	BMI (kg/m²)	34.3	36.5	NS	34.8	39.2	0.059

	Skeletal muscle index (cm²/m²)	52.9	61.9	0.028	57.6	65.1	0.054
	Whole muscle density index (UH/cm²)	0.208	0.185	NS	0.200	0.163	0.0051

suggesting a muscle-liver axis in the pathogenesis of NAFLD complications.

THU042

Exercise performance in patients with non-alcoholic steatohepatitis

Oliver Glass[1], Ying Wang, PhD[2], Stephanie Buir[2], Cynthia Guy[3], Manal Abdelmalek[2]. *[1]Duke University, Medicine, Durham, United States; [2]Duke University, Gastroenterology, Durham, United States; [3]Duke University, Pathology, Durham, United States*
Email: oliver.glass@duke.edu

Background and Aims: Prior studies indicate that those with nonalcoholic fatty liver disease (NAFLD) have poorer exercise capacity compared to age-matched controls. Moreover, cross-sectional data in those with NAFLD suggest an inverse correlation between disease severity and self-reported exercise intensity. The underlying contributors of poor exercise capacity in patients with NAFLD is unclear. Our aim was to evaluate exercise performance in patients with biopsy-proven nonalcoholic steatohepatitis (NASH).
Method: Patients with biopsy-proven NASH (n = 10), graded and staged according to the NASH Clinical Research Network grading and staging system, and controls (n = 11), those without a diagnosis of biopsy-proven NAFLD were recruited. Participants performed 10-intervals of vigorous-intensity interval training (30 seconds exercise, 60 seconds rest) on a Concept2 indoor rowing machine at 80–90% of predicted maximum heart rate (220-Age). Intensity was recorded after each interval using the BORG scale of perceived exertion. Age, BMI, distance, power output, and $BORG_{peak}$ were compared between groups using Exact-Wilcoxon rank sum test or Fisher's exact test. Generalized linear modeling was used to adjust for age, gender, and BMI.
Results: Mean ages of participants were 51.0 ± 14.9 in the NASH group and 42.4 ± 13.6 in controls, $p > 0.05$. BMI was higher in the NASH group (32.5 ± 3.3) compared to controls (26.6 ± 4.6). Mean power output (watts) over the 10 exercise intervals was significantly lower in the NASH group (103.6 ± 30.4) compared to controls (231.0 ± 140.4), $p < 0.01$. Total distance rowed (meters) after 10-intervals was also lower in the NASH group (987.2 ± 115.7) compared to controls (1266.6 ± 259.4), $p < 0.01$. $BORG_{peak}$ was lower in the NASH group (14 ± 1) compared to controls (17 ± 2), $p < 0.01$. After adjusting for age, gender, and BMI the difference in mean power output, total distance, and $BORG_{peak}$ all remained significant, $p < 0.01$.
Conclusion: Compared to controls, those with NASH have lower exercise power output, rowing distance, and perceived exercise intensity. Failure to reach perceived exercise intensity beyond steady state (BORG ≥ 17) may serve as a potential biomarker for poor metabolic function as well as an underlying contributor of poor exercise performance in those with NASH.

THU044

Obesity and alcohol intake modify the impact of genetic variants on the risk for incident liver disease in the general population

Panu Luukkonen[1,2,3], Martti Färkkilä[4], Pauli Puukka[5], Antti Jula[5], Veikko Salomaa[5], Satu Männistö[5], Annamari Lundqvist[5], Liisa Valsta[5], Markus Perola[5], Fredrik Åberg[6,7]. *[1]Yale University, Department of Internal Medicine, New Haven, CT, USA; [2]University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [3]Minerva Foundation Institute for Medical Research, Helsinki, Finland; [4]Clinic of Gastroenterology, Helsinki University and Helsinki University Hospital, Helsinki, Finland; [5]Finnish Institute for Health and Welfare, Finland; [6]Transplantation and Liver Surgery Clinic, Helsinki University Hospital, Helsinki University, Helsinki, Finland; [7]The Transplant Institute, Sahlgrenska University Hospital, Gothenburg, Sweden*
Email: fredrik.aberg@helsinki.fi

Background and Aims: Genetic variants and modifiable lifestyle factors including abdominal obesity and alcohol intake are risk factors for liver disease. We studied the interaction between genetic variants, abdominal obesity and alcohol intake for incident advanced liver disease (ILD).
Method: Our study included 32,942 persons (mean age 50 yrs, 47% men) who participated in health-examination surveys (FINRISK1992–2012 or Health 2000) with available data on alcohol intake (median 26.0 g/wk), waist-hip ratio (WHR, mean 0.89) and genotypes associated with liver disease in PNPLA3, TM6SF2, MBOAT7, SERPINA1 and HFE. A genetic risk score (GRS) was calculated as the sum of these risk alleles. Data were linked with national health registers for liver-related outcomes (hospitalizations, malignancies, and death). Exclusions were baseline clinical liver disease or viral hepatitis. Analyses were adjusted for age, WHR and alcohol intake.
Results: TM6SF2 rs58542926 ($p < 0.05$) and SERPINA1 rs28929474 ($p < 0.02$) genotypes interacted significantly with WHR. Among carriers of these risk variants, the cumulative incidence of liver disease was significantly higher than non-carriers when WHR exceeded ~1.0, but not below WHR 1.0. The GRS showed a dose-

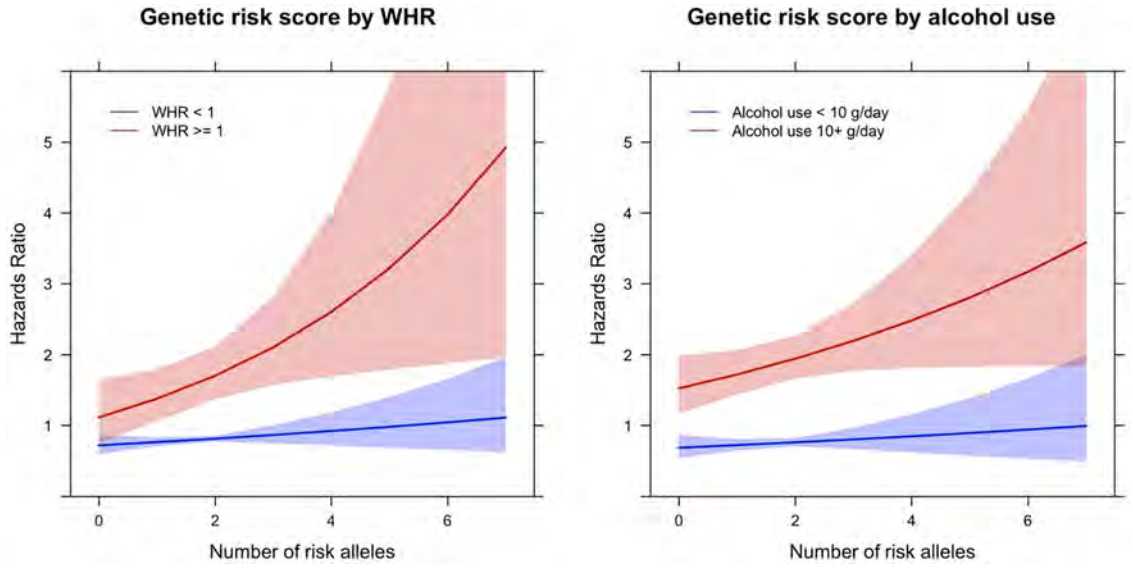

Figure: (abstract: THU044)

dependent risk increase for ILD with a 2.5-fold increase in subjects with ≥ 4 risk alleles (22% of subjects) as compared to non-carriers (14% of subjects). WHR modified this relationship, as in subjects with WHR above 1.0 (15% of subjects) the carriers of >4 risk alleles had over 3-fold higher liver disease risk as compared to non-carriers (Figure). In contrast, in subjects with WHR below 1.0 (85% of subjects), the GRS had no effect on ILD. In addition, alcohol intake modified the relationship between GRS and ILD, as in subjects drinking above 10 g/d (28% of subjects), carriers of >4 risk alleles had over 3-fold higher ILD risk compared to non-carriers (Figure). In contrast, in subjects drinking below 10 g/d (72% of subjects), the GRS had no effect on ILD.

Conclusion: The impact of several genetic variants on the risk of ILD is markedly modified by abdominal obesity and alcohol intake. Among lean abstainers and light drinkers, the common genetic risk factors do not substantially increase the risk of liver disease, which highlights the importance of lifestyle modification in prevention of advanced liver disease.

THU045

Non-alcoholic steatohepatitis is associated with liver mitochondrial DNA damage and genome instability of cytochrome b, a component of the cellular respirasome supercomplex

Carlos Pirola[1], Martin Garaycoechea[2], Diego Flichman[3], Gustavo Castaño[4], Silvia Sookoian[1,5]. [1]*Instituto de Investigaciones Medicas (IDIM), Genetica y Biologia Molecular de Enfermedades Complejas, Ciudad Autonoma de Buenos Aires, Argentina;* [2]*Hospital El Cruce – Nestor Kirchner, Departamento de Cirugia, Florencio Varela, Argentina;* [3]*Facultad de Farmacia y Bioquimica, Departamento de Virologia, Ciudad Autonoma de Buenos Aires, Argentina;* [4]*Dr. Abel Zubizarreta Hospital, Departamento de Medicina Interna, Ciudad Autonoma de Buenos Aires, Argentina;* [5]*Instituto de Investigaciones Medicas (IDIM), Hepatologia Clinica y Molecular, Ciudad Autonoma de Buenos Aires, Argentina*
Email: pirola.carlos@conicet.gov.ar

Background and Aims: The progression of nonalcoholic fatty liver disease (NAFLD) into severe histological forms is paralleled by the occurrence of complex molecular processes. Damaged liver mitochondria and mitochondrial respiratory chain dysfunction are hallmark features of advanced disease. Mitochondrially encoded cytochrome B (cytochrome b, *MT-CYB*) —a member of the oxidative phosphorylation system, is a key component of the respirasome supercomplex. Here, we hypothesized that NAFLD severity is associated with liver tissue cytochrome b mutations and damaged mitochondrial DNA (mtDNA).

Method: We included 252 liver specimens of NAFLD patients–from mild to severe histological disease, which were linked to clinical and biochemical information. We sequenced the *MT-CYB* gene and we used a semi-long run real-time PCR method to detect damaged mtDNA. HPLC–mass spectrometry was used to explore circulating level of Krebs cycle metabolites in a sub-sample of patients.

Results: Compared to simple steatosis, the liver of patients with nonalcoholic steatohepatitis (NASH) exhibits a high level of *MT-CYB* sequence variation, from 12.1 to 15.6 substitutions per 10^3 bp, respectively (p = 5.5e – 10). The burden of liver *MT-CYB* variants was associated with changes in the level of metabolites, including alpha-ketoglutarate, branched-chain amino acids, glutamate, and hydroxyglutaric acid (Figure). Liver mtDNA damage at the cytochrome b region occurred more often in patients with advanced disease (p = 1e – 3) and high scores of lobular inflammation (p = 6.5e – 3). Nevertheless, the increase of damage level was a distinctive feature of patients with severe obesity (p = 7.9e – 5).

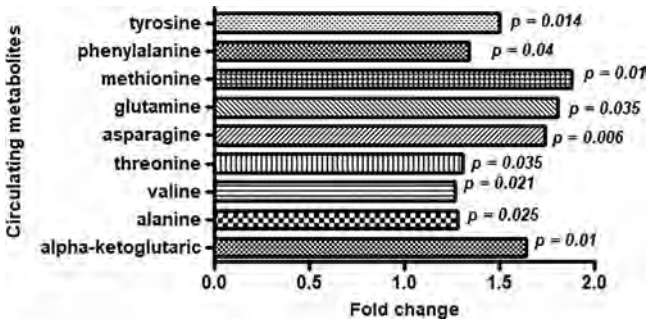

Figure: **C**hanges in the level of metabolites in NAFLD patients with a burden of more than 10 genetic variants in the *MT-CYB* with respect to those with a lower number of polymorphic sites at the locus.

Conclusion: NASH is associated with liver mtDNA damage, in particular, genetic alterations of cytochrome b, an important component of the cellular respirasome

THU046

Barriers and motivators to engaging in physical activity in individuals with NAFLD: implications for physical activity adherence

Philip O'Gorman[1], Sara Naimimohasses[2,3], Ann Monaghan[1], Marie McGrath[2], John Gormley[1], Suzanne Norris[2,3]. [1]*The University of Dublin, Trinity College, Discipline of Physiotherapy, Ireland;* [2]*St. James's Hospital, Department of Hepatology, Dublin, Ireland;* [3]*Trinity College Dublin, Department of Clinical Medicine, Ireland*
Email: pogorma@tcd.ie

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the leading cause of chronic liver disease worldwide. In the absence of approved pharmacological agents, lifestyle modifications including physical activity (PA) and diet are the primary treatment interventions. Studies report that although individuals with NAFLD engage in less PA compared to matched controls, they understand the benefits of PA but lack the confidence to perform it. To date, there is a limited understanding of the barriers and motivators individuals with NAFLD experience in performing PA. Therefore, the objective of this study was to qualitatively assess the perceived barriers and motivators to engaging in PA in a cohort of individuals with NAFLD.

Method: 108 individuals (median age = 55 ± 15 years, 53% male) with biopsy and/or FibroScan proven NAFLD completed a series of questionnaires inclusive of the: Barriers to Becoming Active Quiz (BBAQ), Motives for Physical Activity Measure (MPAM), Rapid Assessment of Physical Activity (RAPA) questionnaire and a participant demographic questionnaire. Scores from the BBAQ and MPAM were separated into specific barrier and motivator domains. Barrier domains were further categorised as a significant barrier if a score of ≥ 5/9 was reported. Individuals were classed as physically active or inactive based on responses from the RAPA. Additionally, binary logistic regression was performed in order to assess potential predictors for self-reporting as physically active.

Results: Of the 108 individuals who completed the questionnaires, 23% correctly identified the recommended WHO PA guidelines and 41% of the population self-reported as active. Lack of willpower, lack of energy and lack of time were the most frequently cited barrier domains to engaging in PA with 59%, 40% and 39% of the sample reporting them as significant barriers, respectively. Maintaining one's health and fitness was the most cited motivator domain to engaging in PA. The regression analysis revealed that lack of willpower (OR: 1.367, 95% CI: 1.025–1.823, p = 0.033), maintaining one's health and fitness (OR: 2.421, 95% CI: 1.190–4.926, p = 0.015) and reporting ≥ three significant barriers (OR: 6.369, CI: 2.058–19.608, p = 0.001) represented significant, independent predictors of reporting as physically active.

Conclusion: This study highlights the significant barriers and motivators to engaging in PA reported by NAFLD patients and

additionally, the lack of awareness of the PA guidelines. Lack of willpower and maintaining one's health and fitness were significant predictors of individuals reporting as physically inactive which may represent areas that could be addressed to increase PA participation. Barriers and motivators to engaging in PA should be identified at the individual level to create a personalised approach for PA adherence in order to encourage lifelong adherence to the therapy.

Email: kathryn.kersey@gilead.com

Background and Aims: Approval of new therapies for NASH is currently based on histologic endpoints. However, liver biopsy is invasive and prone to potentially serious complications. Our aim was to describe the incidence of serious adverse events (SAEs) resulting from study-mandated liver biopsies in two phase 3 trials including patients with advanced fibrosis due to NASH.

Method: The phase 3 STELLAR trials enrolled patients with NASH and bridging fibrosis (F3, NCT03053050) or compensated cirrhosis (F4, NCT03053063) and platelets $\geq 100 \times 10^3/\mu L$. Patients underwent liver biopsy during screening to determine eligibility (in the absence of a qualifying historical biopsy) and after 48 weeks of treatment to assess the primary histological endpoint. The incidence and type of biopsy-related SAEs were described, and associations with patient characteristics (eg, demographics, diabetes mellitus, fibrosis stage, platelets, INR, MELD) and site biopsy volume (1–5, 6–12, >12 biopsies during screening) were evaluated.

Results: In total, 3955 biopsies (screening, n = 2362; on treatment, n = 1593) were performed in 2970 patients. Overall, liver biopsy-related SAEs were reported in 28 patients (screening, n = 15; on treatment, n = 13), corresponding to an incidence of 0.7% (95% CI 0.5, 1.0). All but one of these patients required hospitalization and two required blood transfusions, but no deaths were reported. SAEs due to pain, bleeding, and other complications were reported in 0.4% (95% CI 0.2, 0.6), 0.3% (95% CI 0.1, 0.5), and 0.3% (95% CI 0.2, 0.5) of biopsies, respectively. In cases with evaluable fibrosis stage, the incidence of biopsy-related SAEs was 1.2% (95% CI 0.7, 1.8) with biopsies showing cirrhosis compared with 0.4% (95% CI 0.2, 0.7) for those without cirrhosis (p = 0.004). While the incidences of bleeding (0.2% in both groups) and other complications (0.5% for cirrhosis vs 0.2% for non-cirrhosis) did not differ significantly between groups, pain was more frequent with biopsies showing cirrhosis (0.8% vs 0.1% for non-cirrhosis; p = 0.0007). No significant associations were identified between biopsy-related SAEs and other patient characteristics (age, sex, diabetes, BMI, INR, platelets, MELD) or site biopsy volume, either at screening or on treatment.

Conclusion: In these large phase 3 trials, ~1 in 140 study-mandated liver biopsies was associated with an SAE; pre-biopsy patient characteristics and site biopsy volume were not predictive of complications. Although generally safe and well tolerated, these SAEs, as well as the availability of accurate and reliable noninvasive tests (NITs), underscore the importance of transitioning towards NITs to aid patient identification and stratification, and as surrogate endpoints to evaluate treatment response in NASH clinical trials.

THU048

The burden of disease associated with non-alcoholic steatohepatitis patients under standard of care

Raluca Pais[1,2,3], William Green[4], Stuart Mealing[5], Aldo Trylesinski[6], Sandrine Cure[6], Heather Davies[5]. *[1]Hôpital Pitié-Salpétrière; [2]Inserm, Paris, France; [3]Institute Of Cardiometabolism And Nutrition, Paris, France; [4]York Health Economics Consortium (YHEC), United Kingdom; [5]York Health Economics Consortium, York, United Kingdom; [6]Intercept Pharmaceuticals, Inc.*
Email: ralu_pais@yahoo.com

Background and Aims: NASH is a chronic disease that can progress to end-stage liver disease (ESLD). Patients with advanced fibrosis due to NASH are at greater risk for serious liver-related consequences, including decompensated cirrhosis (DCC) & hepatocellular carcinoma (HCC). The aim was to evaluate long-term clinical outcomes for patients with advanced fibrosis without cirrhosis due to NASH receiving current standard of care (SOC) and assess the impact of incorporating data from the simtuzumab trials.

Method: A Markov-model was developed to predict the long-term outcomes of 10,000 hypothetical NASH F3 subjects (median age 55) by following progression across all fibrosis stages and ESLD. Data from the literature on natural disease progression were applied. Firstly, from Harrison S. (2018) who reported outcomes from two simtuzumab trials [1]. Secondly, data reported by Singh S. (2015), which quantified the fibrosis progression rates based on a meta-analysis of natural history studies [2]. This allowed a comparison of outcomes with a combination of both datasets vs. outcomes with data from Singh S. only. Probabilistic sensitivity analysis was undertaken.

Results: Over lifetime, the model estimated that 79.5% & 28.2% of patients progressed to compensated cirrhosis (CC) and DCC respectively when including simtuzumab data. Alternatively, values of 74.4% & 25.1% were generated using Singh S. alone. Similarly, of the 10,000 F3 patient cohort, an additional 255 patients progressed to HCC and 120 liver transplants were estimated after including simtuzumab data. The cohort based on the simtuzumab analysis also lived shorter lives with mean total life years/patient of 14.14 years vs. 15.44 for the Singh analysis. The shorter lifespan was largely due to an increase in liver-related mortality with 49.2% of patients dying due to a liver-related event.

Conclusion: Both analyses indicate that, with SOC, people with advanced fibrosis without cirrhosis due to NASH have a substantial risk of progressing to ESLD (i.e. 30% DCC & 10% HCC respectively) over lifetime. Including simtuzumab data resulted in faster disease progression with more ESLD events predicted to occur. Compared to Singh S. only scenario based on a small numbers of F3 and CC, the analysis based on data from Harrison S. should provide a more robust long-term prediction of outcomes for NASH patients.

Insulin secretion is an independent predictor of hepatic ballooning in non-diabetic subjects with non-alcoholic fatty liver disease

Ramy Younes[1], Chiara Rosso[1], Gian Paolo Caviglia[1], Angelo Armandi[1], Antonella Olivero[1], Maria Lorena Abate[1], Elisabetta Bugianesi[1].
[1]*University of Turin, Division of Gastroenterology, Dept. of Medical Sciences, Turin, Italy*
Email: ramy.younes@unito.it

Background and Aims: The onset and progression of liver damage in Non-Alcoholic Fatty Liver Disease (NAFLD) is tightly associated with insulin resistance (IR) and secondary hyperinsulinaemia. Typically, NAFLD patients showed higher serum levels of both insulin and C-peptide (CP). We aimed to compare fasting IR indices based on insulin and CP and their ability to predict histological features of NASH in a cohort of non-diabetic subjects with biopsy proven NAFLD.
Method: We studied 119 subjects with histological diagnosis of NAFLD (mean age 43 y). Plasma CP was assessed by chemiluminescence assay. HOMA-IR was calculated as [(fasting glucose X fating insulin)/405]; HOMA-IR by CP was calculated replacing insulin with CP in the HOMA-IR formula; CP index (CPi), reflecting beta-cell function thus insulin secretion, was calculated as [(100*CP)/fasting glucose]. Histology was scored according to the SAF score.
Results: Insulin and CP levels significantly increased according to lobular inflammation ($p = 0.013$ and $p = 0.023$, respectively) and hepatic steatosis ($p = 0.046$ and $p = 0.026$, respectively) but only CP showed a stepwise increase according to ballooning ($p = 0.031$) and fibrosis ($p = 0.012$). HOMA-IR by insulin did not significantly increase according to the histological features of NASH while both HOMA-IR by CP and CPi were significantly higher in patients with hepatic ballooning compared to those without (0.54 ± 0.34 vs 0.35 ± 0.16, $p = 0.007$ and 2.80 ± 1.94 vs 1.82 ± 0.86, $p = 0.015$, respectively). At univariate logistic regression analysis, HOMA-IR by CP, but not HOMA-IR by insulin, was significantly associated with advanced fibrosis ($F \geq 2$) (OR = 4.1, 95% CI = 1.1–14.4, $p = 0.031$) and with the presence of ballooning (OR = 23.4, 95% CI = 2.3–233.3, $p = 0.007$). Moreover, CPi was significantly associated with the presence of ballooning (OR = 1.8, 95% CI = 1.2–2.9, $p = 0.009$). After multivariable regression analysis adjusted for the major confounding variables, BMI was significantly associated with $F \geq 2$ (OR = 1.1, 95% CI = 1.0–1.2, $p = 0.024$) while both HOMA-IR by CP and CPi were associated with the presence of ballooning (OR = 18.9, 95% CI = 1.6–217.7, $p = 0.018$ and OR = 1.7, 95% CI = 1.1–2.9, $p = 0.023$, respectively).
Conclusion: In non-diabetic patients with NAFLD, fasting IR indices derived from CP levels were closely related to hepatic ballooning suggesting the importance of insulin secretion in the onset and progression of liver disease.

Email: rosalombardi@hotmail.it

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) may silently progress to advanced fibrosis and cirrhosis in patients with type 2 diabetes (T2DM). In these patients histologic liver fibrosis as well as fibrosis detected by FibroScan® has been related to both liver-related complications and diabetic vascular complications. Since liver biopsy and FibroScan® are not easily available in routine diabetes care, we evaluated whether advanced liver fibrosis, assessed by NAFLD fibrosis score (NFS), correlates with chronic vascular complications in patients with T2DM.
Method: 394 outpatients with T2DM consecutively attending five Italian diabetes centers underwent liver ultrasonography (US) and an extensive evaluation of macro-/micro-vascular diabetic complications. In those with US-detected NAFLD, liver fibrosis was evaluated by both FibroScan® and NFS.
Results: Steatosis by US was present in 351 (89%) patients. Almost all patients (96%) were treated with hypoglycaemic drugs, 58% had at least one chronic vascular complication, 19% a macrovascular complication (myocardial infarction and/or ischemic stroke) and 32% a microvascular one (24% chronic kidney disease; 16% retinopathy; 6% peripheral neuropathy). Prevalence of advanced fibrosis assessed by either FibroScan® (LSM ≥ 8.7/7.2 kPa for the M/XL probe) or NFS (≥ 0.676) was 14% and 18% respectively, with acceptable concordance between the two methods. Prevalence of myocardial infarction and/or ischemic stroke and peripheral neuropathy was higher in patients with NFS ≥ 0.676 compared to those with NFS <0.676 (31% vs. 15%, $p = 0.007$; 19% vs. 3%, $p < 0.001$). NFS was significantly associated with cardiovascular events and peripheral neuropathy (adjusted-OR 2.2, 95%CI 1.0–4.9; $p = 0.05$ and adjusted-OR 5.5, 95%CI 1.7–18.4; $p = 0.005$, respectively), even after adjustment for centre, sex, smoking, haemoglobin A1c, duration of diabetes, hypertension and use of statins or ACE-I/ARBs (age and BMI were not also adjusted for because they were included in the NFS). Similarly, FibroScan®-measured LSM was also independently associated with cardiovascular complications and peripheral neuropathy.
Conclusion: The NFS, which is an easy and affordable non-invasive test of advanced liver fibrosis, may help clinicians in primary care in identifying patients with T2DM and NAFLD at higher risk of having both hepatic and chronic vascular complications, possibly applying more intensive preventive and therapeutic strategies.

Clinical and economic impact of non-alcoholic fatty liver disease in Spain

Salvador Augustin[1], Rocío Aller[2], Javier Crespo[3], José Luis Calleja Panero[4], Juan Turnés[5], Manuel Romero Gomez[6], Antoni Sicras[7]. [1]*Hospital Universitario Valle Hebrón, Barcelona, Spain;* [2]*Hospital Clínico Universitario, Valladolid, Valladolid, Spain;* [3]*Hospital Universitario Marqués de Valdecilla, Santander, Spain;* [4]*Hospital Universitario Puerta de Hierro, Madrid, Spain;* [5]*Hospital Montecelo, Pontevedra, Spain;* [6]*Hospital Universitario Virgen del Rocío, Sevilla, Spain;* [7]*Health Economics & Outcomes Research, Real Life Data, Barcelona, Spain*
Email: antoni.sicras@rlifedata.com

Background and Aims: NAFLD/NASH is a growing concern due to its increased prevalence and incidence in Spain. However, Spain specific data is lacking. This study aims to determine the clinical (progression of fibrosis) and economic (resource use and health costs) consequences of non-alcoholic fatty liver in usual clinical practice in Spain.
Method: Observational, retrospective study based on the review of medical records of patients aged ≥ 18 years who required care in 2017–2018. According to the stage of fibrosis (calculation method: FIB-4), patients were classified into 2 groups: a) F0–F2 and b) F3–F4

(advanced fibrosis). The follow-up was 1 year. Main measures: comorbidity, concomitant medication and resource use and costs. The results were analyzed using multivariate analysis, with a value of $p < 0.05$ considered significant.

Results: 8,151 patients were recruited with a mean age of 61.1 years and 51.5% were male. By groups: a) mild fibrosis n = 7,127 (87.4%) and b) advanced fibrosis n = 1,024 (12.6%; 6.8% with liver cirrhosis). The most frequent comorbidities were dyslipidemia (63%), obesity (52%), hypertension (52%) and diabetes (35%). There was a mean of 2.1 medications per patient. Patients with advanced fibrosis (F3–F4) had a higher mean concomitant medication (2.5 vs. 2.1; $p < 0.001$) and AST/ALT ratio (1.1 vs. 0.8; $p < 0.001$). The mean cost (patient-year) of subjects with advanced fibrosis corrected by covariates was higher (€ 1,812 vs. € 1,128, $p < 0.001$). Patients with diabetes were older and had higher morbidity, concomitant medication, fibrosis stage and total costs.

Conclusion: Patients with advanced fibrosis were associated with high level of comorbidity and concomitant medication, resulting in high health costs for the Spanish National Health System. Patients with diabetes have more comorbidities and severe liver disease, impacting on the costs.

Europe's largest meta-analysis on the prevalence of non-alcoholic fatty liver disease, non-alcoholic steatohepatitis and advanced fibrosis (F3-F4)

Salvatore Petta[1], Hannes Hagström[2], Andreas Geier[3], Vlad Ratziu[4], Llorenç Caballeria[5], Carmen Expósito[6], Rosario Hernández[7], Hans Blokzijl[8], Robert De Knegt[9], Diogo Ferrinho[10], Ioanna Ntalla[10], Alan Smith[10], Heribert Ramroth[10], Philip N Newsome[11]. *[1]Promise, Policlinico Universitario Paolo Giaccone, Section of Gastroenterology and Hepatology, Palermo, Italy; [2]Karolinska University Hospital, Centre for Digestive Diseases, Division of Hepatology, Stockholm, Sweden; [3]University Hospital Würzburg, Division of Hepatology, Department of Internal Medicine II, Würzburg, Germany; [4]Sorbonne Université, Hôpital Pitié Salpêtrière, ICAN, Paris, France; [5]Primary Healthcare Research Support Unit Metropolitana Nord, Primary Healthcare Centre Premià de Mar, Barcelona, Spain; [6]Fundació Institut Universitari per a la recerca a l'Atenció Primària de Salut Jordi Gol i Gurina, Unitat de Suport a la Recerca Metropolitana Nord, Mataró, Spain; [7]Institut Catalana de la Salut (ICS), Centre d'Assistència Primària La Marina, Barcelona, Spain; [8]University Medical Center Groningen, Department of Gastroenterology and Hepatology, Groningen, Netherlands; [9]Erasmus MC University Medical Centre, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [10]Gilead Sciences Europe, Ltd, Hayes, United Kingdom; [11]11National Institute for Health Research Biomedical Research Centre at University Hospitals Birmingham, Centre for Liver and Gastrointestinal Research, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom*
Email: diogo.ferrinho@gilead.com

Background and Aims: The increasing prevalence of nonalcoholic fatty liver disease (NAFLD) fuelled by obesity and diabetes epidemics has become a significant health burden. Information on the prevalence of the disease across Europe is limited. Previous systematic reviews focused on scarce data published up to 2015. Our aim was to estimate the European prevalence of NAFLD, nonalcoholic steatohepatitis (NASH), and advanced fibrosis (stage F3–F4) from more recently published data.

Method: A systematic review identifying observational studies with data on NAFLD, NASH and advanced fibrosis prevalence conducted in Europe was undertaken according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. PubMed was searched for studies published until October 2019. Strict exclusion criteria were applied to eliminate the effect of confounding factors on prevalence estimates. Studies on individuals with alcohol abuse, on liver disease patients related to other etiologies, and studies exclusively enrolling morbidly obese and diabetic patients were

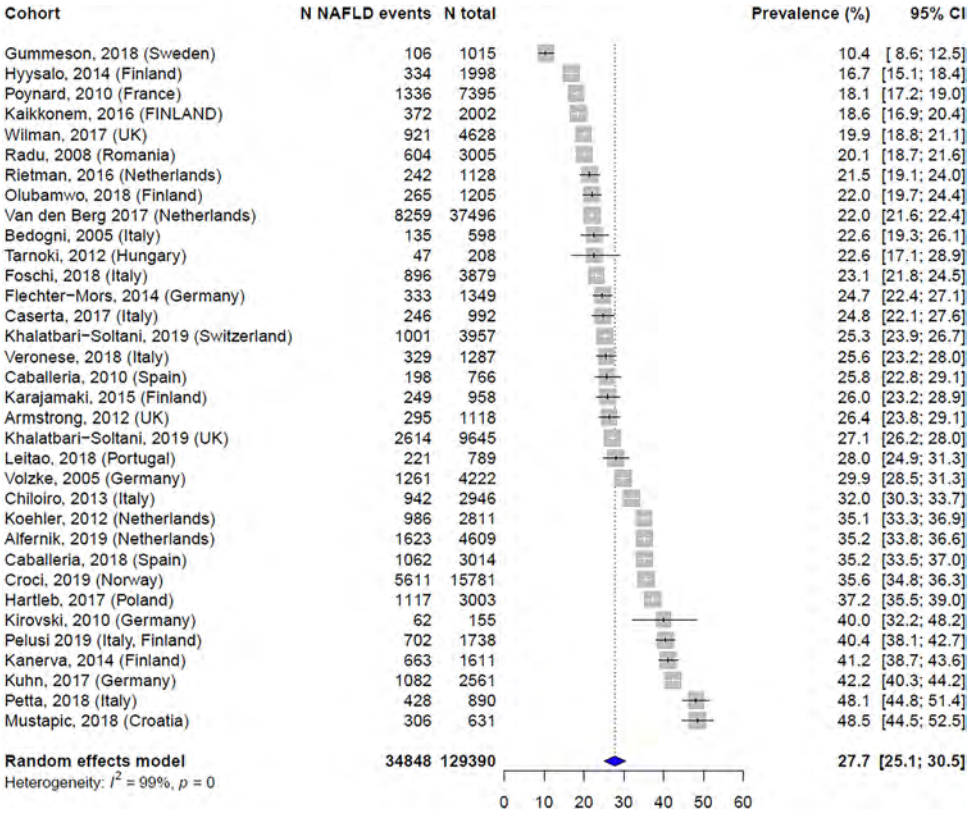

Figure: (abstract: THU053): Forest plot of NAFLD prevalence in European studies.

excluded. We used random effects model meta-analysis to estimate prevalence (95% confidence interval [CI]).
Results: Out of 588 studies identified, 33 studies from 15 European countries met the inclusion criteria comprising 129,390 individuals (>18 years old), of whom 34,848 had NAFLD. The overall NAFLD prevalence estimated in the random effects meta-analysis model was 27.7% (95% CI 25.1–30.5) [Fig. 1]. An estimated 64.1% (95% CI 51.4–75.0) of the biopsy-proven 4,696 NAFLD patients (12 studies) had NASH. Ten studies reported information regarding advanced fibrosis among NAFLD patients. The overall advanced fibrosis prevalence among these patients was 12.8% (95% CI 9.8–16.5). Subgroup meta-analyses by age group, sex, and diagnostic method as well as meta-regression analyses to investigate heterogeneity are ongoing and will be reported.
Conclusion: To our knowledge this is the largest meta-analysis to date providing an overview of the burden of NAFLD, NASH and advanced fibrosis in Europe. These data add to the evidence base and may be particularly useful in European settings that currently lack data.

THU054

Patients receiving liver transplant for NASH cirrhosis have greater muscle loss compared to transplant and non-transplant control

Samarth Patel[1], Mikael Forsgren[2], Emily Lee[3], Emily Zhang[3], Jose Hernandez Roman[4], Mohammad Bilal Siddiqui[4], Danielle Kirkman[3], Chandra Bhati[4], Mohammad Siddiqui[4]. *[1]McGuire Veterans Hospital, Richmond, United States; [2]Linköping University, Sweden; [3]Virginia Commonwealth University, Richmond, United States; [4]VCU Medical Center, Richmond, United States*
Email: samarth.patel@vcuhealth.org

Background and Aims: Skeletal muscle loss is common in patients with cirrhosis and associated with increased morbidity and mortality following liver transplantation (LT). Since most patients receiving LT in the 5th and 6th decade of life, it is unclear if the muscle loss seen after LT is age related or specifically due to LT. Furthermore, NASH, a rapidly growing indication for LT, is associated with pre-LT muscle loss even in the absence of cirrhosis and it is unclear if this worsens following LT. Thus, to overcome these significant limitations we conducted the following prospective study to better define the impact of LT and NASH on skeletal muscle loss and body compartments.
Method: Adult LT recipients (N = 21) were prospectively enrolled at author's institution and underwent body composition MRI. Patients with active malignancy, heart failure, ESRD on dialysis, multi-visceral transplant and rejection within 6 months of enrolment were excluded. Body compartments quantified included: visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), muscle volume, fat free muscle volume (FFMV), muscle fat infiltration (MFI). All these measurements were subsequently standardized to patient height (i.e. VATi, SATi, FFMVi, etc.). To determine the impact of LT on body compartments, LT recipients were matched 1:150 to virtual control group (VCG) from UK imaging biobank with regards to age, gender, and body mass index (BMI) and the data is reported as the number of standard deviations (SD) from the mean of the VCG. The analysis then was stratified to LT for NASH vs. non-NASH etiologies of cirrhosis.
Results: The study included 21 patients (n = 11 for NASH and n = 10 for non-NASH), mean age 61 ± 11 years and mean BMI 32 ± 7 kg/m^2. The subjects with NASH were more likely to have cardiometabolic disease such as obesity, diabetes and dyslipidemia (P < 0.01 for NASH vs. non-NASH). The median time from LT was 2 (IQR 1, 7) years. Compared to VCG, patients transplanted for NASH cirrhosis had higher VATi (3.23 vs. 2.52; P < 0.01) and lower FFMVi (−0.98 vs. 0.03, P = 0.016). (Figure 1) Patients transplanted for non-NASH cirrhosis had similar VATi and FFMVi when compared to VCG cohort. Interestingly, in LT recipients patients transplanted for NASH cirrhosis were likely to have higher VATi (3.23 vs. 0.85; P = 0.01), SATi (5.23 vs. 2.63; P < 0.01), MFI (3.33% vs. −1.92; P = 0.02). In correlative analysis, post-LT factors associated with reduced FFMVi were increased BMI. Similarly, diabetes and increased BMI were associated with FMI in LT recipients.
Conclusion: LT recipients, particularly, those transplanted for NASH cirrhosis are at elevated risk of skeletal muscle loss, which correlates with cardiometabolic risk. This decrease in muscle mass and increase adiposity (i.e. sarcopenic obesity) likely contributes to increased cardiometabolic morbidity and mortality in LT.

THU055

A national cross-sectional survey of health-related quality of life in Chinese patients with non-alcoholic fatty liver disease

Rui Huang[1], Jiangao Fan[2], Junping Shi[3], Yimin Mao[3], Bingyuan Wang[4], Jingmin Zhao[5], Lungen Lu[6], Bihui Zhong[7], Zhengsheng Zou[5], Youqing Xu[8], Yinong Ye[9], Longgen Liu[10], Lianjie Lin[11], Jianping Li[12], Lai Wei[13], Huiying Rao[14]. *[1]Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory for Hepatitis C and Immunotherapy for Liver Disease, Beijing, China; [2]Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]The Affiliated Hospital of Hangzhou Normal University, Hangzhou, China; [4]The First Hospital of China Medical University, Shenyang, China; [5]The Fifth Medical Center of PLA General Hospital,*

Email: raohuiying@pkuph.edu.cn

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are the most common causes of chronic liver disease with known negative impact on patients' health-related quality of life (HROQL). Our aim was to assess the impact of NAFLD on Chinese patients' HRQOL.
Method: In this national cross-sectional survey, patients with NAFLD in absence of other liver disease were identified between March 1st to August 1st 2019. Chronic Liver Disease Questionnaire-Non-Alcoholic Fatty Liver Disease (CLDQ-NAFLD) were used to qualify HRQOL. Logistic regression analysis was performed to identify risk factors of HRQOL by CLDQ-NAFLD.
Results: 5181 NAFLD patients from 90 hospitals among China were included into the analysis (Figure). The mean age was 43.79 ± 13.29 years and 55% were males. 46% were obese. 4%, 0.5% of patients reported a history of NASH or cirrhosis. The mean AST and triglyceride (TG) were 39.9 ± 37.9 U/L and 2.44 ± 2.14 mmon/L. The overall CLDQ-NAFLD score was 5.66 ± 0.89. NAFLD patients had impaired HRQOL in all domains of CLDQ-NAFLD (abdominal symptoms, 5.59 ± 1.07; activity, 5.73 ± 0.95; emotions, 5.66 ± 0.98; fatigue, 5.31 ± 1.10; systemic symptoms, 5.31 ± 1.10; worry, 5.88 ± 1.00). Males were more worried than females (5.84 ± 1.00 & 5.95 ± 1.01, p = 0.000). The young were more worried than the old (p = 0.019), but the old had more difficulty of activity (p = 0.006) and more systemic symptoms (p = 0.000). Besides, some other social characteristics impacted HRQOL in both overall score and all domains (region, p = 0.000; education, p = 0.000; income, p = 0.000). Obesity (p = 0.000) and complications (ex. diabetes, hypertension, hyperlipidemia) (p = 0.000) impacted HRQOL a lot in all domains. Patients with more severe liver disease had significantly lower overall scores (simple fatty liver, 5.67 ± 0.87; NASH, 5.17 ± 1.00; 4.79 ± 1.02, p = 0.000). Logistic regression indicated that obesity, disease progression, cardiovascular diseases, ALT and TG were independent risk factors on the overall score of CLDQ-NAFLD. In the logistic analyses of individual domain, obesity and TG were independent risk factors of all the six domains. ALT and CVD impacted five domains of CLDQ-NAFLD.
Conclusion: In this national cross-sectional survey of NAFLD patients in China, we indicated HRQOL of Chinese NAFLD patients. Significant negative associations between HRQOL and clinical factors such as obesity, disease progression, cardiovascular diseases, ALT and TG emerged. We have to focus on optimally managing care of NAFLD patients and improving their HRQOL.

THU056

Risk factors associated with subclinical atherosclerosis in the patients with biopsy-proven non-alcoholic fatty liver disease

Taeang Arai[1], Masanori Atsukawa[1], Akihito Tsubota[2], Yuji Yoshida[3], Tomomi Okubo[3], Korenobu Hayama[1], Ai Nakagawa[1], Norio Itokawa[3], Chisa Kondo[1], Etsuko Iio[4], Yasuhito Tanaka[4], Katsuhiko Iwakiri[1].
[1]Nippon Medical School, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Bunkyo City, Japan; [2]Jikei University School of Medicine, Core Research Facilities for Basic Science, Research Center for Medical Sciences, Minato City, Japan; [3]Nippon Medical School Chiba Hokusoh Hospital, Division of Gastroenterology, Department of Internal Medicine, Inzai, Japan; [4]Nagoya City University Graduate School of Medicinal Sciences, Department of Virology and Liver Unit, Nagoya, Japan
Email: taeangpark@yahoo.co.jp

Background and Aims: The association between the progress of nonalcoholic fatty liver disease (NAFLD) and subclinical atherosclerosis remains controversial. This study aimed to clarify the factors related to subclinical arteriosclerosis, including the histopathological severity of the disease and PNPLA3 gene polymorphisms, in NAFLD patients.
Method: We measured brachial-ankle pulse wave velocity (baPWV) and maximum intima-media thickness (max-IMT) as an index of subclinical arteriosclerosis in 153 biopsy-proven NAFLD patients. Referring to previous reports, patients with baPWV ≥ 1600 cm/s or max-IMT ≥ 1.1 mm were defined as a risk group for cardiovascular events.
Results: The baPWV and max-IMT values were significantly higher in the advanced fibrosis group than in the less advanced group (baPWV: median, 1679 cm/s vs 1489 cm/s; $p = 5.49 \times 10^{-4}$, max-IMT: 1.2 mm vs 1.0 mm; $p = 3.14 \times 10^{-2}$). Multiple logistic regression analysis revealed that older age, hypertension, and advanced fibrosis were independently linked to baPWV ≥ 1600 cm/s. On the other hand, older age, male and diabetes were independent factors related to max-IMT ≥ 1.1 mm. NAFLD patients were categorized into low-risk group (number of risk factors = 0), intermediate-risk group (= 1), and high-risk group (≥ 2) based on their risk factors (baPWV: risk factors including older age, hypertension, and advanced fibrosis, max-IMT: risk factors including older age, male and diabetes). The prevalence of baPWV ≥ 1600 cm/s was 7.1% (3/42) in the low-risk group, 30.8% (12/39) in the intermediate-risk group, and 63.9% (46/72) in the high-risk group. The prevalence of max-IMT ≥ 1.1 mm was 8.9% (4/45) in the low-risk group, 31.8% (14/44) in the intermediate-risk group, and 51.6% (33/64) in the high-risk group.
Conclusion: We identified factors associated with subclinical arteriosclerosis in NAFLD patients assessed by baPWV and max-IMT, respectively. The differences in the factors associated with baPWV and max-IMT may indicate the need to consider the appropriate use of these two methods for evaluating subclinical arteriosclerosis in NAFLD patients.

THU057
Progression of non-alcoholic fatty liver disease is rare in a Danish tertiary liver centre
Tea Lund Laursen[1], Louise Kristensen[1], Henning Grønbæk[1]. [1]*Aarhus University Hospital, Hepatology and Gastroenterology, Aarhus N, Denmark*
Email: tealaurs@rm.dk

Background and Aims: Data concerning non-invasive discrimination of simple steatosis from non-alcoholic steatohepatitis (NASH) patients and the prediction of risk of disease progression in patients with non-alcoholic fatty liver disease (NAFLD) are conflicting. We aimed to investigate these factors in a NAFLD cohort at a Danish tertiary liver centre.
Method: We retrospectively assessed 135 patients with biopsy-proven NAFLD between 2008–2018 and followed them to the end of 2018 via their electronic patient charts. Patients were divided according to the presence of simple steatosis or NASH based on the steatosis, activity, and fibrosis (SAF) score and the NAFLD activity score (NAS) in liver biopsies. Histological and clinical progression were assessed during follow-up.
Results: NASH patients had higher BMI, liver stiffness, HbA1c, sCD163, and were more prone to have metabolic syndrome at baseline compared with simple steatosis patients. Of the 135 patients, 31 had a follow-up biopsy after a median of 287 days (range: 172 days – 25.5 years); simple steatosis progressed to NASH in 7/25 (28%) cases, and 2/6 (33%) regressed from NASH to simple steatosis. Twenty patients (65%) had the same fibrosis stage on the follow-up biopsy, 7 (23%) progressed, and 4 (13%) regressed. Only 14 (10%) patients progressed clinically during a median follow-up time of 3.8 years (range: 12 days – 27 years) and this mainly included developing type 2 diabetes mellitus (n = 10, 7%). Clinical progression was associated with female sex, and high creatinine, fibrosis stage, activity score, and ballooning in the diagnostic liver biopsies.
Conclusion: The NASH patients separated from simple steatosis patients on several components at baseline including the metabolic syndrome. Histological progression was observed in several patients while some regressed. Only 10% progressed with a clinical event during follow-up, mainly related to more severe histological disease at baseline.

THU058
Health-care burden of NAFLD in European hospital-based outpatient hepatology clinics: real-world prospective data from the CONSTANS study
Vlad Ratziu[1], Dufour Jean-Francois[2], Quentin Anstee[3], Raluca Pais[4], Elisabetta Bugianesi[5], Fabio Marra[6], Sylvia Drazilova[7], Ravaioli Federico[3], Manuel Romero Gomez[8], Swartz Timothy[1], Jörn M. Schattenberg[9]. [1]*Institute of Cardiometabolisme and Nutrition, Sorbone University, Assistance Publique Hopitaux de Paris, Paris, France;* [2]*Hepatology, Department for BioMedical Research, University of Bern, Bern, Switzerland;* [3]*Institute of Cellular Medicine, Newcastle University, Newcastle Upon Tyne, United Kingdom;* [4]*Institute of Cardiometabolisme and Nutrition, Sorbone University, Assistance Publique Hopitaux de Paris, INSERM 0938., Paris, France;* [5]*Division of Gastroenterology and Hepatology, Department of Medical Sciences, University of Turin, Turin, Italy;* [6]*Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy;* [7]*Internal Medicine, Hepatology, Poprad, Slovakia;* [8]*UCM Digestive Diseases, ciberehd and IBIS, Virgen del Rocío University Hospital, University of Seville, Seville, Spain;* [9]*University Medical Center Mainz, Metabolic Liver Research Program, I. Department of Medicine, Mainz, Germany*
Email: ralu_pais@yahoo.com

Background and Aims: In Europe data on the burden of NAFLD in a real-life setting in outpatient hepatology clinics is lacking.
Method: Prospective observational study of pts attending the outpatient hepatology clinic during a 3 month period in 9 centers from 8 European countries. Suspected NAFLD was defined as referrals for steatosis, increased LFTs, hyperferritinemia or cryptogenic cirrhosis. Suspected or already confirmed NAFLD were included in a 6–12 months follow-up study which recorded the final diagnosis, severity of the disease, diagnostic/monitoring work-up and cost of use of medical procedures
Results: 5240 patients were included (N) in Germany (1973), Switzerland (914), France (848), UK (694), Italy (470), Spain (191) and Slovakia (150). The main reasons for referral were: NAFLD 24.8% (including 13.1% suspected NAFLD and 11.7% known NAFLD), viral hepatitis 33.6%, alcoholic liver disease 9.1%, gastrointestinal cancers or cholangiocarcinoma 2.5% and hepatocellular carcinoma or other causes of chronic liver disease 30%. During 7 ± 3.7 months f/u 237 pts underwent liver biopsy. NAFLD was confirmed in 76% (NASH in 54% and NASH cirrhosis in 4.6%) and cryptogenic cirrhosis in 3.8%. In pts without biopsy NAFLD was confirmed in 77% (10% with NASH cirrhosis), NAFLD+moderate alcohol in 6.5% and cryptogenic cirrhosis in 2%. Overall, fibrosis stage 2–4 was diagnosed in 62% of biopsied pts and 40% of adjudicated, non-biopsied pts.
There were 1.5 ± 1.5 f/u visits per pt. Blood tests were performed in 87% of pts and 48% had a diagnostic work-up for other CLD. Imaging was performed in 55% of pts (64% US, 6% CT scan, 7% MRI), serum fibrosis markers in 37% and transient elastography in 36%. 11% of pts were hospitalized for diagnostic procedures. Pharmacological therapy (mainly UDCA and Vitamin E) was prescribed in 9% of pts. Only 18% of pts were referred to a specialist for comorbidities. Overall and per country cost analyses will be provided

%	FR	GR	IT	UK	SK	CH	SP
NAFLD referral	39	17	39	25	47	16	35
Liver biopsy	3.4	4.6	4.9	0.7	0	1.5	0
Fibroscan use	52	38	70	29	0	86	12
Fibrosis biomarkers	61	53	54	0	0	1.4	7

Conclusion: In a large, prospective, European real-life study of tertiary care outpatient hepatology clinics, 25% of pts are currently referred for known or suspected NAFLD which is confirmed in 77% of cases after multiple diagnostic procedures. 40–62% have advanced fibrosis and 8.4–12% cirrhosis. Diagnostic practices vary widely between countries and pt referral for comorbidities is low. NAFLD is becoming a major burden on hepatology outpatient clinics in Europe

THU059

Factors associated with increased overall and cause-specific mortality in non-alcoholic fatty liver disease in an ethnically diverse cohort in the United States

Veronica Setiawan[1], Ju Dong Yang[2], Songren Wang[1], Daniel Stram[1], Mazen Noureddin[2]. [1]*University of Southern California, Preventive Medicine, Los Angeles, United States;* [2]*Cedars-Sinai Medical Center, Los Angeles, United States*
Email: vsetiawa@usc.edu

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) has become the most prevalent chronic liver disease worldwide. We aimed to determine the overall and cause-specific mortality of NAFLD and identify factors associated with mortality in African Americans, Japanese Americans, Latinos, Native Hawaiians, and whites in a population-based Multiethnic Cohort Study.
Method: We conducted a prospective analysis with 2,201 participants with NAFLD (426 with cirrhosis) and 21,545 matched controls. Demographic and risk factor data were collected via baseline and updated using follow-up questionnaires. Deaths were determined through linkage to state death certificate files and the National Death Index. Cox models with covariate adjustment were utilized to calculate hazard ratios (HR) and 95% confidence interval (CI). We determined the association with overall, cardiovascular disease (CVD), non-liver cancer, and liver related mortality.
Results: After an average follow-up of 5.4 years, 582 persons with NAFLD and 3,898 controls died. The most common cause of death in NAFLD was CVD (32%), followed by cancer (22%) and liver disease (9%). After adjusting for age, sex, education, race/ethnicity, body mass index, diabetes mellitus, smoking status, alcohol intake, physical activity and history of cancer or CVD, NAFLD was associated with higher overall (HR = 1.78; 95% CI: 1.61, 1.97), CVD (HR = 1.54; 95% CI: 1.29, 1.83), non-liver cancer (HR = 1.74; 95% CI: 1.41, 2.15), and liver cancer (HR = 17.5; 95% CI: 7.00, 43.7) mortality. The mortality risk associated with NAFLD is highest in African Americans (HR = 3.20; 95% CI: 2.32, 4.41), followed by Latinos (HR = 2.69; 95% CI: 2.19, 3.31), whites (HR = 1.99; 95% CI: 1.57, 2.52), Native Hawaiians (HR = 1.35; 95% CI: 0.89, 2.06) and lowest in Japanese Americans (HR = 1.29; 95% CI: 1.10, 1.51); males and NAFLD with cirrhosis also have elevated overall mortality risk. Among NAFLD patients, factors associated with increased overall mortality were cirrhosis status, being African American, diabetes, smoking, history of CVD; while being female or Japanese American were associated with reduced mortality risk. For CVD mortality, NAFLD with cirrhosis, African Americans, diabetes, and history of CVD had increased risk; while females and moderate alcohol drinkers had lower risk. For non-liver cancer mortality, cirrhosis, diabetes, smoking, moderate alcohol drinking and history of cancer were associated with increased risk. For liver cancer mortality, having cirrhosis and diabetes were associated with increased risk.
Conclusion: In this large multiethnic cohort with comprehensive risk factor data, NAFLD was independently associated with higher overall, CVD, non-liver cancer, and liver cancer mortality. Several factors including sex, race/ethnicity, diabetes, comorbid conditions and lifestyle factors influence mortality in participants with NAFLD.

THU060

First 1-year follow up data from the German NAFLD prospective real-life cohort (FLAG study) show low frequencies of lifestyle changes

Wolf Peter Hofmann[1], Jörn M. Schattenberg[2], Lisa Schubert[1], Nektarios Dikopoulos[3], Jeannette Schwenzer[4], Marion Muche[5], Renate Heyne[6], Patrick Ingiliz[7], Kerstin Stein[8], Michael P. Department of Medicine, Mainz, Germany;* [3]*Praxis für Gastroenterologie und Hepatologie, Dornstadt;* [4]*Praxis für Gastroenterologie und Hepatologie, Berlin;* [5]*Charité Universitätsmedizin, Campus Benjamin Franklin Klinik für Gastroenterologie, Berlin, Germany;* [6]*Leberzentrum Checkpoint, Berlin, Germany;* [7]*Zentrum für Infektiologie Berlin Prenzlauer Berg, Berlin;* [8]*Hepatologie Magdeburg, Magdeburg, Germany;* [9]*Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [10]*Goethe University Frankfurt, Medizinische Klinik 1, Frankfurt, Germany;* [11]*Saarland University Hospital, Klinik für Innere Medizin II, Homburg/Saar, Germany;* [12]*Leberzentrum Hamburg, IFI an der Asklepiosklinik St. Georg, Hamburg, Germany*
Email: wolfpeter.hofmann@icloud.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) affects approximately 25% of the German population. However, there is only limited knowledge about the prevalence of NAFLD with advanced fibrosis, the frequencies of lifestyle interventions (e.g. nutritional counselling) over time and their effect on body weight loss and liver function tests. Cohort studies in a "real life" setting represent a suitable tool to study clinical outcomes in patients with NAFLD and assess current standards of health care.
Method: The fatty liver assessment in Germany (FLAG) study is a prospective, multicentric cohort study initiated by the association of gastroenterologists in private practice (BNG) in cooperation with academic medical centers and the German Liver Foundation covering secondary and tertiary health care levels. Data collection is performed using an electronic case report form, and data quality is verified by plausibility checks and off-site monitoring. Patients characteristics as well as laboratory parameters that allow calculation of non-commercial, non-invasive liver fibrosis scores and genetic profiles are collected. Liver stiffness measurement (LSM) data are included when available. Lifestyle interventions, medication as well as clinical events are assessed at baseline and followed-up prospectively.
Results: Today, 674 patients with NAFLD spanning a broad range of disease severity are included in the FLAG study. Baseline data were reported previously, including 52% men with a mean age of 52 years. According to FIB-4 index, 7% of the patients have significant fibrosis (F3-F4, Fib-4-Index >3.25). Here, we report 1-year follow up (FU) data from the first 115 patients. Total body weight increased in 48/115 patients (42%). Highest weight loss of >5% total body weight was observed in 19/115 (17%) of patients. In those with the highest weight loss, ALT activities (U/L) decreased significantly ($p < 0.01$) over time (mean ± SD, 70 ± 44 vs. 39 ± 23 at baseline vs. 1-year FU, respectively). HbA1c values (mg%) decreased numerically (mean ± SD, 6.1 ± 1.0 vs. 5.8 ± 0.4, $p > 0.05$). In patients who gained weight, ALT levels at baseline and during FU (57 ± 28 vs. 71 ± 48 U/L, $p = 0.08$) and HbA1c values (5.90 ± 0.70 vs. 5.91 ± 0.77 mg%) showed a slight increase or remained unchanged, respectively. Nutritional counselling was performed in 23% of all patients only, however, its frequency did not differ between groups.

Conclusion: In this prospective, multicentric cohort study, first 1-year FU data of patients with NAFLD provide insights in real life patient care in Germany. Weight loss was associated with a significant decrease of ALT levels, however, only 17% of all patients showed a weight loss of >5% total body weight after the first year of FU. The results underscore that lifestyle interventions such as nutritional counselling are limited and should be strengthened.

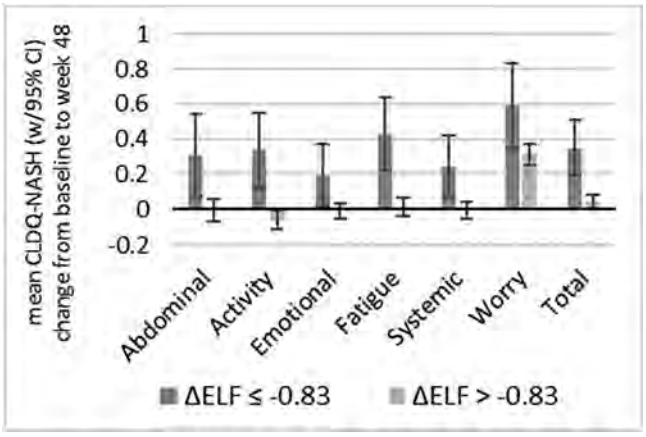
Fibrosis non-invasive tests capture changes in patient-reported outcomes of patients with advanced non-alcoholic steatohepatitis

Zobair Younossi[1,2,3], Stephen Harrison[4], Quentin Anstee[5], Eric Lawitz[6], Vincent Wai-Sun Wong[7], Manuel Romero Gomez[8], Michael Trauner[9], Takeshi Okanoue[10], Marianne Camargo[11], Kathryn Kersey[11], Mani Subramanian[11], Robert Myers[11], Zachary Goodman[1,2,3], Maria Stepanova[12]. *[1]Betty and Guy Beatty Center for Integrated Research; [2]Center for Liver Diseases, Department of Medicine; [3]Inova Health Systems; [4]University of Oxford, Radcliffe Department of Medicine, United Kingdom; [5]Institute of Clinical and Translational Research, Faculty of Medical Sciences, Newcastle University, Newcastle -upon-Tyne, United Kingdom; [6]Texas Liver Institute, University of Texas, San Antonio, United States; [7]The Chinese University of Hong Kong, China; [8]Hospital Universitario Virgen del Rocio, Sevilla, Spain; [9]Medical University of Vienna, Vienna, Austria; [10]Saiseikai Suita Hospital, Suita City, Osaka, Japan; [11]Gilead Sciences, Inc, Foster City, United States; [12]Center for Outcomes Research in Liver Disease, Washington DC, United States*
Email: zobair.younossi@inova.org

Background and Aims: Non-alcoholic steatohepatitis (NASH) can impair health-related quality of life and other patient-reported outcomes (PROs) which can be further impacted by histologic fibrosis stage or noninvasive tests (NITs) for fibrosis.
Method: Patients with NASH (NAS ≥ 3) and advanced fibrosis (NASH CRN stage F3) or compensated cirrhosis (CC, F4) were enrolled in two Phase 3 clinical trials of selonsertib (STELLAR). PROs were prospectively collected using SF-36, CLDQ-NASH, EQ-5D, and WPAI at pre-treatment baseline and during treatment. Liver biopsies were collected at baseline and week 48. The trials were terminated after week 48 due to the lack of efficacy of selonsertib.
Results: A total of 1,679 patients with biopsy-proven NASH were included (802 F3 and 877 CC, 40% male, 74% white, 49% employed, 74% with diabetes, 42% history of psychiatric comorbidities). Compared with NASH patients with F3 fibrosis, NASH-CC patients were more frequently female, white, had more gastrointestinal and psychiatric comorbidities, and a higher prevalence of diabetes (77% vs. 70%) (all $p < 0.05$). At baseline, NASH-CC patients had lower scores in Role Physical, Bodily Pain, and Social Functioning of SF-36, EQ-5Q utility, and all but one domains of CLDQ-NASH ($p < 0.05$). In multivariate analysis adjusted for demographics, BMI, and comorbidities, the presence of CC was independently associated with lower scores in the domains of Activity, Emotional, and Worry of CLDQ-NASH ($p < 0.05$). Patients who improved histologic fibrosis stage after 48 weeks were more likely to have histologic cirrhosis at baseline (58% vs. 50%, $p = 0.02$) but otherwise had less active disease [lower ballooning stage, less diabetes, lower AST, higher platelet count and albumin, lower CRP and GGT, better fibrosis NIT scores such as APRI, FIB-4, Fibrotest, ELF, Hepamet, NAFLD Fibrosis Score, and liver stiffness by transient elastography (LS by TE) (all $p < 0.01$). Achieving ≥ 1 stage histologic fibrosis improvement (without or regardless of worsening of NASH) was not associated with any improvement in PROs (all $p > 0.05$). Patients with a decrease in % collagen (absolute ≥ 0.9 percentage points or relative ≥ 14% from baseline) experienced improvement in General Health scores ($p < 0.05$). In addition, patients with decreases in NAS score (≥ 2 points), LS by TE (≥ 4.6 kPa), and ELF score (≥ 0.83 points) experienced improvement of scores in most domains of CLDQ-NASH ($p < 0.05$) (Figure).



Conclusion: In addition to baseline impairment associated with the disease severity in patients with advanced NASH, there was association of NIT improvement with PRO improvement.

Alcoholic liver disease

Gut transcriptomics reveals potential therapeutic strategies for the restoration of epithelial barrier repair in alcohol-related liver cirrhosis

Antonio Riva[1,2], Jasmohan S Bajaj[3], Andrew Fagan[3], Roger Williams[1,2], Shilpa Chokshi[1,2]. *[1]Institute of Hepatology (Foundation for Liver Research), London, United Kingdom; [2]Faculty of Life Sciences and Medicine (King's College London), London, United Kingdom; [3]Virginia Commonwealth University and McGuire VAMC, Department of Gastroenterology, Hepatology and Nutrition, Richmond (Virginia), United States*
Email: a.riva@researchinliver.org.uk

Background and Aims: Liver cirrhosis induces a profound state of immunodeficiency, rendering patients highly susceptible to bacterial infection and increased mortality. We have previously shown that gut hyperpermeability and consequent increased bacterial translocation are central in driving this phenomenon in Alcohol-related Liver Disease (ALD) (Riva et al, Gut 2018; Markwick et al, *Gastroenterology* 2015); however, the specific pathways associated with intestinal damage in ALD are not well characterised.
Method: Genome-wide transcriptome profiling (~20,000 coding genes, ~40,000 long non-coding RNA) was performed in colon tissue from 10 alcohol-cirrhotic patients (ARC; F = 5, age = 57.2 ± 1.7, MELD = 12.7 ± 1.3, lactulose = 4, no alcoholic hepatitis/infections/antibiotics) and 10 healthy controls (HC; F = 1, age = 52.2 ± 2.5). We investigated differential gene expression and functional clustering by "Gene Ontology" (GO), "Kyoto Encyclopaedia of Genes and Genomes" (KEGG) pathways and "Gene Set Enrichment Analysis" (GSEA). We also measured surrogate markers of bacterial translocation (D-Lactate, Endotoxin) as indicative of gut barrier disruption in ARC patients.
Results: ~8,400 coding genes were differentially expressed in ARC vs HC colon. Most upregulated genes were functionally involved in transcriptional processes, ribosomal/chromatin structure, intercellular adhesion and energy metabolism. GSEA identified upregulated cell adhesion pathways in ARC vs HC, driven by tight and adherens

junction (TJ/AJ) genes including claudin 3, occludin, ZO-1, E/LI-cadherin and catenins. Differential expression of TJ/AJ-modulating long non-coding RNAs was consistent with the observed transcriptional changes in coding genes. Interestingly, downregulated gene clusters did not achieve significant enrichment. Quantification of plasma D-Lactate and endotoxin (Lps) confirmed the presence of bacterial translocation in ARC vs HC.
Conclusion: In conclusion, transcriptional profiling highlights major alterations in intestinal cell adhesion pathways in ALD patients suggestive of active ongoing barrier protection and epithelial repair. Further research investigating these pathways in experimental models as new targets to restore barrier integrity in ALD is warranted.

THU063
Specific alterations of the immune checkpoint secretome are linked with antibacterial immunity in alcohol-related liver disease
Antonio Riva[1,2], Douglas Corrigall[1,2,3], Huyen Adams[1,2,4], Nicola Harris[1,2], Yong Xin Sieh[1,2], Gavin Wright[3], Sarah Fairclough[3], Alex Evans[4], Debbie L. Email: a.riva@researchinliver.org.uk

Background and Aims: Alcohol-related liver disease (ALD) is characterised by a hyperinflammatory state that co-exists with profound immunoparesis. Checkpoint receptors (CR) are key regulators of immunity and we have shown a role for two inhibitory T-cell CRs (PD1/TIM3) expressed on the membrane (m) of antibacterial T cells in patients with acute alcoholic hepatitis (AH), which when neutralised in-vitro can rescue antibacterial responses (Markwick et al, 2015). However, individual roles of PD1 and TIM3 in driving immune derangements remain unclear. Recent evidence has also revealed that soluble (s) forms of CRs can in many contexts modulate autoimmunity and responses to infection/malignancy. Their role in ALD is unknown.
Method: In 22 patients with alcohol-related cirrhosis (ARC), 13 with AH and 13 healthy controls (HC) we measured PD1/TIM3 and their ligands on the membrane of immune cells by flow cytometry and as soluble forms in plasma by ELISA. CR gene expression was assessed by gene microarray. In addition, we explored the kinetics and relationship between sCRs and mCRs in *E. coli*-challenged PBMCs. Finally, rescue of antibacterial responses by neutralisation of CRs was investigated in-vitro.
Results: Plasma levels of sTIM3 were increased in ALD vs HC ($p = 0.00002$), and hyperexpression of mTIM3, mPD1 and mPDL2 was detected on ALD PBMC vs HC (AH > ARC; $p < 0.002$). Multivariate analysis revealed sTIM3 as (a) the dominant plasma sCR in ALD, (b) the strongest patient discriminator by AUROC and OPLS-DA, and (c) the only sCR directly correlated to gene expression. TIM3 ligands galectin 9 (sGal9) and sCEACAM1 were also increased in ALD vs HC (AH > ARC; $p < 0.002$). Upon *E. coli* challenge mCR expression changed comparably in ALD and HC PBMCs, and in-vitro neutralisation of TIM3 pathway led to enhanced antibacterial cytokine production (IFNγ/IL-17) and antinflammatory cytokine production (IL-10) in AH.
Conclusion: In conclusion, sTIM3 is hyper-secreted in ALD patients, particularly those with greater disease severity, in correlation with inhibitory mTIM3 expression on ALD immune cells. Blockade of the TIM3-ligand synapse restores antibacterial immunity and increases the production of antinflammatory cytokines, revealing TIM3 as a key checkpoint receptor mediating hyperinflammatory immunodeficiency in AH. Anti-TIM3 therapy is currently being used in Phase I clinical trials for advanced solid tumours and warrants further investigation as an immunomodulatory therapeutic strategy for ALD.

THU064
Proton pump inhibitors increase the risk of oral cancer among patients with alcoholic cirrhosis
Astrid Højmark Andersen[1], Lars Bossen[1], Peter Jepsen[1,2]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark;* [2]*Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus N, Denmark*
Email: aha@clin.au.dk

Background and Aims: Proton pump inhibitors (PPIs) increase risk of complications in patients with liver cirrhosis, most likely caused by alterations in the gut and oral microbiome. The risk of oral cancer is increased by alcohol intake and smoking, but oral microbiome alterations have also been suggested as a risk factor. We aimed to examine the association between PPI use and the risk of oral cancer among patients with alcoholic cirrhosis.
Method: We conducted a registry-based Danish nationwide historical cohort study including 17,632 patients diagnosed with alcoholic cirrhosis between 2000 and 2017. Follow-up started on the date of alcoholic cirrhosis diagnosis, and ended at diagnosis of oral cancer, death or 31 December 2017, whichever occurred first. We collected data on PPI use from the Danish National Prescription Registry. We used Cox regression to estimate the hazard ratio (HR) of oral cancer in PPI users vs. non-users adjusting for confounding by gender, age, calendar year, severity of alcoholic cirrhosis and smoking. PPI use was set as a time-dependent exposure. We examined the association between PPI use and pharyngeal cancer with identical methods.
Results: At inclusion, 4,302 patients (24%) used PPIs, and 15,357 patients (87%) used PPIs at some point. Of the study population, 12,002 patients (68%) were male, the median age at inclusion was 58.5 years (IQR 51.1–65.2) and 5,800 patients (33%) were smokers. At inclusion, 6,668 patients (38%) had a history of ascites, and 1,806 patients (10%) had a history of variceal bleeding. Oral cancer was diagnosed in 131 patients, and 12,121 patients died during follow-up. The 10-year cumulative risk of oral cancer was 0.98% (0.66–1.42) among baseline PPI users vs. 0.89% (0.72–1.09) among baseline nonusers. PPI users had a higher rate of oral cancer than non-users (adjusted HR = 1.79, 95% CI 1.21–2.65), but PPI users did not have a higher mortality than non-users (adjusted HR = 1.04, 95% CI 0.99–1.08). PPI use did not increase the risk of pharyngeal cancer (adjusted HR = 1.06, 95% CI 0.75–1.50).
Conclusion: PPIs are widely used among patients with alcoholic cirrhosis. PPI use increased the risk of oral cancer, but the 10-year risk of oral cancer was low. These findings call for further investigation of the links between PPI use, oral microbiome and cancer development.

THU065
Analysis of the influence of alcoholic abstinence on mortality in patients with alcoholic liver cirrhosis
Ángela Suárez-Noya[1], Carmen Álvarez-Navascués[1], Alejandro Nieto Jara[1], Celia Del Caño Cerdán[1], Maria Luisa Gonzalez Dieguez[1], Valle Cadahía-Rodrigo[1], Maria Varela[1], Manuel Rodríguez[1]. [1]*Hospital Universitario Central de Asturias, Liver Unit, Division of Gastroenterology&Hepatology, Oviedo, Spain*
Email: angelasuareznoya@gmail.com

Background and Aims: Alcohol abstinence (AA) is the main treatment of alcoholic liver cirrhosis (ALC) but there are few data about its influence on mortality. The aim was to know if AA reduces the risk of death in patients with ALC.
Method: 754 patients with ALC, Child A/B, included in a hepatocellular carcinoma surveillance programme prospectively followed biannually. AA was defined as absence of any consumption from

inclusion. Any death after liver transplant (LT) was considered liver-related mortality (LRM). 83% males, median age 56 years, 64% with previous liver decompensation, 77% Child A, 75% with varices. 14 variables collected at inclusion were analyzed together with AA during follow-up.
Results: During 72 months (33–119), 368 patients (49%) remained abstinent, 350 (46%) died and 70 (9%) received a LT. 207 (59%) were LR deaths, 125 (36%) non LR and 18 of unknown etiology. Any cause mortality (ACM) at 5, 10 and 20 years was 24%, 45% and 77%. Age (HR:1.042;CI95%:1.026–1.059), male sex (HR:1.665;CI95%:1,.06–2.301), BMI<25 (HR:1.951;CI95%:1.428–2.666), previous decompensation (HR: 1.360;CI95%:1.041–1.777), platelet count (HR:1.002; CI95%:1.000–1.005) and AST>UNL (HR:1.612;CI95%:1.261–2.061) were independently associated with higher risk of ACM. Conversely, abstinence (HR:0.642;CI95%:0.505–0.815) was associated with lower risk. LRM at 5, 10 and 20 years was 17%, 30% and 52%. Variables associated with higher risk of LRM were: age (HR 1.032;CI95%:1.013–1.050), male sex (HR:2.052;CI95%:1.340–3.142), previous decompensation (HR:1.883;CI95%:1.338–2.651), Child B (HR:1.681; CI95%:1.242–2,330), platelet count (HR:1.005;CI95%:1.002–1.008) and AST>ULN (HR:1.701;CI95%:1.242–2.330). Abstinence (OR:0.553; CI95%:0.414–0.738) was associated with a lower risk. Non LRM at 5, 10 and 20 years was 8%, 18% and 48%. Variables associated with higher risk of non LRM were age (HR:1.038;CI95%:1.011–1.066), BMI<25 (HR:2.581;CI95%:1.579–4.218), tobacco use (HR:1.844;CI95%:1.111–3.060) and inclusion after 2005 (HR:2.184;CI95%:1.332–3.581), while abstinence was associated with risk reduction (HR:0.616; CI95%:0.421–0.902).
Conclusion: Alcohol abstinence in patients with alcohol-related cirrhosis reduces the risk of any cause mortality, liver-related mortality as well as non liver-related mortality. However, variables associated with advanced liver disease have a substantial weight on liver-related and all cause mortality; consequently, early diagnosis of alcohol-related liver disease is essential.

THU066
Non-invasive criteria for diagnosis of alcoholic hepatitis: use in clinical practice and correlation with prognosis

Emma Avitabile[1], Elisa Pose[1,2,3], Isabel Graupera[1,2,3], Marta Carol[1], Martina Perez[1], Marta Cervera[1], Núria Fabrellas[4], Adria Juanola[1,2], Octavi Bassegoda[1], Cristina Solé[1,2,3], Elsa Solà[1,2,3], Pere Ginès[1,2,3].
[1]Liver Unit, Hospital Clínic de Barcelona, Barcelona; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS); [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas (CIBEREHD); [4]Universitat de Barcelona
Email: EPOSE@clinic.cat

Background and Aims: liver biopsy is still considered the gold standard for the diagnosis of alcoholic hepatitis (AH). Nonetheless, in clinical practice diagnosis of AH is frequently done by clinical and analytical criteria. International guidelines recommend the use of clinical criteria for diagnosis of alcoholic hepatitis in clinical practice. The National Institute on Alcohol Abuse and Alcoholism (NIAAA) clinical criteria were recently proposed for clinical diagnosis of AH. However, to date, studies on the correlation between NIAAA criteria and histological criteria for the diagnosis of AH are still lacking. The aim of this study was to evaluate the consistency among NIAA clinical criteria and the histological criteria for diagnosis of AH.
Method: a prospective cohort of patients with alcohol related liver disease who underwent a liver biopsy was studied in a 4-year period. In this cohort, two groups were characterized retrospectively based on the pre-biopsy probability of presenting AH in high or low probability of AH. Pre-biopsy high probability of AH was defined in those patients with jaundice accompanied or not by clinical decompensation of cirrhosis and active alcohol consumption, in which the reason for liver biopsy was referred as "suspicion of AH" in the medical records. Patient's clinical and laboratory information was collected prospectively at baseline and during the follow-up. Histological characteristics and NIAAA clinical criteria (jaundice in the previous 8 weeks, alcohol intake of more than 40/60 g in female/male, AST >50 UI/l, ratio AST/ALT >1.5 and both <400 UI/l, bilirubin>3 mg/dl) were reviewed retrospectively in all the patients.
Results: 114 patients were included; among them 63 (55%) had high pre-biopsy probability of AH and 51(45%) low. Histological criteria for AH were met by 59 patients and NIAAA criteria by 48. Positive predictive value (PPV) of NIAAA criteria for AH diagnosis was 81% (34 out of 48) with a false negative rate(FNR) of 30% (20 out of 66). In the high HA pre-biopsy probability group, NIAAA PPV was 84% (33 out of 39) with a FNR of 53% (7 out of 13). One-year overall survival rate was 77% in the whole cohort. Patients who met both NIAAA and histological criteria of AH had the worst survival rate (62%), followed by those that only met histological criteria for AH (75%); instead, patients who were diagnosed with AH only through NIAAA criteria but did not meet histological criteria had similar survival rate to that of patients without AH (87% in both cases, p = 0.039).
Conclusion: in a not-selected cohort of patients with alcoholic liver disease diagnostic power of the NIAAA clinical criteria was moderate, with a not negligible amount of false positive and false negative rates. This fact is clinically relevant considering that patients with histologically proven AH have a worse prognosis.

THU067
Early life ethanol exposure has long-term impacts on the transcriptome and epitranscriptome of rat liver

Yu-Wei Leu[1], Shu-Huei Hsiao[1]. *[1]National Chung Cheng University, Department of Biomedical Sciences, Chia-Yi, Taiwan*
Email: bioshh@ccu.edu.tw

Background and Aims: Fetal alcohol spectrum disorder (FASD) is a birth defect due to maternal alcohol consumption during pregnancy. Children with FASD are characterized with neurobehavioral deficits and growth anomalies, but little is known about liver histopathologic and molecular features in patients with FASD. Thus we aimed to investigate whether early life ethanol exposure could have long-term impacts on liver development and genomic constitution.
Methods: In a rodent model of FASD, rat pups were given ethanol (5.25 g/kg/day) via oral intubation on postnatal day (PD) 4–9 (equivalent to human third trimester), then the livers from ethanol-treated and age-matched control littermates were collected at different ages (1, 3, 6, and 12 months of life) for high-throughput RNA sequencing, reverse transcription PCR (RT-PCR) and histological analysis.
Results: Consistent with case reports from human FASD patients, livers from our animal model exhibited hepatomegaly and fat deposition in hepatocytes, and these histopathologic features lasted up to 12 months of life. Both transcriptome and epitranscriptome were also persistently and concordantly changed, with genes involved in the lipid metabolism and immune system were most affected.

Conclusion: Early life ethanol exposure can cause long-lasting deleterious alterations in liver at both histological and molecular levels. The identified molecular signatures not only contribute to the

etiology of early life ethanol-induced liver pathogenesis, but also provide as potential targets for therapeutic intervention.

THU068

Alcohol recurrence and outcome in patients transplanted for alcoholic cirrhosis: impact of the 6-month rule

Claire-Anne Perignon[1,2,3,4,5], Faouzi Saliba[1,2,3], Sophie-Caroline Sacleux[1], Lisa Blecha[1], Valérie Caillez[1], Philippe Ichai[1,2,3], Audrey Coilly[1,2,3], Marc Boudon[1,2,3,6], Elise Lemaitre[1], Bruno Roche[1,2,3], Rodolphe Sobesky[1,2,3], Eleonora De Martin[1,2,3], Daniel Cherqui[1,2,3,6], Eric Vibert[1,2,3], René Adam[1,4,5], Jean-Charles Duclos-Vallée[1,2,3,6], Didier Samuel[1,2,3,6].

Email: claire-anne.perignon@orange.fr

Background: Liver transplantation (LTx) is generally recommended for patients with decompensated alcoholic cirrhosis (Meld>15) with a time from alcohol abstinence to LTx >6 months. The latter rule is still debated as the 6-month per says could not contraindicate alone LTx in the last guidelines. On the other hand, early LTx became a possible option for treatment of highly selected patients with acute alcoholic hepatitis (AAH) non-responding to medical treatment.
Method: This is a retrospective study that recruited in our center all LTx patients for alcoholic cirrhosis during the period of 2013–2017. Patients were stratified into 3 groups according to period of abstinence prior to LTx: >6 months (group 1); <6 months (group 2) and biopsy proven AAH refractory to medical treatment (group 3). Alcoholic recurrence was defined by any alcohol consumption reported by the clinicians, or on oriented/protocol liver biopsies and prospectively by a specific survey send to all patients. The survey allowed characterizing the recurrence via the AUDIT-C score.
Results: Among the 172 LTx patients recruited in the study, 21 and 13 patients were respectively in group 2 and 3. The mean MELD score at time of LTx was respectively 19.4 ± 9.3, 31.6 ± 10.7 and 34.6 ± 8.4 (Group 1, 2 and 3). The 1 and 5-year patient survival were respectively 93%, 84% and 100% and 79%, 76% and 100% (Group 1, 2 and 3, global Log rank, p = 0.24). Overall, 46 patients had post-transplant alcohol recurrence. Of the 122 patients who responded to the survey, 16 patients with a recurrence not identified by the clinicians were revealed. Alcohol recurrence rates were respectively 26%, 24% and 54% in groups 1, 2 and 3 (p = 0.5). In the multivariate analysis, factors associated with alcohol recurrence were AAH {OR = 5, 95%CI (1.49–17.43), p = 0.009}, consumption of toxic substances prior to LTx {OR = 3.24, IC95% (1.13–9.25), p = 0.028}. The fact that in the survey the patient admit that alcohol was the leading cause of his cirrhosis was a protective factor for recurrence {OR = 0.39, 95%CI (0.11–1.29), p = 0.12}.
Conclusion: AHH and consumption/abuse of toxic substances prior to LTx were the main determinant of post-transplant alcohol recurrence. The absence of differences in survival and recurrence rate between group 1 and 2 support the fragility of the 6-month rule and the importance of a multidisciplinary and a multifactorial approach for optimal selection of these patients to LTx.

THU069

Early liver transplantation in active drinkers with and without alcoholic hepatitis: a monocentric case series

Debora Angrisani[1], Adelaide Panariello[2], Chiara Mazzarelli[1], Paola Prandoni[2], Raffaella Viganò[1], Marcello Vangeli[1], Rosa Stigliano[1], Stella De Nicola[1], Giovanni Perricone[1], Aldo Airoldi[1], Mauro Percudani[2], Luca Saverio Belli[1]. *[1]ASST GOM Niguarda, Hepatology and Gastroenterology Unit, Milan, Italy; [2]ASST GOM Niguarda, Mental Disease Unit, Milan, Italy*
Email: deborangrisani@hotmail.it

Background and Aims: Early liver transplant (eLT) is an effective therapeutic option for patients with severe alcoholic hepatitis (SAH). Whether eLT should also be offered to active drinkers with rapidly progressive acute liver failure who do not have a definite diagnosis of SAH, is unknown. Here we report the outcome of eleven active drinkers with severe acute liver impairment and diagnosis of probable SAH who received eLT.
Method: all active drinkers consecutively admitted to our unit from April 2016 to June 2019 with clinically diagnosed "probable SAH" defined according to NIAAA criteria and with a Maddrey Score (MS) >32, were included in the study. Patients not improving after medical therapy, irrespective of the use of steroids, were evaluated for eLT. The definite diagnosis of SAH was based on the histology of the explanted liver. Psycho-social selection performed by a dedicated team and tailored support pre- and post-LT were the cornerstone of the program.

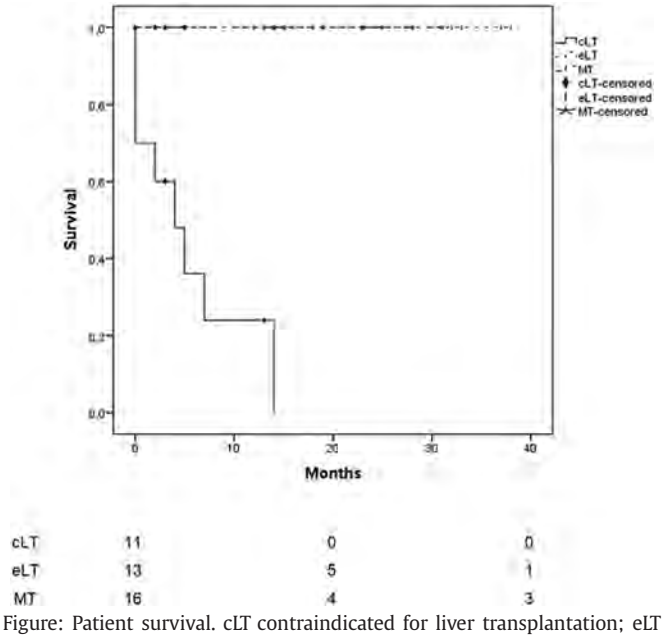

Figure: Patient survival. cLT contraindicated for liver transplantation; eLT early liver transplantation; MT improved with medical treatment/support (two patients received liver transplant beyond six months).

Results: Forty consecutive patients with alcoholic cirrhosis and acute severe liver failure due to probable SAH were enrolled. The great majority (33/40, 82%) did not receive CS mainly for active infection (24/40, 60%). Sixteen (40%) patients, with median baseline MS 64 and MELD-Na 24, improved with medical treatment/support (MT). None died after a median follow up of 14 months (5–23); two received liver transplant beyond six months. The remaining twenty-four patients were evaluated for eLT. Eleven (27.5%) patients were excluded from eLT due to psychiatric or medical contraindication. Median FU in this group was 4 months (0–7). Thirteen (32.5%) patients, with a median baseline MD 94 and MELD-NA 36, underwent eLT. All patients undergoing eLT are alive, after a median follow up of 18 months (12–33) To date one patients relapsed in heavy alcohol use about 25 months after eLT. On explant, all LT recipients had cirrhosis with only 6 also having alcoholic steato-hepatitis confirmed.
Conclusion: eLT should be considered in active drinkers with acute severe liver failure irrespective of definite diagnosis of SAH. Stringent psycho-logical support pre and post LT is crucial to avoid alcohol relapse.

THU070

Long-term outcome of symptomatic alcoholic hepatitis with a Maddrey discriminant function <32

Degré Delphine[1], Rudolf E. Stauber[2], Englebert Gaël[3], Sarocchi Francesca[4], Verset Laurine[5], Florian Rainer[2], Walter Spindelböck[2], Njimi Hassane[6], Trépo Eric[3], Thierry Gustot[3], Carolin Lackner[4], Pierre Deltenre[3,7], Christophe Moreno[3]. *[1]CUB Hôpital Erasme, Université Libre de Bruxelles, Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Brussels, Belgium; [2]Medical University of Graz, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Graz, Austria; [3]CUB Hôpital Erasme, Université Libre de Bruxelles, Department of Gastroenterology, Hepatopancreatology and Digestive Oncology, Brussels, Belgium; [4]Medical University of Graz, Institute of Pathology, Graz, Austria; [5]Institut Bordet, Université Libre de Bruxelles, Department of Pathology, Brussels, Belgium; [6]Université Libre de Bruxelles, Biomedical Statistics, Brussels, Belgium; [7]Clinique St Luc, Department of Gastroenterology and Hepatology, Bouge, Belgium*
Email: christophe.moreno@erasme.ulb.ac.be

Background and Aims: Patients with alcoholic hepatitis and a modified Maddrey's discriminant function (mDF) <32 have a low risk of short-term mortality. However, few data exist concerning long-term outcomes. The aims of this study were to evaluate 5-year survival rates and to identify predictive factors for long-term prognosis in this patient population.

Method: We studied patients from 2 centres who were admitted for hepatic decompensation (ascites, hepatic encephalopathy, or jaundice) and who had histological findings of steatohepatitis and an mDF <32. Clinical and biological parameters were recorded at the time of liver biopsy and alcohol consumption was recorded during follow-up. We performed Cox proportional hazard survival analysis to identify factors associated with 5-year survival.

Results: One hundred and twenty-one patients were included (male: 64%, mean age: 51.5 ± 10.3 years, presence of cirrhosis: 84%). The median MELD and mDF scores were 14 [25th–75th percentile: 11.7–16.1] and 19 [25th–75th percentile: 11.1–24], respectively. During follow-up, 30% of the patients remained abstinent. Survival rates at 1, 6, 12, 24, and 60 months were 96.7 ± 1.6%, 90.1 ± 2.7%, 80.8 ± 3.6%, 69.9 ± 4.3%, and 50.7 ± 4.9%, respectively. The majority of deaths (80%) were liver-related. In multivariable analysis, encephalopathy at baseline and alcohol abstinence were predictive of 5-year survival. The 5-year survival rates of patients without and with encephalopathy at baseline were 60.5 ± 5.8% and 29.7 ± 8%, respectively, and the 5-year survival rates of abstinent and non-abstinent patients were 74.8 ± 8% and 40.9 ± .8%, respectively.

Conclusion: Mortality of patients with alcoholic hepatitis and an mDF <32 presenting with an acute decompensation is around 50% at 5 years. Hepatic encephalopathy at baseline and lack of alcohol abstinence impair long-term prognosis. New treatment strategies, including measures to ensure abstinence, are required.

THU071

Genetic variant PNPLA3 I148M accelerates fat accumulation in livers of mice with ASH/NASH via damping of PPAR alpha and PPAR gamma signalling pathways

Eleonora Patsenker[1], Veera Raghavan Thangapandi[2], Jane Beil-Wagner[3], Thorsten Buch[3], Johannes vom Berg[3], Jochen Hampe[2], Felix Stickel[1]. *[1]University of Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland; [2]Technische Universität Dresden, Medical Department 1, Dresden, Germany; [3]University of Zürich, Institute of Laboratory Animal Science, Zürich, Switzerland*
Email: eleonora.patsenker@usz.ch

Background and Aims: Non-alcoholic (NAFLD) and alcoholic (ALD) liver disease are leading causes of progressive fatty liver disease, particularly in patients with both entities. *PNPLA3* rs738409 is a risk locus for progressive NAFLD, NASH and ALD, but the exact mechanism of how the loss of function in the PNPLA3 gene drives progression is incompletely understood.

Method: Variant *PNPLA3* rs738409 (*PNPLA3*^{I148M}) mutation was introduced to C57Bl6 mice by CRISP-Cas9-based genome editing and confirmed by sequencing. Hepatic steatosis was induced by a combination of alcohol (10% in drinking water) and Western Diet (WD, TD.88137) (EtOH/WD) for 25 weeks. Liver fibrosis, inflammation, steatosis and damage were assessed by blood and tissues histology, qPCR and various biochemical analyses and compared between groups.

Results: EtOH/WD resulted in body, liver and spleen weights increases, but no modulating effect of genotypes was found. In line, hepatic fibrosis levels, measured by hydroxyproline, ALT, AST, as well as *PC alpha 1(I)*, *TGF beta 1*, *alpha SMA* mRNAs, did not differ between *PNPLA3*^{WT} and *PNPLA3*^{I148M}, whereas inflammation markers *IL1 beta, Cxcl1, Cxcl2 and IL-10* mRNA were highly upregulated (up to 2-fold, $p < 0.05$) in *PNPLA3*^{I148M}. In addition, *PNPLA3*^{I148M} showed 16% higher hepatic TG content compared to *PNPLA3*^{WT} ($p = 0.01448$), while in cirrhotic *PNPLA3*^{I148M} it was non-significantly reduced. *PPAR alpha* and *PPAR gamma* were 30–50% downregulated in both – fibrotic and cirrhotic *PNPLA3*^{I148M} on EtOH/WD, as well as the expression of *Scd1, FADP4, FASN* and *Cidec* were suppressed. Interestingly, in *PNPLA3*^{I148M} on a control diet, *FASN* and *IL1 beta* were 1.6- and 4-fold induced, respectively, if compare to *PNPLA3*^{WT}.

Conclusion: Presence of *PNPLA3* rs738409 results in enhanced fatty acid synthesis, decreased activity of *PPAR alpha* and *PPAR gamma* and consequent suppression of beta-oxidation, eventually leading to enhanced triglyceride formation in response to an EtOH/WD treatment as a model of *hedonism-associated steatohepatitis* (HASH).

Delisting of liver transplant candidates after improvement in alcohol-related decompensated cirrhosis: a multicentric study on incidence and outcomes

Elisa Pose[1], Abiguei Torrents[2], Valeria Perez-Campuzano[3], Isabel Campos-Varela[4], Emma Avitabile[1], José Castellote Alonso[3], Lluis Castells[4], Jordi Colmenero[1], Jaume Tort[2], Pere Ginès[1], Gonzalo Crespo[1]. *[1]Hospital Clínic, IDIBAPS, CIBERehd, University of Barcelona, Liver Unit, Barcelona, Spain; [2]Institut Català de la Salut, Organització Catalana de Trasplantaments, Barcelona, Spain; [3]Hospital Bellvitge, IDIBELL, University of Barcelona, Liver Transplant and Hepatology Unit, Barcelona, Spain; [4]Hospital Vall d'Hebron, CIBERehd, Autonomous University of Barcelona, Liver Unit, Internal Medicine Service, Barcelona, Spain*
Email: gcrespo@clinic.cat

Background and Aims: Delisting following recompensation has been reported in a proportion of liver transplant (LT) candidates, particularly HCV-infected patients when viral eradication is achieved. The information regarding this issue is much scarcer for other etiologies of liver disease. We aimed to investigate delisting for improvement in a multicentric cohort of LT candidates, focusing on patients with alcohol (ETOH)-related cirrhosis.
Method: Retrospective study within the OCATT registry data. All LT candidates admitted in the waiting list (WL) for LT due to decompensated cirrhosis (DC) in Catalonia (Spain) between 2007 and 2018 were included. The etiologies of liver disease considered were ETOH, HCV, non-alcoholic fatty liver disease (NAFLD), cholestatic, and others. Patients with mixed etiologies and those admitted in the WL for indications other than DC were excluded. We analyzed the probability of delisting due to improvement in the whole cohort and according to the etiology. In ETOH DC patients, baseline characteristics associated with delisting for improvement were evaluated, and clinical outcomes of these patients described.
Results: During the study period, 1230 patients with DC were admitted in the WL (420 ETOH, 403 HCV, 70 NAFLD, 108 cholestatic, 229 others). In the whole cohort, 6.2% of patients were delisted for improvement. In patients with ETOH DC, probability of delisting was 8.6% (n = 36), similar to that in HCV (7.7%, n = 31), and significantly higher than in patients with NAFLD (1.4%, n = 1), cholestatic diseases (1.8%, n = 2), or other causes (3.1%, n = 7) (p = 0.04). In patients with ETOH DC, delisting for improvement was more likely in women (18% vs 7%, p = 0.025), and in patients with lower MELD score at WL admission (p < 0.001). After a median follow-up of 44 months after delisting, 67% of ETOH DC delisted (n = 24) remained alive without LT, 6% (n = 2) were readmitted in the WL and underwent LT, 11% (n = 4) died due to non-hepatic causes, and 17% (n = 6) died due to liver-related causes.
Conclusion: Delisting following improvement is relatively frequent in ETOH and HCV DC, and extremely rare in other etiologies of liver disease. Female gender and low MELD score at WL admission are associated with higher chances of delisting for improvement in ETOH DC. After delisting for improvement in ETOH DC, the incidence of liver complications is similar to that reported in the literature in patients with HCV that are delisted after viral eradication.

THU073

A novel lymphocyte proliferation assay accurately predicts 90-day survival in severe alcoholic hepatitis patients

Euan Yates[1], Huey Tan[1], Ashwin Dhanda[1]. *[1]University of Plymouth, Faculty of Health: Medicine, Dentistry and Human Sciences, Plymouth, United Kingdom*
Email: euan.yates@plymouth.ac.uk

Background and Aims: Severe alcoholic hepatitis (SAH) is an inflammatory condition with high mortality (37.8% at 6 months)[1]. Corticosteroids are the only current therapy to improve short term outcome but one third fail to respond. Identifying patients whom corticosteroid treatment would benefit is crucial. The Dexamethasone Inhibition of Lymphocyte Proliferation Assay (DILPA), accurately predicts 6-month survival in SAH patients[2]. An improved radiation-free assay, bromodeoxyuridine (BrdU) incorporation in lymphocyte steroid sensitivity (BLISS) assay, has been developed and validated in healthy controls[3]. We assessed the diagnostic capability of BLISS in SAH patients.
Method: Peripheral blood was drawn from patients between 0–72 hours of presenting to University Hospitals Plymouth NHS Trust with a clinical diagnosis of SAH (heavy alcohol use, new jaundice, coagulopathy, discriminant function [DF] >32). The primary outcome measure was 90-day survival. Peripheral blood mononuclear cells, isolated by density gradient centrifugation, were stimulated with lymphocyte mitogen in the absence or presence of dexamethasone and cultured for 48 hours as previously described[3]. Proliferation was determined by measuring BrdU incorporation using a commercial kit. The maximum suppression of proliferation by corticosteroids (Imax) was calculated.

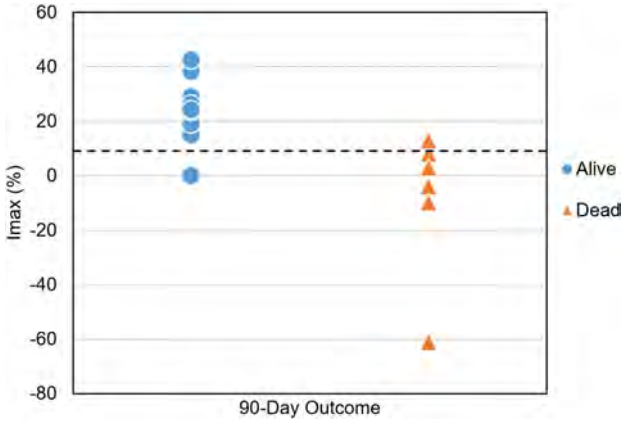

Figure 1. Imax values of SAH patients grouped by 90-day outcome.

Results: 16 patients were recruited (8 female, median age 50, mean DF 67.1) 10 patients survived to 90 days, having significantly higher Imax than non-survivors (23.80% v –0.5%; p = 0.002) with a single data point overlapping between groups (Figure 1). AUROC for Imax was 0.95 (95% CI 0.84–1.0). Using the optimum cut-point of Imax 14% had a sensitivity of 90% in identifying steroid responsive patients with a negative predictive value of 86%. Lille score of survivors was lower than non-survivors (0.32 v 0.84; p = 0.005), however applying the established threshold of 0.45 misclassified 2 patients as steroid non-responders. Imax did not correlate with Lille score (r^2 = 0.06).
Conclusion: The BLISS assay differentiates survivors from non-survivors at 90 days, showing promise as a tool to determine the patients most suited to corticosteroid treatment. Validation in a larger multicentre cohort is underway as part of the Multicentre Cohort Study in AH (MICAH) trial.

THU074

Alcohol use disorder and liver fibrosis - cases are missed through failure to test

Freya Rhodes[1,2], Sara Cococcia[1], Declan Connoley[3], Preya Patel[1], William Rosenberg[1,2]. *[1]University College London, Department of Liver and Digestive Health, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, Hepatology, London, United Kingdom; [3]Monash University, Faculty of Medicine, Nursing and Health Sciences, Melbourne, Australia*
Email: F.rhodes@doctors.net.uk

Background and Aims: Alcohol Use Disorders (AUD) account for 7.2% hospital admissions per year in the UK. While a proportion of these people are recognised to have liver disease and are managed by liver specialists, many are managed by a wide range of physicians and their liver disease may be missed even if their AUD is recognised. We aimed to use non-invasive tests for liver fibrosis to investigate the prevalence of occult liver disease in patients recognised to have AUD but not known to have liver disease.
Method: Prospective service evaluation of liver fibrosis in consecutive patients referred to the Alcohol Specialist Nurse (ASN) at the Royal Free Hospital from Nov' 2018–19. Patients were excluded if they were already known to have liver disease. Liver fibrosis was assessed using the Enhanced Liver Fibrosis (ELF) test performed on serum extracted from 5 ml of blood, analysed on an Advia Centuar. Patient demographic, blood test and imaging data were recorded along with alcohol histories. Patients with ELF scores ≥ 10.5 were invited for fibroscans and outpatient hepatology assessments.
Results: We included 85 patients (71.8% male), mean age of 52 (±13.8). Median alcohol intake was 140 units/week (IQR 87–280) and mean duration of excess alcohol 18 years (±13.4). The commonest reason for presentation to hospital was symptomatic alcohol withdrawal (n = 33/85). Other reasons included falls/trauma (10/85), pancreatitis (8/85), mental health (10/85), and 'other' (24/85). None had a prior history of liver disease. Three patients had documented signs of CLD. Liver function tests, checked in 81/85 patients were abnormal in 56/81 (69.1%). ELF scores ranged from 6.87–13.78, (mean = 9.82 ± 1.23). Of the total cohort, 22/85 (26%) had an ELF score ≥ 10.5. Of these, 25% had normal LFTs. All but one (84/85) had previously attended A&E in the last 5 years, (median number of presentations = 4, IQR 1.5–9) without assessment or diagnosis of liver disease.
Conclusion: Over a quarter of patients in this cohort with AUD had evidence of advanced liver fibrosis that had been undetected prior to 'opportunistic' ELF testing. The vast majority had had recent hospital attendances representing additional missed opportunities for investigating liver disease. LFTs cannot be relied upon to for detection of liver disease in AUD. We propose that clinicians consider using non-invasive tests to assess liver fibrosis in all patients admitted to hospital with AUD.

Decreasing incidence of alcoholic liver disease in Denmark: a nationwide study

Frederik Kraglund[1], Thomas Deleuran[1,2], Gro Askgaard[1,3], Peter Jepsen[1,4]. [1]*Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark;* [2]*Randers Regional Hospital, Department of Medicine, Randers NØ, Denmark;* [3]*Zealand University Hospital, Department of Internal Medicine, Sorø, Denmark;* [4]*Aarhus University Hospital, Department og Clinical Epidemiology, Aarhus N, Denmark*
Email: frekra@clin.au.dk

Background and Aims: Alcohol exposure has decreased in Denmark since 1994. We described the incidence, prevalence, and hospital care of alcoholic liver disease during the last two decades.
Method: Through the nationwide healthcare registries, we identified all Danish patients with a first-time diagnosis of alcoholic liver disease (ICD-10: K70.x) in the 1994–2017 period. We computed standardised incidence rates, standardised prevalence, and we enumerated inpatient admissions and outpatient and emergency room visits. Moreover, we computed incidence rates by 5-year birth cohorts (1930–1979) and 5-year age groups (30–79 years).
Results: The standardised incidence rate of alcoholic liver disease peaked at 362 (95% CI: 346–378) per 1,000,000 population in 2009 and decreased steadily to 258 (95% CI: 245–271) per 1,000,000 population in 2017. This decrease was most pronounced in men aged 15–44 and women aged 45–64. The 1950–1959 birth cohorts had the highest age-specific incidence rates, and the rates decreased sequentially with each following birth cohort. The number of inpatient admissions and emergency room visits decreased from 2009 to 2017, while the number of outpatient visits increased. The prevalence of alcoholic liver disease (0.22%) and the mean admission length per inpatient admission (6.5 days) were stable from 2009 onwards.

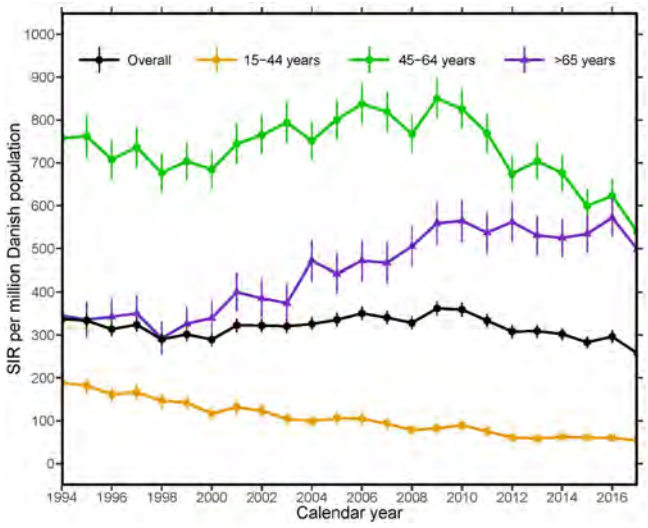

Figure: Standardised incidence rate (SIR) of alcoholic liver disease per million Danish population by age groups 1994–2017.

Conclusion: The incidence and overall hospital burden, but not the prevalence, of alcoholic liver disease has decreased since 2009 in Denmark. We anticipate a further decrease in the incidence of alcoholic liver disease in the future, since younger birth cohorts with a lower age-specific incidence have yet to reach the age of peak alcoholic liver disease incidence.

Fibroblast growth factor 21 response in a preclinical model of alcohol induced acute-on-chronic liver injury

Christidis Grigorios[1], Ersin Karatayli[2], Rabea Hall[3], Susanne N Weber[2], Frank Lammert[2], Senem C. Karatayli[2]. [1]*Homburg, Internal Medicine II, Gastroenterology, Endocrinology and Metabolism, Homburg, Germany;* [2]*Homburg University Medical Center, Internal Medicine II, Gastroenterology, Endocrinology and Metabolism, Homburg, Germany;* [3]*Homburg University Medical Center, Internal Medicine II, Gastroenterology, Endocrinology and Metabolism, Homburg, Germany*
Email: grigorischris@yahoo.gr

Background and Aims: Fibroblast growth factor (FGF) 21, the major regulator of glucose and lipid homeostasis, has been shown to play a potential role in bile acid metabolism. Here we aim to investigate FGF21 response in an ethanol-induced acute-on-chronic liver injury (ACLI) model in *Abcb4*$^{-/-}$ mice with deficiency of the hepatobiliary phospholipid transporter.
Method: Total hepatic and ileal RNA was extracted from wild-type (WT) C57BL/6J and *Abcb4*$^{-/-}$ (KO) mice, which were either fed control diet (WT/Cont and KO/Cont groups) or ethanol diet (5% v/v), followed by an acute ethanol binge (5 mg/kg) (WT/EtOH and KO/EtOH groups; n = 28/group). Hepatic expressions of *Fgf21*, *Fgfr1*, *Fgfr4*, *Klb*, *Srebf1*, *Cyp7a1*, *Cyp8b1*, *Cyp27a1*, *Shp*, *Fxr*, *Ppara* and *Mtor* as well as ileal mRNA levels of *Fgf15*, *Fgfr1*, *Klb*, *Fxr* and *Diet1* were evaluated using the $2^{-\Delta\Delta Ct}$ method. Plasma FGF15 and FGF21 levels were determined by ELISA.
Results: Ethanol exposure significantly upregulated *Fgf21* in WT and *Abcb4*$^{-/-}$ mice ($p = 0.009$ and 0.026, respectively) as compared to their control diet-fed counterparts, although no significant difference was observed. FGF21 elevation was demonstrated in plasma of WT/EtOH and KO/EtOH groups ($p = 0.040$ and 0.048, respectively). No

differences were observed for hepatic expression of *Fgfr1*, *Fgfr4*, *Klb*, *Srebf1*, *Shp*, *Fxr* and *Mtor* between groups. Ethanol challenge resulted in significant induction of hepatic *Ppara* expression in both WT (p = 0.021) and KO mice (p = 0.023). Of note, *Cyp7a1* and *Cyp27a1* were significantly repressed in livers from WT/EtOH (p = 0.044 and p = 0.007, respectively) and KO/EtOH groups (p = 0.035 and p = 0.001, respectively), as compared to WT/Cont. Significant repression of *Cyp8b1* was observed only in KO/EtOH group in comparison to WT/Cont (p = 0.041), WT/EtOH (p = 0.029), and KO/Cont groups (p = 0.027). While plasma FGF15 levels did not differ between groups, ileal expression of *Fgf15* and *Fxr* was induced in WT/EtOH compared with WT/Cont mice (p = 0.029 and p = 0.007, respectively). Ileal *Fgfr1, Klb* and *Diet1* did not differ.

Conclusion: Hepatic expression of *Cyp7a1,* which encodes the rate-limiting enzyme of bile acid synthesis, was markedly suppressed after alcohol consumption, regardless of genotype. Simultaneous upregulation of *Fgf21* and repression of *Cyp7a1* in liver, concurrently with invariant hepatic *Shp, Fxr, Klb* and *Fgfr4* and plasma FGF15 levels, suggest that upon ethanol challenge, bile acid metabolism might be regulated by FGF21, resulting in inhibition of *Cyp7a1* through an FGF15-independent pathway in our model.

THU077

Mortality in biopsy-proven alcohol-related liver disease: population-based cohort study of 3,453 individuals

Hannes Hagström[1,2,3], Maja Thiele[4], Bjorn Roelstraete[5], Jonas Söderling[5], Jonas F Ludvigsson[5,6,7,8]. Email: hannes.hagstrom@ki.se

Background and Aims: Patients with alcohol-related liver disease (ALD) are at increased risk of death, but current risk estimates rarely accounts for histological disease severity and lacks a matched reference population for comparison. We examined overall and disease-specific mortality in a nationwide cohort of biopsy-proven ALD.

Method: Population-based cohort study in Sweden. Individuals with an ICD code for ALD and a liver biopsy between 1969–2017 were included and compared to an age-, gender-, year- and municipality-matched reference population. Histopathology subgroups of ALD patients were studied. National registers were used to ascertain overall and disease-specific mortality. Cox regression adjusted for relevant confounders was used to estimate hazard ratios (HRs).

Results: We identified 3,453 patients with ALD that were matched to 16,535 reference individuals. Median age at baseline was 58 years, 65% were men and 52% had cirrhosis. After a median follow-up of 5.7 years (range 0.3–47.1), 74% (deaths = 2,557) of all patients with ALD died, compared to 31% (deaths = 5,107) of controls (adjusted [aHR] = 4.70; 95%CI = 4.35–5.08). The risk of liver-related death was particularly high (43% of all deaths, aHR = 167.6, 95%CI = 101.7–276.3). Mortality was significantly increased also in ALD patients without cirrhosis, was highest in the 12 month period after biopsy, but persisted after ≥ 10 years of follow-up (aHR = 2.74; 95%CI = 2.37–3.16). Heavy drinking was found in around 1/3 of ALD patients after baseline and was associated with a higher risk of mortality (aHR 1.30, 95%CI = 1.21–1.41).

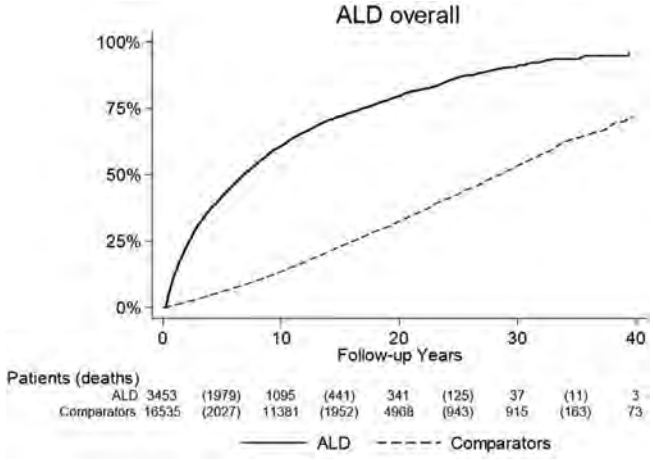

Figure: Kaplan-Meier failure curve of overall mortality or liver transplantation in patients with ALD, compared to reference individuals.

Conclusion: Persons with biopsy-proven ALD has an almost five-fold risk of dying than the general population. Risk estimates can be used to better inform clinicians and patients on short-term and long-term risks in ALD.

THU078

Inhibition of cytochrome P-4502E1 by clomethiazole improves alcoholic liver disease in alcohol-dependent patients: a short-term, randomized, controlled clinical trial

Helmut Seitz[1], Sebastian Mueller[1], Hohmann Nicolas[2], Fabian Schroeder[1], Bernardo Moreira[1], Haidong Teng[1], Walter-Emil Haefeli[1], Thomas Bruckner[1]. [1]*University of Heidelberg, Alcohol Research Center, Heidelberg, Germany;* [2]*University of Heidelberg, Nationales Centrum für Tumorerkrankungen, Heidelberg, Germany*
Email: helmut_karl.seitz@urz.uni-heidelberg.de

Background and Aims: Alcoholic liver disease (ALD) is a major health problem worldwide without effective treatment options except abstinence thus far. The pathophysiology of ALD includes, among others, oxidative stress via generation of reactive oxygen species (ROS). ROS cause lipid-peroxidation, protein alterations, and DNA injury. One important source of ROS is microsomal ethanol metabolism catalyzed by cytochrome P4502E1 (CYP2E1). Chronic ethanol consumption induces CYP2E1 primarily in the liver and, thus, deteriorates ALD and stimulates alcohol-mediated carcinogenesis in animals. Conversely, inhibition of CYP2E1 by clomethiazole (CMZ), a strong CYP2E1 inhibitor, decreases oxidative stress in cell cultures and improves ALD in animal studies.

Method: To study whether CYP2E1 inhibition improves ALD in humans, we performed a randomized controlled clinical trial in alcohol-dependent patients who were admitted for alcohol detoxification therapy (ADT) (EudraCT 2012-005730-11). All patients were non cirrhotic as identified by fibroscan <12 kPa and all had serum AST activity of more than twice the upper limit of normal. The patients were randomly assigned for ADT either with CMZ (n = 27) or clorazepate (CZP; n = 27) for 7 to 10 d.

Results: CMZ almost completely inhibited CYP2E1 measured by chlorzoxazone test 24 h after start of CMZ (p < 0.0001). Already after 4 d of treatment, serum AST- (mean ± SEM: 97 ± 11 vs. 59 ± 7 U/l; p < 0.04) and ALT activity (110 ± 14 vs. 70 ± 10 U/L; p < 0.02) were significantly lower during CMZ than during CZP. After 8 d of treatment serum transaminase activity between the two groups was as follows (AST: 73 ± 11 vs. 47 ± 5 U/l; p < 0.004 and ALT: 108 ± 14 vs. 55 ± 8 U/l; p < 0.0006). Concurrently, ADT with CMZ significantly decreased hepatic fat content (p < 0.05) as evaluated by controlled attenuation parameter (CAP), but not during CZP (p = 0.081). Similarly, only with CMZ a significant correlation was found

between hepatic fat at admission and the change of hepatic fat between admission and discharge ($r = 0.64$; $p < 0.001$).
Conclusion: This study underlines for the first time in humans the role of CYP2E1 as a pathogenic factor in ALD and shows that its inhibition improves ALD. Because CMZ with its addictive potential can only be given for a short period of time, it is mandatory to search for non-toxic CYP2E1 inhibitors to treat ALD.

THU080

Role of fecal microbiota transplantation in severe alcoholic hepatitis: assessment of impact on prognosis and short-term outcomes

Radha Dhiman[1], Anima Sharma[2], Akash Roy[1], Madhumita Premkumar[1], Sunil Taneja[1], Ajay Kumar Duseja[1], Sandeep Grover[3]. *[1]Postgraduate Institute of Medical Education and Research, Hepatology, Chandigarh, India; [2]Postgraduate Institute of Medical Education and Research, Hepatology, Chandigarh, India; [3]Postgraduate Institute of Medical Education and Research, Psychiatry, Chandigarh, India*
Email: hod.hepatology@gmail.com

Background and Aims: Severe alcoholic hepatitis (SAH) transitioning to acute on chronic liver failure, mortality rate often exceeds 50%. Targeting intestinal dysbiosis, found to be intricately linked with the disease's pathogenesis, could provide insights into novel therapeutic strategies. This study was conducted to evaluate the role of fecal microbiota transplantation (FMT) on short-term survival, prognostic scores and to assess its feasibility, tolerability and safety.
Method: Patients aged 18–60 years with SAH were included. Patients received a 5-day oral antibiotic course prior to the FMT procedure. Healthy consenting family members were selected as stool donors after screening. FMT was performed in a single setting with freshly prepared (6 hours) stool suspension constituted from 30 g of donor stool homogenized with 100 mL of normal saline delivered through a nasojejunal tube. The patients were followed up on days 7, 30 and 90 post procedure. Matched controls received standard of care (SOC) during the same period.
Results: 51 patients with SAH were screened; 33 satisfied the inclusion criteria, of which 13 (39.4%) consented to FMT. Mean age (39.6 vs 40.7 years), Child-Pugh (11.5 vs 12.1), Model for End-stage Liver Disease (25.2 vs 25.6) and Maddrey's discriminant function (87.0 vs 83.6) scores at baseline in FMT vs SOC arms were not significantly different. 1- and 3-month survival rates were higher in patients in FMT arm compared to those in SOC arm (Table). Resolution of hepatic encephalopathy and ascites were higher in patients in FMT arm compared to those in SOC arm (Table). Event rates of spontaneous bacterial peritonitis and upper gastrointestinal bleed were similar in both groups (Table). Excessive flatulence (100%), gastroesophageal reflux (53.8%) and nausea (23.1%) were the commonest side effects in patients in the FMT arm.

Parameter	FMT arm	SOC arm	P value
N	13	20	
Mean age (Years)	39.6 ± 17.1	40.7 ± 13.1	0.68
1-month survival	13 (100%)	12 (60%)	0.016
3-month survival	7 (53.8%)	5 (25%)	0.14
Resolution of hepatic encephalopathy	6/6 (100%)	8/14 (57.1%)	0.11
Resolution of ascites in survivors	7/7 (100%)	2/5 (40%)	0.045
Spontaneous bacterial peritonitis	4/13 (30.76%)	5/20 (25%)	1.0
Upper gastrointestinal bleed	3/13 (23.07%)	7/20 (35%)	0.70

Conclusion: FMT was feasible, tolerable and safe in patients with SAH. FMT was associated with a lower one-month mortality rate and higher rate of ascites resolution. There was a trend toward improved three-month survival and resolution of hepatic encephalopathy.

THU081

In alcoholic hepatitis, cytokeratin 18 serum fragments reflect its severity and predict responsiveness to prednisolone

Stephen Atkinson[1], Jane Grove[2,3], Stephanie Liebig[4], Stuart Astbury[2,3], Robert D. Goldin[1], Alberto Quaglia[5], Heike Bantel[4], Neil Guha[2,3], Mark Thursz[1], Pavel Strnad[6], Guruprasad Aithal[2,3]. *[1]Imperial College London, Department of Hepatology, United Kingdom; [2]Nottingham University Hospitals NHS Trust and the University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; [3]University of Nottingham, Nottingham Digestive Diseases Centre, United Kingdom; [4]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Germany; [5]King's College Hospital, Institute of Liver Studies, United Kingdom; [6]University Hospital RWTH Aachen, Gastroenterology, Metabolic Diseases and Intensive Care, Germany*
Email: stephen.atkinson@imperial.ac.uk

Background and Aims: Up to 40% of patients with severe alcoholic hepatitis (sAH) die within 6 months of presentation making prompt diagnosis and appropriate treatment essential. Cytokeratin 18 (CK18) serum fragments have been widely used as markers of hepatocellular injury. The aim was to determine the association between serum CK18 and histological features, prognosis, and a differential response to prednisolone in patients with sAH.
Method: CK18-M65 and CK18-M30 were quantified in pre-treatment serum from patients recruited to the Steroids or Pentoxifylline for Alcoholic Hepatitis (STOPAH) trial ($n = 824$). Histology was assessed using the Laennec fibrosis grade and Alcoholic Hepatitis Histological Score in 134 available cases.
Results: CK18-M30 and CK18-M65 levels were higher in cases with severe inflammation (both $p < 0.0001$) or ballooning (both $p < 0.01$) on biopsy. Serum CK18-M30 ($p = 0.0016$) and CK18-M65 ($p = 0.0032$) were both significantly associated with 90-day mortality in patients who did not receive prednisolone. A significant interaction was noted between prednisolone and high serum CK18-M30 (defined as >5000 IU/L, $p_{interaction} = 0.0162$). When dichotomised by this cut point, prednisolone was associated with a significant reduction in mortality in those with high (odds ratio 0.43, 95% confidence interval 0.19–0.95, $p = 0.040$) but not low, CK18-M30 (odds ratio 1.27, 95% confidence interval 0.88–1.84, $p = 0.20$).
Conclusion: In patients with sAH serum CK18 fragments are strongly correlated with its severity and 90-day mortality. A cut-off of CK18-M30 >5000 IU/L appears to define a population of patients with severe inflammation in whom a beneficial response to prednisolone is seen at 90 days.

THU082

Multi-modal training of specialty clinical trainees improves the detection and subsequent interventions for alcohol use disorder

Hamzeh Saraireh[1], Joseph Redman[1], Sasha Mangray[1], Samarth Patel[1], Brian Davis[1], Michael Fuchs[1], Puneet Puri[1], HoChong Gilles[1], James Wade[1], Jasmohan S Bajaj[1]. *[1]Virginia Commonwealth University and McGuire VA Medical Center, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: Pts seen in hepatology clinics require alcohol use disorder (AUD) screening. While usually done directly, a structured approach using AUDIT-10 is preferred. We first collected data retrospectively regarding AUD detection, aimed to train providers and follow them prospectively to gauge improvement.
Method: *Retrospective(Retro)*: Clinic encounters over the last 1 yr were evaluated by 2 reviewers in 2 cohorts (Cohort 1: 6mth-1 yr prior to training & cohort 2: 6 mths-end). Encounters were evaluated for (1) whether alcohol was asked about (2) if yes, was it followed by AUDIT-10 & (3) was intervention suggested. *Training*: GI providers were asked about AUD & training was provided to ask pts regarding alcohol & follow up with AUDIT-10 & referral as neeeded. AUDIT-10 templates in the EMR were shown. *Prospective(Prosp)*: Similar data as the retro study were collected for 6 mths post-training. Changes in (a)

alcohol inquire (b) AUDIT-10 provision (c) alcohol-related counselling & interventions between cohorts were compared.
Results: *Training*: 17 providers (10 trainees) underwent training. Most trainees had little familiarity with DSM-V criteria, were unfamiliar with AUDIT-10 & did not consult with mental health. *Pt comparisons*: 239 pts were in retrospective cohort 1 (95% men), 139 in cohort 2 (96% men) and 125 (95% men) were in the prospective group. Groups were similar with respect to age, advanced fibrosis, alcohol etiology, & active alcohol use. *Alcohol-related activities*: Significantly higher percent in the prosp received counselling. In pts with active drinking, further inquiry via AUDIT-10 was higher in prosp pts. This resulted in higher intervention rates compared to both retro gps. Missed opportunities were lower in prosp pts. No differences were seen between the 2 retro cohorts.

Table: Comparison between retrospective and prospective cohorts

N (%) or mean ± SD	Retro 1 (n = 239)	Retro 2 (n = 139)	Prosp (n = 125)	P value (all gps)
Age	62.8 ± 9.4	61.5 ± 9.0	62.3 ± 9.4	0.61
F0-F2/F3-F4 Fibrosis (n)	118/121	71/68	60/65	0.53
Alc etiology	81 (34%)	50 (36%)	37 (30%)	0.41
Alcohol-related questions				
Asked about alcohol?	198 (83%)	105 (76%)	112 (90%)	0.09
Active drinker?	74 (31%)	44 (32%)	57 (46%)	0.42
Alcohol-related counselling provided?	260 (71%)		110 (88%)	<0.0001
In active drinkers only	*N = 74*	*N = 44*	*N = 57*	
AUDIT-10 performed? ‡ †	25 (35%)	15 (34%)	**41 (72%)**	<0.0001
AUDIT-10 score	10.3 ± 7.1	8.9 ± 8.1	8.7 ± 7.2	0.32
Alcohol-related interventions ‡†	7 (9%)	3 (7%)	**22 (39%)**	<0.0001
Missed opportunities ‡†	49 (65%)	29 (66%)	**16 (28%)**	<0.0001

‡p < 0.05 comparing Prosp vs Retro1, †p < 0.05 comparing Pros vs Retro2

Conclusion: Specific training and education about AUD to providers greatly improves rates of screening for & action taken as a result of detection of AUD & problem drinking. The familiarity of GI fellows with AUD-related instruments can be improved with training & placing AUDIT-10 in the EMR.

THU083

Temporal change in the plasma metabolome profile is indicative of outcome in severe alcoholic hepatitis

Jaswinder Maras[1], Adil Bhat[1], Gaurav Yadav[1], Arun Thakur[1], Shiv Kumar Sarin[2]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: shivsarin@gmail.com

Background and Aims: Severe alcoholic hepatitis (SAH) has a high mortality, and corticosteroid therapy is effective in reducing 28 day mortality in about 60% patients. There is limited data on the serial metabolomic profile of SAH patients on corticosteroid therapy and clinical outcomes (responder, R, Lille score <0.45 at day 7, or non-responder, NR) till 60 days.
Methods: We analyzed plasma metabolome at baseline, day 4,7,14 and 28 using ultra-high performance liquid chromatography and high-resolution mass spectrometry. Multivariate projection analysis identified metabolites in the discovery cohort (n = 35, R = 23, NR = 12) which were evaluated in the validation cohort of 100 patients (70 R, 30 NR).
Results: A total of 671 features were annotated by using metabolomic/spectral databases. SAH plasma showed significant increase in 181 metabolites linked to tryptophan metabolism, bile acids, butanoate metabolism, nitrogen metabolism and others, whereas significant decrease in 199 metabolites linked to glutathione metabolism, TCA cycle, pyruvate metabolism and others as compared to healthy subjects (FC ± 1.5, $p < 0.05$). Corticosteroid exposure for 4days increased plasma metabolites linked to tryptophan metabolism, bile-acids, nitrogen metabolism and reduced metabolites linked to sphingolipid metabolism, biosynthesis fatty-acids, glutathione metabolism, energy metabolism in NRs compared to R(FC ± 1.5,$p < 0.05$). Similarly, corticosteroid exposure for 7, 14 or 28days significantly increased plasma metabolites linked to inflammation; tryptophan, butanoate, arachidonic/leukotriene metabolism and decreased metabolites associated to antioxidant pathway (glutathione metabolism), biosynthesis of fatty acids and alternate energy pathways in NR (FC>1.5, $p < 0.05$). Increased plasma levels of 3-hydroxyanthranilate, L-kynurenine, 3-Indoleacrylic acid (tryptophan metabolism) and arachidonate, lecithin, leukotriene-C4, prostaglandin-B1 (arachidonic/leukotriene metabolism) significantly correlated to severity and mortality ($r > 0.4$; $P < 0.01$). Upon validation, baseline levels of L-kynurenine (OR, 2.1(1.5–3.2) Indoleacrylic acid (OR, 3.0 (2.4–8.2), lecithin (OR, 1.5(1.2–2.9) and prostaglandin B1(OR, 3.5(1.8–9.2) were the most significant predictors of non-response and non-survival (AUROC>0.80; $p < 0.05$) in our study cohort.
Conclusion: Corticosteroid over exposure has hazardous effect particularly on non-responsive patients. Temporal changes in plasma metabolome signatures associated with tryptophan and arachidonic/leukotriene metabolism can reliably predict at baseline steroid response and disease outcome in SAH patients.

Pharmacokinetics of DUR-928 in alcoholic hepatitis patients - a phase 2a study

Jaymin Shah[1], Christina Blevins[2], Deborah Scott[2], WeiQi Lin[3]. [1]*Durect Corporation, Clinical Pharmacology, Cupertino, United States;* [2]*Durect Corporation, Clinical Operation, Cupertino, United States;* [3]*Durect Corporation, Clinical, Cupertino, United States*
Email: jaymin.shah@durect.com

Background and Aims: DUR-928 is an endogenous small molecule that epigenetically modulates the gene expression of various nuclear receptors which play important roles in lipid homeostasis, inflammation, cell survival and regeneration. The potential use of DUR-928 as a treatment for acute organ injury, including alcoholic hepatitis (AH), has been demonstrated in multiple pharmacology studies in animal disease models. The primary objective of this Phase 2a study is to assess the safety and pharmacokinetics (PK) of DUR-928 in moderate and severe AH patients.
Method: The study is an open-label, multi-center, dose escalation safety/PK Phase 2a trial. All patients received DUR-928, at dose of 30, 90, or 150 mg, by intravenous infusion for 2 hrs on Day 1 and Day 4 (if still hospitalized), and were followed for 28 days. Part A of the study consisted of patients with moderate AH (MELD 11–20) and Part B included patients with severe AH (MELD 21–30).
Results: Total of 19 patients (12 severe AH, and 7 moderate AH) participated in the study. DUR-928 was well tolerated. The drug exposure (both AUC and C_{max}) in AH patients was dose proportional. Time to maximum drug concentrations (T_{max}) was at the end of 2 hour infusion. The half-life ($t_{1/2}$) of DUR-928 ranged from 4 to 6 hours. Mean clearance of DUR-928 was about 5–7 L/hr. PK parameters of DUR-928 were similar between the moderate and severe AH groups. Compared to PK parameters of DUR-928 in healthy subjects, there was a 2-fold increase in C_{max} and a 6-fold increase in AUC in AH patients at the same dose level. The clearance of DUR-928 was decreased by 80% in AH patients as compared to that in healthy subjects from an earlier study. In addition, encouraging efficacy signals, including early reduction from baseline of serum bilirubin levels and reduction of MELD on Day 28, and high treatment response rate (based on Lille score) were observed in the study (1, 2).

Conclusion: DUR-928 was well tolerated at doses tested in AH patients, including severe AH patients. Compared to the healthy subjects, AH patients had a much slower clearance, resulting in a 2-fold higher C_{max} and 6-fold higher AUC. However, the drug exposure was not affected by the severity of the disease.

Alterations and role of bioactive lipid metabolites (oxylipins) in human and experimental ALD: associations with disease severity

Jeffrey Warner[1], Kara Zirnheld[1], Vatsalya Vatsalya[1], Dennis Warner[1], Josiah Hardesty[1], Craig J. McClain[1], Irina Kirpich[1]. *[1]University of Louisville School of Medicine, Gastroenterology, Hepatology, and Nutrition, Louisville, United States*
Email: irina.kirpich@louisville.edu

Background and Aims: Alcoholic liver disease (ALD) is a major contributor to total liver disease burden worldwide. ALD pathogenesis is not well understood and there is no effective therapy. Oxylipins, including epoxy- and dihydroxy-fatty acids (Ep-FAs and dihydroxy-FAs, respectively), are important signaling molecules that regulate various biological processes. Evidence suggests Ep-FAs are beneficial, anti-inflammatory lipid mediators, whereas the properties of dihydroxy-FAs are not well determined. In this study we aimed to: i) examine alcohol-induced alterations in plasma oxylipin levels in human ALD and ii) investigate the effects of dihydroxy-FAs in experimental ALD.
Method: Human studies: plasma lipidomic analysis was performed on 44 moderate (mAH) and severe (sAH) alcoholic hepatitis patients and 29 socially drinking healthy controls (HC). Animal studies: male C57BL/6 mice were subjected to a chronic-binge animal model of ALD (NIAAA model). Mice were administered either 8,9-DiHETE or a combination of 9,10-DiHOME and 12,13-DiHOME by i.p. injection once daily for two days prior to sacrifice. Liver injury, inflammation, and steatosis were evaluated. Primary mouse hepatocytes were treated with 8,9-DiHETE, 9,10-DiHOME, 12,13-DiHOME and baseline or palmitic acid (PA)-induced cell death was evaluated.
Results: Among dihydroxy-FAs, 8,9-DiHETE was elevated in both mAH and sAH compared to HC. 9,10-DiHOME was significantly elevated in mAH but not in sAH, while 12,13-DiHOME was similar in AH patients and HC. 9,10- and 12,13-EpOMEs were significantly decreased in both mAH and sAH compared to HC. Multivariable regression analysis revealed a moderate association between low 12,13-EpOME/high 8,9-DiHETE and plasma cytokeratin 18 M65 (CK18 M65), a marker of necrotic cell death in sAH ($r^2 = 0.3333$, $p = 0.0478$). *In vivo*, 8,9-DiHETE treatment modestly, while 9,10/12,13-DiHOME significantly, increased liver injury in mice as determined by elevated plasma ALT levels. Dihydroxy-FA treatment had minor effects on hepatic inflammation. *In vitro*, 8,9-DiHETE treatment significantly exacerbated PA-induced cell death of primary mouse hepatocytes, whereas 9,10-DiHOME, and 12,13-DiHOME had no effect on PA-induced or baseline cell death.
Conclusion: Plasma lipidomic analysis in human ALD identified distinct alterations of several plasma oxylipins between mAH and sAH. These bioactive lipid mediators may serve as novel biomarkers of ALD severity and represent therapeutic targets to prevent and/or attenuate progression of ALD. Dihydroxy-FAs, specifically 8,9-DiHETE, exacerbated liver injury in mice and increased PA-induced cell death in primary hepatocytes. Future studies are warranted to dissect the effects of individual dihydroxy-FAs in ALD.

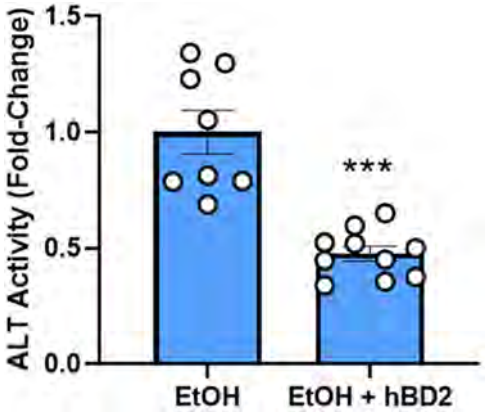
Alcohol-induced liver injury is attenuated by human beta defensin in experimental ALD via improvements in the gut-liver axis

Jeffrey Warner[1], Ida Larsen[2], Dennis Warner[1], Josiah Hardesty[1], Ying Song[1], Rui Sun[3], Zhongbin Deng[3], Peter Nordkild[4], Craig J. McClain[1], Benjamin Jensen[2], Irina Kirpich[1]. *[1]University of Louisville School of Medicine, Gastroenterology, Hepatology, and Nutrition, Louisville, United States; [2]Laval University, University Institute of Cardiology and Pulmonology, Quebec City, Canada; [3]University of Louisville School of Medicine, Oncology, Louisville, United States; [4]Defensin Therapeutics ApS, Copenhagen, Denmark*
Email: irina.kirpich@louisville.edu

Background and Aims: Alcohol-induced liver disease (ALD) is associated with altered gut microbiota, compromised intestinal barrier functions, and endotoxemia, which further exacerbate liver damage. Currently, ALD has very limited effective therapeutic options. Defensins are small host peptides with bactericidal/immunomodulatory functions, which demonstrated beneficial effects in various animal models associated with inflammation. Here, we tested the hypothesis that human beta defensin 2 (hBD2) would attenuate ethanol-induced liver injury via improvement of gut barrier integrity and beneficial changes in the gut microbiome.
Methods: Male C57BL/6J mice were chronically fed ethanol (EtOH) for 5 weeks. During the final week, a subset of mice was administered 1.2 mg/kg hBD2 by oral gavage (8 treatments). Liver steatosis, injury and inflammation were evaluated. Pro-inflammatory lymphocytes were analyzed by flow cytometry in the intestine and mesenteric lymph nodes (MLN). Fecal microbiome was determined by 16S sequencing. Mouse intestinal enteroids were established and subjected to IFN-γ ± hBD2 treatment.
Results: Compared to EtOH-fed mice, EtOH + hBD2 treated animals revealed reduced hepatic steatosis, less liver damage as demonstrated by a 50% decrease in plasma ALT levels ($p < 0.05$), and a 60% decrease in the number of TUNEL-positive hepatocytes ($p < 0.05$). Further, hBD2 treatment reduced hepatic neutrophil numbers by 70% ($p < 0.05$) with a concomitant decrease in the expression of several proinflammatory genes, including chemoattractant cytokines, *Mip2a* and *Mcp1.* MLN-derived lymphocytes showed a decrease in pro-inflammatory Th1 ($CD4^+$ $IFN\gamma^+$) and Th17 ($CD4^+$ $IL17a^+$) cell populations by 55% and 33% respectively in EtOH + hBD2 compared to EtOH-fed mice. Fecal microbiome analysis revealed similar alpha diversity but a significant difference in composition, including increase in *Bifidobacterium* and decrease in *Akkermansia* in EtOH+hBD2 compared to EtOH treated mice. These changes have previously been linked to protection from and exacerbation of barrier dysfunction, respectively, in other liver disease states. Finally, small intestine enteroids treated with IFN-γ had decreased expression of the tight junction proteins, including *Ocln*, which was attenuated by co-treatment with hBD2.



Conclusion: Oral treatment with hBD2 of mice chronically fed EtOH significantly reduced liver injury and inflammation and led to favorable changes in the immune status and the gut microbiome. These results thus support hBD2 as a potential therapeutic agent for ALD acting via improvement of the gut-liver axis.

Email: jenniferryan@doctors.org.uk

Background and Aims: Alcohol-related liver disease (ALD) is characterised by impaired anti-bacterial immunity, driven by intestinal hyperpermeability and bacterial translocation. Type III interferons (IFN Lambda (L) 1/2/3/4) are important anti-pathogen cytokines with central roles in systemic and mucosal defenses. Polymorphisms in the genes encoding the IFNL proteins play an important role in chronic HCV infection. Here we explore the unknown role of IFNL in ALD, specifically examining neutrophils, liver, colon, plasma and assess the impact of single nucleotide polymorphisms (SNPs) in IFNL.
Method: IFNL1/2 and IFNL-receptor (R) expression were determined by qPCR in (A) Neutrophils challenged with/without *E. coli* from 7 patients with alcoholic hepatitis (AH), 13 patients with alcohol-related cirrhosis (ARC) and 12 controls (HC); (B) Colonic tissue from 10 ARC and 10 HC; (C) Liver tissue of AH/HC (GEOdata). Plasma IFNL1/2/3 were measured by ELISA in 42 AH, 26 ARC and 10 HC. Neutrophil phenotype and function were assessed by FACS post-IFNL treatment. Selected SNPs in IFNL were assessed in 804 AH, 305 ARC, 11029 HC and 2238 alcohol-dependent drinkers with no liver disease.
Results: Neutrophil IFNL1 was induced by *E. coli* in HC ($p = 0.001$) and ARC ($p = 0.005$), but was completely abrogated in AH. We observed intrahepatic IFNLR expression in AH/HC and IFNLR hyper-expression in ARC colon ($p = 0.003$). There was no intrahepatic or colonic gene detection for IFNL1 or IFNL2. The majority of AH patients (63%) were positive for plasma IFNL2/3 compared to ARC (43%). *In vitro* treatment with IFNL1 increased neutrophil TLR4 expression. No significant differences were identified in the IFNL SNPs between the four groups. However, in AH carriage of *IFNL4:*rs117648444 was significantly associated with infection at presentation, when adjusted for age and MELD score ($p = 0.028$).
Conclusion: Neutrophil anti-bacterial IFNL1 production is deficient in AH while carriage of *IFNL4:*rs117648444 may increase susceptibility to infection. We also show colonic IFNLR expression is increased in ARC, suggesting that this compartment, which is central to the immunopathogenesis in ALD, may be susceptible to IFNL-mediated modulation. Overall these findings point to widespread disruption of Type III interferon function in patients with ALD.

THU088

The role of PNPLA3, MBOAT7 and TM6SF2 during alcohol detoxification: different mechanisms of fibrosis and steatosis development

Johannes Mueller[1], Vanessa Rausch[1], Teresa Peccerella[1], Omar Elshaarawy[1], Sebastian Mueller[1]. [1]*Salem Medical Center and Center for Alcohol Research, University of Heidelberg, Heidelberg, Germany*
Email: sebastian.mueller@urz.uni-heidelberg.de

Background and Aims: In genome wide association studies PNPLA3, MBOAT7 and TM6SF2 were identified as important risk genes for the development of alcoholic cirrhosis, however, their functions and molecular mechanisms are still poorly understood. We here present first data on the role of PNPLA3, MBAOT7 and TM6SF2 genotypes on liver stiffness (LS), steatosis (CAP) and inflammation during alcohol withdrawal.
Method: 763 patients with ALD which were hospitalized for alcohol withdrawal at Salem Medical Center between 2007 and 2018 were genotyped for PNPLA3 s738409, MBOAT7 rs626283 and TM6SF2 rs58542926 polymorphisms. All patients had routine laboratory, abdominal ultrasound and a transient elastography measurement (FibroScan) at admission. In 512 patients, data after 6.3 days of alcohol withdrawal was available.
Results: 71% of the patients were male, median age was 52 years, median BMI was 24.7 kg/m^2 and median alcohol consumption was 163 g/day. At admission, no difference between the genotypes of PNPLA3, MBOAT7 and TM6SF2 was seen regarding age, BMI, gender, alcohol consumption or transaminase levels. Significant differences were observed for PNPLA3 and MBOAT7 during alcohol detox. While MBOAT7 was associated with higher LS, no differences were observed between genotypes upon alcohol detoxification. In contrast, PNPLA3 caused clearly a delayed resolution of LS during withdrawal of alcohol due to inflammation. This could be recapitulated when looking at serum markers of liver inflammation. In a sub-analysis of n = 108 liver biopsies, inflammation was highly associated with PNPLA3 but not MBOAT7 and TM6SF2. More interestingly, PNPLA3 was associated with higher steatosis. No effect at all was seen for MBOAT7 on steatosis. For TM6SF2, no differences regarding LS, CAP or transaminases were seen between the genotypes before or after detoxification. A multivariate model confirmed that PNPLA3 was associated with steatosis and inflammation but not fibrosis. MBOAT7 was only associated with fibrosis/cirrhosis but not inflammation or steatosis.
Conclusion: These first genotype data on a "human alcohol knock-out" intervention underscore important difference between the three genes. PNPLA3 seems to primarily drive fibrosis through inflammation while MBOAT7 seems to have a direct effect on fibrosis. TM6SF2 showed no effect. Finally, alcohol detoxification could be a novel interventional approach to further dissect metabolic mechanisms and their associations with genotypes.

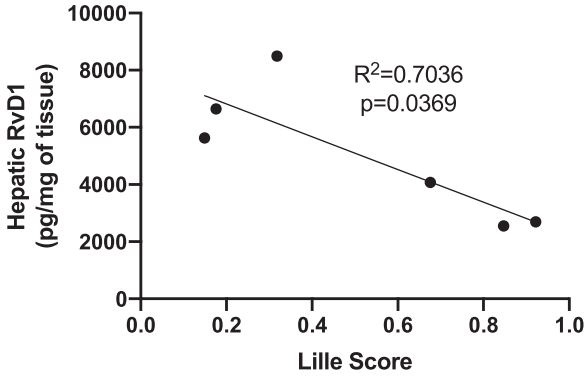
THU089

Loss of the resolvin D1-formula peptide receptor 2 signaling axis leads to pro-inflammatory transcriptional reprogramming in alcoholic liver disease

Josiah Hardesty[1], Jeffrey Warner[1], Dennis Warner[1], Ying Song[1], Craig J. McClain[1], Irina Kirpich[1]. [1]*University of Louisville, Gastroenterology, Hepatology, and Nutrition, Louisville, United States*
Email: irina.kirpich@louisville.edu

Background and Aims: Alcoholic liver disease (ALD) is a spectrum of liver disorders ranging from steatosis to steatohepatitis, and further progressing to fibrosis. Alcoholic Hepatitis (AH) is a clinical manifestation of severe liver damage often coinciding with systemic infection and inflammation. Formyl peptide receptor 2 (FPR2) is a mediator of inflammation resolution through interaction with the lipid-derived metabolite resolvin D1 (RvD1). In this study we aimed to investigate RvD1-FPR2-mediated transcriptional responses controlling the resolution of inflammation.

Method: For translational studies we utilized liver tissue samples acquired from AH patients (n = 7) and non-drinking controls (n = 12). Hepatic FPR2 and RvD1 levels were measured and used for regression analysis with markers of AH severity and prognosis (ABIC, MELD, and Lille Scores). The expression of signal transducer and activator of transcription 1 (STAT1) and early growth response 1 (EGR1), which regulate the transcription of inflammatory genes in response to bacteria and cytokines commonly increased in ALD/AH, were measured. For animal studies, female *Fpr2*$^{-/-}$ and WT mice were fed control or ethanol (EtOH)-containing diets *ad libitum* for 5 weeks and liver disease endpoints were measured. BMDMs isolated from naïve WT and *Fpr2*$^{-/-}$ mice were subjected to LPS + RvD1 in the presence or absence of EtOH.



Results: Hepatic RvD1 was negatively correlated with AH severity (ABIC, $R^2 = 0.78$; Lille Score, $R^2 = 0.70$). Hepatic FPR2 protein was reduced, while *STAT1* and its target gene guanylate binding protein 2 (*GBP2,* which releases intracellular LPS from bacteria and promotes pyroptosis) were significantly elevated in AH relative to controls. Hepatic *EGR1* was increased and positively associated with MELD score in AH ($R^2 = 0.7368$). Compared to WT, *Fpr2*$^{-/-}$ EtOH-fed mice had exacerbated EtOH-induced liver injury and inflammation. As compared to WT, *Fpr2*$^{-/-}$ mice fed EtOH had elevated levels of hepatic *Egr1.* LPS-stimulated WT but not *Fpr2*$^{-/-}$ murine macrophages had reduced *Egr1* and *Gbp2* after RvD1 treatment suggesting a potential mechanism of RvD1-FPR2-mediated resolution of inflammation.
Conclusion: The RvD1-FPR2 axis is compromised in AH associated with elevation of *STAT1* and *EGR1.* Genetic ablation of *Fpr2* exacerbates experimental ALD accompanied by elevated *Stat1* and *Egr1.* RvD1 mechanistically acts through negative regulation of STAT1 and EGR1 in a FPR2 dependent manner in murine macrophages.

THU090

High risk of futile over-referrals or late under-referrals among patients suspected of alcohol-related or non-alcohol-related fatty liver disease: real-world evidence reveal opportunities to optimize referral patterns to secondary care

Katrine Prier Lindvig[1], Charlotte Wernberg[1], Maja Thiele[1], Aleksander Krag[1]. [1]*FLASH Center for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, odense C, Denmark*
Email: katrine.prier.lindvig@rsyd.dk

Background and Aims: We are facing an increased focus and expanded possibilities to treat alcohol-related (ALD) and non-alcohol-related fatty liver diseases (NAFLD). However, compensated cirrhosis and liver fibrosis are mostly silent disease and challenging to diagnose in primary care. Consequently, patients are frequently diagnosed at a symptomatic stage with decompensation. On the other hand, patients at risk of ALD and NAFLD that will never progress to advanced fibrosis may be referred for futile expensive and invasive investigations due to lack of applicable decision tools in primary care. We aimed to investigate the referral patterns, to a secondary liver center, of patients with suspected advanced fibrosis or related complications due to fatty liver disease.
Method: Audit of all referrals in 2016 and 2017 to a secondary care liver clinic. We evaluated the general physician's referral diagnosis from ICD-10 codes and electronic patient referral records and compared to the diagnostic conclusion made by experienced hepatologists after completing the liver clinic investigations. Two MD's reviewed all patients' electronic medical files. We labelled referrals as either: futile (no liver disease or mild fibrosis), timely (significant fibrosis or compensated cirrhosis) or too late referred (decompensated disease).
Results: 188 referrals from primary care or other non-hepatology departments were reviewed. 63% were male, mean age was 55 years. In total, 174/188 (92.5%) had a liver assessment in the department, 46.8% was returned to GP or the referring unit, and the other half, 50.0% remained in the department as a hepatology out-patient. One third (32.4%), of referred patients was judged as futile referred, furthermore, one third (29.7%) of referred patients was judged as referred to late. The last third of patients was judged as being timely referred to the department. If FibroScan was applied in all patients, the mean LSM was 5.6 kPa, 18.6 kPa, and 45.5 kPa if judged futile, timely and too late, respectively.
Conclusion: Only one-third of patients referred on suspicion of alcohol-related or non-alcohol-related fatty liver disease are correctly referred, in a timely manner. One-third of patients are futile referrals without liver disease, while another one-third is referred at the stage of decompensated cirrhosis.

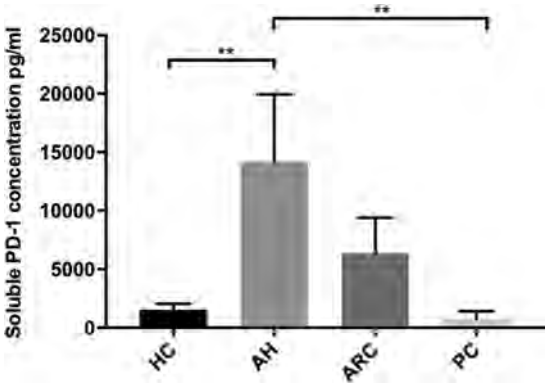
THU091

Patients with alcoholic hepatitis present strong Th1 cellular immune responses to alcohol dehydrogenase related to impairment of the PD-1/PD-L1 pathway due to high circulating levels of soluble PD-1

Laura Blackmore[1], Brandon Turner[1], Xiaohong Huang[1], Munther Hussain[1], Debbie L. Shawcross[1], Yun Ma[1]. [1]*Institute of Liver Studies and Transplantation, King's College London, King's College Hospital, London, United Kingdom*
Email: laura.blackmore@nhs.net

Background and Aims: Alcoholic hepatitis (AH) is characterised by florid hepatic inflammation, liver failure and high short-term mortality. We have previously reported that AH patients present strong cellular immune responses to alcohol dehydrogenase (ADH), with a predominant Th1 and a limited Th2 response. We have also observed that AH patients have a reduced frequency of suppressive PD-1 expressing CD4 T cells. The imbalanced cellular immune response to ADH is related to a defect in the PD-1/PD-L1 pathway, which negatively regulates T cells and is essential for the maintenance of peripheral tolerance. In this study, I aimed to evaluate the role of circulating soluble PD-1 (sPD-1) in patients with AH.
Method: PBMC and plasma were collected from 29 AH patients (20 female, median age: 43, range 25–63), 12 alcohol-related cirrhosis (ARC) patients (4 female, median age: 61, range 37–74), 9 pathological controls (PC) (NASH, PSC; 4 female, median age: 58, range 39–70), and 14 healthy controls (HC) (6 female, median age: 38.5, range 28–64). 1×10^5 cells/well were cultured with T cell stimulator and IL-2, with and without 10μM of 8 antigenic ADH peptides. Cells were cultured for 8 days in the presence or absence of anti-PD-1, anti-PD-L1 or combined anti-PD-1/PD-L1 neutralising antibodies. Cells were harvested and FACS used to determine T cell phenotype and frequency of cytokine producing T cells. Duplicate cell cultures were pulsed with 0.25 μCi/well ^{3}H-thymidine for 18 hours and harvested onto glass-fibre lined membranes. Thymidine incorporation was measured using a β-counter and expressed as the stimulatory index (SI). Proliferative responses were positive when $SI \geq 2.5$. Plasma (100 μl/well) was used to measure concentrations of soluble PD-1

using a sandwich ELISA according to the manufacturers standard protocol (DuoSet ELISA for human sPD-1, R&D Systems).
Results: In AH, positive PBMC proliferative responses were observed in the presence of ADH peptides, but not in their absence. Frequency of PD-1^{+ve}CD4^{+ve} lymphocytes was significantly higher in the presence of ADH peptides and no PD-1/PD-L1 blockade in HC than in AH (4.40 ± 0.54 versus 1.90 ± 0.26, p = 0.003). Mean baseline soluble PD-1 concentration was significantly higher in AH than in HC (14,205 ± 5741 versus 1536 ± 521.4 pg/ml, p = 0.0075) and PC (14,205 ± 5741 versus 755.9 ± 658.6 pg/ml, p = 0.0032). No other significant differences in sPD-1 were identified between groups.



Conclusion: Soluble PD-1 has been shown to counteract PD-L1 mediated suppression of CD4^{+ve} T cell proliferation in a number of autoimmune diseases. We have identified significantly higher levels of sPD-1 in patients with AH, who demonstrate inappropriate proliferative cellular immune responses to ADH. This may explain some of the beneficial effects of immune suppression in the treatment of AH. Further investigation of the role of sPD-1 is warranted in AH.

THU092

Differential roles of receptor interacting protein 3 and mixed lineage kinase like in murine models and patients with alcohol- and non-alcohol related liver disease

Tatsunori Miyata[1], Xiaoqin Wu[1], Xiude Fan[1], Kyle Poulsen[1], Megan McMullen[1], Srinivasan Dasarathy[1], Laura Nagy[1]. [1]*Cleveland Clinic*
Email: len2@po.cwru.edu

Background and Aims: The intricate balance between cell death and pro-survival pathways is critical for regulating liver injury and inflammation during progression of ALD or NAFL/NASH. Previous work identified a critical role for *rip3,* a kinase regulating necroptotic cell death, in mediating chronic ethanol-induced, but not high fat diet-induced, liver injury in mice. In humans, RIP3 expression is low in healthy livers, but is increased in livers of patients with ALD and NAFL/NASH. However, very little data are available on direct comparisons of expression of the RIP1-RIP3-MLKL molecular machinery between patients with different etiologies of liver disease. Based on these data, here we investigated two questions: 1) is there a differential role for *mlkl*, the down-stream effector of RIP3 in the necroptotic pathway, in murine models of AH and NASH and 2) can RIP1-RIP3-MLKL be used as biomarkers to distinguish AH from NASH in patients.
Method: *Mlkl*$^{-/-}$ mice and their wild-type littermates were exposed to Gao-binge (acute on chronic) ethanol or high fat fructose and cholesterol diets (FFC). Liver tissue and plasma from patients with AH and NASH, as well as healthy controls (HC) were used for Western blot and ELISA.
Results: Despite the protective effect of *rip3*-deficiency in murine models of chronic ethanol exposure, *mlkl*-deficient mice were not protected from Gao binge-induced liver injury. In contrast, *mlkl*$^{-/-}$, but not *rip3*$^{-/-}$, mice were protected from FFC-induced liver injury. Western blot studies of liver samples from patients with NASH, AH, and healthy controls revealed distinct differences in expression patterns of phospho-RIP1, RIP1, RIP3, phospho-MLKL, and MLKL between HC, AH and NASH patients. pMLKL was higher in NASH vs AH and HC while phospho RIP1 was higher in AH vs NASH and HC. RIP1 and RIP3 concentration, assessed by ELISA in plasma, was also different between AH and NASH, with RIP3 increased in AH vs NASH and HC and RIP1 increased in NASH vs AH and HC. No differences in circulating MLKL were identified between AH, NASH and healthy controls.
Conclusion: Overall, the data from murine models indicate important non-canonical functions of RIP3 and MLKL differentially contribute to ethanol- and FFC diet-induced injury. Differential expression of proteins in the RIP1-RIP3-MLKL signaling pathway in liver and plasma from patients suggest that these differences might be leveraged to develop predictive models to distinguish AH and NASH.

Email: lili.niu@cpr.ku.dk

Background and Aims: Alcohol-related liver disease (ALD) progresses through a range of histological lesions starting with alcohol-related fatty liver, to subclinical steatohepatitis, which drives accumulation of fibrosis, and ultimately cirrhosis. The plasma proteome changes corresponding to the severity of these disease entities remain to be elucidated. Mass spectrometry (MS) – based plasma proteomics holds great potential for biomarker discovery in an unbiased manner. We therefore investigated the plasma proteome in a cohort of 459 ALD patients compared to age-, BMI- and gender-matched healthy participants (HP, n = 136), to identify proteins differentially abundant between ALD and HP, and across the ALD spectrum, in dimensions of both steatosis, inflammation and fibrosis, and degrees of severity.
Method: Plasma samples were prepared on an automated liquid handling system. Proteome profiles were acquired on an LC-MS/MS platform using a hybrid BoxCar/DIA acquisition mode with a throughput of 30 samples per day. The resulting spectra were analyzed with Spectronaut™. Data analysis was done with Python scripts and the Perseus software.
Results: In total, we quantified 524 proteins. Three of six previously identified proteins associated with non-alcoholic fatty liver disease – PIGR, ALDOB, and LGALS3BP – were also upregulated in ALD compared to HP (by 158%, 95% and 64% respectively). There is a quantitative shift in proteome composition across biopsy-verified liver fibrosis stages, characterized by a decrease of liver-specific proteins including apolipoproteins, coagulation factors and organic substance transporters, and an increase of extracellular matrix proteins (ECM1, FBLN1, LUM, COL6A3, COL18A1, VWF, LGALS3BP, and TGFBI), transmembrane proteins and immunoglobulins. Of interest, we found dysregulation in components of Insulin Growth Factor (IGF) system, specifically a decrease of IGFBP3 and IGFALS (by nearly 50%), in contrast, to an increase in levels of IGFBP7 and

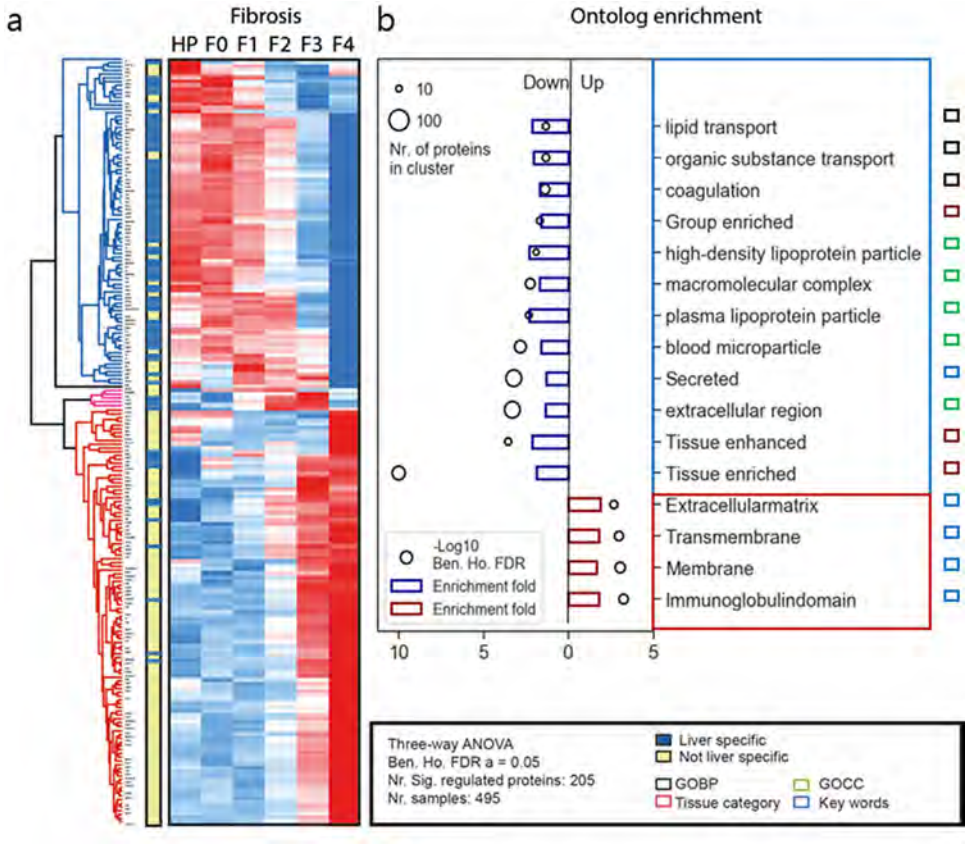

Figure: (abstract: THU093)

SPARCL1, both in a fibrosis stage dependent manner. In search of protein signatures representing liver fibrosis, inflammation and steatosis, we identified proteins correlating with severity of all three lesions. A prediction model based on six proteins (sensitivity, specificity, and MCC score of 0.86, 0.95 and 0.8) outperforms or is at par with the best-in-class markers and tests in detecting advanced liver fibrosis (ELF, FIB-4, APRI, PROC3, TF and 2D-SWE).

Conclusion: This study revealed novel patterns of protein dysregulation in alcohol associated liver disease. Proteins in these patterns likely play an active role in the process of fibrogenesis and reshaping the liver structure and function; they might consequently represent therapeutic targets. Prediction models based on pure proteomic features demonstrate similar accuracy as existing best-in-class biomarkers.

THU094

Defective gut adaptive immunity during early alcoholic liver disease

Luca Maccioni[1], Boris Pirlot[1], Isabelle Leclercq[1], Yves Horsmans[2], Bernd Schnabl[3], Peter Stärkel[1,2]. *[1]Institute of Experimental and Clinical Resarch (IREC), Laboratory of Hepato-Gastroenterology (GAEN), Brussels, Belgium; [2]Cliniques universitaires Saint Luc, Department of Hepato-Gastroenterology, Brussels, Belgium; [3]University of California San Diego (UCSD), Department of Medicine, Division of Gastroenterology, San Diego, United States*
Email: luca.maccioni@uclouvain.be

Background and Aims: Alcoholic liver disease (ALD) severity is associated with increased microbial translocation (MT) and gut barrier dysfunction. Mucosal T cells, specialists of adaptive immunity, act as local gate keepers to protect against microbial invasion. However, their role during ALD in humans is still unknown. We aimed to assess the links between gut adaptive immunity, microbial translocation and ALD progression in alcohol use disorder (AUD) patients.

Method: Actively drinking AUD patients (n = 37) admitted to a rehabilitation program were included. Fasting blood and liver stiffness (kPa)/controlled attenuation parameter (CAP) measurements were obtained at admission and distal duodenal biopsies one day after.

Serum markers for gram– and gram+ microbial translocation (soluble CD14 and peptidoglycan recognition proteins (PGRPs), respectively) and liver cell damage (cytokeratin18 (CK18-M65)) were assessed by ELISA, duodenal immune cells by immunohistochemistry/flow cytometry.

ALD severity was clinically defined as: *non-progressive ALD*, i.e. no liver disease (normal AST, ALT, CAP < 250 dB/m, no fibrosis); simple steatosis (normal AST, ALT, CAP > 250 dB/m, no fibrosis) and *progressive ALD*, i.e. steato-hepatitis, *SH* (elevated AST, ALT, CAP > 250 dB/m, no fibrosis); steato-fibrosis (*SH* and significant fibrosis (kPa >7.6)).

Results: The duodenal mucosa of AUD patients was characterized by a reduction of CD3+CD8+ T cells compared to healthy subjects (n = 15). Within the CD8+ T cell pool, tissue-resident memory CD8+ (TRM; KLRG1-, CD103+) were significantly ($p < 0.05$) reduced. In addition, TRM of AUD patients had low CD69, a regulator of TRM tissue residency. Both changes (low TRM, low CD69) occurred independently from ALD severity. TRM inversely associated with PGRPs levels, a marker of gram+ translocation, suggesting their role in immunosurveillance.

By contrast, programmed cell death protein 1 (PD1), a master regulator of adaptive immunity, was down-regulated while the senescence marker CD57 was increased in CD8+ T cells of AUD patients with clinically progressive ALD and high CK18-M65, a marker of liver cell damage, compared to controls. This shift to the

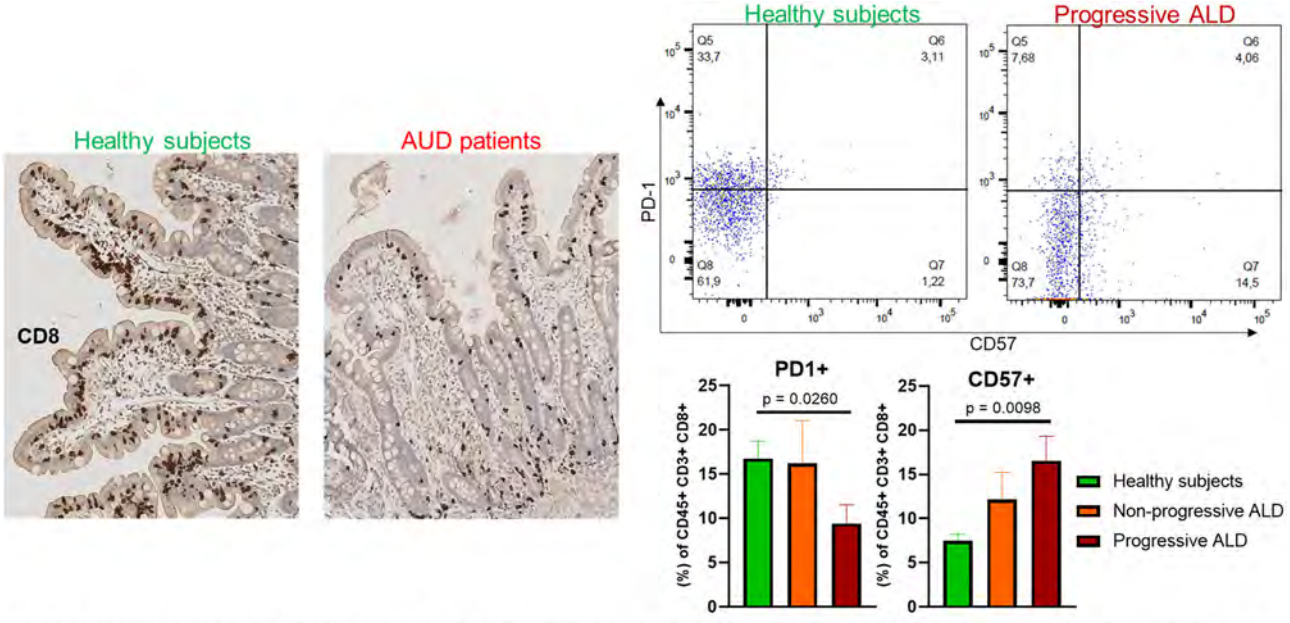

Figure: Representative duodenal sections stained for CD8 (left) of healthy controls and AUD patients; PD1 and CD57 down- and up-regulation ,respectively, (right) in progressive ALD

Figure: (abstract: THU094)

senescent phenotype (CD8+, PD1l$_{ow}$, CD57+) was associated with high sCD14, signing gram- translocation and points to an impairment of gut adaptive immunity.

Conclusion: In AUD patients, progressive ALD is linked to impaired gut adaptive immune responses which likely contribute to defective gut microbial immunosurveillance.

THU095

Metabolic and genetic risk factors predict advanced alcohol-related liver fibrosis regardless of drinking pattern

Mads Israelsen[1,2,3], Helene Bæk Juel[4], Sönke Detlefsen[2,5], Bjørn Stæhr Madsen[1], Maria Kjærgaard[1,2,3], Mary Jo Fernandez Jensen[4], Stefan Stender[6], Aleksander Krag[1,2,3], Torben Hansen[4], Maja Thiele[1,2,3]. *[1]Odense University Hospital Denmark, Department of Gastroenterology and Hepatology, Liver Research Center, Odense C, Denmark; [2]University of Southern Denmark, Institute of Clinical Research, Odense, Denmark; [3]OPEN, Odense Patient Data Explorative Network, Odense, Denmark; [4]University of Copenhagen, Novo Nordisk Foundation Center for Basic Metabolic Research, Copenhagen, Denmark; [5]Odense University Hospital Denmark, Department of Pathology, Odense; [6]Rigshospitalet, Department of Clinical Biochemistry, Copenhagen*
Email: mads_israelsen@hotmail.com

Background and Aims: Excess drinking causes half of all liver-related deaths, but there is not a clear dose-response relationship between alcohol intake and development of cirrhosis. We hypothesized that genetic risk factors, insulin resistance and dyslipidemia may explain the heterogeneity in the severity of alcohol-related liver disease (ALD). Our aim was to improve precision of fibrosis staging in patients at risk of ALD due to harmful drinking.

Method: We performed a biopsy-controlled, cross-sectional study in patients with a history of excess drinking, with central scoring of liver biopsies for fibrosis stage and NAFLD activity score (NAS). We genotyped four polymorphisms (PNPLA3, TM6SF2, MBOAT7, HSD17B13), and determined the homeostatic model assessment of insulin resistance (HOMA-IR) from fasting insulin and blood glucose. We assessed dyslipidemia from plasma levels of triglycerides, HDL-, LDL- and total cholesterol. We performed multivariable proportional logistic regression to assess predictors of fibrosis while adjusting for age, sex, smoking, and whether patients were actively drinking or abstinent at inclusion.

Results: We included 325 patients (76% males, age 55 ± 11 years, 49% were abstinent from alcohol at inclusion, and 25% had advanced fibrosis). Insulin resistance was present in 54% of the patients, and worsened with every stepwise increase in fibrosis stage, while there was a global decrease in LDL, HDL and total cholesterol with increasing fibrosis (see Figure). Of the genetic polymorphisms, having one or two PNPLA3 or TM6SF2 risk alleles significantly increased fibrosis risk. In multivariable regression, insulin resistance was the strongest independent predictor for having a one-stage or more increase in fibrosis (OR = 3.22) followed by decreasing LDL-cholesterol (OR = 0.72) and presence of risk gene polymorphisms PNPLA3 (CG, OR = 1.61; GG, OR = 2.09) and TM6SF2 (CT, OR = 1.80; TT, OR = 8.15). In a subgroup analysis, HSD17B13 (TA) seemed to be protective against advanced fibrosis in patients with PNPLA3 CG or GG genotypes (OR = 0.56). Active drinking (OR = 4.52), insulin resistance (OR = 3.83) and PNPLA3 risk allele (OR = 1.59) were independent predictors of a one-point or more increase in the NAFLD activity score (NAS). All shown ORs have $p < 0.05$.

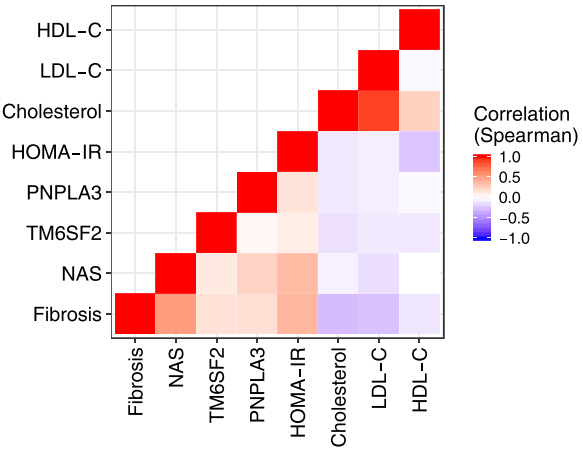

Figure: Heatmap showing the Spearman correlations between selected markers of liver disease, liver-related single-nucleotide polymorphisms,

glucose- and lipid metabolism. HDL-C, HDL-cholesterol; LDL-C, LDL-cholesterol; NAS, NAFLD activity score; Fibrosis, Kleiner fibrosis score.

Conclusion: Metabolic changes and genetic risk polymorphisms are highly prevalent and substantially increase the odds of having advanced liver fibrosis in alcohol-related liver disease, regardless of drinking pattern.

THU096

The Stanford integrated psychosocial assessment for transplantation (SIPAT) is an effective tool at identifying limited sobriety candidates with alcohol-related liver disease and low risk of relapse

Mai Sedki[1], Aijaz Ahmed[1], Filza Hussain[2], Jose Maldonado[2], Aparna Goel[1]. *[1]Stanford University, Gastroenterology and Hepatology, United States; [2]Stanford University, Psychiatry*
Email: maisedki@gmail.com

Background and Aims: Carefully selected patients with alcohol related liver disease (ALD) and less than six months of sobriety have acceptable post-liver transplant (LT) outcomes. A fair, equitable system to identify ALD patients that are unlikely to recover hepatic function with sobriety along with a low risk of alcohol relapse remains a challenge. Our study assesses the Stanford Integrated Psychosocial Assessment for Transplantation (SIPAT) in identifying suitable LT candidates with limited sobriety.

Method: Single centre retrospective study of all LT recipients (LTR) with ALD from 2015–2019. SIPAT is a validated tool performed being used at our center since 2013. The score ranges from 0–80, with a lower score indicating a favourable psychosocial profile. An official policy for limited (<6 months) sobriety was implemented in 2018 to include psychiatric and addiction medicine consultation and a post-LT relapse prevention plan (RPP). Post-LT outcomes were assessed and compared between those with and without limited sobriety.

Results: Of 103 LTR, mean age was 53.6 years, 75% male, 45% Caucasian and 38% Hispanic origin. 16 LTRs had limited sobriety. Marital status, education background and socioeconomic status was similar in those with limited and extended sobriety. Median SIPAT score was 27 and did not differ between groups ($p = 0.31$). LTRs with limited sobriety were more likely to be presenting with first decompensation ($p = 0.01$) and hepatorenal syndrome ($p < 0.01$). Rates of graft rejection (29%), infection (26%), and 1-year survival (88%) were similar in both cohorts. Alcohol relapse occurred in 7% and33% of LTRs returned to work. Of 7 LTRs with relapse, 5 had sustained use and only 1 was in the limited sobriety cohort. Factors associated with relapse included pre-LT renal replacement therapy ($p = 0.01$) and coexisting psychiatric illness ($p = 0.02$). Relapse was associated with failure to comply with immunosuppression ($p = 0.04$), relapse prevention plan ($p < 0.01$) and support system breakdown ($p = 0.03$). Presence of psychopathology on SIPAT assessment was significantly associated with relapse (OR 6.4, 95% CI 1.7–34.9, $p = 0.03$). The limited sobriety LTR group had excellent outcomes, 81% were adherent to their implemented RPP, with negative toxicology screens, follow-up with addiction medicine and regular attendance at support groups. Return to work rates for the limited sobriety group were significantly higher (69%) compared to those without limited sobriety (26%) ($p = 0.001$).

Conclusion: LT for ALD with limited sobriety achieves excellent outcomes in carefully selected patients. The previously validated psychosocial evaluation tool, SIPAT may be a useful adjunct in the selection of LT candidates with limited sobriety and should be studied prospectively.

THU097

The development and severity of alcoholic hepatitis is associated with decreased intestinal microbiome-derived secondary bile acid isoursodeoxycholic acid

Mark Muthiah[1,2], Ekaterina Smirnova[3], Puneet Puri[4], Naga Chalasani[5], Vijay Shah[6], Kayla Gelow[7], Faridoddin Mirshahi[4], Arun Sanyal[4]. *[1]National University Health System, Gastroenterology and Hepatology, Singapore; [2]National University of Singapore, Medicine, Singapore; [3]Virginia Commonwealth University, Biostatistics, United States; [4]Virginia Commonwealth University, Gastroenterology, Hepatology and Nutrition, United States; [5]Indiana University, Gastroenterology, United States; [6]Mayo Clinic, Gastroenterology and Hepatology, United States; [7]Indiana University, Gastroenterology and Hepatology, United States*
Email: arun.sanyal@vcuhealth.org

Background and Aims: Nonalcoholic steatohepatitis (NASH) is associated with specific perturbations in bile acid profiles linked to disease severity [*Hepatology*, 2018 Feb;67(2):534–548]. It is not known if similar changes are also seen alcoholic hepatitis (AH). *Aims:* (1) To define the changes in bile acid profile induced by (A): heavy alcohol consumption (B): moderate and severe AH (MAH, SAH defined by MELD ≤ or >20). (2) To define the relationship of changes in bile acid profile to severity of AH.

Method: Patients with moderate and severe AH (MAH, SAH - defined by MELD score ≤ or >20 respectively) were compared to controls without overt liver disease (normal LFTs, hepatic imaging and liver stiffness) who drank heavily (HC) and normal controls (NC) without an alcohol use disorder or overt liver disease. Bile acid profiles in plasma and feces were quantified by LC/MS. Correcting for false discovery, significant differences in pair-wise comparisons were established by Welch two-sample t-test ($p < 0.05$).

Results: 73 patients were studied (NC: 20, HC: 20, MAH: 11, and SAH: 22). The groups were matched by demographic profiles. The mean MELD scores for MAH and SAH were 15 and 27. ***A: Changes induced by heavy alcohol consumption (HC vs NC):*** Total primary bile acids were increased in plasma; both glycine and taurine-conjugated cholic acid and chenodeoxycholic acid (GC, GCDC, TC, TCDC) were increased ($p < 0.05$). Sulfated GCDC was also increased ($p < 0.01$). The unconjugated secondary bile acid deoxycholic acid (DCA) was reduced ($p < 0.05$), but both glycine and taurine-conjugated ursodeoxycholic acid (GUDCA, TUDCA) were increased ($p < 0.05$). ***B: Changes induced by AH (HC vs MAH/SAH):*** Total primary bile acids were increased in plasma but not in stool; both glycine and taurine-conjugated cholic acid and chenodeoxycholic acid (GC, GCDC, TC, TCDC) were increased ($p < 0.001$). There was isolated increment in fecal TCDC ($p < 0.005$). Unconjugated and glycine- and taurine-conjugated secondary bile acids were decreased in stool and in plasma ($p < 0.05$). Of note deoxycholate (conjugated or unconjugated) which is increased in NASH was not increased in AH. However, plasma taurolithocholic acid and glycolithocholic acid were both increased significantly in AH ($p < 0.05$); these were mostly in sulfated form. ***C: Changes related to severity of AH (MAH vs SAH):*** There was a stepwise increase in C4 from HC to MAH to SAH ($p < 0.005$ for both). Also, the intestinal microbial metabolite isoursodeoxycholic acid was progressively and significantly decreased from NC to HC to MAH to SAH. There was also a trend for decreased UDCA and 7-keto deoxycholic acid in stool in SAH (p 0.05–0.1).

Conclusion: AH promotes bile acid synthesis. Alcohol consumption increases endogenous UDCA synthesis. The development and severity of AH is related to a progressive decline in the hydrophilic, gut microbiome-derived secondary bile acid isoursodeoxycholic acid.

THU098

H2O2, the major reactive oxygen species produced during alcohol metabolism in liver induces autophagy without involving mTOR

Cheng Chen[1], Teresa Peccerella[1], Vanessa Rausch[1], Sebastian Mueller[1].
[1]*University of Heidelberg, Center for Alcohol Research, Heidelberg, Germany*
Email: medical_chen@163.com

Background and Aims: Alcohol-mediated reactive oxygen species (ROS) formation in the liver, mainly H_2O_2, contributes to disease progression and eventually hepatocellular carcinoma development in patients with ALD. Enhancement or activation of autophagy, with the suppression of mTOR signaling, is likely to play an important role in early stages of the alcoholic liver disease (ALD). However, with the progression of the disease, the expression of mTOR increases dramatically leading to the suppression of autophagy. According to recent literature, this is accompanied with significant hepatic lipid accumulation and iron deposition as well as inflammation under persistent alcohol exposure. It is also known, that H_2O_2 is involved in the regulation of autophagy in both acute and chronic ALD models, however, the exact underlying molecular mechanisms are still unclear. Therefore, we investigated in vitro and in vivo by using alcohol mouse model alterations in mTOR signaling as well as downstream effects induced by H_2O_2 and low oxygen tension.
Method: Huh7 hepatoma cells and VL-17A cells (stably transfected with CYP2E1 and ADH) were cultured with the GOX/CAT system, which allows an independent control of hydrogen peroxide as well as oxygen levels, in combination with different doses of ethanol. LC3B, p62, mTOR and autophagy related proteins (e.g. AMPK, AKT, STAT3) were analyzed by western blot. Same analyses were performed in liver tissues of C57BL/6 mice treated with acute (alcohol binge) and chronic ethanol (20% ethanol in the drinking water) for 4 weeks (n = 4).
Results: H_2O_2 significantly increased LC3B activation and this effect could be efficiently blocked by N-acetyl cysteine (NAC), which is a ROS scavenger. Interestingly, even though the LC3B activation was increased by H_2O_2, the m-TOR expression was not suppressed as normally expected. Co-treatment of hepatoma cells with H_2O_2 and the mTOR inhibitor Rapamycin led to an increased autophagic flux as compared to single H_2O_2 and Rapamycin treatment. The in vivo experiments showed a combined activation of LC3B and suppressed p62 and AKT levels as well as enhanced p-AMPK expression in the livers of the acute alcohol group. In contrast, mice exposed to chronic alcohol showed blocked autophagic flux with dramatically increased LC3-I and p62 levels.
Conclusion: Our findings underscore an important role of H_2O_2 in regulating autophagy during acute and chronic alcohol ALD exposure. Further studies will be needed to address the differences between acute and chronic alcohol-mediated effects as well as to identify H_2O_2-induced signaling pathways that regulate autophagy.

THU099

Early diagnosis of alcohol-related liver disease and timely intervention: the role of alcohol care teams

Joshua Stapleton[1], Nicola Kalk[1], Michael Heneghan[2], Naina Shah[3].
[1]*South London & Maudsley N H S Trust, United Kingdom;* [2]*King's College Hospital, London, United Kingdom;* [3]*King's College Hospital, United Kingdom*
Email: nkshah26@yahoo.com

Background and Aims: Mortality due to Alcohol related liver disease continues to rise. The National Health System (NHS) in the UK spends £3.5 billion a year on alcohol related problems, of this cost 78% is for Hospital based care yet patients with Alcohol related Liver disease usually present late with complications. Alcohol care team (ACT) was established in October 2018 at the King's College Hospital, London with an aim to reduce alcohol related hospital admissions and readmissions and to improve patient care. The team comprises of a Consultant Hepatologist, Consultant Addiction Psychiatrist and 6 nurses.
Method: 1700 patients with Alcohol use disorder (AUD) presented to the ACT between October 2018–19. Alcohol harm was assessed using the Alcohol Use Disorders Identification Test (AUDIT). Inpatients are jointly reviewed by an Addiction Psychiatrist and the Hepatologist. Patients were assessed for signs of chronic liver disease, offered brief/enhanced motivational intervention +/– anti relapse medication and sign posted to the community services. More recently, patients presenting with AUD in the Emergency Department (ED) and the Acute medical wards are offered bedside Fibroscan to screen for Liver disease.
Results: 30% (500/1700) had spectrum of Liver disease, 51% (253/500) had cirrhosis, 10% (27/253) had decompensated Liver disease; 49% (247/500) were noted to have fatty liver on ultrasound. Only a third of patients (84/253) with cirrhosis were known to the Hepatology team despite frequent attendances to the Hospital. Following the involvement of ACT more than 70% of the patients are now attending the Liver outpatients (OPA) and successfully achieving abstinence/harm reduction.
Fibroscan was offered to n = 46 with no known Liver disease. 35/46 had an AUDIT score>20 (dependence), the median Liver stiffness measure (LSM) = 11.5. 5/46 had an AUDIT score 15–19 (higher risk), the median LSM = 8, 6/46 had an AUDIT score 8–15 (increasing risk), the median LSM = 4.2 (Fig 1). Though the patients require a repeat FS after a period of abstinence, its implementation has led to abstinence/harm reduction and influenced their engagement with Liver services. The above interventions have enabled the patients to link in with the

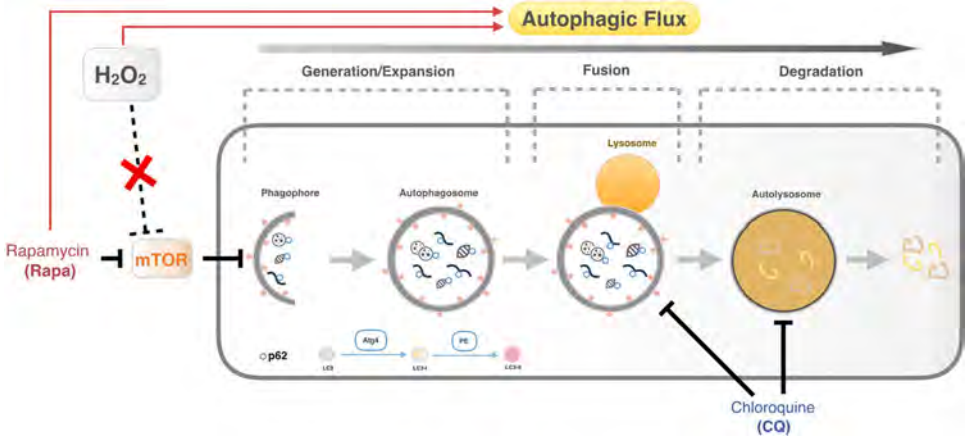

Figure: (abstract: THU098)

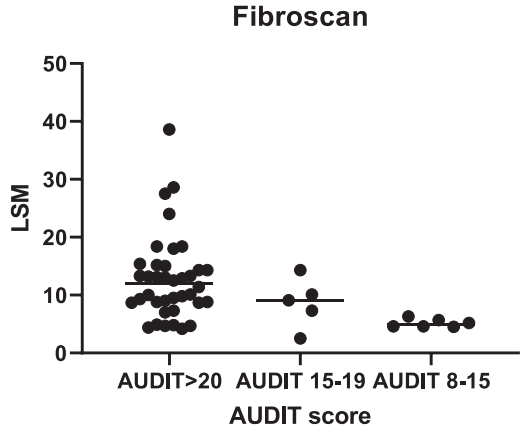
Community and Hospital services thereby reducing Hospital admissions and readmissions



Conclusion: Multidisciplinary approach in the management of AUD in patients with Chronic Liver disease is imperative in preventing further progression of Liver disease and associated complications.
Though recently established, early identification of Liver disease using Fibroscan in patients with AUD is feasible at the first point of contact.
Early identification of Liver disease and timely intervention is vital in preventing the progression to chronic Liver disease.
High LSM readings are found in patients with high AUDIT score but we need more data to establish this correlation.

THU100

A scoring system to predict infection in alcohol-associated hepatitis

Daniel Penrice[1], Serena Shah[1], Brian Davis[2], Arun Sanyal[2], Patrick S. Kamath[1], Vijay Shah[1], Douglas Simonetto[1]. [1]*Mayo Clinic, Rochester, United States;* [2]*VCU, Richmond, United States*
Email: penrice.daniel@mayo.edu

Background and Aims: Alcohol-associated Hepatitis (AAH) is a serious form of liver injury with mortality as high as 30–40% at 28 days. Multiple factors contribute to poor outcomes in this population, and superimposed infections are likely to increase mortality. Predicting the risk of infection in patients admitted with AAH can be challenging and the role of prophylactic antibiotics remains unclear. We aimed to identify predictors of infection in patients with AAH and create a scoring system to risk stratify these patients at the time of admission.
Method: We performed a retrospective analysis of patients admitted to two independent tertiary centers with a diagnosis of AAH from 1998–2016 (test cohort, n = 252). The diagnosis of AH was confirmed by manual chart review using the recent NIAAA definition. Infections were categorized by location and time of diagnosis: hospital-acquired infection (48 hours after admission until discharge) and post-hospital infections (up to 6 months after discharge). Patients who presented with community-acquired infection were excluded from analysis.
Results: The cohort was 66% male and the median age was 48 (21–83). Corticosteroids were used in 33% of all AAH patients. The overall infection rate in our cohort was 27%. Of those with infections, 46% were hospital acquired and 54% were acquired post-hospitalization. Variables found to be significant risk factors for bacterial infection included the presence of ascites on admission (HR 2.06), corticosteroid administration (HR 1.70), MELD greater than 23 (HR 2.61) and white blood cell count on admission per point (HR 1.02) (Figure 1). A scoring system was developed to predict infection at 7, 30, and 180 days from initial presentation: 1.03*MELD + 1*WBC + 1.61 (if ascites present) + 1.28 (if corticosteroids given) (Figure 2).

	HR (95% CI)	p-value
MELD on Admission (per point)	1.05 (1.02, 1.09)	0.002
Ascites on admission (Yes vs No)	2.06 (1.26, 3.36)	0.004
WBC on Admission (per 1 unit)	1.02 (1.00, 1.05)	0.048
Corticosteroids (Yes vs No)	1.70 (1.05, 2.75)	0.031

	Risk of infection within:		
Score	7 days	30 days	180 days
15	3.4%	11.0%	19.1%
20	3.8%	12.3%	21.2%
25	4.3%	13.7%	23.5%
30	4.8%	15.3%	26.0%
35	5.4%	17.0%	28.8%
40	6.1%	18.9%	31.7%
45	6.8%	21%	34.9%
50	7.6%	23.3%	38.3%
55	8.5%	25.8%	41.9%
60	9.5%	28.5%	45.7%
65	10.7%	31.4%	49.7%
70	11.9%	34.6%	53.9%
75	13.3%	38%	58.1%
80	14.8%	41.5%	62.4%
85	16.5%	45.3%	66.8%

Conclusion: In an analysis from a multi-center cohort of patients admitted with AAH we found that MELD score, ascites, WBC count, and the use of corticosteroids were significant predictors of the development of bacterial infection. In addition, we have developed a scoring system to help stratify patients at risk of infection within the following 180 days. In the future, we hope to utilize this scoring system to help dictate the use of prophylactic antibiotics in patients with AAH.

THU101

Unexpected protective role of the chemokine lix after Gao-binge ethanol feeding in mice

Kyle Poulsen[1], Christopher Kibler[1], Xiude Fan[1], Megan McMullen[1], Laura Nagy[1]. [1]*Cleveland Clinic, Inflammation and Immunity, Cleveland, United States*
Email: poulsenk79@gmail.com.

Background and Aims: Members of the chemokine system of ligands and receptors are implicated in the progression of Alcohol-associated Liver Disease (ALD). The goal of the current study was to determine if there are pathophysiological changes to the entire system of chemokines in ALD patients and following Gao-Binge ethanol feeding in mice to identify novel therapeutic targets associated with the chemokine system.
Method: Weighted gene correlation network analysis (WGCNA) was performed on microarray data from livers of healthy control and alcoholic hepatitis (AH) patients (GSE28619) to evaluate the coordinated expression of chemokines in livers of ALD patients. Mice were fed ethanol per the Gao-binge protocol and chemokine release was determined in plasma. Primary murine hepatocytes were used for mechanistic studies.
Results: The top 50% differentially expressed genes (3789) of GSE28619 were selected to construct the co-expression network for WGCNA. The correlation between Module eigengenes (MEs) and the clinical traits was calculated to identify the modules that are highly related to AH. Modules with absolute values of MEs above 0.9 were selected. Members of the C-X-C chemokine family, including *CXCL1, CXCL2, CXCL5, CXCL6* and *CXCL8*, were highly associated with AH as compared to healthy controls. In mice, the mouse-specific C-X-C chemokine LIX, a homolog to human CXCL5 and CXCL6, was uniquely

increased in the plasma as compared against all other circulating chemokines after Gao-binge feeding. Surprisingly, anti-LIX treatment exacerbated ethanol-induced liver injury as measured by ALT and expression of *Ccl2, Cxcl1, Cxcl2* and *Il-1Beta* mRNA as compared to IgG controls. Expression of Cxcl1, Ccl2 and LIX protein was also increased in liver homogenates. Since hepatocytes are known to release these chemokines, LIX was neutralized in primary hepatocyte cultures. Consistent with the *in vivo* data, LIX neutralization led to increased release of chemokines Ccl2, Cxcl1, Cxcl2, and LIX into cell culture supernatants.

Conclusion: The C-X-C chemokines are strongly associated with ALD progression. The mouse homolog of human CXCL5 and CXCL6, LIX, is prominently upregulated after Gao-Binge feeding in mice and likely participates in a negative feedback loop to prevent excessive inflammation in the liver. This study suggests that chemokine signaling through hepatocytes might regulate expression inflammatory genes in ALD.

THU102

Shedding light on BASH: a novel experimental model of advanced liver damage

Raquel Benedé[1], Feifei Guo[1], Olga Estévez Vázquez[1], Marius Woitok[2], Kang Zheng[3,4], Iris Asensio[5,6,7], Ignacio Juárez Martín-Delgado[3], José Manuel Martín Villa[3], Javier Vaquero[5,6,7], Rafael Bañares[5,6,7], Christian Liedtke[2], Francisco Javier Cubero[3,4], Yulia Nevzorova[1,2,4].

Email: rabenede@ucm.es.

Background and Aims: Based on recent clinical studies it has been suggested to refer patients with an intermediate alcohol drinking pattern and with signs of metabolic risk, including obesity and type 2 Diabetes Mellitus, i.e. clinical features of **b**oth alcoholic and non-**a**lcoholic **s**teato**h**epatitis as **BASH.** Yet, BASH is not well described and presents a large grey area in the field of Hepatology with a huge unmet need of pre-clinical and clinical studies as well as new innovative experimental animal models.

Method: C57BL/6 female mice received 10%v/v alcohol in sweetened drinking water in combination with a Western diet (WD) up to 23 weeks (BASH model). Mice receiving either only sweetened alcohol or only WD were used as controls. Serum markers of liver damage, liver and epididymal white adipose tissue (eWAT) histology, hepatic inflammation and fibrosis progression were analysed in detail.

Results: Animals fed with our novel experimental BASH model elicited a significant increase in the body-mass index (BMI) accompanied by a pronounced hypertrophy of adipocytes, as well as massive infiltration of macrophages, and robust collagen deposition in Ewat (Fig. 1A).

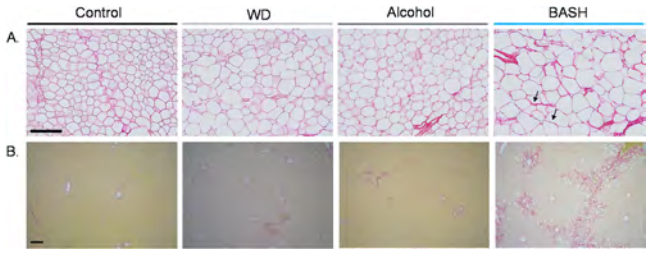

Figure 1. Sirius Red staining of eWAT (A) and liver tissue (B).

Moreover, progressive metabolic perturbations characterized by hypercholesterolemia and fasting hyperglycemia were found in the BASH group. In our experimental model, alcohol potentiated the effect of WD with regard to dramatic hepatomegaly, hepatocyte enlargement, profound hepatic steatosis and drastically increased levels of hepatic triglycerides. Significant liver damage was characterized by elevated plasma ALT and LDH levels, positive TUNEL staining and compensatory hepatic proliferation.

Notably, the BASH feeding also resulted in significant lobular inflammation and intrahepatic accumulation of CD45, CD11b and F4/80-positive immune cells and upregulated mRNA expression of TNFα and CCl2.

Importantly, BASH - mice exhibited advanced hepatic fibrosis, collagen accumulation, activation of hepatic stellate cells (HSC) and upregulation of Collagen IA1 and MCP-1 transcripts (Fig. 1B).

Conclusion: Our novel model of BASH displays enhanced obesity, glucose intolerance, liver damage, prominent steatohepatitis and hepatic fibrosis, as well as inflammation and fibrosis in the eWAT tissue. Altogether, the BASH model perfectly mimics all histological, metabolic, transcriptomic gene signatures of human BASH and therefore it can facilitate preclinical development of therapeutic targets in the future.

THU103

Duration of alcohol abstinence as a predictor of alcohol relapse - the more the better?

Ricardo Crespo[1], Sonia Bernardo[1], Rui Barata[2], Sofia Saraiva[3], Sara Gonçalves[4], Helena Cortez-Pinto[1,5], Mariana Machado[1,5].
[1]Hospital de Santa Maria, CHULN, Gastroenterology and Hepatology, Lisboa, Portugal; [2]Hospital Curry Cabral, CHULC, Nephrology, Lisboa, Portugal; [3]Portuguese Oncology Institute, Gastroenterology, Lisboa, Portugal; [4]Hospital de Santa Maria, CHULN, Nephrology, Lisboa, Portugal; [5]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal
Email: rr.crespo91@gmail.com.

Background and Aims: Alcohol abstinence is the mainstay of treatment of alcohol-related disorders, particularly liver disease. Heavy drinkers that achieve durable alcohol abstinence significantly reduce their risk of developing liver disease, and might not need surveillance. Furthermore, treatment modalities such as liver transplantation have been denied to patients with alcohol use disorder, unless these patients undergo a 6 months period of alcohol abstinence. However, there is no solid scientific evidence supporting the role of duration of alcohol abstinence as a predictor for alcohol relapse. We aimed to evaluate the risk factors for alcohol relapse in patients with alcohol use disorder.

Method: 123 long-term heavy alcohol consumers without chronic liver disease were prospectively recruited from a rehabilitation clinic in 2002 and followed until 2018. Alcohol consumption pattern and abstinence were registered.

Results: Baseline alcohol consumption was 330 ± 222 g/day for 25 ± 13 years, 65% being abstinent for 6 ± 27 months. The mean follow-up was 14 ± 3 years. Alcohol relapse occurred in 53%. Relapse did not associate with gender, amount, years or lifelong alcohol intake, binge drinking, type of beverage consumed, presence of alcoholism stigmata or family history of alcoholism or liver disease. There was a trend to higher GGT level at baseline in those with alcohol relapse (96 ± 161 *vs.* 58 ± 93 IU/L, p = 0.093). Relapse negatively associated with baseline abstinence duration: OR 0.306 [0.142–0.685] for 1-month and 0.276 [0.114–0.668] for 6-months. However, that association was weak and similar for 1 or 6-months abstinence (AUROC 0.362 ± 0.050, p = 0.009 and 0.385 ± 0.052, p = 0.029, respectively).

Conclusion: Alcohol consumption relapse was only weakly associated with the duration of baseline abstinence, and 6 months abstinence did not perform better than 1 month. These results

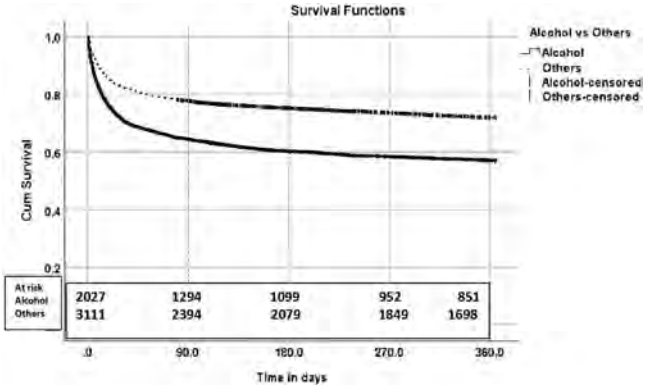
suggest the need for better predictors for alcohol relapse, reinforcing the concept that the 6 month abstinence rule for liver transplantation, although useful to allow spontaneous recovery of liver function, is not a good predictor of sustained abstinence.

THU104

Alcohol-related liver cirrhosis patients have higher-disease severity, one-year morbidity and mortality after index hospitalisation- followup of a cohort of 5,138 patients

Priyanka Jain[1], S Muralikrishna Shasthry[2], Ashok Choudhury[2], Guresh Kumar[1], Ankit Bhardwaj[1], Vinod Arora[2], Vijayraghavan Rajan[2], Ankur Jindal[2], Rakhi Maiwall[2], Manoj Kumar[2], Vikram Bhatia[2], Shiv Kumar Sarin[2]. [1]*Institute of Liver and Biliary Sciences, Department of Clinical Research, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India*
Email: shasthry@gmail.com.

Background and Aims: Liver cirrhosis (LC) is becoming an increasingly important cause of morbidity and mortality globally. Survival decreases following decompensation and reduces further, with every hospitalization. We studied the clinical profile and long-term outcomes comparing alcohol related LC with all non-alcohol etiologies (viral hepatitis, NAFLD, etc,).
Method: LC patients hospitalized between January, 2010 to June, 2017, with atleast ≥ 1year follow-up were included. Logistic regression was used to measure odds-ratios and Poisson regression for incidence risk ratios for alcohol related LC outcomes.
Results: 5138 LC patients [age 49.8 ± 14.6 yr, male 79.5%; alcohol 39.5% (n = 2027), Child A:B:C-11.7%:41.6%:46.8%] from their index hospitalization were analysed. The median time from diagnosis of cirrhosis to index hospitalization was 2(0.2–10) years. During the one year follow-up, 1707(33.2%) patients died; 1248(24.3%) during index hospitalization; 59.5% (2316/3890) of the survivors, required at least one readmission in the following year, with additional mortality of 19.8%. Alcoholic cirrhotics compared to non-alcohol etiologies were significantly more often ($p < 0.001$) male (97.7% vs. 67.7%), younger (40–50 group: 36.2% vs. 20.2%) with higher liver related complications at baseline [sepsis (20.3% vs.14.9%), ascites (82.2% vs. 65.9%), spontaneous bacterial peritonitis (21.8% vs. 15.7%), hepatic encephalopathy (41.0% vs.25.0%), acute variceal bleed (32.0% vs.23.7%)] and acute kidney injury (30.5% vs. 19.6%) with greater disease severity CTP (10.6 ± 2.0 vs. 9.0 ± 2.3) and higher MELD scores (21.49 ± 8.47 vs. 16.85 ± 7.79). Mortality was higher in alcohol etiology compared to non- alcoholics with a lower one year probability of survival (57.7% vs. 72.7%, $p < 0.001$).



Conclusion: A fourth of cirrhosis patients die during the index hospitalization and 60% require at least another rehospitalization in the following year. Alcoholic cirrhosis present at younger age with more severe liver disease with higher morbidity and mortality than patients with other etiolgies of cirrhosis and therefore require greater attention.

THU105

Comparitive hepatic proteome analysis in low and high dose ab libitum alcohol mice model of liver injury

Sudrishti Chaudhary[1], Adil Bhat[1], Anupama Parasar[1], Archana Rastogi[1], Jaswinder Maras[1], Shiv Kumar Sarin[1], Shvetank Sharma[1]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine*
Email: shvetankss@gmail.com.

Background and Aims: In most previous animal models of alcohol liver disease (ALD), how drinking pattern affects initiation and disease progression is not fully explored. In these models there has been a lack of comparison with hepatic proteome variations as expressed over time with low and high dose of ethanol. We aim to capture the alcohol induced proteomic variations and associated liver injury and repair proteins in longer duration ad libitum mouse model.
Methods: C57/B6 male mice (aged 6–8 weeks) fed with *ad libitum* 5% or 25% EtOH in the Lieber-DeCarli liquid diet daily for 12 weeks. Liver histology, liver injury marker and biochemical parameters were evaluated. Label free quantitative proteomic analysis by high resolution mass spectrometry was then performed. Student's two-tailed unpaired t-test was used to determine statistical significance followed by pathway analysis.
Results: At 12-weeks H&E staining showed marked steatosis in ethanol fed mice with increase in expression levels of liver injury markers in mice fed 25% EtOH compared to controls. We identified total of 4474 proteins. Out of 476 differentially expressed proteins (DEPs) in 5% EtOH fed mice 251 were up and 225 were down-regulated. Whereas in 25% EtOH fed mice group, Of the 1107 DEPs 154 were up and 953 downregulated (1.5FC; $p < 0.05$). Bioinformatic analysis of upregulated proteins showed unique pathways linked to processes of inflammatory-mediators, HIF1 signaling, arachidonic acid metabolism whereas unique pathways associated to down-regulated proteins were amino-acid, P450 xenobiotic metabolism, and oxidative phosphorylation ($p < 0.05$). Moreover, mice fed 25% EtOH displayed down-regulation of AMPK regulated proteins, but increased calcium-binding protein (CAB39) and decreased phosphoenolpyruvate carboxykinase 2, (PCK2) compared to 5% EtOH (FC> ±1.5; $p < 0.05$). A significant number of proteins were identified in 25% EtOH group were linked to inflammatory processes, most prominently damage associated proteins and neutrophil associated proteins. Moreover, this study identified target proteins such as Apolipoprotein A-II (Apoa-2), peroxisomal acyl-coenzyme A oxidase-1 (Acox1), ATP-binding cassette-3 (Abcd3), and damage associated high mobility proteins (Hmgn5). In high dose of EtOH fed mice the identified proteins correlated with α-SMA, TGF-β ($r^2 > 0.74$, $p < 0.05$).
Conclusion: Hepatic proteome analysis revealed dose dependent effect in EtOH-induced steatosis and liver injury suggesting a linkage between lipid metabolism, arachidonic acid metabolism and AMPK signaling, thus highlighting the effect of low and high dose ethanol intake paradigms on liver injury outcomes.

THU106

Neuro-immunological pathway alters the phenotype of bone marrow F4/80+CD11b+ macrophages during chronic alcohol consumption

Young-Ri Shim[1], Jun-Hee Lee[1], Hee-Hoon Kim[1], Won-Il Jeong[1]. [1]*Korea Advanced Institute of Science and Technology (KAIST), Biomedical Science and Engineering Interdisciplinary Program, Daejeon, Korea, Rep. of South*
Email: syoungri@kaist.ac.kr.

Background and Aims: Bone marrow (BM) is an important organ for immunity and haematopoiesis. In alcoholic liver disease, infiltrated macrophages from BM cause liver damage through inflammatory responses. However, the precise mechanism of phenotypic changes in macrophage by alcohol have not been well elucidated in BM yet. Here, we investigated the effect of chronic alcohol consumption on the phenotypic change in BM macrophages.

Method: Wild type and GREAT (IFN-γ reporter) mice or mice with natural killer (NK) cell-specific Grm5 depletion were fed with liquid ethanol (EtOH) or isocaloric (Pair) diet for 8 weeks. The phenotypic changes of immune cells in BM were assessed by flow cytometry. In vitro, BM stromal cells (BMSCs), BM NK cells and BM macrophages were treated with ethanol, glutamate or IFN-γ. Moreover, glutamate production was examined by HPLC. In addition, western blotting, immunostaining, and qRT-PCR analysis were performed.
Results: As results of immunostaining, the expression of alcohol dehydrogenase 1 (ADH1) was significantly increased in BMSC around capillaries of EtOH-fed mice compared to Pair-fed controls. In parallel, high expression of *Adh1* and *Aldh2* mRNAs was observed in LepR$^+$ BMSCs by analyzing the public data base of single cell sequencing in mouse BM. *In vitro,* ethanol treatment increased the expression of *Adh1* mRNA and glutamate excretion in BMSCs through xCT transporter. Interestingly, IFN-γ production was specifically increased in BM NK cells near ADH1-expression BMSCs in EtOH-fed mice compared to those of Pair-fed mice. However, IFN-γ production was significantly decreased by depletion of metabotropic glutamate receptor 5 (mGluR5) in NK cells. In addition, IFN-γ treatment elevated the expression of pro-inflammatory mediators such as *Il1b, Il6,* and *Tlr4* mRNAs, whereas it decreased the mRNA expression of CX3C chemokine receptor 1 (*Cx3cr1*) in F4/80$^+$CD11b$^+$ BM cells.
Conclusion: Chronic alcohol consumption induced xCT-mediated excretion of glutamate in BMSCs, and released glutamate stimulated mGluR5-expressing BM NK cells to produce IFN-γ for the polarization of BM F4/80+CD11b+ cells into pro-inflammatory cells. Consequently, primed BM F4/80$^+$CD11b$^+$ cells by alcohol metabolism could migrate into the liver and aggravate alcoholic liver injury.

Email: thierry.gustot@erasme.ulb.ac.be.

Background and Aims: Severe forms of alcohol-related liver disease are associated with increased susceptibility to infections contributing largely to their poor prognosis. The cellular and molecular mechanisms responsible for this altered host defense are incompletely understood. We explored phenotypic profiles of the main subsets of the mononuclear phagocyte system (composed of monocytes and dendritic cells [DCs]) in ALD.
Method: We performed whole blood phenotypic analysis and ex vivo stimulation with various pathogen-associated molecular patterns (PAMPs) in 34 patients with alcohol-related cirrhosis (18 of which had biopsy-proven severe alcoholic hepatitis [sAH]), 12 healthy controls and 11 patients with chronic alcohol consumption without significant liver disease. We also evaluated the transcriptomic (RNA-seq) and chromatin accessibility (ATAC-seq) profiles of sorted CD14$^+$ monocytes from a subset of patients.
Results: Circulating monocytes and cDCs from patients with sAH displayed complex alterations characterized by increase of activation and inhibitory surface markers and impaired pro-inflammatory response, particularly in the IL-12p70/IFNγ/CXCL10 axis, upon stimulation with PAMPs representative of gram-negative bacteria (LPS, Pam3CSK4) or fungal pathogens (Zymosan). Their decreased ability to produce more than one cytokine (polyfunctionality) upon PAMPs stimulation was correlated with the risk of developing infection at 28 days and mortality at 90 days (Figure). Moreover, sorted CD14$^+$ monocytes of patients with sAH displayed altered transcriptional profile characterized by downregulation of genes related to key immune pathways such as innate immune responses, cytokines, response to IFNs and antigenic presentation and dysregulation of genes of metabolic pathways such as lipid metabolism, cellular respiration and translation. This profile displays striking similarities with monocytes from patients that recovered from sepsis or exposed to IL-10. Moreover, we observed extensive modifications in the chromatin accessibility, mainly in the enhancer regions with increase for AP1 (Jun/Fos), CEBP and MAF binding sites and decrease of NF-kB, STATs or IRFs motifs, in the monocytes from sAH patients. Based on the binding and expression target analysis package, regulatory regions that were more or less accessible were clearly associated with genes that were up or down-regulated in monocytes from sAH, respectively.
Conclusion: The altered transcriptional program and functional properties of monocytes from sAH patients contributing to their susceptibility to infection have strong epigenetic determinants.

Email: xavier.verhelst@uzgent.be.

Background and Aims: Alcoholic hepatitis (AH) is a severe liver disease with high mortality if left untreated. The hallmark of AH diagnosis remains histologic examination of a liver biopsy specimen. Transjugular liver biopsy being not available in all centers, there is a need for non-invasive biomarkers of AH. We recently showed that circulating fragments of cytokeratin-18, called M65, are higher in patients with HA and identified cut-off values. The goal of this study was to assess plasma N-glycomic profile of patients with HA and determine whether this glycomic profile could allow non-invasive diagnosis of HA in patients with clinical suspicion of this disease.
Method: Plasma N-glycomic profiles were analysed using DNA sequencer assisted fluorophore assisted carbohydrate electrophoresis (DSA-FACE). This analysis was performed on plasma samples from a prospective cohort of patients with a clinical suspicion of AH (n = 87) who underwent a transjugular liver biopsy. An optimal glycomic profile related to the diagnosis of AH was defined using logistic regression.
Results: Out of the 87 patients included (82% male, median age 53), 44 patients had biopsy proven AH. Patients with AH had a different plasma protein glycosylation profile from patients without AH, characterized by increase in branch fucosylated triantennary glycan (NA3Fb), known to be related to acute phase response, and decrease of undergalactosylated glycans (NG1A2FB). A combination of these glycans (log NA3Fb/NG1A2F) was higher in patients with AH than in those without (OR 3.9 (p = 0.001; 95% CI 1.8–8.8)) (Fig. A). Using –1.0 and –0.4 as thresholds for this combination of glycans to exclude and diagnose HA respectively, liver biopsy could be avoided in 69% of the patients and 75% were correctly classified. When restricting the analyses to the 63 patients with a suspicion of severe AH (age, bilirubin, INR, and creatinine (ABIC) score B or C), using the same cut-offs, liver biopsy could be avoided in 65% of patients with a diagnostic accuracy of 81%. Combining the glycomic marker with plasma M65 levels further increased diagnostic accuracy for AH to 97% and could avoid liver biopsy in 55% of patients with ABIC score B or C (Fig. B and C).
Conclusion: A specific plasma glycomic signature (log NA3Fb/NG1A2F) is strongly associated with the presence of biopsy proven AH in patients with a clinical suspicion of this disease. Combining this glycomic signature with plasma M65 concentration in patients with a suspicion of severe AH can avoid liver biopsy in 55% of the patients, with a high diagnostic accuracy of 97%. These markers

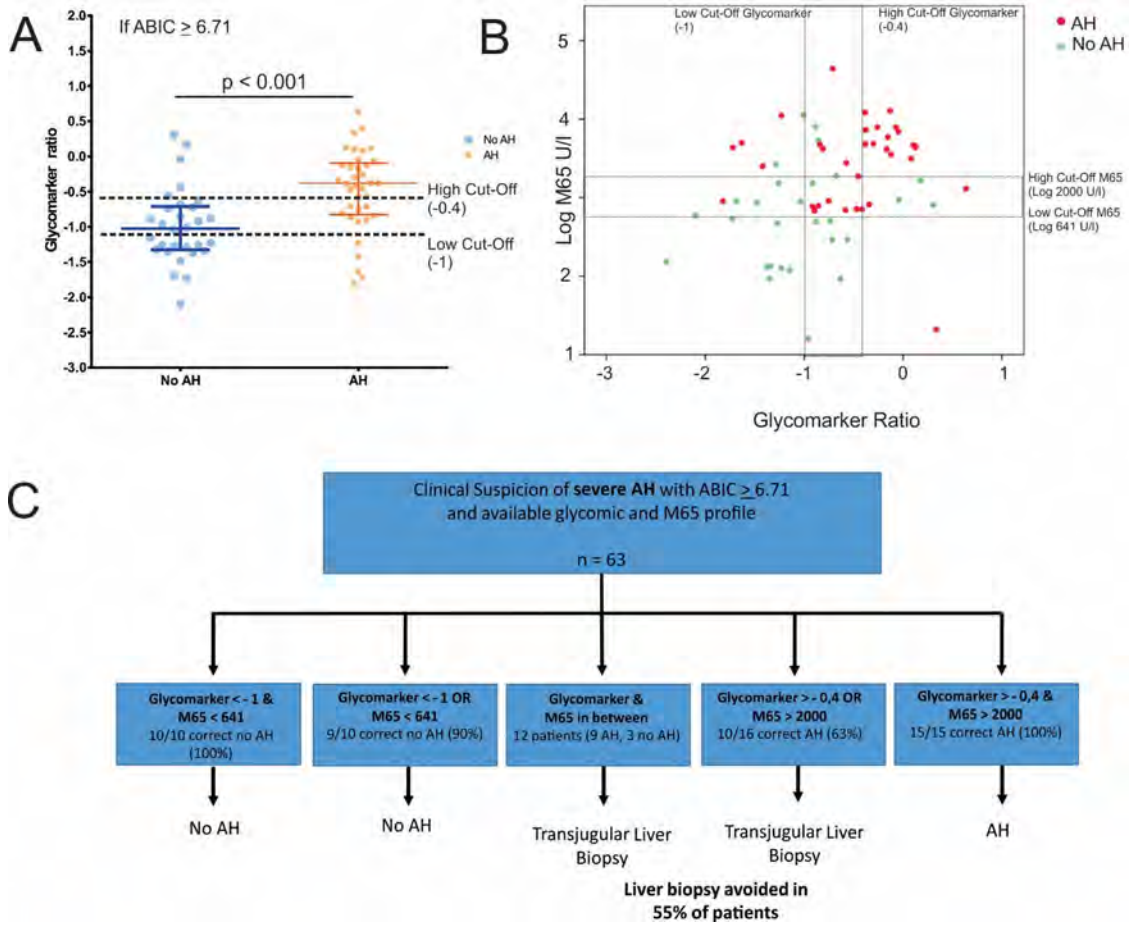

Figure: (abstract: THU108)

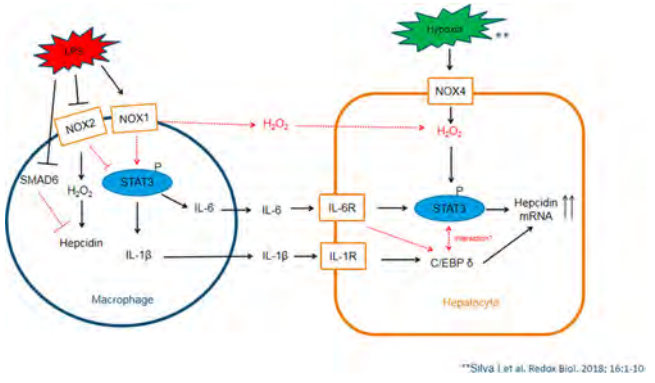
can be analysed using routine equipment, facilitating clinical implementation.

THU109

Role of NOX1 on hepcidin signaling in the crosstalk between macrophages and hepatocytes

Linna Yu[1], Cheng Chen[1], Shijin Wang[1], Teresa Peccerella[1], Vanessa Rausch[1], Sebastian Mueller[1]. [1]*University of Heidelberg, Center for Alcohol Research, Heidelberg, Germany*
Email: sebastian.mueller@urz.uni-heidelberg.de.

Background and Aims: Liver-secreted hepcidin is the systemic master switch of iron homeostasis and its dysregulation leads to iron accumulation in most of chronic liver diseases. Hepcidin is regulated by iron, inflammation or H_2O_2, but the role of NOX1 and its products ROS/H_2O_2 in monocyte-derived macrophages on hepcidin regulation under (patho)physiological conditions is poorly understood. We here investigate the role of NOX1 on regulating hepcidin and cytokines in inflammatory macrophages and subsequent effects on hepatocytes mimicking (patho)physiological conditions (cell ratios, oxygen levels and inflammation).
Method: THP-1 monocytes were differentiated into macrophages and co-cultured with Huh7 cells at (patho)physiological cell ratios (4:1) and treated with different LPS concentrations (10 ng/ml and 100 ng/ml) under normoxia (21% O_2) or hypoxia (1% O_2). The exposure of Huh7 cells to macrophage-conditioned medium with LPS was also investigated. Hepcidin, IL-1β, IL-6, C/EBPδ and SMAD6 mRNA levels were assessed by qRT-PCR and the expression of NOX1, p-STAT3, STAT3 and p-SMAD1/5/8 proteins were analyzed by western blot.
Results: LPS significantly increased NOX1, p-STAT3, IL-1βand IL-6 levels in THP-1 macrophages, but decreased STAT3 expression in a concentration-dependent manner under 21% and 1% O_2. Interestingly, 10 ng/ml LPS increased the expression of hepcidin whereas 100 ng/ml LPS decreased the expression of hepcidin under 21% O_2. In contrast, both LPS concentrations decreased the expression of hepcidin 1% O_2 in THP-1 macrophages. In addition, LPS decreased SMAD6, p-SMAD1/5/8 and CEBPδin THP-1 macrophages under 21% O_2. Notably, treatment of Huh7 cells with LPS had no effect on the expression of IL-6, IL-1β, CEBPδ and hepcidin in Huh7 cells under 21% O_2. Using inflammatory macrophage/hepatocyte co-cultures with direct cell-cell interactions under 21% O_2 increased IL-6, IL-1β, CEBPδ and hepcidin expression level in a concentration-dependent manner but did not further increase hepcidin in direct macrophage/hepatocyte co-cultures under 1% O2.



Conclusion: Our findings underscore a possible role of NOX1 and subsequent ROS/H_2O_2 concentrations on hepcidin regulation and induction of cytokine production in inflammatory macrophages involving the STAT3 signaling pathway. In the future, we aim at studying in detail hepcidin signaling by using WT and truncated hepcidin promoter constructs and siRNA-mediated knockdown of TLR4, NOX1, STAT3 or C/EBPδ.

Autoimmune and chronic cholestatic liver disease: Experimental and pathophysiology

Single-cell analysis of self-antigen-specific CD4 T cells reveals the B helper signature and the peripheral reservoir of autoreactive T cells in autoimmune hepatitis

Amédée Renand[1], Cervera-Marzal Iñaki[2], Gil Laurine[2], Dong Chuang[2], Kervagoret Erwan[1], Hélène Aublé[3], Sarah Habes[4], Cardon Anaïs[1], Jean-Paul Judor[1], Jean-François Mosnier[5], Sophie Brouard[1], Jérôme Gournay[4], Pierre Milpied[2], Sophie Conchon[1]. [1]*Nantes Université, Inserm, Centre de Recherche en Transplantation et Immunologie, UMR 1064, Nantes, France;* [2]*Aix Marseille Université, CNRS, INSERM, Centre d'Immunologie de Marseille-Luminy, CIML, Marseille, France;* [3]*CHU Nantes, Centre d'Investigation Clinique gastro-nutrition, Nantes, France;* [4]*CHU Nantes, Service Hepato-gastro-entérologie et Assistance Nutritionnelle, Nantes, France;* [5]*CHU Nantes, Service Anatomie et Cytologie Pathologiques, Nantes, France*
Email: amedee.renand@univ-nantes.fr.

Background and Aims: In autoimmune disorders, CD4 T cell-dependent chronic B cell activation towards multiple self-antigens promotes the production of pathogenic auto-antibodies. In autoimmune hepatitis (AIH), the presence of anti-Soluble Liver Antigen (SLA or SepSecs) autoantibodies is associated with significantly reduced overall survival. However, the molecular signature and precise phenotype of autoreactive CD4 T cells in human autoimmunity have been elusive, even more so for rare diseases like AIH.
Method: Here, we combined brief *ex vivo* restimulation with pools of overlapping antigen-derived peptides and integrative single-cell RNAseq (scRNAseq) to characterize the circulating CD4 T cell response against Soluble Liver Antigen (SLA or SepSecs) in seropositive (defined as positive for anti-SLA auto-antibodies) and seronegative AIH patients.
Results: Only seropositive AIH patients had detectable amounts of SLA-specific CD4 T cells, which had a conserved memory CXCR5^{neg} PD-1^{high} CCR6^{neg} phenotype. Single-cell RNA-seq revealed their pro-inflammatory/B-Helper profile with high expression of *IL21, IFNG, TIGIT* and *CTLA4*, but also *NR3C1, CD109, KLRB1* and *CLEC2D*, among other genes. Strikingly, the expanded SLA-specific CD4 TCR clonotypes identified by scRNAseq were only found in the circulating CXCR5^{neg} PD-1^{high} CD4 T cell population, which was significantly increased in the blood of AIH patients and shared B helper capacity with the classical CXCR5^{high} PD-1^{high} CD4 T_{FH} population. Finally, we identified a specific phenotype (PD-1+CD38+CD27+CD127-CXCR5-) of T cells linked to disease activity during AIH.
Conclusion: Altogether, our results provide for the first time a fine and comprehensive characterization of autoreactive CD4 T cells in the rare autoimmune disorder AIH, thereby identifying the phenotypic niche and specific molecular signature of pathogenic B helper self-reactive CD4 T cells. The transcriptomic and phenotypic analysis presented in this study will be instrumental to track autoreactive CD4 T cells in other immune disorders and to design new therapeutic strategy.

THU111

FXR agonists repress innate and adaptive effector cytokine production in primary sclerosing cholangitis

Astha Malik[1], Louis Matuschek[1], Tiffany Shi[1], Mary Mulen[1], Ramesh Kudira[1], Ruchi Singh[1], Mr. Sean Maynor[1], Brandee Wagner[2], Alexander Miethke[1]. [1]*Cincinnati Children's Hospital Medical Center, Division of Pediatric Gastroenterology, Hepatology & Nutrition, Cincinnati, United States;* [2]*Metacrine, Inc., San Diego, United States*
Email: alexander.miethke@cchmc.org.

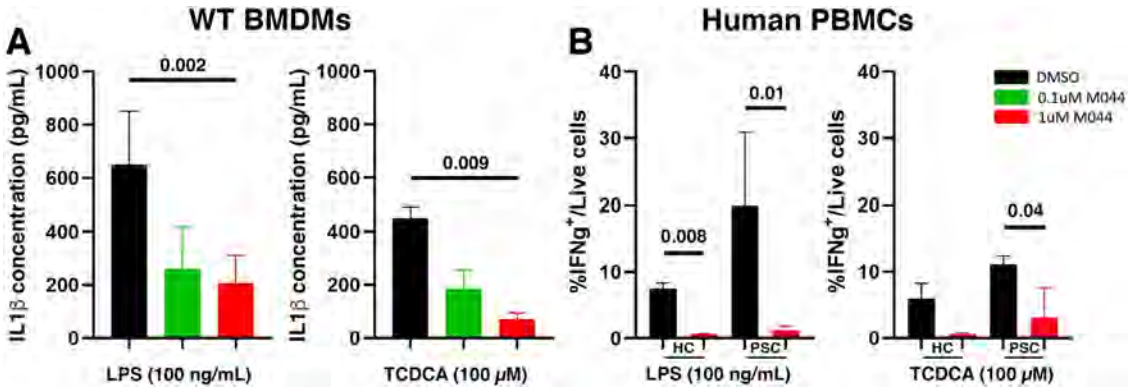

Figure: (abstract: THU111)

Background and Aims: While the etiology of primary sclerosing cholangitis (PSC) remains unknown, toxic bile induced injury to cholangiocytes and sterile inflammation likely contribute to the progressive destruction of bile ducts and fibrosis in this autoimmune liver disease. Farnesoid X receptor (FXR) agonists were recently found to improve biomarkers of biliary injury in clinical trials in PSC. Here we aim to delineate the mechanism of action by which FXR agonists attenuate liver inflammation in PSC.
Method: Transgenic mice lacking FXR expression in myeloid cells (FXRΔMP) were generated from Fxrfl/fl and LysM Cre mice. 45-day-old female FXRΔMP (and wild type) were fed 0.1% DDC diet for 7 days to induce cholangiopathy and liver inflammation. Bone marrow derived macrophages (BMDM)s from WT and FXR–/– mice were stimulated with either 100 ng/mL of LPS or 100uM of the hydrophobic bile acid Taurochenodeoxycholic acid (TCDCA) in presence of 0.1 or 1.0 uM of M044, an FXR agonist (or vehicle DMSO) before supernatants were assayed for IL1b using a TR-FRET assay. Peripheral blood mononuclear cells (PBMCs) from healthy controls (HC; n = 2) and from PSC patients (n = 4) were cultured under similar conditions and IFNg- and TNFa-productions were measured by qPCR and flow cytometry.
Results: DDC challenge resulted in higher plasma ALT levels in FXRΔMP compared with wt mice (mean 4140 vs 2340 IU/L, $p < 0.05$). Gene expressions for IL1b, TNFa, and IL6 were increased by 5, 4 and 3-fold, respectively, in hepatic mononuclear cells from FXRΔMP vs wt mice ($p < 0.05$). LPS and TCDCA induced IL1b expression in BMDMs (Fig. 1A). Pretreatment with the FXR agonist M044 dose-dependently reduced IL1b production in wt BMDM, but not in those from FXR–/– mice. Gene expressions for IL1b, NLRP3 and TNFa were increased in freshly isolated PBMC from PSC patients compared with HC, and decreased upon short term cultured with M044. LPS and TCDCA stimulation induced IFNg production in PBMCs from PSC patients, less so from HC, which reduced upon FXR agonist treatment (Fig. 1B). More than 45% of the cellular producers of IFNg in PBMCs from PSC patients resided in the CD4+ or CD8+ lymphocyte compartment.
Conclusion: Hydrophobic bile acids directly induce IL1b production by macrophages. FXR agonists repress these innate macrophages responses which diminishes their capacity for licensing effector cytokine production by CD4 and CD8 lymphocytes. Collectively, our data suggest that the mechanisms of action of FXR agonists in the treatment of PSC includes both the reduction of bile acid de-novo synthesis and suppression of innate and adaptive immune cytokine responses.

Absence of BSEP (ABCB11) protects MDR2 (ABCB4) KO mice from cholestatic liver and bile duct injury through modulating hepatic and intestinal inflammatory signaling

Claudia Fuchs[1], Veronika Mlitz[1], Matteo Tardelli[1], Jelena Remetic[1], Gustav Paumgartner[1], Susanne Wolfrum[2], Annika Wahlström[3], Marcus Ståhlman[3], Hubert schargl[4], Tatjana Stojakovic[4], Falk Hildebrand[5], Christian Wolfrum[6], Naiara Beraza[5], Hanns-Ulrich Marschall[3], Michael Trauner[1]. *[1]Medical University of Vienna, Hans Popper Laboratory of Molecular Hepatology, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria; [2]ETH Zürich, Laboratorium für Organische Chemie; [3]University of Gothenburg, Department of Molecular and Clinical Medicine; [4]Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics; [5]Quadram Institute Bioscience, Norwich Research Park, Gut Microbes and Health Institute Strategic Programme; [6]ETH Zürich, Laboratory of Translational Nutrition Biology, Institute of Food, Nutrition and Health, Swiss Federal Institute of Technology*
Email: michael.trauner@meduniwien.ac.at.

Background and Aims: Metabolic preconditioning with a hydrophilic bile acid (BA) pool protects Bsep KO mice from acquired cholestasis. We aimed to explore whether increased BA detoxification alters inflammatory signaling, thereby improving liver injury in the Mdr2 KO mouse.
Method: Cholestatic liver injury was studied in Mdr2/Bsep DKO and Mdr2 KO mice. BDL WT and Mdr2 KO mice were treated with tetrahydroxylated BA (THBA). Gene expression profile of inflammatory/fibrotic markers was investigated. Immune cell profiling from liver was done by FACS. Cytokine ELISA and microbiota analysis were also performed. Impact of THBA on CDCA induced inflammation in IHH cells and RORgt as well as NFkB signaling in Jurcat cells (GFP-NFkB) were analyzed. Impact of THBA on CDCA induced gut permeability was studied in intestinal organoids.
Results: In contrast to Mdr2 KO, DKO mice displayed increased BA hydroxylation and lack of features of sclerosing cholangitis (hepatic and intestinal inflammation, fibrosis, ductular proliferation). 67% of serum BAs in DKO mice were polyhydroxylated (THBAs most prominent), while Mdr2 KO mice had no such BAs. THBA feeding reduced inflammation (IL1b, Cxcl1 by 50%) and fibrosis (Col1a2 by 80%) in Mdr2 KO. In WT BDL mice, bile infarct size and inflammatory gene expression (F4/80 –50%, Cxcl1 –55% and Cxcl2 –75%; $p < 0,05$) were profoundly reduced by THBA. Increased levels of THBAs were associated with reduced RORgt+ (TH17 differentiation) but increased FOXP3+ (Treg differentiation) and GATA3+ (TH2 differentiation) cell in the hepatic CD4+CD3+ T cell pool. Accordingly, serum levels of anti-inflammatory cytokine IL10 (related to TH2 cells), was increased in DKO as well as in THBA fed Mdr2 KO and BDL mice. Also, microbiome composition differs between Mdr2 KO and DKO animals. In vitro,

THBA treatment improved CDCA induced gut permeability in intestinal organoids (eCadherin IHC). In IHH cells, THBA reduced CDCA induced inflammation (mRNA IL8, Icam, Cxcl2; p < 0,05) and attenuated CDCA-induced NFkB activation in GFP-NFkB Jurcat cells. Also in Jurcat cells, THBA attenuated RORgt signaling at mRNA levels (IL23–55%, TGFb-25%; TH17 related cytokines).
Conclusion: Increased formation of THBA (due to absence of Bsep) or THBA administration represses key pro-inflammatory signals such as NFkB and RORgt in hepatocytes and immune cells and reduces intestinal gut permeability, thereby protecting Mdr2 KO mice from cholestasis-associated inflammation and fibrosis.

THU114
Predicted risk of end stage liver disease utilizing the UK-PBC risk score with continued standard of care and subsequent addition of obeticholic acid for 60 months in patients with primary biliary cholangitis

David Jones[1], Marco Carbone[2,3], George Mells[2], Alexander Liberman[4], Elizabeth Smoot Malecha[4], Leigh MacConell[4]. [1]*Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom;* [2]*University of Cambridge, Academic Department of Medical Genetics, Cambridge, United Kingdom;* [3]*University of Milano-Bicocca, Center for Autoimmune Liver Disease, Milano, Italy;* [4]*Intercept Pharmaceuticals, Inc., San Diego, United States*
Email: david.jones@newcastle.ac.uk.

Background and Aims: The UK-PBC Study group developed and validated a long-term prognostic model of primary biliary cholangitis (PBC) based on data collected from over 3000 patients with PBC. The model identified baseline albumin and platelets, in addition to ALT or AST, ALP, and total bilirubin, as independent predictors of risk of end-stage liver disease (ESLD; liver-related death or liver transplant) following 12 months of treatment. POISE was a randomized double-blind (DB), placebo-controlled 12 month Phase 3 trial investigating daily 5 mg to 10 mg obeticholic acid (OCA) for the treatment of PBC. Upon completion of the DB phase, 97% of patients enrolled in an open label extension (OLE) wherein all patients received OCA. The purpose of this analysis is to assess the change in predicted risk of ESLD with the UK-PBC model in patients who had received placebo during the DB phase and then transitioned to OCA during the OLE.
Method: POISE inclusion criteria: PBC diagnosis, ALP ≥ 1.67x ULN and/or total bilirubin >ULN to <2x ULN, stable UDCA dose or unable to tolerate UDCA. 73 patients were randomized to the placebo arm of the POISE trial, 66 of whom enrolled in the OLE. Baseline, month 12 of the DB phase and OLE phase data through 60 months of OCA treatment were included in the UK-PBC algorithm to assess change in predicted risk of ESLD at 5, 10, and 15 years after 12 months of placebo and through the duration of OCA treatment in the same patient population.
Results: At baseline the placebo group was median (IQR) 55 (14) years old, 93% female, 90% white, and 93% received daily UDCA at a median (IQR) dose of 15 (4) mg/kg. After 1 year of continued standard-of-care treatment, placebo patients demonstrated a slight increase in predicted risk of ESLD (Table), due to worsening liver biochemistry. However, after 1 year of OCA treatment, predicted risk of ESLD at 5, 10 and 15 years was reduced to below baseline levels. Furthermore, through the 60 month duration of the OLE the median risk of ESLD was sustained below baseline levels.
Conclusion: In POISE, the UK-PBC risk score predicted a trend for increased risk of ESLD in patients with PBC treated with placebo for 12 months in addition to standard of care. Addition of OCA led to sustained improvements in serum biochemistry and reductions in predicted risk of ESLD for up to 60 months of OCA treatment.

Table. Predicted Risk of ESLD in Patients with PBC Before and After OCA Treatment[1]

Median (IQR)	Baseline (n=73)	DB Month 12 (n=68)	OLE Month 12 (n=58)	OLE Month 36 (n=48)	OLE Month 60 (n=24)
5-Year Risk (%)	1.9 (1.1, 3.5)	2.3 (1.1, 4.4)	1.4 (0.8, 3.3)*	1.3 (0.7, 2.1)*	1.6 (1.0, 2.7)*
10-Year Risk (%)	6.4 (3.8, 11.3)	7.5 (3.6, 14.0)	4.7 (2.7, 10.6)*	4.4 (2.5, 6.9)*	5.2 (3.3, 8.7)*
15-Year Risk (%)	11.5 (6.9, 19.9)	13.5 (6.6, 24.4)	8.5 (5.0, 18.8)*	8.0 (4.5, 12.5)*	9.4 (6.0, 15.7)*

[1] Patients received Placebo ± UDCA for 12 months during the double-blind phase, then OCA ± UDCA throughout the OLE.
*p<0.05. P-value for within group comparison using Wilcoxon Signed Rank test comparing Month 12 DB and Month 12, 36, or 60 OLE

Cell specific transcriptomic analysis reveals a disassociation between treatment response and peripheral markers of immune activation in primary biliary cholangitis

Evaggelia Liaskou[1,2], Victoria Mulcahy[3], Jose-Ezequiel Martin Rodriguez[3], Graeme Clark[4], Richard N. Sandford[3], David Jones[5], Gideon Hirschfield[6], George Mells[3]. [1]*University of Birmingham, Centre for Liver and Gastrointestinal Research and NIHR Birmingham Biomedical Research Centre, United Kingdom;* [2]*University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom;* [3]*University of Cambridge, Academic Department of Medical Genetics, Cambridge, United Kingdom;* [4]*NIHR Cambridge Biomedical Research Centre, SMCL Next Generation Sequencing Hub, Cambridge, United Kingdom;* [5]*Newcastle University, Institute of Cellular Medicine and NIHR Newcastle Biomedical Research Centre, Newcastle-upon-Tyne;* [6]*University of Toronto, Toronto Centre for Liver Disease, University Health Network and Department of Medicine, Toronto, Canada*
Email: gfm26@medschl.cam.ac.uk.

Background and Aims: Primary biliary cholangitis (PBC) is an autoimmune liver disease. The first line therapy for PBC is UDCA; however, ~30% of patients do not respond (high-risk patients). Herein, we studied the transcriptomic profile of innate and adaptive immune cells in low and high-risk patients in order to understand whether differential gene expression could reveal biomarkers for more precise risk and treatment stratification of PBC patients.
Method: 47 patient samples (93.6% female) across 6 UK-PBC Research Centres were analysed; 16 high-risk (ALP >3 × ULN on treatment with UDCA, mean ALP = 481), 16 low-risk (ALP < 1.5 × ULN, mean ALP = 116.9) and 15 matched controls. The following immune cell subsets were sorted from peripheral blood mononuclear cells: 1) $CD19^+$ B cells, 2) $CD4^+CD25^{high}CD127^{low}$ Treg cells, 3) $CD4^+CCR6^+CXCR3^-$ Th17 cells, 4) $CD4^+CCR6^-CXCR3^+$ Th1 cells and 5) $CD14^+$ monocytes. RNA was extracted (mean integrity = 8.41) and sequenced on Illumina HiSeq2500 or HiSeq4000. RNA sequencing alignment and statistical analysis was completed with STAR and DESeq2 packages respectively. Weighted Gene Co-expression Network Analysis was used to construct gene co-expression networks.
Results: In case-controls analysis, in Th1 cells, we identified gene co-expression networks with eigengene correlated with disease status (Pearson's correlation coefficient [PCC] = 0.59, p = 0.0005) that were enriched for pathways of regulation of NFκB induction, cell death, TNF pathway, JAK-STAT signalling, all supportive of a high Th1 immune cell activation. In Th17 cells, we identified co-expression networks with eigengene correlated with disease status (PCC = 0.47, p = 0.008), enriched for IL-17, TNF and NFκB signalling pathways and Th17 cell

differentiation, supportive of Th17 cell activation. Some overlap with previously identified pathways from GWAS studies was also identified (e.g. *TNFAIP3, IRF8, SPIB).* In CD14 cells, we found no clear pathway enrichment, suggesting that other cell types might be involved in innate hypersensitivity observed in PBC. In within-case analysis (i.e. high versus low-risk patients), no clear informative pathway enrichment was shown in any cell type, suggesting that stratification by risk of disease progression, based on ALP, does not identify any distinct transcriptomic signals.

Conclusions: Cell specific transcriptomic analysis, using peripheral blood, in patients with PBC revealed regulatory pathways relevant to disease biology. Regardless of treatment stratification based on biochemical response to UDCA the immune pathways seemed to remain activated. Overall, TNF, IFNγ and JAK-STAT signalling pathways appear to be activated and thus biologically important in patients with PBC.

THU116

Distinct intrahepatic molecular signature between relapse and sustained remission of autoimmune hepatitis before initiation of immunosuppression withdrawal

Finn Derben[1], Bastian Engel[1], Johannes Hartl[2], Danny Jonigk[1], Geffers Robert[3], Ansgar Lohse[2], Michael P. Manns[1], Christoph Schramm[2], Elmar Jaeckel[1], Richard Taubert[1]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]University Medical Centre Hamburg-Eppendorf, 1st Department of Medicine, Hamburg, Germany; [3]Helmholtz Centre for Infection Research, Genome Analytics, Braunschweig, Germany*
Email: Finn.C.Derben@stud.mh-hannover.de.

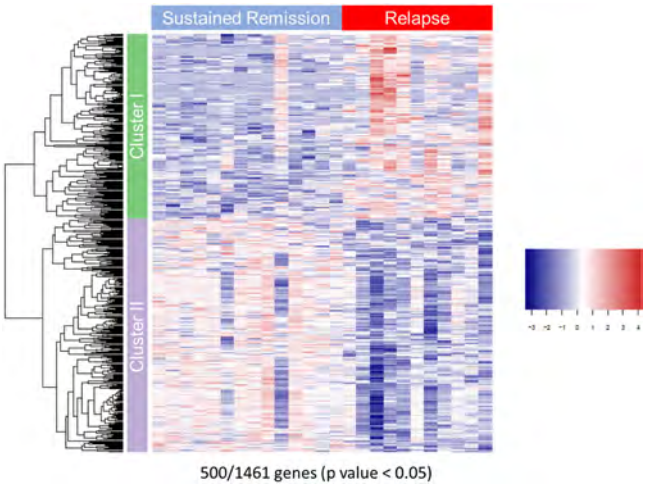
Background and Aims: The majority of autoimmune hepatitis (AIH) patients reach biochemical remission (BR) under steroid and azathioprine based therapies. After at least 2 years of BR an immunosuppression withdrawal can be attempted, although a relapse is common even when histological remission of AIH is achieved. So far, immunosuppression withdrawal is done in an "trial and error" manner in the absence of validated prediction factors beyond the achievement of histological remission.

Method: 29 patients with AIH under ongoing immunosuppressive therapy with biopsy proven histological remission (HAI<4) with subsequent complete withdrawal of immunosuppressants were recruited at two centers (Hannover: n = 22; Hamburg: n = 7). Intrahepatic gene expression was analyzed via mRNA sequencing from pre-weaning liver biopsies. Additionally, intrahepatic T cell compartment including regulatory T cells (Treg) was analyzed in immune histology.

Results: Immunosuppression was withdrawn after in median 72 (range: 27–170) months of therapy and after 53 (7–128) months of documented biochemical remission. AIH relapsed in 15/29 (52%) of patients after 11 (0.5–67) months.

When baseline laboratory characteristics before initiation of weaning were compared, patients with subsequent relapse had lower ALP (p = 0.011; AUC = 0.789), higher bilirubin levels (p = 0.017; AUC = 0.766), both within the normal range, and higher mHAI (p = .037; AUC = 0.766). Liver infiltration with T cell ($CD4^+$ and $CD8^+$) and $CD4^+FOXP3^+$ regulatory T cells was not significantly different between patients with and without relapse.

In the transcriptome sequencing of pre-weaning liver biopsies 1461 transcripts were differentially expressed (adjusted p-value < 0.05) between patients with and without AIH relapse (Figure). Interestingly, most significantly regulated genes were not related to obvious immune functions. Area under the curve of significantly regulated genes to predict relapse ranged from 0.545–0.944 with 11 genes with an AUC>0.900. Pathway analysis and further generation of a predictive molecular biomarker is matter of ongoing work.



Conclusion: Clinical routine and histological parameters seem inferior to intrahepatic gene expression analysis to predict relapse after immunosuppressant withdrawal. The molecular phenotype of baseline liver biopsies before immunosuppression withdrawal promise a better diagnostic tool for personalized medical approaches in the future than currently used clinical routine parameters.

Email: martin.kummen@medisin.uio.no.

Background and Aims: While the composition of the gut microbiome in primary sclerosing cholangitis (PSC) is known to differ from healthy controls (HC), it would be of major importance to delineate functional microbiome changes which could influence the host and disease phenotype. We therefore performed, to our knowledge, the first shotgun sequencing study to characterize the genetic potential of the gut microbiome in PSC as compared with HC and patients with inflammatory bowel disease (IBD) but without liver disease.

Method: Fecal DNA from 2 cohorts from Norway and Germany (in total PSC n = 141 (n = 80 (56.7%) with concomitant IBD), HC n = 158, IBD without PSC n = 93) were subjected to metagenomic shotgun sequencing, generating ~15 billion paired end sequences. Abundance of bacterial species, enzymes and metabolic pathways (MetaCyc) were calculated using the HUMAnN2 and MetaPhlAn2 pipelines, and analysed using generalized linear models and a random effects meta-analysis (Q_{fdr} <0.05, unless otherwise stated).
Results: PSC patients had markedly fewer microbial genes compared to HC (p < 0.001), but borderline more genes than IBD patients (p = 0.05). Compared to HC, PSC patients showed enrichment of several *Clostridium* and *Veillonella* species, and a depletion of e.g. *Eubacterium spp., Barnesiella intestinihominis* and *Ruminococcus obeum. Klebsiella pneumoniae* was only detected in 24% of the PSC patients but at higher frequency than HC (4%, p < 0.001). Comparing PSC to IBD there was a significant increase in the prevalence of *Ruminococcus spp.* Extensive differences were observed between PSC patients and controls when analysing microbial gene functions and metabolic pathways, including changes in biosynthesis of essential nutrients like branched-chain and aromatic acids, several B vitamins and chorismate. There were fewer genes related to chorismate biosynthesis in PSC vs HC, while higher levels were found in PSC with IBD compared to IBD. When directly comparing PSC patients with and without IBD there were no differences for any species or functions. Notably, there was increased abundance of genes related to e.g. ammonia production and antibiotic resistance in PSC compared to HC.
Conclusion: The gut microbiome in PSC exhibits large compositional and functional differences compared to HC, irrespective of the presence of IBD. The impact of these on the disease severity and progression should be investigated further to identify potential disease-modifying targets.

Obeticholic acid but not bezafibrate treatment improves cholestasis-induced cognitive decline

Lucy Gee[1], Rachel Burgoyne[1], Fiona Lebeau[1], David Jones[2,3], Fiona Oakley[1]. [1]*Newcastle University, Biosciences Institute, Newcastle upon Tyne, United Kingdom;* [2]*Newcastle upon Tyne Hospitals Trust, Newcastle upon Tyne, United Kingdom;* [3]*Newcastle University, Translational and Clinical Research Institute, Newcastle upon Tyne, United Kingdom*
Email: l.m.gee@ncl.ac.uk.

Background and Aims: Primary Billiary Cholangitis (PBC) is a chronic cholestatic liver disease. PBC and other cholestatic patients experience cognitive symptoms, including problems with short-term memory and concentration, associated with central fatigue. This 'brain fog' has major indications for poor quality of life in patients, partly because it is not improved by currently licensed therapy. Recent trial data have suggested that the PPAR-α agonist Bezafibrate is effective at improving liver injury markers in PBC patients needing 2nd line therapy.
The aim of this study was to utilise the Bile Duct Ligation (BDL) model to explore the potential therapeutic benefit of Bezafibrate, with emphasis on cognitive symptoms. We compared BZ with approved 2nd line therapy - FXR signalling anti-cholestatic agent Obeticholic Acid (OCA).
Method: C57BL/6 mice underwent BDL surgery. Sub-groups of BDL were treated with either Bezafibrate (n = 7), or OCA (n = 9), or left untreated (n = 16). Spatial memory and cognitive function were evaluated by standardised behavioural tests. Animals were harvested at day 10 with liver and brain taken for histology.
Results: Liver fibrogenesis (αSMA+ myofibroblasts and Picrosirius Red) was significantly reduced in both Bezafibrate and OCA treated mice when compared to BDL (Table 1).

Table 1

	BDL	OCA	Bezafibrate
PSR	4.8%	**1.8% (⇩−62%)** ***	**1.4% (⇩−70 %)** ***
αSMA	4.12%	**2.3% (⇩−45%)** **	**2.2% (⇩−47%)** **
P21	34.5	**7 (⇩−80%)** ***	75.8 (⇧+120%) ***
Time in Novel Arm	30.6%	**65% (⇧+111%)** **	35.27% (+15%)

p21+ cellular senescence in the liver is a known feature of cholestatic disease and associated with disease progression. p21+ senescent hepatocytes are elevated in BDL but significantly reduced with OCA therapy. Conversely, Bezafibrates treatment showed no reduction in cellular senescence (Table 1), and in fact led to more hepatocyte senescence in this model.
Spatial memory (as assessed by the Time in the Novel Arm in the Y-maze) was impaired in BDL mice but OCA therapy rescued the cognitive decline, leading to near normal cognitive ability. In contrast, Bezafibrate treatment had no beneficial effect on cognition and spatial memory in the BDL model.
Conclusion: We report that Bezafibrate limited liver fibrosis but failed to reduce liver cellular senescence and to improve cognitive function in BDL, even when used as an early intervention. Consistent with our previous studies, OCA therapy attenuates fibrogenesis and prevents cognitive symptoms in cholestatic BDL mice. Our data suggests that the cognitive effects of OCA are through a direct FXR-mediated effect rather than an indirect effect through reduced cholestasis.
Obeticholic acid but not Bezafibrate may provide an effective treatment for patients experiencing cognitive deficit, if used early in the disease process.

THU119
Negative immune regulator LNK/SH2B3 contributes to the development of autoimmune liver disease in mice under fatty-metabolic stress

Tatsuya Kanto[1], Taizo Mori[1], Sachiyo Yoshio[1], Hironari Kawai[1], Yuriko Tsutsui[1], Yuichi Yoshida[1], Shiori Yoshikawa[1], Yosuke Osawa[1]. [1]*National Center for Global and Medicine, Liver Disease, Chiba, Japan*
Email: kantot@hospk.ncgm.go.jp.

Background and Aims: In search for disease susceptible genes in autoimmune liver disease, GWAS study has identified a missense variant of Lnk/Sh2b3 (Lnk) as a risk of autoimmune hepatitis (AIH). We previously reported that Lnk gene is a negative regulator of immune cell activation through Janus kinase 2 and 3 signaling and plays an essential role in hematopoiesis. However, the causal relationship between Lnk gene and the pathogenesis and regulatory mechanism of liver autoimmunity is undisclosed. By using a Lnk knockout (KO) mice, we sought to test the hypothesis that metabolic stress to the liver could enhance the risk of autoimmune phenotypes in patients who possess relevant genetic predisposition.
Method: In order to clarify the impact of metabolic stress/lipid storage on the expression of Lnk/Sh2b3 gene, we examined the expression of Lnk in liver tissue or PBMC obtained from patients with NASH /NAFLD. Furthermore, Lnk deficient mice were loaded with normal diet (ND) or high fat and high cholesterol diet (HF/HCD) for 6 or 12 weeks and serum and liver tissues were analyzed.
Results: The expression of Lnk/Sh2b3 was significantly decreased in PBMC and liver tissue of NASH/NAFLD patients compared with healthy individuals. Lnk KO mice showed no sign of liver inflammation with ND. However, with HF/HCD feedings, AST and ALT levels and inflammatory cytokines were significantly elevated in Lnk KO mice. Moreover, significant increase of IgG and IgM and autoantibodies (anti-nuclear antibody, ANA) were observed in serum of Lnk KO mice. Histological analysis in the liver of Lnk KO HF/HCD mice showed that hepatic steatosis was aggravated and inflammatory foci around blood vessels was observed. However, interface hepatitis, typical findings of

AIH, was not observed. Analysis of intra-hepatic lymphocytes showed that CD8+ T cells, NK cells and CD19^{+} CD138^{+} plasmacytes were especially increased. Liver fibrosis was comparable at 12 weeks between wild type and Lnk KO mice fed with HF/HCD.
Conclusion: Lnk KO mice fed with HF/HCD mimic some aspects of disease entity of autoimmune traits combined with NAFLD/NASH. This mice model conveys the message that metabolic stress, or fatty liver disease, should be avoided in order to prevent the onset of autoimmune liver disease, especially those who have genetic predisposition.

THU120

Mast cell activation mediates biliary immunobiology and subsequent immune response in a model of primary biliary cholangitis

Lindsey Kennedy[1], Vik Meadows[1], Debjyoti Kundu[1], Pietro Invernizzi[2], Marco Carbone[2], Gianfranco Alpini[1,3], Heather Francis[1,3]. [1]*Indiana University School of Medicine, Indianapolis, United States;* [2]*University Of Milano-Bicocca, Italy;* [3]*Richard L. Roudebush VA Medical Center, United States*
Email: heafranc@iu.edu.

Background and Aims: Primary biliary cholangitis (PBC) is characterized by biliary senescence, inflammation, and bridging fibrosis. Mutations in human leukocyte antigen (HLA, the major histocompatibility complex [MHC]) genes have been identified and may correspond with enhanced helper (CD4+) and cytotoxic (CD8+) T cell infiltration during PBC. Mast cells (MCs) infiltrate the liver during cholestasis, including PBC, and inhibition of MC activation reduces biliary senescence and liver fibrosis. MCs communicate with CD8+ T cells, macrophages and neutrophils in chronic liver disease; however, MC mediation of immune response during PBC has not been studied. We aimed to evaluate the role of MC activation in the promotion of immune responses during PBC.
Method: We used female wild-type (WT) and dnTGFβRII (at 34 wk of age, model of late stage PBC) mice treated with saline or cromolyn sodium (to block MC activation) for 1 wk by IP implanted osmotic minipump. MC presence was determined by staining for chymase and tryptase and activation was determined by serum tryptase and HA levels by EIA. Serum levels of antimitochondrial antibodies (AMA) were assessed by EIA. Liver inflammation was determined by immunostaining for MPO and F4/80. Biliary expression of MHC I (presents to CD4+ T cells) and MHC II (presents to CD8+ T cells) along with hepatic expression of CD4+ and CD8+ T cells was evaluated by immunostaining. Expression of IL-6 and TGF-β1 (pro-inflammatory for CD4+ T cells) and IL-4 and IFN-γ (increase cytotoxicity in CD8+ T cells) was determined by *q*PCR in total liver. Female human control and advanced stage (Stage III/IV) PBC samples were utilized and MC co-localization with CD4+ and CD8+ T cells was determined by immunostaining.
Results: dnTGFβRII mice had increased MC number/activation along with elevated serum AMA levels, which decreased following cromolyn treatment. Liver inflammation increased in dnTGFβRII mice but decreased after cromolyn treatment. Biliary expression of MHC I and II increased in dnTGFβRII mice, but was downregulated following cromolyn treatment. Changes in MHC expression corresponded with enhanced CD4+ and CD8+ T cell number, and increased expression of IL-6, TGF-β1, IL-4 and IFN-γ in dnTGFβRII mice, but these findings decreased in cromolyn treated mice. In humans with advanced stage PBC, increased portal MC presence corresponded with enhanced CD4+ and CD8+ T cells expression.
Conclusion: MC infiltration/activation is increased in advanced stage PBC and correlates with increased liver inflammation and immune response. Inhibition of MC activation reduces hepatic inflammation, biliary MHC expression and T cell infiltration. MCs may play a role in the autoimmune response noted in patients with PBC; therefore, inhibition of MC activation may be therapeutic for PBC patients.

THU121

MSCs attenuate cona-induced autoimmune hepatitis in mice through Nrf2/HO-1 pathway by altering macrophage polarization

Wentian Liu[1], Huimin Liu[2]. [1]*Tianjin Medical University General Hospital, Department of Gastroenterology, Tianjin, China;* [2] *Tianjin First Central Hospital, Nankai University, Organ Transplant Center, Tianjin, China*
Email: lwentian64@163.com.

Background and Aims: The study found that Autologous transplantion of mesenchymal stem cells (MSCs) reduces concanavalin A (ConA)-induced Autoimmune hepatitis in mice. However, the mechanism of action of MSCs in ConA-induced Autoimmune hepatitis is still unclear.
Method: Zinc protoporphyrin (Znpp, the Ho-1 activity inhibitor) and Hemin (a HO-1 inducer) were injected into a mouse model of immunological Autoimmune hepatitis induced by ConA. The mice were sacrificed 12 hours after ConA injection. Blood samples and liver tissues were collected. The experimental animals were randomly divided into five groups: normal group, ConA group, ConA+MSCs group, ConA+MSCs+Znpp group and ConA+Hemin group; liver cell apoptosis was detected by TUNEL staining; liver cell proliferation was detected by Ki-67 immunohistochemical staining; The expressions of TNF-α, IFN-γ and IL-6 in serum were detected. The expressions of HO-1, Nrf2, INOS, Arg1, TNF-α, IFN-γ and IL-6 were detected by RT-PCR. The expression of HO-1 and Nrf2 in mice was detected by Western Blot; the expression of INOS and CD206 in mice was detected by immunofluorescence double staining.
Results: Compared with the ConA group and the Znpp group, the serum levels of ALT and AST in the MSCs group and the Hemin group were significantly lower(Fig 1). HE staining results showed that liver damage was improved in the MSCs group and Hemin group(Fig 2). The TUNEL immunofluorescence staining confirmed that the number of TUNEL positive cells in the MSCs group and the Hemin group was significantly lower than that in the ConA group and the Znpp group (Fig 3), while the number of Ki-67 positive cells in MSCs group and Hemin group was significantly higher than that in ConA group and Znpp group(Fig 4). The expression of TNF-α IFN-γ and IL-6 in conA group and Znpp group was higher than that in MSCs group and Hemin group(Fig 5). The RT-PCR assay also confirmed the difference

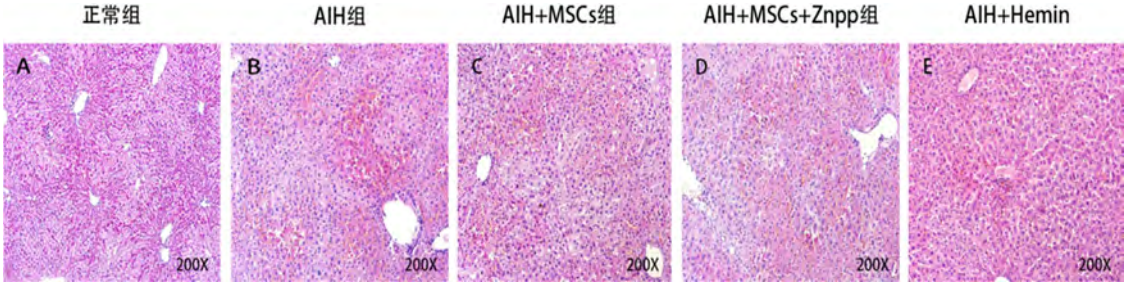

Figure: (abstract: THU121)

in expression of the above three inflammatory factors at the mRNA level(Fig 6). Western Blot assay showed high expression of HO-1 and Nrf2 in MSCs and Hemin groups(Fig 7). Immunofluorescence double staining showed that the expression of CD206 in MSCs group and Hemin group was significantly higher than that in ConA group and Znpp group, while the expression of INOS was significantly lower than that in ConA group and Znpp group(Fig 8). RT-PCR detection confirmed Arg1 in MSCs and Hemin group from mRNA level. High expression, and low expression of INOS in the MSCs and Hemin groups (Fig 8).
Conclusion: Our data demonstrate that MSCs attenuate ConA-induced Autoimmune hepatitis in mice, and the mechanism involves by altering macrophage polarization through Nrf2/HO-1 pathway.

THU122

Klebsiella in the mucosal gut microbiota in primary sclerosing cholangitis is associated with more severe disease

Mikal Jacob Hole[1], Kristin Kaasen Jørgensen[2], Simen H. Hansen[1], Alexandra Götz[1], Kirsten Muri Boberg[1], Tom Hemming Karlsen[1], Martin Kummen[1,3,4], Johannes R. Hov[1]. [1]*Oslo University Hospital and University of Oslo, Norwegian PSC Research Center, Department of Transplantation Medicine, Oslo, Norway;* [2]*Akershus University Hospital, Department of Gastroenterology, Oslo, Norway;* [3]*Research Institute of Internal Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway;* [4]*Institute of Clinical Medicine, University of Oslo, Oslo, Norway*
Email: m.j.hole@studmed.uio.no

Background and Aims: *Klebsiella pneumoniae* has been identified as a potential gut pathobiont in primary sclerosing cholangitis (PSC). Experimental evidence has suggested that the *K. pneumoniae* species is able to disrupt the epithelial barrier and elicit inflammation in the liver. We aimed to investigate the presence of *Klebsiella* in mucosal biopsies of PSC patients and its potential clinical impact.
Method: 184 consecutive PSC patients underwent ileocolonoscopy between 2006 and 2008. After excluding patients with previous colectomy or liver transplantation, we included 84 patients (79% inflammatory bowel disease [IBD], 77% male, median age 40 years and median 3.3 years disease duration) with biopsies available from at least two out of four segments (terminal ileum, ascending, descending and sigmoid colon). During a median observation time of 7.5 years, 52 patients (62%) were liver transplanted or died. DNA was extracted from biopsies and subjected to 16S rRNA amplicon sequencing (V3-V4) and analyzed using QIIME2. The dataset was rarefied to 9137 reads per sample.
Results: Sequences mapping to the *Klebsiella* genus in any segment were detected in 13 patients (15%). *Klebsiella* in any segment were associated with a higher mean Amsterdam-Oxford PSC risk score (AOM) (2.32 [1.86–2.78] vs. 1.94 [1.78–2.10], p = 0.037) and AST-to-platelet-ratio index (1.57 [0.94–2.21] vs. 1.00 [0.74–1.25], p = 0.009) compared to those without. There were no associations between *Klebsiella* and age, gender or IBD. Patients with *Klebsiella* in any segment had numerically shorter liver transplantation-free survival (median 4.2 vs. 8.7 years, p = 0.20, Kaplan-Meier analysis). Considering individual segments, *Klebsiella* in the sigmoid (n = 10/69, 14%) was associated with reduced survival (2.4 vs. 8.7 years, p = 0.026), but not independent from AOM risk score ($HR_{Klebsiella}$ 1.86 [0.88–3.90], p = 0.11, Cox regression). Other PSC-associated microbiota features like low diversity (Shannon) or increased *Veillonella* did not associate with survival, although, the group with microbiota diversity below median in the ascending colon had higher AOM score (p = 0.042) compared to those with above median.
Conclusion: The presence of *Klebsiella* in the gut mucosa is associated with more severe PSC. Further analyses are necessary to define abundance at species level. The possibility of targeting specific bacteria to modify the disease in subsets of PSC patients should be investigated further.

THU123

Downregulation of the bile acid receptor TGR5 in livers of PSC patients and ABCB4−/− mice

Maria Reich[1], Lina Spomer[1], Jan Stindt[1], Katharina Fuchs[1], Johannes R. Hov[2], Tom Hemming Karlsen[2], Dirk Nierhoff[3], Christoph Schramm[4], Dieter Häussinger[1], Verena Keitel[1]. [1]*Clinic for Gastroenterology, Hepatology and Infectious Diseases, Heinrich-Heine-University, Düsseldorf, Germany;* [2]*Norwegian PSC Research Center, Department of Transplantation Medicine and Institute of Clinical Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway;* [3]*Clinic for Gastroenterology and Hepatology, University of Cologne, Köln, Germany;* [4]*I. Department of Medicine and Martin Zeitz Center for Rare Diseases, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*
Email: maria.reich@uni-duesseldorf.de

Background and Aims: The localization of TGR5 in cholangiocytes and immune cells, the choleretic, anti-inflammatory and anti-apoptotic functions of the receptor suggest that TGR5 is important for the pathogenesis of liver diseases and in particular of biliary diseases. Aim of this study was to evaluate changes in TGR5 expression and localization in livers from PSC patients as well as from Abcb4$^{-/-}$ mice, which serve as an animal model for sclerosing cholangitis.
Method: TGR5 expression and localization in livers from PSC patients (cryopreserved IPSCIG cohort (n = 22) and paraffin embedded German cohort (n = 10)) and Abcb4$^{-/-}$ animals were evaluated using immunofluorescence staining and confocal laser scanning microscopy. TGR5 mRNA expression was analyzed in isolated intrahepatic and extrahepatic bile ducts from Abcb4$^{-/-}$ mice and WT controls by real-time PCR in relation to an endogenous housekeeping control. BECs (biliary epithelial cells) were isolated by microdissection and outgrow method or by FACS using positive selection for EpCAM from livers of 6–8 weeks-old animals. Biliary epithelium organoids were generated from human bile and liver biopsy samples. Human BECs were isolated from patients with alcoholic liver disease or non-alcoholic steatohepatitis. For Western-Blot analysis cell lysates were separated by SDS-page and blotted onto PVDF membranes. Detection was carried out using anti-TGR5, phospho-p44/42 MAPK, p44/42 MAPK and anti-GAPDH antibodies. The concentration of serum cytokine levels in Abcb4$^{-/-}$ and WT mice was determined using a Luminex cytometric bead assay.
Results: Reduced TGR5 staining intensity was detected in BECs from early and late stage liver tissue of PSC patients as well as in BECs of Abcb4$^{-/-}$ mice. Analysis of isolated intrahepatic and extrahepatic bile ducts showed a significant decrease in TGR5 mRNA in Abcb4$^{-/-}$ mice as compared to the respective controls. In addition, TGR5 mRNA levels were significantly lower in EpCAM^{+}-cells derived from Abcb4$^{-/-}$ animals. Stimulation of human biliary organoids and human BECs with recombinant IL-8 significantly supressed TGR5 mRNA expression and TGR5 protein levels, respectively. Moreover, the murine IL-8 homologues KC and MIP-2 were significantly increased in serum of Abcb4$^{-/-}$ mice compared to the WT controls and stimulation of isolated WT cholangiocytes with IL-8 homologues significantly decreased TGR5 mRNA in murine BECs.
Conclusion: The bile acid receptor TGR5 was significantly down-regulated in BECs of liver tissue from PSC patients with both early and late disease stages. Moreover, a significant reduction of TGR5 mRNA was detected in intrahepatic and extrahepatic bile ducts as well as in isolated BECs from Abcb4$^{-/-}$ mice livers. Our data demonstrate that IL-8 stimulation suppresses TGR5 mRNA and protein levels in murine and human BECs or biliary organoids.

THU124

Insufficient deletion of autoreactive CD4 T cells and plasticity of Tregs drive spontaneous autoimmune hepatitis in mice

Max Preti[1], Lena Schlott[1], David Luebbering[1], Daria Krzikalla[1], Anna-Lena Müller[1], Miriam Schakat[1], Sören Alexander Weidemann[2], Ansgar W. Lohse[1], Dorothee Schwinge[1], Christoph Schramm[1], Christina Weiler-Normann[1], Antonella Carambia[1], Johannes Herkel[1]. *[1]Universitätsklinikum Hamburg-Eppendorf, Department of Medicine I, Hamburg, Germany; [2]Universitätsklinikum Hamburg-Eppendorf, Department of Pathology, Hamburg, Germany*
Email: j.herkel@uke.de

Background and Aims: Autoimmune hepatitis is a chronic inflammatory liver disease, which is associated with an adaptive immune response to hepatic antigens. We have previously described a new mouse model of autoimmune hepatitis, which is characterized by hepatocellular expression of an MHC class II-restricted CD4 T cell epitope of lymphocytic choriomeningitis virus (GP61–80) under control of the albumin promoter, and by abundance of cognate Smarta1 CD4 T cells recognizing GP61–80 (EASL Abstract in: Journal of Hepatology 2017; Vol.66, Issue 1, S74). By using these Alb-iGP_smarta mice, we elucidated some of the mechanisms that induce the loss of tolerance to liver antigens in experimental AIH.
Method: Autoreactive CD4 T cells and regulatory T cells in Alb-iGP_Smarta mice were identified with I-A(b) GP66–77 tetramers and analyzed by flow cytometry. Ectopic lymphoid structure formation in the liver was characterized by histological analysis of liver sections taken at various disease stages.
Results: Autoreactive T cells were not deleted in the thymus or in the periphery, due to antigen ignorance. Starting at 20 weeks of age, Alb-iGP_Smarta mice spontaneously developed CD4 T cell-mediated hepatitis with typical disease features of human AIH, including elevated IgG and serum transaminases, antinuclear autoantibodies, and lymphocytic periportal infiltrates with interface hepatitis. The development of AIH was facilitated by pathogenic maturation of autoreactive CD4 effector T cells towards IFN-γ and TNF-α co-producing cells, which seemed to occur locally in the liver within transiently formed portal ectopic lymphoid structures. Autoantigen-specific regulatory T cells in the liver displayed a selective increase of plasticity and instability, marked by IL-17 production, reduced Foxp3 expression and a less demethylated *Foxp3* locus, providing a possible explanation for their obvious inability to arrest the pathogenic maturation of CD4 effector T cells and AIH exacerbation.
Conclusion: Our findings indicate that AIH is driven by pathogenic maturation of previously ignorant autoreactive CD4 effector T cells, in combination with selectively increased

THU125

MIR-506 as one of potential determinants of different phenotypic presentation of ulcerative colitis in patients with primary sclerosing cholengitis (PSC)

Ewa Ostrycharz[1], Agnieszka Kempinska-Podhorodecka[1], Piotr Milkiewicz[2], Malgorzata Milkiewicz[1]. *[1]Pomeranian Medical University, Szczecin, Poland, Department of Medical Biology, Szczecin, Poland; [2]Medical University of Warsaw, Liver and Internal Medicine Unit, Warsaw, Poland*
Email: milkiewm@pum.edu.pl

Background and Aims: Primary sclerosing cholangitis (PSC) is commonly accompanied by ulcerative colitis (UC), most frequently localized in the right colon. Impairment of $Cl^{-}/HCO3^{-}$ exchanger (AE2), promoted by release of Ca2+ *via* inositol-1,4,5-trisphosphate-receptor (InsP3R3), decreases luminal pH of the colon facilitating the entry of protonated toxic bile salts and sensitizing apoptotic stimuli. Non-coding miR-506 down-regulates AE2, InsP3R3, and also sphingosine kinase-1(SPHK1), the enzyme that activates sphingosine-1, a bioactive lipid involved in immune cell trafficking. We analyzed expressions of miR-506 and its target genes in colonic tissues of patients with PSC with concomitant UC (PSC-UC) and UC alone.
Method: Ascending and sigmoid colon biopsies were obtained from patients with PSC-UC (n = 11), UC (n = 8) and controls (n = 11). The relative levels of microRNAs and mRNAs were evaluated by real-time PCR. A potential effect of ursodeoxycholic acid (UDCA) was examined in Caco-2 cells.
Results: There was a significant increase in miR-506 level (6.7-fold, p = 0.0005 vs controls, and p = 0,0001 vs UC) in the ascending colon of PSC-UC patients. This was associated with downregulation of AE2 (43% reduction, p = 0.029 vs controls), with no changes seen in InsP3R3 and SPHK1 expressions. On the contrary, in the sigmoid colon of PSC-UC, miR-506 expression was substantially suppressed (60% reduction, p < 0.0001 vs controls) and accompanied by induction of SPHK1 mRNA (2.5-fold, p = 0.02 vs controls),while the other investigated factors remained unchanged. In reverse, expression of miR-506 in patients with UC was substantially suppressed both in the ascending and sigmoid colon (80% and 79% reduction, respectively) and the SPHK1 expression was noticeable enhanced (6.2-fold, and 3.8-fold, respectively). In contrast to PSC-UC group, the level of AE2 mRNA was enhanced (1.5-fold, p = 0.03 vs controls) in UC ascending colon, but InsP3R3 mRNA levels were comparable to control values in both parts of colon. UDCA did not affect the basal expression of miR-506.
Conclusion: A different phenotypic presentation of colitis in PSC may, at least partially, be related to miR-506 expression. In ascending colon of PSC-UC the upregulation of miR-506 may result in the failure of bicarbonate secretion, while in UC a downregulation of miR-506 may lead to enhanced production of sphingosine-1-phosphate that is involved in inflammatory responses.

THU126

Co-stimulatory molecules OX40 and CD30 mediates the regeneration of the liver epithelium in a mouse primary scletosing cholangitis model

Naruhiro Kimura[1], Atsunori Tsuchiya[2], Peter Lane[1], David Withers[1], Shuji Terai[2], Wei-Yu Lu[1]. *[1] Institute of Immunology and Immunotherapy, College of Medical and Dental Sciences, Birmingham, United Kingdom; [2]Division of Gastroenterology and Hepatology, College of Medical and Dental Sciences, Niigata city, Japan*
Email: N.kimura@bham.ac.uk

Background and Aims: Primary Sclerosing Cholangitis (PSC) is a chronic liver disease characterized by the accumulation of inflammation and fibrosis of the bile ducts. Efficient treatment for PSC is lacking due to the lack of understanding about the disease pathogenies. Regulatory T cells (Tregs) have been suggested to have important roles in PSC pathogenesis, and its regulation in the PSC microenvironment is less known. Tumor necrosis factor receptors OX40 and CD30 are T cell co-stimulatory molecules required for promoting T cell survival, effector phenotype and regulatory function. To investigate whether co-stimulatory molecules are required to facilitate the tissue regenerating potential of Tregs on the background of biliary injury, we utilised the OX40−/−CD30−/− double knockout (dKO) mice with the feeding of 3,5-diethoxycarbonyl-1,4-dyhydro-collidine (DDC) diet to induces cholestatic liver injury.
Method: dKO (n = 6) and wild type (WT) BL6 mice (n = 4) were fed with DDC diet for 7 days. Immune cells in the liver were isolated and liver histology were analyzed before and after injury.
Results: At homeostasis, WT mice have 4 times more Tregs in the liver compared to the dKO mice (4.1 ± 0.3% vs 1.1 ± 1.1%/CD4 + cells). Tregs in the dKO mice have impaired expansion following DDC diet compared to the WT group (7.4 ± 1.5% vs 2.3 ± 0.95% CD4+ cells). Further analysis demonstrated that liver sinusoidal endothelial cells are a major source of OX40 Ligand (OX40L) in the liver, and the level of OX40L expression significantly decreased after DDC diet (95 ± 0.2% vs 35.8 ± 3.7% /CD31 + cells). Histological findings showed that the dKO mice had significantly impaired hepatocyte regeneration

demonstrated by the increased in senescence marker p21 (58.9 ± 17.0 vs 24.7 ± 8.9 cells/field) and decreased proliferation marker Ki67 on Hnf4a+ hepatocytes compared to the WT mice (1.7 ± 1.1 vs 3.3 ± 1.6 cells/field) following injury, whilst no significant difference was detected at the homeostatic level.
Conclusion: Our results showed that costimulatory molecules OX40 and CD30 are able to regulate the degree of cellular senescence in response to injury, and suggest that this is controlled through a T-cell mediated manner in particularly through the regulation of Tregs.

THU127

Developing antigen-specific immunotherapy for autoimmune hepatitis type 2 by identification of T cell epitopes

Naomi Richardson[1], Suzan Warner[2,3], Vincenzo Ronca[2], Deirdre Kelly[3], Ye Htun Oo[2,4], David Wraith[1]. [1]*University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom;* [2]*University of Birmingham, Centre for Liver and Gastrointestinal Research, Birmingham, United Kingdom;* [3]*Birmingham Children's Hospital, Liver Unit, Birmingham, United Kingdom;* [4]*Queen Elizabeth Hospital Birmingham, Liver Transplant and Hepato-biliary Unit, Birmingham, United Kingdom*
Email: naomirichardson.12@gmail.com

Background and Aims: Antigen-specific immunotherapy can modulate T-cell mediated immunological diseases by inducing tolerance. Autoimmune hepatitis type 2 (AIH2) is a severe autoimmune liver disease with unmet clinical needs, in which T-cells specific to autoantigen cytochrome P450 2D6 (CYP2D6) help perpetuate tissue damage. We aim to identify T-cell epitopes of CYP2D6 with tolerogenic potential, as a novel immunotherapy for AIH2 could offer an alternative to lifelong immunosuppression.
Methods: Paediatric and adult AIH2 patient (n = 16), adult AIH1 patient (n = 16) and healthy donor (n = 46) PBMC samples were screened for antigen-specific activation to 30mer peptides of CYP2D6 using ^{3}H-thymidine incorporation. Peptide-stimulated adult AIH2 samples were analysed for production of 13 T-cell cytokines. A flow based assay to enrich for rare antigen-specific CD4+ T-cells based on activation-induced markers (AIM+) and isolation by FACS prior to T-cell cloning is under development. HLA-DR transgenic mice (*HLA-DRB1*0401* and *DRB1*0301*) were immunised with CYP2D6 30mer peptides. Spleen and draining lymph node cells were stimulated *ex vivo* with 30mer peptide and overlapping 15mers. T-cell responses were assessed by proliferation, and IFN- γ and IL-2 ELISAs. T-cell hybridomas comprised of activated HLA-DR transgenic T lymphocytes and thymoma cell line BW5147 were generated for detailed epitope mapping. *HLA-DRB1*0701* transgenic mice for similar experiments are being re-derived.
Results: CYP2D6 is a highly immunogenic protein with Pep1, Pep2 and Pep4 recording frequent strong responses in AIH2 patients. Similar patterns are observed in healthy donors with the addition of responses to Pep9. Pep2 and Pep4 induce high levels of IL-6 production in adult patients. These peptides produce significant T-cell responses in HLA-DR4 and HLA-DR3 transgenic mice and T-cell hybridomas specific to these peptides recognise both the native CYP2D6 protein and overlapping 15mers.
Conclusions: Autoimmune Hepatitis Type 2, as a clinically challenging autoimmune liver disease, may benefit from the realisation of novel treatments. By combining approaches including interrogation of immune responses of AIH2 patients, AIH1 patients, healthy donors and humanised mouse models we can explore the immunogenicity and hierarchy of peptide epitopes in AIH2. Our aim, in progress, has been to identify T cell epitopes of CYP2D6 to develop a peptide cocktail for antigen-specific immunotherapy of AIH2.

Email: munozas@farm.ucm.es

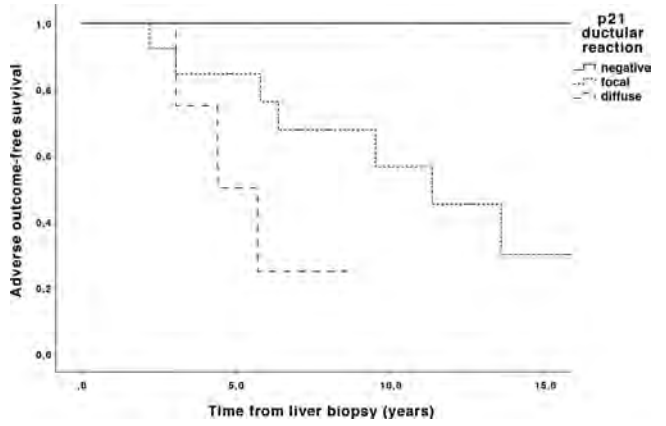
Background and Aims: The epidermal growth factor receptor (EGFR) pathway is known to be an important player in both liver regeneration and hepatocarcinogenesis, but its role during cholestatic liver injury remains elusive and so it does its regulatory activity on adult hepatic progenitor cells (HPC) expansion and function in the cholestatic liver. Thus, the aim of this work is to analyze the effect of inhibiting EGFR signaling on the liver regenerative response and liver damage progression upon a cholestatic insult, with an eye on HPC.
Method: We have used a validated transgenic mouse model expressing a liver-specific truncated form of human EGFR which lacks its tyrosine kinase domain and acts as a dominant negative mutant (deltaEGFR). WT and deltaEGFR mice were submitted to 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)-induced cholestatic liver damage for 1–6 weeks. Immunohistochemistry, immunofluorescence, western blot and RT-qPCR analyses were performed to characterize the gene/protein expression profile of inflammatory and fibrotic signals, HPC markers as well as to measure cell proliferation. Biochemical markers of liver damage were also measured in serum.
Results: Results show that lack of EGFR kinase activity leads to decreased liver damage and fibrosis upon DCC treatment, evidenced by lower serum biomarkers of liver injury (alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase and total bilirubin), and a lower induction of fibrosis markers. Interestingly, this is associated with a stronger ductular reaction and increased HPC expansion in response to DDC based on H&E staining, cytokeratin 19 immunohistochemistry, Ki67 immunofluorescence staining and HPC markers expression analysis. Additionally, profound changes in the expression profile of inflammatory mediators are observed in deltaEGFR mice, which suggest an altered inflammatory response. To clarify the EGFR-dependent mechanisms behind the altered liver regenerative response to DDC-induced cholestasis further experiments are being performed using an *in vitro* model of bile acid-induced cholestatic injury.
Conclusion: Collectively, our results reinforce the suitability of the deltaEGFR mouse model to allow us advance in our understanding on the mechanisms governing liver injury responses while supporting a major role for EGFR signaling pathway in regulation of liver regeneration and HPC behavior during chronic cholestatic liver injury. Ongoing mechanistic studies will help us elucidate the EGFR-dependent mechanisms underneath such role.

THU129

The role of cellular senescence in the natural course of primary sclerosing cholangitis

Nora Cazzagon[1], Samantha Sarcognato[2], Giorgia Corrà[1], Sara De Martin[3], Vincenza Guzzardo[2], Annarosa Floreani[1], Maria Guido[2], Francesco Paolo Russo[1]. [1]*Department of Surgery, Oncology and Gastroenterology – DiSCOG, University of Padova, Padova, Italy;* [2]*Department of Medicine – DIMED, University of Padova, Padova, Italy, Padova, Italy;* [3]*Department of Pharmaceutical and Pharmacological Sciences, University of Padova, Padova, Italy*
Email: nora.cazzagon@gmail.com

Background and Aims: Cellular senescence (CS) is a physiological mechanism of irreversible cell cycle arrest in response to damage, that prevents uncontrolled replication of injured cells. The role of CS in the pathogenesis of human chronic liver diseases has been recently reported. Primary sclerosing cholangitis (PSC) is a rare cholangiopathy of unknown etiopathogenesis and the role of CS in PSC has not yet been clarified. To evaluate hepatic expression of CS markers in PSC patients and its correlation with clinical-pathological features and prognosis.
Method: Thirty-five PSC patients (14 males, median age at diagnosis 27 years) followed-up for 12 (0.5–29) years with at least one available liver biopsy performed at diagnosis and/or during follow-up were retrospectively enrolled. Clinical, laboratory data, Mayo Risk Score (MRS) and Amsterdam-Oxford Model (AOM) at the time of liver biopsy were collected. The endpoint was survival without liver transplantation or cirrhosis decompensation. Grading and staging were assessed by 2 expert pathologists according to Nakanuma. Immunohistochemical stains for CS markers, p16 and p21, were performed and semi-quantitatively scored by a three-tier scale based on the positivity extent (negative, focal or diffuse) in native bile duct (NBD) and ductular reaction (DR).



Results: p16 expression in NBD and DR was directly correlated with hepatitis activity ($p = 0.02$ and $p = 0.05$), cholestasis-related histological lesions ($p = 0.09$ and $p < 0.001$), fibrosis ($p < 0.001$ for both) and disease stage ($p = 0.005$ and $p < 0.001$). p21 expression in NBD and DR was directly correlated with hepatitis activity ($p = 0.001$ and $p = 0.03$), cholestasis-related histological lesions ($p < 0.001$ for both), fibrosis ($p < 0.001$ for both) and disease stage ($p < 0.001$ and $p = 0.003$). By multivariate analysis p16 expression in DR was independently associated with advanced disease stages (HR 13.6 (95% CI 2.6–72.6), $p = 0.002$). p16 and p21 expression in DR was directly related to MRS ($p = 0.02$ for both) and AOM ($p < 0.001$ and $p = 0.007$). p16 and p21 expression in NBD was directly related to AOM ($p = 0.03$ for both). Finally, p21 expression in DR was independently associated with adverse outcome-free survival (HR 4.6 (95%CI 1.6–13.6) $p = 0.005$) (Figure).

Conclusion: In PSC CS marker expression is related to disease stage, clinical severity and prognosis, suggesting a role of senescence in the pathogenesis and progression of the disease.

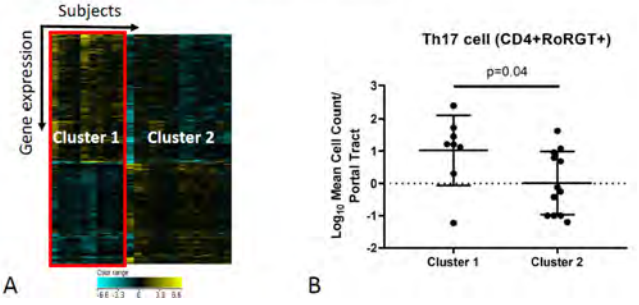
THU130

Upregulation of hepatic TH17 response is associated with large duct disease and advanced hepatic fibrosis in pediatric autoimmune liver disease

Simon Lam[1], Immaculeta Osuji[1], Annika Yang vom Hofe[1], Jonathan Dillman[2], Divya Sharma[3], Ruchi Singh[1], Rebekah Karns[1], Alexander Miethke[1]. [1]*Cincinnati Children's Hospital Medical Center, Gastroenterology, Hepatology and Nutrition, Cincinnati, United States;* [2]*Cincinnati Children's Hospital Medical Center, Radiology, Cincinnati, United States;* [3]*University of Cincinnati Medical Center, Pathology, Cincinnati, United States*
Email: Simon.Lam@ahs.ca

Background and Aims: In autoimmune hepatitis (AIH), primary sclerosing cholangitis (PSC), and autoimmune sclerosing cholangitis (ASC), the presence of biliary injury portends a course refractory to medical therapy. We aimed to elucidate the predominant hepatic immune responses associated with biliary injury and fibrosis using RNA sequencing (RNAseq) and multi-parameter immunofluorescence (IF) on liver biopsy samples obtained at the time of a prospective research MRI.
Method: 24 subjects (male = 13, mean age = 15 y, PSC = 2, ASC = 10, AIH = 12) undergoing liver biopsy were prospectively enrolled. RNAseq was performed on liver tissue at a depth of 50 million reads with raw reads aligned to Hg38 using Kallisto. A moderated t-test was used to compare shared gene expression of protein coding transcripts. Magnetic resonance cholangiopancreatography (MRCP) and MR Elastography (MRE) were performed within a median of 23 days from biopsy. A radiologist and pathologist, both blinded to clinical and RNA data, classified MRCPs as abnormal in the presence of extra-/intrahepatic ductal dilatation or strictures and staged histopathologic liver fibrosis, respectively. Liver sections from 20 subjects underwent IF with antibodies against panCK, CD4, CD8, RoRGT, FOXP3 and TBET followed by image acquisition and automated quantitative image analysis.

Figure 1: (A) The unsupervised analysis of hepatic gene expression in 24 children with autoimmune liver disease identified two clusters of subjects with a share gene expression pattern. (B) Quantitative image analysis revealed a 7-fold increase in Th17 cells per portal tract in cluster 1 compared to cluster 2.



Results: An unsupervised analysis of liver RNAseq data identified two patient clusters (Figure 1A). Genes associated with IL17 responses and extracellular matrix remodeling were upregulated in cluster 1. By IF, although the frequency of CD4+ and CD8+ cells did not differ, there was a 4-, 7- and 9-fold increase in the frequency of IL17 (RoRGT+) producing cells, Th17 cells (CD4+RoRGT+) (Figure 1B) and Th17.1 cells (CD4+RoRGT+TBET+) per portal tract, respectively, in cluster 1 ($p < 0.05$ for all). The proportion of Th17.1 cells within the Th17 population was also higher in cluster 1 (73% vs 31%, $p < 0.001$). Importantly, MRCPs were abnormal in 10/10 patients in cluster 1

compared to 2/14 in cluster 2 ($p < 0.001$). 80% of subjects had a clinical diagnosis of PSC/ASC in cluster 1 vs 38% in cluster 2 ($p = 0.04$). Mean liver stiffness measurements by MRE (3.9 vs 2.8 kPa, $p = 0.02$) and Ishak histopathological stage of fibrosis (4.0 vs 1.8, $p = 0.003$) were also higher in cluster 1.

Conclusion: Large duct injury and advanced fibrosis in pediatric ASC and PSC is associated with an upregulation of the IL17 pathway, including pathogenic Th17.1 cells which are thought to be refractory to corticosteroid therapy. These RoRGT+ cells may represent novel therapeutic targets in pediatric patients with advanced PSC.

THU131

Elevated levels of systemic bacterial vesicles in autoimmune hepatitis are associated with non-response to corticosteroid therapy

Sukriti Sukriti[1], Purnima Tyagi[1], Preeti Negi[1], Chhagan Bihari[2], Shiv Kumar Sarin[3]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Pathology, New Delhi, India; [3]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: shivsarin@gmail.com

Background and Aim: Autoimmune hepatitis (AIH) is characterized by self-perpetuating immune-mediated inflammatory liver damage with or without fibrosis. Corticosteroids remain the main stay of treatment. Microbiome-liver axis has been recognised as a major modulator of autoimmunity and sepsis. We investigated the presence and activity of bacterial EVs in plasma and their interactions with immune cells in AIH patients and their association with steroid response.

Method: Fractionated pre-therapy plasma of AIH patients [n = 28, biopsy proven- noncirrhotic, F < 4, international simplified score $\geq$ 7, HAI score >4, ALT (148 ± 58.4 IU/ml), AST (140.7 ± 60.2 IU/ml){16 responders (R) and 12 non-responders (NR)] to corticosteroid therapy, and healthy controls (n = 12) for bacterial EVs [by ultracentrifugation using anti-OMPA (outer membrane protein A) and anti-LPS quantified using flow cytometry and western blot]. PBMCs of AIH patients were primed with bacterial vesicles (OMVs-2ug/ml) and (OMV+dynasore-80uM, to block the entry of OMVs inside the cells) for 24 hour and analysed for frequency, activation of total T (CD3+CD4+CD8+) cells, mucosal associated invariant T (CD3+CD161+TCRvα7.2+) cells, intracellular IL-17A and granzyme B release and B (CD19+) cells using multi-colour flowcytometry.

Results: Levels of systemic bacterial EVs (OMPA+LPS+) were higher in AIH patients than controls (28.3 ± 5.6 vs. 2.4 ± 1.1 EV/ul; $p < 0.001$), and were higher in moderate to severe than minimal to mild hepatic histological activity ($p = 0.042$). At baseline, NR to corticosteroids had higher bacterial EVs than R (39.6 ± 10.8 EV/ul vs. 12.4 ± 3.2; $p < 0.001$ with AUC = 0.71 CI [0.79–0.83]. Protein blots confirmed higher bacterial EV-associated LPS and OMPA in plasma fractions of NRs than R ($p = 0.003$). OMVs in NR PBMCs strongly stimulated the secretion of IL-17A ($p = 0.015$) and granzyme B ($p = 0.052$) from MAIT cells and also increased the frequency of activated MAIT cells (%MAIT+CD69+) ($p = 0.001$) than R. Even with OMV+ dynasore treatment, no inhibition was found in cytokine release in NR, suggesting overwhelming presence of OMVs in the cells of NR and continuous cellular activation.

Conclusion: Increased systemic OMPA and LPS-positive bacterial EVs are present at baseline in AIH patients and are able to induce marked immune activation through MAITs cells, which could contribute to corticosteroid resistance.

THU132

Single cell RNA sequencing reveals naive T cells ready for effector function in livers of patients with primary sclerosing cholangitis

Email: t.poch@uke.de

Background and Aims: Although genetic association analysis points towards immune dysregulation contributing to the pathogenesis of Primary Sclerosing Cholangitis (PSC), the role of specific immune cell populations within the liver of patients with PSC remains elusive. Here, we report on a comprehensive phenotypic and functional investigation of the liver infiltrating T cells of patients with PSC.

Method: Liver infiltrating and peripheral T lymphocytes were isolated from patients with PSC (n = 16) undergoing liver transplantation (LTX). As controls we used T cells from the same compartments from patients with alcoholic liver disease (ALD, n = 16) and blood of healthy donors (n = 10). Liver infiltrating T cells were sorted and processed for single cell RNA sequencing (scRNA-Seq) and cellular indexing of transcriptome and epitopes by sequencing (CITE-Seq). T cells from both compartments underwent flow cytometry-based deep immune phenotyping. Finally, naïve T cells were analyzed for proliferation capacity, cytokine production and differentiation capacity *in vitro*.

Results: By combining scRNA-Seq, CITE-Seq and multi-parameter flow cytometry, we observed a unique immunophenotype of liver infiltrating and peripheral T cells in PSC, when compared to ALD and healthy controls. A subset of liver infiltrating naïve-like $CD4^+$ T cells was identified in PSC patients with end-stage liver disease. Using flow cytometry, we confirmed the presence of phenotypically naïve $CD4^+$ T cells in PSC livers and found they were increased in frequency compared with ALD. Transcriptome analysis using scRNA-Seq revealed high expression of markers such as *STAT3* suggesting a possible predisposition to acquire a Th17 phenotype. *In vitro*, PSC-derived naive $CD4^+$ T cells showed higher rates of proliferation and production of cytokines associated with Th17 cells compared to healthy controls.

Conclusion: We here provide the first comprehensive atlas of intrahepatic T cells in PSC. Naïve-like $CD4^+$ T cells ready to differentiate into Th17 cells were identified within the liver and their abundance was increased in liver and blood of PSC compared to ALD. We propose these cells as potential contributors to disease pathogenesis.

THU133

Integrated analysis of GWAS and mRNA microarray identified IFN-? and CD40l as the central upstream-regulators in primary biliary cholangitis

Kazuko Ueno Ueno[1,2], Yoshihiro Aiba[3], Yuki Hitomi[2,4], Shinji Shimoda[5], Olivier Gervais[6], Yosuke Kawai[1,2], Minae Kawashima[7], Nao Nishida[1], Kaname Kojima[8], Masao Nagasaki[6], Katsushi Tokunaga[1,2], Minoru Nakamura[3,9].

Email: ueno-k@m.u-tokyo.ac.jp

Background and Aims: Ten to 20% of patients with primary biliary cholangitis (PBC) are resistant to current standard therapy including ursodeoxycholic acid and progress to liver cirrhosis and hepatic failure. Therefore, there is a substantial need for novel treatments based on the pathogenesis of PBC through integrated pathway analysis with genes identified by GWAS and microarray.
Method: We performed the analysis of disease-pathways and their upstream-regulators by Ingenuity Pathway Analysis using the dataset 1 of GWAS (1920 PBC cases and 1770 controls) which included 261 annotated genes derived from 6760 SNPs (p-value<0.00001) and dataset 2 of mRNA microarray of liver biopsy specimens (36 PBC cases and 5 normal controls) which included 1574 genes (fold expression change>2, $p < 0.05$). Hierarchical clustering was performed using dataset 2. The genes identified in microarray were categorized into nine distinct cell types defined by a published data (Nat. Commun. 2018; 9:4383)).
Results: There were 27 genes (HLA, IKZF3, PRKCB, etc.) that were overlapped between the datasets 1 and 2, while there were 10 overlapped pathways (Th1, Th2 pathways, etc.) and 149 overlapped upstream regulators between the two datasets. Of these 149 upstream regulators, IFNG and CD40L were most significant among 7 upstream regulators that showed fold expression change >2 in the microarray. Hierarchical clustering divided the 36 patients into 2 clusters (Group 1 with higher- and Group 2 with lower- disease-activity). Most of the differently expressed genes between Group 1 and Group 2 belonged to the immune system and their upstream analysis predicted that IFNG and CD40L are the most significant upstream regulators among 40 regulators identified. In addition, we identified 10 and 7 downstream molecules of IFNG and CD40L, respectively, in cell type-specific manner. Of these downstream molecules, we found TNFRSF13C as a therapeutic target under clinical trials (e.g. VAY736) in sicca syndrome.
Conclusion: This study objectively identified the central role of IFNG and CD40L in both disease-susceptibility and -activity in PBC. In addition, new potential therapeutic targets were identified on pathways regulated by IFNG and CD40L.

THU134

FcRL4+ b cells are associated with inflamed bile ducts in patients with primary biliary cholangitis and locally capture IGA immune complexes

Yuxin Susan Liu[1,2], Karim Raza[1], Evaggelia Liaskou[2,3], Stefan G. Hübscher[3,4], Gideon Hirschfield[2,5], Zania Stamataki[2,3], Dagmar Scheel-Toellner[1,2]. *[1]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom; [2]University Hospitals Birmingham NHS Foundation Trust and University of Birmingham, NIHR Birmingham Biomedical Research Centre, Birmingham, United Kingdom; [3]University of Birmingham, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom; [4]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [5]University of Toronto, Toronto Center for Liver Disease, Toronto, Canada*
Email: yxl757@student.bham.ac.uk

Background and Aims: Primary biliary cholangitis (PBC) is an autoimmune liver disease characterised by an inflammatory infiltrate, leading to the slow and progressive destruction of the small bile ducts. The surface protein Fc Receptor-like 4 (FcRL4) is expressed by a subset of memory B cells. They were first identified in the mucosa-associated lymphoid tissue and are implicated in the pathogenesis of rheumatoid arthritis and Sjogren's syndrome. Here, FcRL4-expressing B cells were quantified in end-stage liver disease. Their localisation, rate of proliferation, differentiation stage, and the functional role of FcRL4 as an IgA receptor were investigated.
Method: Liver-infiltrating mononuclear cells were isolated from explant livers from patients undergoing liver transplantation at the Queen Elizabeth Hospital, Birmingham, UK. These cells were analysed using flow cytometry for markers of B cell differentiation, activation and proliferation. Immunohistochemistry staining of formalin-fixed paraffin-embedded (FFPE) sections was used to determine the localization of FcRL4-expressing cells.
Results: We have identified and characterised a population of $FcRL4^+$ B cells in end-stage liver disease.
In PBC ($n = 15$), $FcRL4^+$ cells represent 1.5% (median) of the total B cell population. This population is significant smaller in other end-stage liver diseases ($p = 0.0003$), including primary sclerosing cholangitis ($n = 14$), non-alcoholic steatohepatitis ($n = 10$), and polycystic liver disease ($n = 9$), as well as donor organs that did not meet criteria for transplantation ($n = 10$). Staining of PBC FFPE sections showed that the $FcRL4^+$ cells were found in close proximity to damaged biliary epithelium. When compared to $FcRL4^-$ B cells, the FcRL4 expressing B cells are highly proliferative, enriched for $CD11c^+CD21^-$ age-associated B cells and $CD27^+IgD^-$ class-switched memory cells, and expressed higher levels of co-stimulatory receptors CD80 and CD86. FcRL4 acts as a receptor for IgA aggregates and $FcRL4^+$ B cells were able to capture these aggregates both in vivo and in vitro. $FcRL4^+$ B cells were enriched for IgA^+ cells.
Conclusion: $FcRL4^+$ B cells were enriched around inflamed bile ducts in end-stage PBC. These B cells have an activated phenotype and the ability to harvest IgA immune complexes present in bile. The activity of $FcRL4^+$ B cells suggests a functional role in the local inflammatory IgA-mediated immune response and may contribute to PBC pathogenesis.

THU135

Bile from patients with chronic liver diseases activates MAIT cells

Fei Zheng[1,2,3], Laura Valestrand[1,2,4], Tom Hemming Karlsen[1,2,3,4], Niklas Björkström[5], Xiaojun Jiang[1,2], Espen Melum[1,2,3,4]. *[1]Norwegian PSC Research Center, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Oslo, Norway; [2]Research Institute of Internal Medicine, Oslo University Hospital, Oslo, Norway; [3]Institute of Clinical Medicine, University of Oslo, Oslo, Norway; [4]Section of Gastroenterology, Division of Surgery, Inflammatory Diseases and Transplantation, Oslo University Hospital, Oslo, Norway; [5]Center for Infectious Medicine, Department of Medicine Huddinge, Karolinska Institutet, Karolinska University Hospital, Huddinge, Sweden*
Email: ZHENG.FEI@MEDISIN.UIO.NO

Background and Aims: Chronic cholestatic liver diseases are characterized by progressive biliary inflammation leading to bile duct destruction and fibrosis. Mucosal-Associated Invariant T cells (MAIT cells) are a subset of innate-like T cells prevalent in human liver that recognize antigens presented by MR1. Although MR1 on the biliary epithelium is known to be able to present and active MAIT

cells, it is currently unclear if bile contains antigen activating MAIT cells. We aimed to determine if bile contains antigens that can be presented by cholangiocytes and activate MAIT cells.
Method: Bile samples were collected at the time of liver transplantation from 10 patients with primary sclerosing cholangitis (PSC, a chronic cholestatic liver disease), and 4 patients with other liver diseases serving as controls. PBMCs were isolated from healthy controls. Bile were either directly incubated with PBMCs, or with antigen presenting cells (THP1 and H69, a monocyte and cholangiocyte cell line) followed by washings and co-culture with PBMCs. MAIT cells activation was blocked with an anti-MR1 antibody (clone 26.5). Activation markers on MAIT cells were examined by flow cytometry.
Results: Four out of fourteen bile samples led to activation of MAIT cells in terms of increased Granzyme B expression when incubated with bile. The activation elicited by bile samples was partially MR1 restricted as it was partially blocked by an anti-MR1 antibody. Using serial dilutions of the bile samples a clear dose-response relationship was evident. The antigens in bile could also be taken up by THP1 cells and presented to MAIT cells. In the same manner H69 cells, representing the epithelial lining of the bile ducts, could take up and present antigens to MAIT cells.
Conclusion: Bile samples from patients with chronic liver diseases can contain MR1 restricted antigens that can be presented by cholangiocytes and activate MAIT cells. Their presence in bile can be due to bacteria or bacterial metabolites in bile, or a yet unknown endogenous antigen. These findings suggest that MAIT cells can take part in driving or modulating bile duct inflammation.

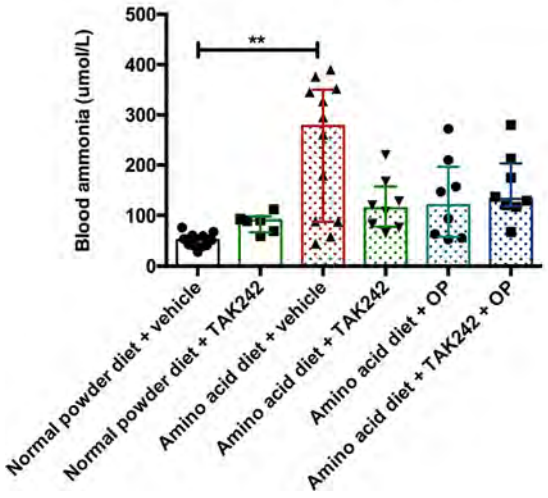
Cirrhosis and its complications: Experimental and pathophysiology

THU136
Inhibition of toll-like receptor 4 signaling reduces hyperammonemia by modulating urea cycle function

Annarein Kerbert[1], Cornelius Engelmann[1], Yalda Sharifi[1], Abeba Habtesion[1], Fausto Andreola[1], Rajiv Jalan[1]. [1]*University College London, Royal Free Campus, Institute for Liver and Digestive Health, London, United Kingdom*
Email: a.kerbert@ucl.ac.uk

Background and Aims: The severity of hepatic encephalopathy is modulated by the synergistic effects of ammonia and inflammation. We have previously shown that administration of lipopolysaccharide (LPS) to cirrhotic animals is associated with hyperammonemia (HA), but the underlying mechanism is unknown. We hypothesized that the LPS/Toll-like receptor 4 (TLR4) axis modulates ammonia levels by impacting on the urea cycle and that inhibiting TLR4 may be a novel therapy for the treatment of HA.
Method: *Study 1 (LPS-induced HA)*: Cirrhosis was induced in rats by bile duct ligation (BDL), followed 4w later by 0.025 mg/kg LPS i.p. (n = 4–6). The TLR4 antagonist TAK-242 (10 mg/kg i.p.) was injected 3 hours before LPS (n = 7). *Study 2 (HA in TLR4 knock-out):* HA was induced by an amino acid diet (AA) for 14 days (10 g/20 g of normal powdered diet (NP)) in WT and TLR4$^{-/-}$ mice (n = 6–12). *Study 3 (TAK-242 in liver naïve HA):* HA was induced as in study 2. Mice were treated on day 10–14 with vehicle, 10 mg/kg TAK-242 i.p. or 0.3 g/kg Ornithine Phenylacetate i.p. (OP, ammonia scavenger, +control). Biochemistry and mRNA and protein expression of urea cycle enzymes (UCEs) was assessed.
Results: *Study 1:* Ammonia increased throughout sham, BDL and BDL +LPS ($p < 0.001$). TAK-242 was associated with a reduction in ammonia ($p < 0.01$) and higher coma-free survival (100% vs. 15%). Gene expression of all UCEs (particularly CPS1) decreased throughout sham, BDL and BDL+LPS (all $p < 0.05$), which was prevented by TAK-242 (all $p < 0.05$). *Study 2:* In WT mice, HA was induced by the AA diet vs. NP diet ($p < 0.01$). This effect was attenuated in TLR4$^{-/-}$ ($p = 0.059$). Protein expression of CPS1 was markedly upregulated in TLR4$^{-/-}$+NP as compared to WT+NP. *Study 3:* HA was induced by the AA diet and reduced by TAK-242 and/ or OP (Figure). CPS1 mRNA and protein expression was significantly increased in AA+vehicle ($p < 0.05$), but not in the TAK-242/ OP treatment groups. As the p53 pathway has been shown to be a regulator of ammonia metabolism by suppressing the UCEs, we showed in study 2 a downregulation of p53 mRNA in TLR4$^{-/-}$ mice relative to WT ($p < 0.05$) and in study 3 an upregulation in the AA+vehicle group ($p < 0.05$), which was attenuated by TAK-242 ($p < 0.01$) and OP ($p < 0.05$).

Figure: Inhibition of TLR4 signaling with TAK-242 reduces circulating ammonia levels in a liver naive model of hyperammonemia.



Conclusion: We show that TLR4 signaling contributes to the development of HA by modulating UCEs. The activation of the p53 pathway by ammonia may be involved as the underlying mechanism. TAK-242, a TLR4 inhibitor, is a potential novel therapy for HA.

THU137
Acute kidney injury is associated with reversible platelet dysfunction in hospitalized patients with decompensated cirrhosis

Email: alberto.zanetto@yahoo.it

Background and Aims: Recent evidence suggests that acute kidney injury (AKI) is the main predictor of post-paracentesis bleeding in patients with cirrhosis and ascites. With the hypothesis that the increased bleeding tendency in AKI is due to platelet dysfunction, we performed a prospective comparative study evaluating platelet function in patients with decompensated cirrhosis with and without AKI.
Method: Platelet function was assessed using whole blood lumiaggregometry to evaluate both platelet aggregation (an *in vitro* marker

Table: (abstract: THU137)

	AKI (n = 40)	**No AKI** (n = 40)	
Age (years)	56 (52–65)	57 (52–64)	
Male gender (%)	60	73	
Child-Pugh^	10 (7–13)	10 (7–12)	
Ascites (%)	83	85	
MELD score	25 (20–29)	18 (11–26)	
Previous decompensation (%)	90	85	
Total bilirubin, mg/dL	2.9 (1.9–4.7)	2.6 (1.5–5.8)	
INR	1.7 (1.4–1.8)	1.5 (1.3–1.8)	
Creatinine, mg/dL	1.8 (1.6–2.5)	0.8 (0.7–0.9)	
			p value
Platelet aggregation, Ω			
Collagen 1	12 (7–18)	16 (10–22)	0.03
Collagen 5	15 (11–20)	22 (15–27)	0.002
ADP	14 (9–18)	12 (9–18)	0.8
Platelet secretion, nmol			
Thrombin	0.28 (0.20–0.40)	0.57 (0.40–0.70)	<0.001
Collagen 1	0.12 (0.00–0.24)	0.34 (0.21–0.41)	<0.001
Collagen 5	0.22 (0.14–0.33)	0.48 (0.32–0.63)	<0.001
ADP	0.20 (0.10–0.27)	0.38 (0.26–0.61)	<0.001

of platelet response to vessel injury) and platelet secretion (an *in vitro* marker of granule release). Platelets were stimulated with collagen 1 μg/mL, collagen 5 μg/mL, ADP 10 μM and thrombin 50 μM. In patients with AKI, platelet function was re-evaluated after AKI resolution. Inpatients with AKI but without liver disease were included as controls.

Results: Eighty patients with decompensated cirrhosis were recruited (40 each with and without AKI). As shown in the table, Child class, type of decompensating event and platelet count were comparable in both study groups. Patients with decompensated cirrhosis and AKI had lower collagen-induced aggregation and lower collagen-, ADP-, and thrombin-induced secretion, indicative of a more severely impaired platelet function. With AKI resolution (n = 23/40), both aggregation and secretion recovered and became comparable to values in patients with cirrhosis without AKI. The impairment in platelet function in patients with cirrhosis and AKI as well as the significant improvement after AKI resolution were confirmed after adjusting the analysis for the severity of thrombocytopenia. Compared to healthy individuals, controls with AKI but without liver disease (n = 10) had significantly lower platelet aggregation and secretion.

Conclusion: In patients with decompensated cirrhosis, the presence of AKI is associated with significant platelet dysfunction that is fully reversible upon AKI resolution. These abnormalities likely contribute to the increased bleeding risk in these patients.

THU138

Different inflammasome activation predisposes for acute-on-chronic liver failure depending on hepatic compensation in human and experimental liver cirrhosis

Email: amonteiro.sofia@gmail.com

Background and Aims: Systemic inflammation predisposes acute decompensated (AD) cirrhosis to development of acute-on-chronic liver failure (ACLF), characterized by high mortality.
With supportive treatment, patients with AD can improve becoming recompensated. While AD is associated with ACLF development, little is known about the outcome of patients recompensated after an AD. In this study we hypothesize that proinflammatory markers such as IL-1alpha and IL-1beta predict development of ACLF in compensated and recompensated patients.

Method: 249 patients with cirrhosis were included and followed prospectively for fatal ACLF development. Patients were divided in compensated and recompensated (previous AD). Systemic inflammation was assessed by two inflammasome-driving interleukins (ILs): IL-1alpha (Caspase-4/11 dependent) and IL-1beta (Caspase-1 dependent). In rats, bile duct ligation was performed to induce cirrhosis and lipopolysaccharide exposition was used to induce AD and subsequent recompensation. IL-1alpha and IL-1beta serum levels and up- /downstream gene expression in liver and peripheral blood mononuclear cells were measured.

Results: Patients developing ACLF showed significantly higher baseline levels of IL. Recompensated patients and patients with detectable IL had higher rates of ACLF development than compensated patients. Baseline CLIF-C AD (HR 1.106), albumin (HR 0.872) and IL-1alpha (HR 1.248) were independent predictors of ACLF development in compensated patients; CLIF-C AD (HR 1.079) and IL-1beta (HR 1.184) in recompensated patients. Compensated rats showed significantly higher IL-1alpha gene expression and recompensated rats had higher levels of IL-1beta with higher hepatic gene expression.

Conclusion: Previous AD is an important risk factor for ACLF development and is possibly linked with inflammasome activation. The animal models confirmed the results of the cohort study showing

a link between ACLF development and IL-1alpha in compensated cirrhosis and IL- 1beta in recompensated cirrhosis.

THU139

Impaired splenic function in liver cirrhosis: a study in 69 patients with cirrhosis from outpatient hepatology clinic in a tertiary hospital in northern Greece

Lamprini Kirkineska[1], Dimitrios Katsampoukas[2], Stamatia Georga[2], Xenia Kevrekidou[1], Vasilios Perifanis[3], Eustratios Moralidis[2], Georgios Arsos[2], Themistokis Vasileiadis[1]. *[1]Aristotle University, 3rd Internal Medicine Department, Thessaloniki, Greece; [2]Aristotle University, 3rd Nuclear Medicine Department, Thessaloniki; [3]Aristotle University, 1st Internal Medicine Department, Thessaloniki, Greece*
Email: drlambrini@gmail.com

Background and Aims: The role of the spleen as an important part of efficient immune response is more recognised over the last years. Our purpose was to investigate and quantify the degree of splenic dysfunction in patients with liver cirrhosis (LC) of various staging and etiology.

Method: 69 patients with LC were examined in hepatology clinic, at Papageorgiou Hospital, Greece, between 2014 and 2016. Diagnosis of cirrhosis was established through combination of laboratory findings (haematological parameters and imaging modalities) in the majority of cases.Liver biopsies were only performed for other indications. Etiology of cirrhosis was viral-28% (of which hep. B 52%), alcoholic-23%, NASH-14.3%, mixed –20.2%, autoimmune-7.2%, other-7.2%. Staging according to Child-Pugh (CP) score was: A-39%, B-41% and C-20%.

Splenic function was determined through pit cell count (PCC) and scintigraphy.

Samples of peripheral venous blood of 60 patients were examined in optical microscope, equipped with special lens and prism obtained especially for this research study. Number of PCC was calculated applying Differential Interference Contrast (D.I.C.) microscopy technique. A number of PCC above 2% was considered suggestive of splenic dysfunction, based on data from previous research.

All 69 patients underwent splenic scintigraphy with use of heat damaged, T99m-labelled red cells. Functional Splenic Volume (FSV-% uptake/ml) was calculated in all patients through SPECT/CT data analysis with use of specific software (OSIRIX). In addition, dynamic scintigraphy was performed in 27 patients, and the velocity of red cell clearance from circulation was calculated. Very few data was available regarding this advanced scintigraphic procedure and all parameters were calculated de novo.

Results: From D.I.C. microscopy, PCC percentage was >2% (diagnostic of spleen dysfunction) in 72% of patients with LC,ranging from 0.5% to 15% and there was a strong correlation between number of PCC and CP stage (p-value < 0.0001). From spleen scintigraphy, FSV was significantly decreased in patients with advanced LC compared to healthy subjects (ranging from 0.01%/ml to 0.33%/ml) and the correlation between FSV and CP score was statistically significant (p-value < 0.05).

Conclusion: As far as we are aware, our study was the largest including both calculation of pitted red cell count and performance of heat damaged, 99 m -labelled red cells scintigraphy in a population of patients with LC of various etiology and stages.

Splenic function is impaired in our population of patients with LC, regardless of etiology, and appears more significant in advanced stages (CT B and C). Splenic dysfunction and its potential implications need to be considered by clinicians managing patients with LC.

THU140

Histological characterization of muscle and adipose tissue in patients with cirrhosis receiving liver transplant

Maryam Ebadi[1], Vera C. Mazurak[2], Vickie Baracos[3], Abha Dunichandhoedl[2], Elora Rider[2], Khaled Dajani[4], David Bigam[4], Norman Kneteman[4], James Shapiro[4], Aldo J Montano-Loza[1]. *[1]University of Alberta, Division of Gastroenterology and Liver Unit, Edmonton, Canada; [2]University of Alberta, Division of Human Nutrition, Edmonton, Canada; [3]University of Alberta, Department of Oncology, Cross Cancer Institute, Edmonton, Canada; [4]University of Alberta, Department of Surgery, Edmonton, Canada*
Email: montanol@ualberta.ca

Background and Aims: Body composition abnormalities are frequent in cirrhosis, and emerging evidence suggests that male sex is a risk factor for sarcopenia development and sarcopenia-related mortality, whereas female patients have a higher risk of losing subcutaneous adipose tissue in cirrhosis. Differences in skeletal muscle substrate metabolism by sex might contribute to this discrepancy. To better understand the pathophysiology of sarcopenia, sexual dimorphism in skeletal muscle fiber type and size as well as adipose tissue histological characteristics were investigated.

Method: CT images taken at the 3rd. lumbar vertebra were used to determine cross sectional areas of muscle, visceral and subcutaneous adipose tissue expressed by cm^2/m^2. Sarcopenia was defined as skeletal muscle index (SMI) <39 cm^2/m^2 in women and <50 cm^2/m^2 in men as published earlier. Biopsies of rectus abdominis muscle, periumbilical subcutaneous adipose tissue and visceral adipose tissue (omental) were obtained from the incision site at the time of liver transplant (LT) surgery. Muscle fiber boundaries were demarcated using laminin and dystrophin stain for muscle fiber size calculation. Fiber types were classified based on the isoforms of myosin heavy chain (MyHC). Adipose tissue sections were stained with Harris hematoxylin, and counterstained with eosin for histological analysis. Comparison between groups was made using Fisher's exact test and Mann-Whitney U test.

Results: Of 20 consented patients, 55% were male with a mean age of 50 ± 2 years, MELD score of 20 ± 1 points and mean BMI of 26 ± 1 (kg/m^2) at the time of LT. Sarcopenia was present in 60% of men and 33% of women. Lumbar SMI (cm^2/m^2) was significantly lower in sarcopenic patients compared to non-sarcopenic patients in both males (38 ± 2 vs. 60 ± 4; p = 0.001) and females (29 ± 9 vs. 44 ± 2; p = 0.049). No difference in mean muscle fiber area of total and per fiber type was observed by sex and sarcopenia. Sexual dimorphism was observed in the proportions of fiber types and MyHC isoforms (Figure). Percentage of MyHC type I (59% vs. 45%, p = 0.04) and consequently proportion of type I oxidative fibers (58% vs. 42%, p = 0.01) was higher in females compared to males. MyHC type IIA fibers, however, were more prevalent in males compared to females (55% vs. 40%, p = 0.009). Although visceral adipose tissue index (cm^2/m^2) tended to be higher in males (41 ± 9 vs. 22 ± 5; p = 0.09), no difference in the size of adipocytes by sex was observed for adipose tissue removed from visceral and subcutaneous depots (Figure).

Conclusion: Higher proportion of muscle type I oxidative fibers that are more resistant to atrophy in females might contribute to the sex differences in sarcopenia prevalence and related complications in cirrhosis.

Background and Aims: Several single nucleotide polymorphisms (SNPs) have been associated with hepatocellular carcinoma (HCC) in hepatitis C virus (HCV) cirrhotics, however their role in patients cured by direct-acting antivirals (DAA) is still undefined. We assessed the association between a genetic risk score (GRS) based on the combination of 4 SNPs (PNPLA3 rs738409, MBOAT7 rs641738, TM6SF2 rs5842926, GCKR rs1260326) and HCC in a cohort of DAA-treated patients.
Method: Consecutive HCV cirrhotics receiving DAA between December 2014–2016 in a single Center were genotyped. Cirrhosis was defined histologically or non-invasively (Liver stiffness measurement [LSM] ≥ 12 kPa). HCC was diagnosed and staged according to international recommendations. GRS score was calculated as already described.
Results: 509 patients were analyzed: median age 64 (28–87) years, 58% males, LSM 19.4 (12.0–75.0) kPa, 87% Child-Pugh score A (CPT) A. Genotypes distribution was as follows: PNPLA3 CC (46%), CG/GG (54%); MBOAT7 CC (29%), CT/TT (71%); TM6SF2 CC (91%), CT/TT (9%); GCKR CC (26%), CT/TT (74%). Median GRS score in the overall population was 0.3 (0–1.1). Patients' main clinical features were similar across SNPs genotypes. During a median follow-up of 43 (3–57) months from DAA start, de novo HCC developed in 36/452 (8%) patients, 4-year estimated cumulative probability of HCC being 9% (95% CI 7–12%). Male sex (Hazard Ratio [HR] 2.54; 95% CI 1.15–5.63; p = 0.02), diabetes (HR 2.39; 95% CI 1.20–4.74; p = 0.01), albumin (HR 0.35; 95% CI 0.19–0.64; p = 0.001) and GRS score >0.6 (HR 2.30; 95% CI 1.03–5.11; p = 0.04) were independently associated with de novo HCC. Indeed, 4-year cumulative rates of HCC resulted 6% vs. 12% in males vs. females (p = 0.01); 17% vs. 7% in diabetic vs. non-diabetic (p = 0.001); 21% vs. 7% in patients with albumin ≤ or >3.5 g/dl (p < 0.001) and 16% vs. 7% in patients with a GRS score > or ≤0.6 (p = 0.01), respectively. By combining independent risk factors for HCC, 4-year cumulative incidence resulted 20% vs. 5% in patients with or without two different risk factors, respectively (p < 0.0001).
Conclusion: In a large, single-center cohort of consecutive HCV cirrhotic patients treated with DAA, a genetic risk score was independently associated with de novo HCC, together with clinical predictors (male sex, diabetes, albumin values). Combination of clinical and genetic predictors could allow better HCC risk stratification at the individual level.

The bone marrow pool of megakaryocytes and their ability to proliferate are preserved in rats with advanced cirrhosis

Iris Asensio[1,2,3], Carolina Franco[1,2], Jose Ignacio Fortea[1,2,3], Elena Vázquez-Ogando[1,2], Marta Puerto[1,2,3], Carolina Fernández-Mena[1,2], Johanna Sierra[1,2], Christian Ruiz[1,2], Cristina Ripoll[4], Rafael Bañares[1,2,3,5], Javier Vaquero[1,2,3]. *[1]HGU Gregorio Marañón, Hepatogastro Lab, Madrid, Spain; [2]Instituto de Investigación Sanitaria Gregorio Marañón (IiSGM), Madrid, Spain; [3]CIBEREHD, Spain; [4]Martin-Luther-Universität Halle-Wittenberg, Innere Medizin I, Halle, Germany; [5]Universidad Complutense, Facultad de Medicina, Madrid, Spain*
Email: j.vaquero@iisgm.com

Background and Aims: Hypersplenism is considered the main factor responsible for thrombopenia in cirrhosis. Recent studies suggest that additional mechanisms leading to reduced platelet production may also contribute as liver disease progresses. Our **Aim** was to comprehensively assess the peripheral and central factors responsible for platelet production in experimental liver disease.

Method: Cirrhosis was induced in male SD rats (200 gr bw) by oral gavage with carbon tetrachloride (CCl4) b.i.w for 4, 8 and 12 weeks. Control rats received water (H2O) instead of CCl4, and all rats had phenobarbital (35 mg/dl) in drinking water. In an additional set, animals receiving H2O or CCl4 for 12 weeks were administered a s.c. dose of Romiplostim (thrombopoietin (TPO) agonist) or Vehicle and they were euthanized 6 days later. Liver disease was evaluated by blood cell count, biochemistry and coagulation analyses, liver- and spleen- to-bw ratios, histology (H&E and Sirius Red), and by a hemodynamic study to measure portal pressure (ileocolic vein). The mRNA expression of *Tpo* and its receptor *Mpl* were quantified in liver and bone marrow by real time RT-PCR with Taqman probes. The levels of TPO in arterial blood and regional venous beds were measured by ELISA. Bone marrow from femur and tibia was FFPE and megakaryocytes were counted in H&E-stained sections (total surface = 2 mm^2/rat).

Results: CCl4-treated rats progressively developed liver disease, presenting at 12 weeks advanced micronodular cirrhosis, liver atrophy (Liver-to-BW ratio (%): 3.61 ± 0.32 vs 2.64 ± 0.24, $p < 0.01$), splenomegaly (Spleen-to-BW ratio (%): 0.15 ± 0.04 vs 0.39 ± 0.10, $p < 0.001$), thrombopenia ($x10^9$/L: 650 ± 137 vs 343 ± 244, $p < 0.05$), coagulopathy (INR, $p < 0.01$), and high portal pressure (mmHg: 6.16 ± 1.08 vs 11.70 ± 2.84, $p < 0.01$). At this time, *Tpo* mRNA expression was unchanged and *Mpl* mRNA was increased ($p < 0.05$) in liver, whereas both *Tpo* and *Mpl* mRNA expressions were reduced in bone marrow (both $p < 0.05$) of CCl4-treated rats. The arterial concentration of TPO was similar in H2O- and CCl4 groups (pg/ml: 146 ± 38 vs 174 ± 38, $p = 0.24$), and the regional A-V differences supported a TPO efflux from the liver and net uptake in bone marrow (femoral vein). Megakaryocyte counts in CCl4-treated rats were similar or even tended to be higher than in Control rats at all time points. Romiplostim induced important elevations of circulating platelets and megakaryocyte cell counts in both groups, but the platelet cell count still remained lower in CCl4-treated rats ($p < 0.001$).

Conclusion: The pool of bone marrow megakaryocytes and their ability to proliferate are not reduced in rats with advanced liver disease. Therefore, inadequate levels of circulating TPO relative to platelet cell count and/or intrinsic impairment of platelet production by megakaryocytes are the two mechanisms that could explain a potential impairment of platelet production in advanced cirrhosis.

Bile acids modify ROS production, impair chemotaxis and delay apoptosis of neutrophils in vitro

Irina Komarova[1], Angela Horvath[1], Bettina Leber[2], Nicole Feldbacher[1], Sonja Vermeren[3], Vanessa Stadlbauer[1]. [1]*Medical University of Graz, Department of Internal Medicine, Division of Gastroenterology and Hepatology, Graz, Austria;* [2]*Medical University of Graz, Department of Surgery, Division of Transplantation Surgery;* [3]*University of Edinburgh, Center for Inflammation Research*
Email: irina.komarova@medunigraz.at

Background and Aims: Immune dysfunction is a life-threatening problem for liver cirrhotic patients. The pathophysiology of neutrophil function changes in these patients, which lead to the increased risk of bacterial infections, is still to be explained. Bile acids (BA) are highly elevated and composition is altered in liver cirrhosis. BA were shown to play a role in multiple processes in human organism, including immune response. We hypothesize that BA in the concentrations found in systemic circulation of liver cirrhotic patients can influence neutrophil function.

Method: Human neutrophils were isolated from peripheral blood of healthy volunteers with Percoll gradients. ROS (reactive oxygen species) production was assessed after 45 min BA (Sigma-Aldrich, Vienna, Austria) pre-treatment of TNFalpha primed or mock primed neutrophils and stimulation or not with fMLP (N-formyl-met-leu-phe). Cells were mixed with HRP (horseradish peroxidase) and luminol and total ROS production was measured in real-time by chemiluminescence. Chemotaxis towards fMLP of BA treated neutrophils was measured with ChemoTX disposable chemotaxis systems (Neuro Probe, Gaithersburg) and ibidi chemotaxis chambers (ibidi GmbH, Gräfelfing). Flow cytometry analysis of Annexin/PI stained neutrophils was used to assess the amount of necrotic and apoptotic cells.

Results: BA mix ($p = 0.003$) containing 15 BA in the concentrations found in liver cirrhotic patients (cholic acid (CA), chenodeoxycholic acid (CDCA), lithocholic acid (LCA), deoxycholic acid (DCA), ursodeoxycholic acid (UDCA) and their tauro and glyco conjugates) stimulated ROS production in neutrophils. DCA, CDCA and LCA had a tendency to inhibit fMLP stimulated ROS production. DCA ($p = 0.043$), CDCA ($p = 0.030$), LCA ($p = 0.018$) and their tauro and glyco conjugates, tauro ($p = 0.014$) and glyco ($p = 0.044$) ursodeoxycholic acids (UDCA) significantly decreased chemotaxis of neutrophils up to 90% in response to fMLP. Glyco CDCA interfered significantly with chemotactic directionality ($p = 0.030$). BA mix ($p = 0.013$), LCA ($p = 0.042$), CDCA ($p = 0.015$), UDCA ($p = 0.032$) delayed neutrophil apoptosis.

Conclusion: BA in the concentrations found in liver cirrhotic patients modify neutrophil ROS production, impair chemotaxis and delay apoptosis. Increased BA levels and altered composition in liver cirrhosis can therefore be the reason for the neutrophil dysfunction and prospective target for prevention of bacterial infections in these patients.

THU144

Neuro and hepatic inflammation and steatosis are modulated by gut microbial changes after isolated hepatic vagotomy and antibiotics in cirrhosis

Yuan Zhang[1], Derrick Zhao[1], Jun-Kai Yan[1], Yanyan Wang[1], Yunling Tai[1], Jason Kang[1], Siddhartha Ghosh[1], Masoumeh Sikaroodi[2], Phillip Hylemon[1], Patrick Gillevet[2], Huiping Zhou[1], Jasmohan S Bajaj[1]. [1]*Virginia Commonwealth University and McGuire VA Medical Center, Richmond, United States;* [2]*George Mason University, Manassas, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: Cirrhosis & hepatic encephalopathy (HE) includes an altered gut-liver-brain axis. While microbiota changes in germ-free mice have been described, the role of individually isolating the liver-brain axis & microbial alterations is unclear.

Aim: Define the effect of non-absorbable antibiotics (NAbx) & isolated hepatic vagotomy on gut microbiota, liver inflammation and brain inflammation in the setting of cirrhosis.

Method: 10 wk old C57BL/6 mice were divided into conventional (Conv) & those with isolated hepatic vagotomy (Vago, Fig 1A). Subgroups from both were gavaged with CCl4 for 12 wks to develop cirrhosis. After cirrhosis, Conv & Vago cirrhotic subgroups were further treated with 2 wks of Streptomycin+Polymyxcin B(NAbx). All gps were sacrificed at 14 wks & frontal cortex, colon & liver were harvested. Data were compared between groups.

Microbiota: 16sRrNA sequencing of colon. *Neuro-inflammation*: qRT-PCR of mRNA expression of inflammation (MCP-1), microglial activation (IBA-1). *Liver inflammation/histology*: A blinded pathologist determined steatosis & inflammation grades. qRT-PCR mRNA levels of SREBP1c, MCP-1 & fatty acid oxidation enzyme stearoyl-CoA desaturase 1(SCD-1) were performed.

Results: No behavioral changes were seen & all mice lived till sacrifice at 14 wks.

Microbiota: Conv cirrhosis has higher dysbiosis with ↓beneficial (Lachnospiraceae & Ruminococcaceae) & ↑ pathobionts (Enterobacteriaceae) vs controls. NAbx ameliorated this dysbiosis. Vagotomy was related to lower dysbiosis with ↑beneficial taxa at baseline, after cirrhosis & even after NAbx compared to conv mice at similar stages.

Brain: Neuro-inflammation: Significant ↑ in MCP-1 which occurred post-cirrhosis in conv & Vago mice were reduced after NAbx (Fig B).

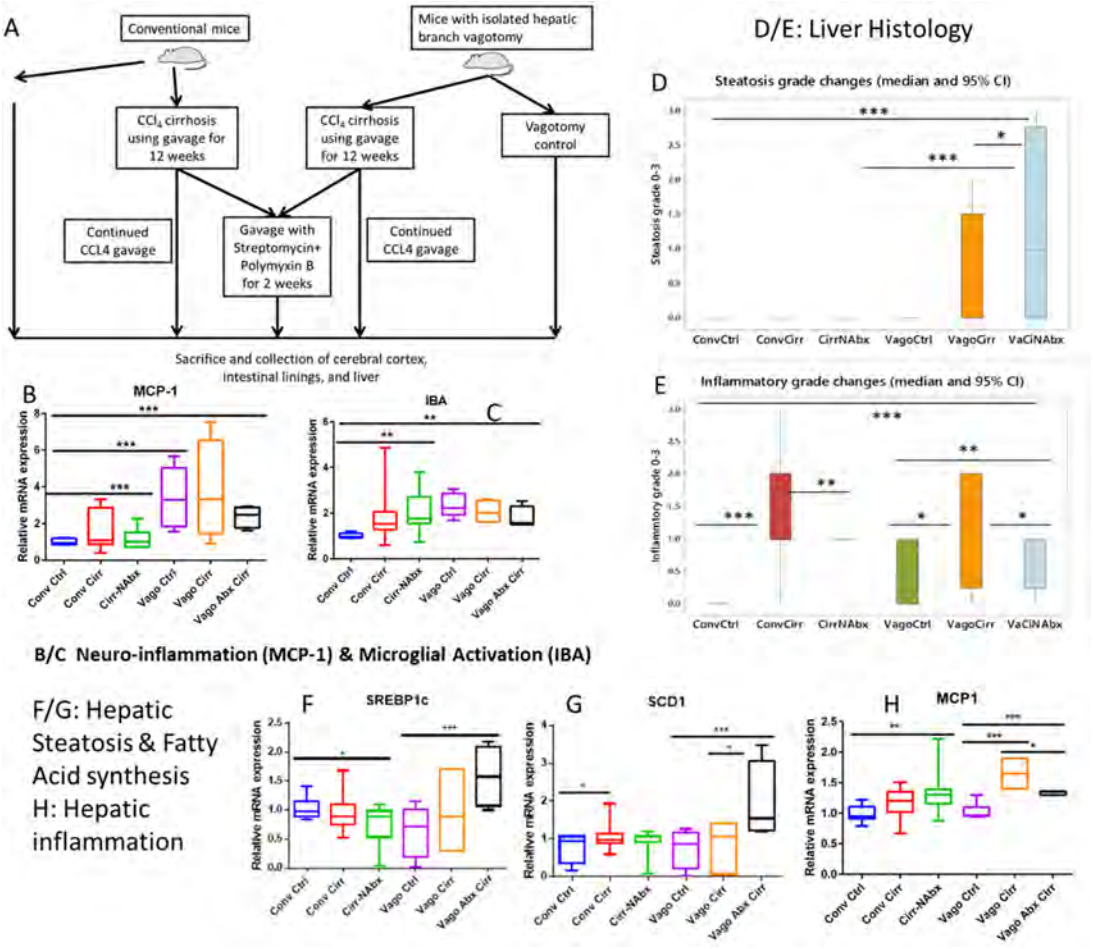

Figure: Overview and Results of Experiment. ***p < 0.001, **p < 0.01.

Microglial activation: IBA ↑ post-cirrhosis in conv mice & was ↓ postNAbx but vagotomy completely abolished this activation (Fig C). *Liver*: *Histology*: No steatosis was seen in conv mice groups but this increased post-Vago cirrhosis & was highest after NAbx in Vago-cirrhosis. Inflammation was seen post-cirrhosis in Conv mice, which reduced post-NAbx. Inflammation was higher at baseline in Vago, ↑ post-cirrhosis & ↓post-NAbx(Fig D/E). *mRNA*: SREBP1c &SCD-1 increased post-Vago cirrhosis & even further post-NAbx (Fig F–G). MCP-1 also worsened post-vago cirrhosis and ↓postNAbx (Fig H).
Conclusion: Liver-specific vagotomy is associated with lower gut dysbiosis, greater liver inflammation and steatosis, neuro-inflammation despite the abolition of microglial activation in mice with cirrhosis. Additive NAbx improves liver and brain inflammation but worsens steatosis after vagotomy. Liver and brain inflammation are independently important targets, in addition to the microbiota, in beneficially modulating the gut-liver-brain axis in cirrhosis

THU145
Effective albumin concentration and albumin function improve after long-term albumin treatment in patients with decompensated cirrhosis

Email: paolo.caraceni@unibo.it

Background and Aims: In addition to its oncotic power, human albumin (HA) carries several other biological functions supporting the pleiotropic activity of the molecule. The ANSWER trial[1] showed that long-term HA administration in patients with cirrhosis and uncomplicated ascites improves overall survival and reduces the incidence of complications. Such benefits were associated to a significant increase in serum albumin concentration. The present ancillary study to the ANSWER trial aimed to assess whether long-term HA administration has any effect on both structure and function

of the circulating HA pool and on the pro-inflammatory state that characterized decompensated cirrhosis.
Method: Patients from the ANSWER cohort with available plasma samples at baseline and 6–8 months after randomization were included in the study. HA structural microheterogeneity was evaluated by liquid chromatography/electrospray ionization mass spectrometry. Effective albumin concentration was defined as the amount of serum albumin with fully preserved molecular structure. Binding efficiency (BE) and detoxification efficiency (DTE) were determined by electron paramagnetic resonance spectroscopy. A panel of circulating cytokines was measured by Luminex assay.
Results: Twenty-seven patients from the standard medical treatment (SMT) and 31 from the SMT+HA arms were included in the analysis. Baseline clinical and biochemical characteristics were comparable between the two groups. Serum albumin concentration increased significantly after 6–8 months of HA treatment (from 3.1 [2.8–3.5] to 4.1 [3.8–4.4] g/dL, $p < 0.001$) but not in the SMT arm (from 3.0 [2.8–3.4] to 3.1 [2.6–3.8] g/dL, $p = 0.846$). Similarly, significant rises of the effective albumin concentration (from 0.77 [0.55–1.05] to 0.93 [0.65–1.26] g/dL, $p = 0.015$) as well as both BE (+16.8 [3.7–31.12] %, $p < 0.001$) and DTE (+15.4 [5.5–41.7] %, $p < 0.001$) were only found in the SMT +HA arm. Finally, circulating pro-inflammatory cytokines, such as interleukin (IL)-6 and IL-33, were significantly reduced only in patients from the SMT+HA arm.
Conclusion: Besides the rise in the serum albumin concentration, long-term HA treatment significantly increases the amount of the effective albumin concentration, corresponding to the fraction of the circulating albumin pool with a fully preserved structure. This finding was associated with an improvement of the albumin binding/detoxification dysfunction and systemic inflammation.

SLU7 downregulation potentiates liver damage through hepatic de-differentiation

María Gárate-Rascón[1], Miriam Recalde[1], Maddalen Jimenez[1], María Elizalde[1], María Azkona[1], Marina Bárcena-Varela[1], Leticia Colyn[1], Maria U Latasa[1], Iker Uriarte[1,2], Maite G Fernandez-Barrena[1,2,3], Matías A Avila[1,2,3], Maria Arechederra[1,3], Carmen Berasain[1,2,3]. [1]*Centre of Applied Medical Research (CIMA)-University of Navarra, Pamplona, Spain;* [2]*CIBERehd, Instituto de Salud Carlos III, Madrid, Spain;* [3]*Instituto de Investigaciones Sanitarias de Navarra-IdiSNA, Pamplona, Spain*
Email: cberasain@unav.es

Background and Aims: The splicing factor SLU7 plays a central role in liver homeostasis securing the transcriptional program characteristic of the functional and quiescent adult liver. SLU7 downregulation induces a transcriptional switch characteristic of the fetal and transformed hepatocyte including the promotion of the fetal Hnf4alpha P2 promoter. As a result, SLU7 knockdown impairs liver metabolic functions and induces aerobic glycolysis and liver growth. Furthermore, SLU7 is required to preserve genome stability. SLU7 expression is reduced in the liver of cirrhotic patients, suggesting a role in the loss of hepatic functions observed in these patients. In the present work we aim to study the contribution of SLU7 downregulation to the hepatic response to damage.
Method: Chronic liver damage was induced by 6 weeks CCl4 administration to wild-type (SLU7 +/+) and SLU7 haploinsufficient (SLU7 +/–) mice. Acute liver damage was induced upon acetaminophen (APAP) administration. SLU7 was overexpressed using an adeno-associated virus (AAV-SLU7). Serum transaminases were measured, and hematoxylin-eosin and Sirius red staining were performed. Gene expression was studied by qPCR, Western blot and IHQ.
Results: Hepatic SLU7 expression was reduced after CCl4-induced chronic damage parallel to an induction of the fetal Hnf4a-P2 promoter, also observed in the liver of cirrhotic patients. SLU7 +/– mice showed significantly higher levels of serum transaminases, larger areas of necrosis and higher activation of hepatic stellate cells resulting in an increased expression and deposition of collagen. These events were accompanied by increased oxidative stress, a significantly higher activation of HNF4a-P2 promoter and the decrease of several liver specific genes. Accordingly, we found that SLU7 overexpression significantly attenuated chronic liver damage, impairing the induction of oxidative stress, the activation of HNF4a-P2 and the inhibition of hepatocyte specific genes. APAP-induced acute liver damage in wild type mice transiently reduced hepatic SLU7 expression. Liver damage was again significantly increased in SLU7 +/– mice as evidenced by serum transaminases and histology analysis. SLU7 +/– mice exhibited higher levels of oxidative stress, an induction of HNF4a-P2 activity, a reduction in glycogen content, a sustained expression of CYP2E1 and a reduction in CYP3A4 expression. The administration of AAV-SLU7 significantly attenuated APAP these events.
Conclusion: SLU7 downregulation contributes to liver damage. Mechanistically this can be associated to the reprograming of liver transcriptome and the induction of fetal isoforms including those expressed from HNF4a-P2 promoter resulting in an increased oxidative stress.

THU147

Endotrophin predicts clinical outcome and mortality in patients with compensated cirrhosis

Mette Juul Nielsen[1], Rebecca Harris[2], Diana Leeming[1], Jane Grove[2], Morten Karsdal[1], Neil Guha[2]. [1]*Nordic Bioscience A/S, Biomarkers and Research, Herlev, Denmark;* [2]*Nottingham University Hospitals NHS trust and University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom*
Email: mju@nordicbio.com

Background and Aims: Prediction of hard endpoints is important for optimal patient management. Endotrophin, a hormone derived from type VI collagen and produced by fibroblasts, has previously been associated to liver fibrosis. Here we investigated if PRO-C6, a serological biomarker of endotrophin, could predict clinical outcome and mortality in a compensated cirrhosis cohort.
Method: 172 patients with mixed aetiology of cirrhosis were consecutively recruited from the Nottingham compensated cirrhosis cohort study (3CN). Patients were assessed for clinical outcomes using digital hospital records or contacting primary care physicians. Primary Liver Outcome (PLO) was defined as first event of ascites, variceal bleed, encephalopathy, HCC, or liver related death. Any outcome (AO) was defined as first event of PO, death, decompensation, jaundice or liver transplantation. Death was defined as either overall survival (OS) or liver related mortality (LRM). PRO-C6 was assessed in serum at baseline and compared to Model for End-Stage Liver Disease (MELD).
Results: The cohort included 64% males; mean age of 59.6 years with mixed etiology of alcoholic (40%), non-alcoholic (33%), autoimmune (12%) or viral liver disease (15%). Mean time to first event was 3.9 years. No difference in PRO-C6 levels was observed between etiologies ($p = 0.201$), thus were pooled for further analyses. PRO-C6 levels were significantly elevated in patients with PLO, AO and OS ($p < 0.0001$). Cox regression analyses showed that both PRO-C6 and MELD were independent predictors of clinical outcome and survival. Kaplan-Meier analyses showed that PRO-C6 levels above the median predicted poorer clinical outcome (PLO: HR = 3.4, $p < 0.001$; AO: HR = 3.2, $p < 0.001$), and shorter survival time (LRM: HR = 3.2, $p < 0.05$; OS: HR = 2.9, $p < 0.05$). Similar differences were found for MELD above the median. Combining the two markers further improved the prognostic value (PLO: HR = 19.5, $p < 0.0001$; AO: HR = 11.9, $p < 0.0001$), and

shorter survival time (LRM: HR = N/A, p < 0.01; OS: HR = 13.6, p = 0.001).
Conclusion: Endotrophin (PRO-C6) is associated with clinical outcome and survival independent of MELD and provides prognostic value for compensated cirrhosis patients. This suggests that collagen signals are important drivers of disease progression in patients with chronic liver disease.

THU148
Characterization of lymphocyte subsets in ascites during spontaneous bacterial peritonitis: MAIT cells show the strongest increase
Christian Niehaus[1], Benedikt Strunz[2], Martin Cornillet[2], Christine Falk[3,4], Ansgar Schnieders[1], Benjamin Maasoumy[1,4], Svenja Hardtke[5], Michael P. Manns[1,4], Anke Kraft[1,4], Niklas Björkström[2], Markus Cornberg[1,6,7,8,9]. *[1]Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Karolinska Institutet, Karolinska University Hospital Huddinge, Center for Infectious Medicine, Department of Medicine Huddinge, Stockholm, Sweden; [3]Hannover Medical School, Institute of Transplant Immunology, Hannover, Germany; [4]German Center for Infection Research (DZIF), Partner-site Hannover-Braunschweig; [5]German Center for Infection Research (DZIF), Hepnet Study-House German Liver Foundation, Hannover, Germany; [6]German Center for Infection Research (DZIF), Partner-site Hannover-Braunschweig, Hannover, Germany; [7]Centre for Individualised Infection Medicine (CIIM), Hannover, Germany; [8]Helmholtz Centre for Infection Research (HZI), Braunschweig, Germany; [9]Hannover Medical School, Cluster of Excellence Resolving Infection Susceptibility (RESIST, EXC), Hannover, Germany*
Email: cornberg.markus@mh-hannover.de

Background and Aims: Patients with advanced liver cirrhosis have an increased susceptibility to bacterial infections such as spontaneous bacterial peritonitis (SBP). As part of the cirrhosis-associated immune dysfunction present in these patients, mucosal associated invariant T (MAIT) cells, that have the capacity to respond towards bacteria, are severely diminished in circulation and liver tissue. However, the role of MAIT cells in decompensated cirrhosis, especially in the peritoneal cavity and during SBP, remain elusive. In this study, we aimed to investigate the immune compartment of patients with decompensated cirrhosis and SBP and reveal differences between SBP and Non-SBP patients.
Method: Matched peripheral blood and ascites fluid from 35 patients with decompensated cirrhosis, with or without spontaneous bacterial peritonitis were analyzed. Lymphocyte subsets as well as monocyte subsets were determined and phenotype and function were analyzed using high-dimensional flow cytometry. Obtained data were also compared to blood samples of healthy controls (n = 24) and compensated cirrhosis patients (n = 11).
Results: Among all immune subsets analyzed in ascites**,** MAIT cells (CD161+ Vα7.2+ CD4-) were the most enriched population in SBP versus non-SBP. MAIT cell percentages as well as total numbers were significantly increased in the peritoneal cavity of patients with SBP (p = 0.004; p = 0.008 respectively). MAIT cells isolated from non-infected ascites show an activated tissue resident phenotype. This phenotype was not significantly altered during SBP. Compared to the decreased and impaired MAIT cells isolated from blood, peritoneal MAIT cells show higher cytokine responses to in-vitro stimulation with *E. coli* or IL-12 + IL-18. This was not diminished during SBP.
Conclusion: Despite severely diminished MAIT cell numbers and impaired phenotype in circulation, peritoneal MAIT cells remain abundant, activated, and highly functional in decompensated cirrhosis and are the most increased lymphocyte population in SBP. This suggests that peritoneal MAIT cells could be a potential target for immune intervention strategies in patients with decompensated liver cirrhosis and SBP.

Immune cell response in progressing liver cirrhosis is dominated by neutrophil granulocytes
Rhea Veelken[1], Becker Christina[2], Sandra Krohn[1], Niklas Aehling[1], Adam Herber[1], Andreas Boldt[2], Ulrich Sack[2], Thomas Berg[1], Cornelius Engelmann[3]. *[1]University Hospital Leipzig, Section of Hepatology, Leipzig, Germany; [2]University of Leipzig, Institute of Clinical Immunology, Leipzig, Germany; [3]University College London, Institute for Liver and Digestive Health, London, United Kingdom*
Email: rhea.veelken@medizin.uni-leipzig.de

Background and Aims: Progression of liver cirrhosis is associated with systemic inflammation leading to further tissue injury. Little is known about the immune cell phenotype in acute decompensation (AD) and acute-on-chronic liver failure (ACLF). This study aimed at analysing the pattern of immune cell subsets in blood samples of patients with progressing liver cirrhosis.
Method: 63 blood samples of patients with AD (n = 50) or ACLF grade 1 (n = 13) were collected retrospectively from patients' records. Leukocyte subpopulations were identified by flow-cytometry using forward and sideward scatter and markers of lymphocyte (LY) subsets: CD3 T-cells, CD4 T-helper cells, CD19 B-cells, CD8 cytotoxic T-cell, CD16/56 NK-cells. The function of neutrophil granulocytes (NG) was assessed by phagocytosis (PA) and oxidative burst activity (OBA) assays. Values were expressed as median [range].
Results: ACLF patients had a higher MELD Score (p = 0.0022) and tended to have higher CRP level (p = 0.0722) and white blood cell count (WBC) (p = 0.12) compared to AD patients. As a sub-analysis of the AD cohort, we considered the CLIF-C AD score to distinguish between high (CLIF-C AD ≥ 60), medium (CLIF-C AD45–60) and low risk (CLIF-C AD≤45) liver disease progression. There was a stepwise increase of the aforementioned parameters except for CRP level throughout CLIF C AD groups (MELD p = 0.0015, CRP p = 0.29, WBC p = 0.009). NGs were significantly higher in patients with ACLF compared to AD (ACLF 4.87 10^9/l [2.9–26.3], AD 3.1 10^9/l [1.7–10.70], p = 0.0119) whereas LY subpopulation were unaltered. This finding was underlined by a higher NG/LY ratio of 8.86 10^9/l [3.25–13.80] in ACLF compared to 4.170 10^9/l [1.4–22.6] (p = 0.0040) in the AD cohort. NG of 4.9 10^9/l [2.4–11.3] were also significantly increased in CLIF-C AD ≥ 60 patients compared to 3.05 10^9/l [1.7–12.4] in CLIF-C AD45–60 and 2.3 10^9/l [1–3.7] CLIF-C AD≤45 (p = 0.0013). The same

effect was detectable for the NG/LY ratio with values of 5.38 10^9/l [2.4–22.66], 4.32 10^9/l [2.1–13.5] and 2.33 10^9/l [1.4–12] (p = 0.0466), respectively. The number of NG correlated positively with the Organ failure score (r = 0.2774, p = <0.001) MELD Score (r = 0.1957, p = 0.0005), Child-Pugh Score (r = 0.1653, p = 0.0015) and CLIF-C AD-Score (r = 0.1887, p = 0.0006). No such changes were found in LY or the other mentioned subpopulations. Analyses of PA and OBA of NG showed no significant loss of function in the ACLF and AD cohort (OBA p = 0.1813, PA p = 0.2323).

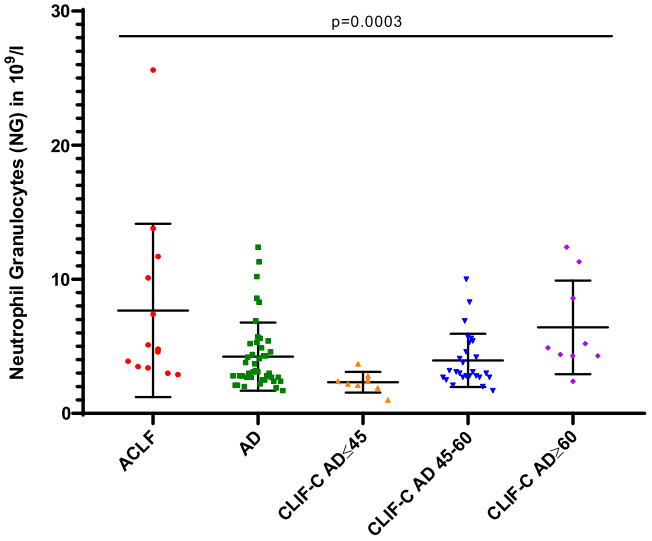

Figure: NG in patients with ACLF, AD and subgroups of AD defined by CLIF-C AD score.

Conclusion: The progression of liver cirrhosis in AD and ACLF is associated with an immune cell pattern dominated by NG whilst LY remain unchanged. PA and OBA seem to be unaffected by the severity of liver disease probably due to lack of high-grade ACLF patients. Further studies are needed to clarify the role of NG and its impact on liver disease progression.

THU150

Proagio: a protein designed to target integrin alpha V beta 3 outside ligand binding site is an effective way to target activated hepatic stellate cells

Ravi Chakra Turaga[1], Ganesh Satyanarayana[1], Malvika Sharma[1], Jenny Yang[1], Jordi Gracia-Sancho[2], Zhi-Ren Liu[1]. *[1]Georgia State University, Biology, Atlanta, United States; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*
Email: rturaga2@gsu.edu

Background and Aims: Chronic Liver Diseases (CLDs) arise from the persistent inflammatory response to injury within the liver parenchyma leading to the activation of hepatic stellate cells (HSCs) leading to uncontrolled secretion and accumulation of fibrillar collagen, in the space of Disse. Accompanying ECM secretions are neo-angiogenesis and sinusoidal remodeling. HSC activation and their subsequent resistance to apoptosis. Accumulation of collagen fibrils is characterized by the presence of a fibrotic scar which disrupts hepatic architecture and its function. The scar alters the structure of the sinusoidal space thereby increasing blood flow resistance and portal hypertension. Here we report a novel approach to induce HSC apoptosis via integrin αVβ3 using a rationally designed protein, ProAgio, to target a non-canonical binding site. ProAgio specifically targets integrin αVβ3 at a novel site thus triggering apoptosis thereby providing a viable treatment option for the progression of CLDs. Aim: To test the efficacy of ProAgio treatment on the reversal of fibrosis and changes in the portal pressure.

Method: To study the expression of integrin αVβ3 and the capability of ProAgio to induce apoptosis, we used mouse models of liver fibrosis, namely, (A) i.p. thioacetamide (TAA) with 10% ethanol in drinking water ad libitum and (B) Oral carbon tetrachloride (CCl4) were used for testing the effect of ProAgio (10 mg/kg) *in vivo*.
Results: Activated HSCs upregulate integrin αVβ3. ProAgio induces apoptosis in activated HSCs via an integrin-mediated death (IMD) like mechanism. During the advent of liver fibrosis, the persistent pro-inflammatory state leads to the pathological activation of HSCs, thereby leading to the aberrant synthesis and accumulation of collagen, this deposition in the sinusoidal space alters the hepatic structures and function, ultimately leading to CLDs. Treatment with ProAgio starkly induced apoptosis in these activated HSCs in in vitro and in vivo model. Mice treated with ProAgio showed reduced activation and increased apoptosis of HSCs in the hepatic parenchyma. HSC apoptosis consequently reduced collagen synthesis and accumulation. ProAgio brings a novel therapeutic option for the treatment of CLDs.
Conclusion: In both the pre-clinical advanced cirrhotic mouse models (TAA and CCl4), ProAgio treatment has demonstrated great efficacy in liver fibrosis reversal and decreased portal hypertension.

THU151

Hepatocytes undergo pyroptosis in response to lipopolysaccharide exposure, and can be sensitised to cell death by ER stress

Ugo Soffientini[1,2], Nigel Beaton[2], Vishal C Patel[1], Roger Williams[1], Shilpa Chokshi[1], Rajiv Jalan[2], Gautam Mehta[1,2]. *[1]Foundation for Liver Research, Institute of Hepatology, London, United Kingdom; [2]UCL, Institute for Liver and Digestive Health, London, United Kingdom*
Email: u.soffientini@researchinliver.org.uk

Background and Aims: Acute-on-chronic liver failure (ACLF) is a common cause of mortality in cirrhosis. Systemic inflammation and non-apoptotic hepatocyte cell death are key features of ACLF. We have previously shown that hepatocyte pyroptosis, an inflammatory mode of cell death occurring in response to bacterial endotoxin (LPS) exposure, is a key feature of ACLF and correlates with disease severity (Soffientini et al 2018). Additionally, cirrhotic mice demonstrate greater sensitivity to LPS exposure, with greater levels of hepatocyte cell death, than non-cirrhotic mice (Soffientini et al 2019). The aim of this study was to determine potential mechanisms of sensitization to hepatocyte pyroptosis in vitro.
Method: Primary human hepatocytes (Lonza Biologicals, UK), or Huh7 (human) and AML12/BNL1MA.7R.1 (murine) hepatocyte cell lines were used for all experiments. All cell experiments were repeated 3–5 times. Cells were exposed to LPS from Klebsiella pneumoniae (Merck, UK) at a very low-dose LPS (0.1–1μg/ml) for 24 hours to mimic gut bacterial LPS translocation. In some experiments, cells were also exposed to a ER stress inducer for 24 hours along with very low-dose LPS (tunicamiycin or brefeldin A, Merck, UK). Subsequently cells were treated with a LPS "hit" (6–100 mg/ml) to induce pyroptosis. Caspase-4/11 activation was assessed by Western blot. Pyroptosis was assessed by cleavage of the effector protein Gasdermin D (GSDMD) by Western blot. Total cell death was assessed by LDH release (Promega LDH-Glo assay).
Results: Human and murine cell lines undergo GSDMD cleavage in response to LPS exposure; Huh7 cells: LPS group vs control, p = 0.065; BNL cells: LPS group vs control, p = 0.085. LDH release was also increased in hepatocyte cell lines; Huh7: LPS group vs control, p = 0.07, BNL cells: LPS group vs control, p < 0.01. Huh7 primed for 24 h with very low-dose LPS (1 μg/ml) and the ER-stress inducer tunicamycin show increased susceptibility to subsequent LPS 'hit' (30 μg/ml; 4 h) compared to LPS hit alone, very low-dose LPS alone or tunicamycin alone (Figure, ANOVA with post-hoc test, p < 0.01). These experiments were replicated in primary human hepatocytes primed for 24 h with very low-dose LPS (100 ng/ml) and tunicamycin, showing susceptibility to a LPS hit (6 μg/ml) (ANOVA with Tukey

post-hoc test, $p < 0.05$). The mechanism of LPS/ER stress priming is through caspase-11 activation: AML cells primed for 24 h with very low-dose LPS (1 μg/ml) and tunicamycin demonstrate activation of caspase-11 compared to tunicamycin or very low-dose LPS alone (ANOVA with post-hoc test, $p < 0.01$).

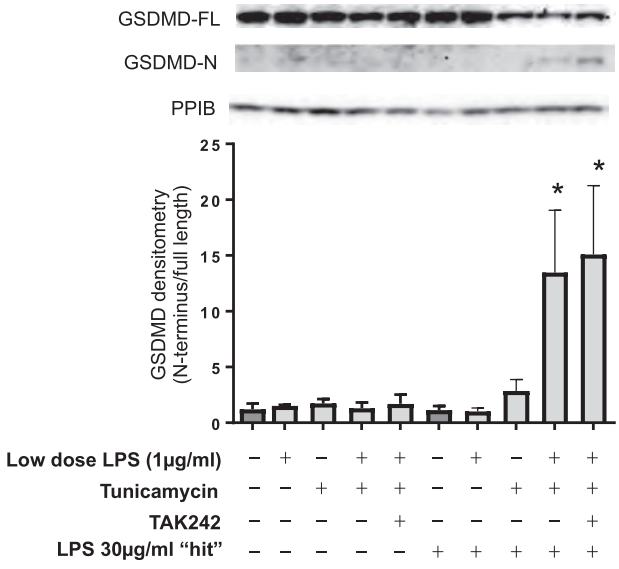

Figure: (abstract: THU151)

Conclusion: ER stress and gut bacterial LPS translocation are features of cirrhosis. These data demonstrate that ER stress and very low-dose LPS exposure sensitize hepatocytes to undergo pyroptosis in response to an LPS 'hit.' This mechanism may underlie the high levels of pyroptotic hepatocyte cell death seen in ACLF.

THU152

Faecal cytokines provide novel insights into the role of gut mucosal inflammation in acute decompensation of cirrhosis

Vishal C Patel[1,2,3], Elizabeth H Gray[1,2], Antonio Riva[1,2], Sarah Azarian[1], Mark J W McPhail[2,3], Roger Williams[1,2], Shilpa Chokshi[1,2], Lindsey Edwards[1,2]. *[1]Foundation for Liver Research, Institute of Hepatology, London, United Kingdom; [2]King's College London, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom; [3]King's College Hospital NHS Foundation Trust, Institute of Liver Studies, London, United Kingdom*
Email: vishal.patel@nhs.net

Background and Aims: Gut dysbiosis increases intestinal inflammation and loss of gut barrier integrity (GBI) in chronic liver disease (CLD). Gut barrier dysfunction enables pathological bacterial translocation (BT), which contributes to cirrhosis-associated immune dysfunction and heightened susceptibility to infection. Little is known about gut-specific inflammation in CLD, and how this differs in patients with acutely decompensated (AD) cirrhosis. Intestinal inflammation is challenging to study in cirrhosis, with difficulty in obtaining representative tissue. We therefore developed a novel approach to characterise intestinal immunopathology by quantifying faecal cytokines (FC) and GBI markers.

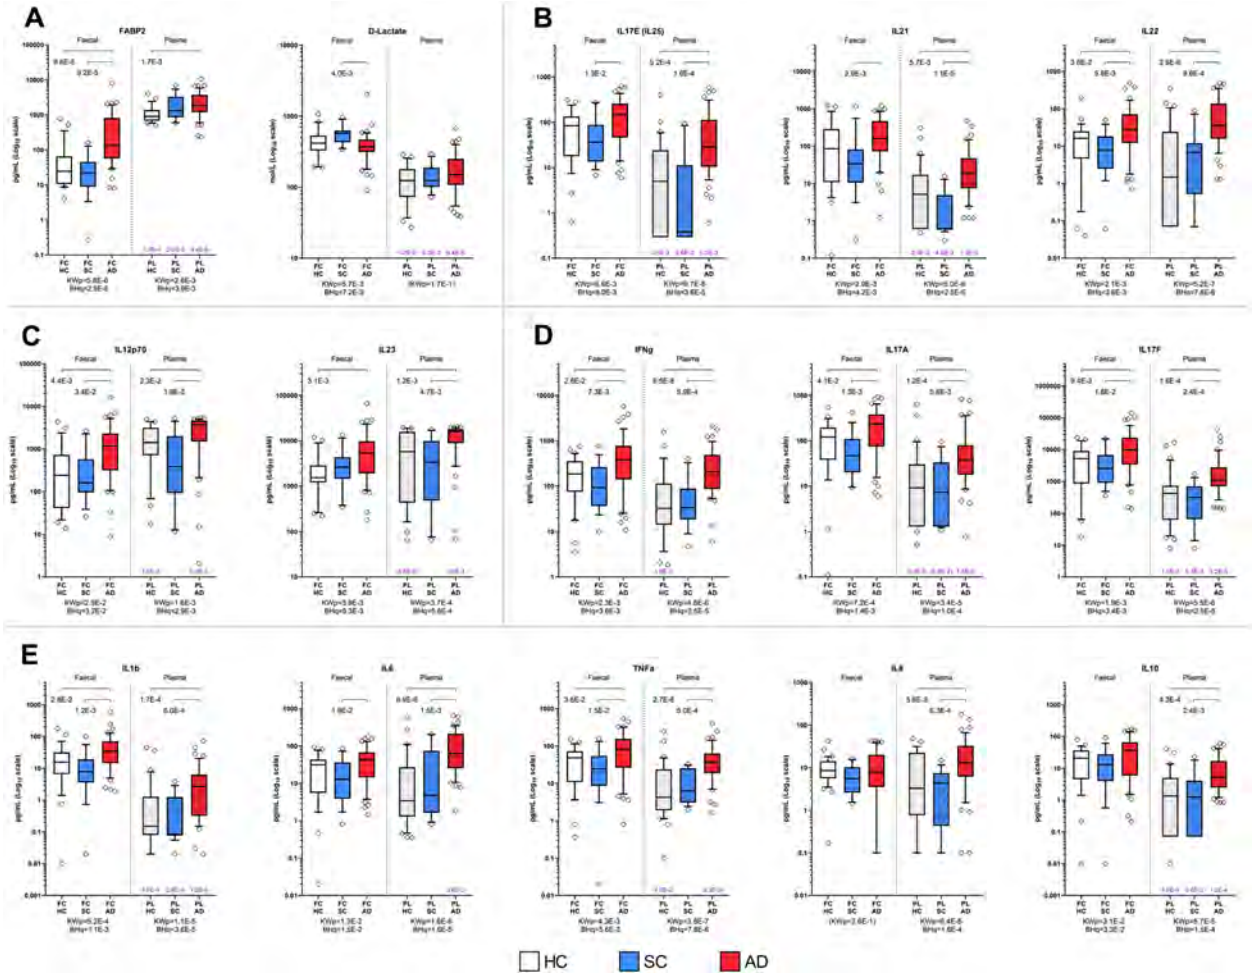

Figure: (abstract: THU152)

Method: Paired faeces and plasma were obtained from 16 patients with stable cirrhosis (SC), 47 AD, and 31 healthy controls (HC). A panel of 15 cytokines and GBI markers including intestinal fatty acid-binding protein-2 (FABP2) and D-lactate were quantified by electrochemiluminescence or ELISA. Correlations between analytes and clinical metadata with univariate and multivariate analyses were performed.
Results: Median ages and MELD scores of AD vs SC patients were 61 (53–68) vs 55 (44–59) years and 18 (13–26) vs 8 (7.0–8.5), respectively. Male gender predominated (AD: 65%; SC: 75%). The causes of cirrhosis were mainly alcohol, non-alcohol-related fatty liver disease and treated hepatitis C. Faecal (F) IL1β, IFNγ, TNFα, IL21, IL17A/F and IL22 were significantly elevated in AD vs SC ($q < 0.01$). F-IL23 was significantly elevated in AD vs HC ($p = 0.0007$). FABP2/D-lactate were significantly increased in faeces in AD vs SC and AD vs HC ($p < 0.0001$) and in plasma ($p = 0.0004$; $p = 0.011$). F-FABP2 correlated most strongly with disease severity (Spearman's rho: Child-Pugh 0.466, $p < 0.0001$; MELD 0.488, $p < 0.0001$). With the exception of IL-8, IL-12 & IL-23, faecal cytokines and F-GBI markers were more discriminant than circulating equivalent molecules in discriminating AD from SC by Principal Component Analysis.
Conclusion: FC-profiling represents a novel approach to the localised measurement of the intestinal cytokine milieu in CLD, and in conjunction with F-D-lactate, with progression to AD from SC being an intestinally initiated and mediated process. These data reveal that AD is characterized by a highly inflamed, permeable gut, and FC profiles are very different from the classical features of systemic inflammation, as assessed by plasma measurements. This is in keeping with skewing T-cell priming towards non-specific upregulation of Th1/17 effector cytokines, and those known to be mediators of gut barrier damage. In AD this perpetuates loss of gut barrier integrity, impairs mucosal healing and propagates BT and systemic inflammation. These data provide insights into intestinal mucosal injury and GBI, as a novel pathobiology in AD.

THU153

Hypofibrinolysis as a contributing mechanism of cirrhotic portal vein thrombosis as evidenced by rotational thromboelastometry (ROTEM)

Steven Pi[1], Amrit Jhajj[2], Alexandre Lefebvre[3], Tyler Smith[4], Jacqueline Trudeau[3], Vladimir Marquez[1]. *[1]University of British Columbia, Adult Gastroenterology, Vancouver, Canada; [2]University of British Columbia, Medicine, Vancouver, Canada; [3]University of British Columbia, Anesthesia, Vancouver, Canada; [4]University of British Columbia, Hematopathology, Vancouver, Canada*
Email: stevenpi@alumni.ubc.ca

Background and Aims: Portal vein thrombosis (PVT) is a well recognized complication of liver cirrhosis. The etiology is thought to be related to a combination of venous stasis from portal hypertension and altered hemostasis from reduced hepatic synthesis of both pro- and anti-coagulant proteins. Rotational thromboelastometry (ROTEM) is a viscoelastic method for investigating the interaction between coagulation factors, platelets, fibrinogen, and fibrinolysis of whole blood. There is a paucity of data examining the ROTEM assay profile of cirrhotic patients with PVT. We hypothesize that cirrhotic patients with PVT will have ROTEM assay profile suggestive of a pro-thrombotic state compared to those without PVT. Thus, the objective of this study was to examine the ROTEM assay profile (i.e. EXTEM Clotting Time [CT], EXTEM Amplitude 10 [A10], FIBTEM, and Maximum Lysis [ML] 30) of cirrhotic patients with PVT compared to those without.
Method: Retrospective study of all patients who received an orthotopic liver transplant at Vancouver General Hospital between Nov 2016 – Oct 2019. ROTEM values were obtained prior to surgical incision liver transplant. Exclusions: Non-cirrhotic patients, anti-platelet or vitamin K antagonists within 5 days of transplant, direct oral anticoagulant within 48 hours, low molecular weight heparin within 24 hours of transplant, heparin before 6 hours of transplant, and those who received frozen plasma immediately before transplant. Chi-square and two tail t-tests (where appropriate) were used to determine statistical significance with $p < 0.05$.
Results: 214 patients were identified with 28 patients excluded based on above criteria. Of the 186 patients remaining, there was no statistically significant difference between gender, mean age, MELD, INR, bilirubin, albumin, platelets, presence of HCC, ascites, hepatic encephalopathy, variceal bleeding, and CKD. Those with PVT had statistically lower ML30 compared to those without. No other significant differences in other ROTEM assays were observed (Table 1).

Table 1: ROTEM assay profile of cirrhotic patients with PVT vs. non-PVT

	PVT (n = 12)	Non-PVT (n = 174)	p-value
EXTEM CT	87.2	83.6	0.88
EXTEM A10	38.8	38.9	0.98
FIBTEM	10.7	11.1	0.83
ML30	2.9	5.8	**0.023**

Conclusion: To our knowledge, this is the first reported study using ROTEM to demonstrate a reduction in the degree of fibrinolysis (ML30) amongst cirrhotic patients with PVT compared to those without. This suggests that hypofibrinolysis may play a mechanistic role in the development of PVT in patients with cirrhosis. Interestingly, there was no difference in other parameters suggesting that coagulation factors, platelets, and fibrinogen function may not play a significant role in its pathogenesis. Further larger prospective studies are warranted to examine the association between ROTEM assay profiles and the development of PVT in cirrhotic patients.

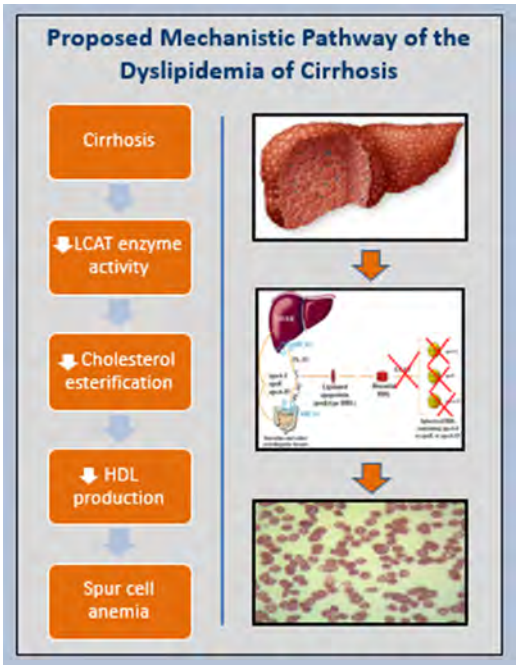
THU154

Lecithin-cholesterol acyltransferase deficiency as an explanatory mechanism for both relative adrenal insufficiency and spur cell anemia in cirrhosis

Brian Wentworth[1], Rebecca Haug[2], Stephen Caldwell[1], Zachary Henry[1]. *[1]University of Virginia Health System University Hospital, Gastroenterology & Hepatology, Charlottesville, United States; [2]University of Virginia Health System University Hospital, Internal Medicine, Charlottesville, United States*
Email: bw8xz@hscmail.mcc.virginia.edu

Background and Aims: Lecithin-cholesterol acyltransferase (LCAT) is a key hepatic enzyme responsible for the esterification of cholesterol and formation of high-density lipoprotein (HDL) molecules. However, in cirrhosis, its production wanes with synthetic dysfunction. Similarly, relative adrenal insufficiency (RAI) and spur cell anemia (SCA) are established sequelae of decompensated cirrhosis. As prior research has linked these findings to an underlying dyslipidemic state, we investigated whether LCAT deficiency could be an explanatory mechanism for their development.
Method: 100 hospitalized, non-critically patients with cirrhosis were prospectively enrolled at our academic liver transplantation center between January 2018 and March 2019. Serum HDL levels and percentage of esterified cholesterol (%CE) were measured, peripheral blood smears were obtained, and a high-dose adrenocorticotropin stimulation test was administered. LCAT deficiency was defined as %CE <60, RAI was defined as an increase in total cortisol level <9 µg/dL, and severe SCA was defined as the presence of ≥ 5% spur cells per high-powered-field. The comparable prevalence of these variables with respect to the severity of chronic liver disease was assessed as the primary outcome of interest. Mortality and transplant-free survival (TFS) were important secondary outcomes.

Results: Child-Pugh (CP) distribution of patients was: A-4, B-52, C-44. Mean MELD-Na was 20 ± 7, HDL was 23 ± 13 mg/dL, and %CE was 63% (21% were LCAT deficient). A third of patients had SCA, with nearly half having the severe phenotype. The prevalence of RAI was 39%; 6-month mortality was 22% and TFS was 47%. Compared to CP-B patients, CP-C patients had lower HDL levels (16 vs. 29 mg/dL, p < 0.001) and increased prevalence of RAI (57% vs. 25%, p = .002) and SCA (50% vs. 20%, p = .002). LCAT deficiency was more prevalent in CP-C patients (48% vs. 4%, p < 0.001) and TFS was worse in CP-C patients (25% vs. 64%, p < 0.001). MELD-Na (HR 1.11, p < 0.001) and RAI were found to be independent predictors of mortality (HR 2.12, p = .030).



Conclusion: Concurrent findings of low HDL levels, decreased circulating cholesterol esters, SCA and the presence of RAI all suggest an underlying deficiency of the LCAT enzyme. This constellation of findings is associated with poor outcomes in the absence of transplantation, with RAI being an independent predictor of mortality.

Acute liver failure and drug induced liver injury

THU155

Plasma perfusion combined with plasma exchange improved survival in chronic hepatitis B related acute-on-chronic liver failure patients

Zhongyuan Yang[1], Zhongwei Zhang[1], Qiuyu Cheng[1], Guang Chen[1], Weina Li[1], Ke Ma[1], Wei Guo[1], Tao Chen[1], Qin Ning[1]. [1]*Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department and Institute of Infectious Disease, China*
Email: 1049446560@qq.com

Background and Aims: Artificial liver support systems (ALSS) have been shown to significantly reduce mortality in patients with acute-on-chronic liver failure (ACLF). However, characteristics of patients who would benefit most from ALSS treatment are poorly understood. This study aimed to delineate the indicators for ALSS and evaluate the effectiveness of plasma perfusion combined with plasma exchange (PP+PE) in patients with hepatitis B virus-related ACLF (HBV-ACLF).

Method: A total of 898 patients with HBV-ACLF in a single center were enrolled retrospectively. Propensity score matching (PSM) was used in case-paired analysis. Hepatic or extra-hepatic organ failures were defined by Chronic Liver Failure-Sequential Organ Failure Assessment (CLIF-SOFA) criteria. Complications included ascites, infection, hepatopulmonary syndrome, hepatorenal syndrome, hepatic encephalopathy and upper gastrointestinal bleeding. Numbers of organ failures or complications were used for risk stratification.
Results: Among all patients, 418 patients received standard medical therapy (SMT) and 480 received PP+PE plus SMT. After one-to-one paired PSM, 293 pairs were enrolled. The PP+PE group showed a significantly lower 28-day transplant-free mortality (TFM) than the SMT group. Furthermore, the PP+PE group displayed a significantly higher cumulative survival rate (CSR) in both 28- and 90-day observation durations. When stratified, patients with two or more organ failures or complications from the PP+PE group showed all observed benefits including significantly lower 28- and 90-day TFM and higher CSR. Moreover, PP+PE treatment significantly increased the resolution of organ failures and complications and ameliorated the development of new organ failures and complications.
Conclusion: PP+PE treatment significantly reversed organ failures and ameliorated the development of new organ failures and complications, thus improving the survival of patients with HBV-ACLF, with superior benefits in patients with two or more organ failures or complications.

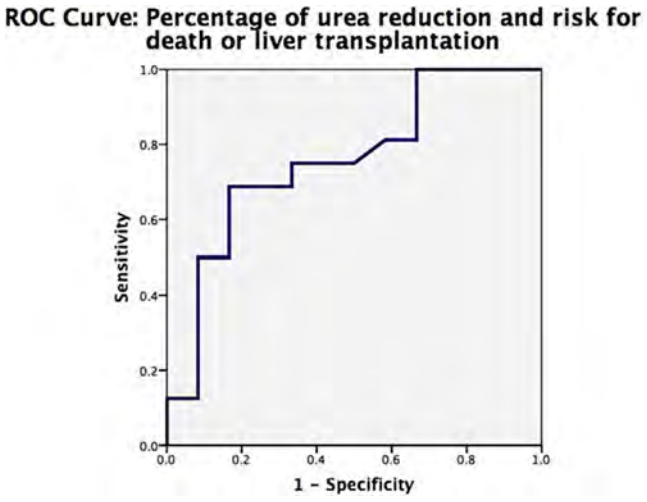
THU156

The role of urea on the prognosis of severe acute liver injury and acute liver failure

Ana Craciun[1], Carolina Simões[1], Ana Valente[1], Cilénia Baldaia[1,2], Carlos Freitas[1], Rui Palma[1], Rui Marinho[1,2], Mariana Machado[1,2].
[1]*Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Gastroenterology and Hepatology Department, Lisboa, Portugal;*
[2]*Faculdade de Medicina, Lisbon University, Lisbon, Portugal*
Email: aanacraciun@gmail.com

Background and Aims: Acute liver injury (ALI) and failure (AFL) represent a continuum of acute liver disease. Current prognostic models are suboptimal in selecting patients for urgent liver transplantation. Urea synthesis is an essential metabolic liver function through ammonia catabolism in the Krebs-Henseleit cycle. It is influenced by protein-diet, liver and renal function. Liver dysfunction associates with decreased activity of urea metabolism enzymes. We aimed to evaluate a possible association between urea kinetics and outcomes in severe ALI/ALF.
Method: 46 adult patients with severe ALI and ALF were evaluated in a retrospective case-control study, admitted to an intensive care unit (ICU) between 2005 and 2018. However, 17 patients were excluded due to acute kidney injury (AKI) or chronic kidney disease (CKD). The primary endpoint was to evaluate the effect and extension of urea kinetics on patients' prognosis defined by "alive" or "death or liver transplanted (LT)."
Results: 29 patients, 18 females (62%), with mean age 43 ± 15 years were included. ALF developed in 62% of the cases. 9 patients were LT (31%) and 7 died (24%) during their hospitalization. The causes of severe ALI and ALF were undetermined (28%), drug-induced liver injury (24%), primarily caused by acetaminophen and anti-tuberculosis agents, viral hepatitis (17%), autoimmune hepatitis (14%), ischemia (10%) and *Amanita phaloides* poisoning (7%). The outcome LT or death was associated with presence and severity of encephalopathy, respiratory failure, serum levels of albumin, INR, factors V and VII, fibrinogen, glucose, phosphorus, and percentage of urea reduction up to the first 5 days after admission. The only independent factors were severity of encephalopathy and phosphorus. Up to 1/4 of patients without encephalopathy died or required LT. The performance of the percentage of urea reduction for discriminating the outcome LT or death was: AUROC 0.76 [0.57–0.94], p = 0.022. A

decrease of > = 30.6% in urea had sensitivity 75%, specificity 67%, positive and negative predictive value 71% and 67%.



Conclusion: This pilot study suggests that urea kinetics might have a potential role as a biomarker for adverse outcomes in patients with severe ALI and ALF. These results encourage further research with multicenter studies controlled for factors that influence urea production such as diet protein content and muscular mass.

THU157

Idiosyncratic drug-induced liver injury in the elderly: an analysis of cases from the Spanish DILI registry

Rianne A. Weersink[1], Ismael Alvarez-Alvarez[1], I Medina-Caliz[1,2], Elvira Bonilla[1], M Robles-Díaz[1,2], Miren Garcia Cortes[1,2], Aida Ortega-Alonso[1,2], Maria Isabel Lucena[1,2,3], Raul J. Andrade[1,2].
[1]UGC Aparato Digestivo. Instituto de Investigación Biomédica de Málaga-IBIMA, Hospital Universitario Virgen de la Victoria, Universidad de Málaga, Málaga, Spain; [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Spain; [3]UCICEC IBIMA, Plataforma SCReN (Spanish Clinical Research Network), Madrid, Spain
Email: raweersink@outlook.com

Background and Aims: As the life expectancy increases worldwide, it is likely that more elderly will suffer from drug-induced liver injury (DILI). Our aim was to study the influence of subgroups of older age (≥ 65 years) on the phenotypic presentation of DILI, the severity and the causative agents.

Method: We examined 882 cases of idiosyncratic DILI from the Spanish DILI registry. Cases were classified by age into four groups: "young" (<65 years; n = 589); "young-old" (65–74 years; n = 169); "middle-old" (75–84 years; n = 108); and "oldest-old" (≥ 85 years of age; n = 16). We compared patient and DILI characteristics, and analysed the causative agents.

Results: The proportion of females decreased from 50% in the young to 43% in the middle-old (p = 0.018), yet in the oldest-old there was a distinct female predominance (75%; p = 0.011). The mean BMI (±SD) in kg/m^2 significantly increased from 25 ± 3.8 in the young to 27 ± 3.8 in both the young-old and the middle-old, while there was no difference with the oldest-old (26 ± 4.8). All elderly age groups had a significantly higher Charlson comorbidity score than the young patients. Non-liver related death was also more common in the elderly age groups (p = 0.048). Both the time to DILI onset and the time to resolution were not different between the age groups. Jaundice was significantly more common in the elderly (63% in the young vs. 84% in the middle-old and 88% in the oldest-old) and DILI was frequently judged as "severe" in the oldest-old (25% vs. 7% in the young; p = 0.029). There was a clear trend towards more cholestatic DILI cases with increasing age: 14% in the young, 26% in both the young-old and middle-old and 50% of cases in the oldest-old was cholestatic DILI, p < 0.001. This trend remained similar when excluding amoxicillin-clavulanate cases and was also reflected in the alkaline phosphatase values, which were significantly higher in the oldest-old compared to both the young and young-old. Anti-infectives were the most common causative agents in all age groups, followed by cardiovascular drugs in the young- and middle-old and central nervous system drugs in the oldest-old.

Conclusion: Elderly patients with DILI have a higher comorbidity burden and non-liver related mortality compared to the young. The phenotypic presentation of DILI in the oldest-old was different compared to the young- and middle-old age groups with a large proportion of cholestatic DILI cases. As this group will be increasing in the coming years this is an important finding for both clinical practice and industry.

Use of the molecular adsorbent recirculating system in acute liver failure: a North American multicenter experience

Andrew MacDonald[1], Ram Subramanian[2], Jody Olson[3], Brianne Shropshire[3], Ravi Vora[2], Mary Flynn[2], Babusai Rapaka[2], Constantine Karvellas[1]. *[1]University of Alberta, Critical Care Medicine and Hepatology, Edmonton, Canada; [2]Emory University, Critical Care Medicine, United States; [3]University of Kansas, Critical Care Medicine, United States*
Email: dean.karvellas@ualberta.ca

Background and Aims: Acute liver failure (ALF) is a rare condition associated with significant mortality. The molecular adsorbent recirculating system (MARS) removes water-soluble and albumin-bound toxins, and aims to allow for native hepatic recovery/sustain ALF patients until a suitable donor organ becomes available for transplant. The role of MARS in transplant-free survival remains in question. This study aimed to evaluate the use of MARS therapy at 3 large North American centres.

Method: Retrospective case series of all ALF patients receiving MARS therapy between January 2009 and January 2019 at the University of Alberta, University of Kansas, and Emory University. Primary outcome was survival to hospital discharge. Secondary outcomes included change in hemodynamic and biochemical parameters post-MARS treatment.

Results: One-hundred four ALF patients (median age 38 [26.5–50.5]; 62.5% female) were treated with MARS (median 3.0 [2.0–6.0] runs; median total duration 24.0 [9.0–33.1] hours), with acetaminophen (APAP) representing the most common etiology (49.0%). Following MARS therapy, APAP patients displayed decreased heart rate (−8.43 [−5.14, −1.72] bpm; p = 0.015) and increased mean arterial pressure (MAP; +8.79 [2.81, 14.78] mmHg; p = 0.005) with no change in vasopressor dosing. No significant change was observed in non-APAP patient hemodynamics. Among APAP patients, ammonia (−50.82 [−74.92, −26.72] mmol/L; p = 0.0001), creatinine (−72.73 [−98.42, −47.06] μmol/L; p < 0.0001), INR (−1.98 [−2.81, −1.15]; p < 0.0001), and lactate (−2.69 [0.4.21, −1.18] mmol/L; p = 0.0008) decreased following MARS, while bilirubin remained unchanged. Post-MARS, non-APAP patients displayed increased MELD score (+5.79 [2.93, 8.59]; p = 0.0002), while no change was observed in APAP patients. Overall, 24 patients underwent orthotopic LT (APAP: 5/51 (9.8%); non-APAP 19/53 (35.8%)). Seventy-five patients (72.1%) survived to 21 days (LT: 22/24 (91.7%); No LT: 53/80 (66.3%)), with 54 patients (51.9%) surviving to 21 days without LT (APAP: 31/51 (60.8%); Non- APAP: 23/53 (43.4%)).

Conclusion: The use of MARS improved the biochemical profile of in ALF patients and, in cases of APAP ALF, improves hemodynamics. A

Variable	APAP (N=51)		Non-APAP (N=53)	
	Change Post- vs. Pre-MARS (95% CI)	P-value	Change Post- vs. Pre-MARS (95% CI)	P-value

larger controlled study is required to evaluate any potential survival advantage (currently ongoing).

THU159

MELD score is the best predictor for transplant-free survival in patients with acute liver injury

Carolina Simões[1], Ana Craciun[1], Ana Valente[1], Cilénia Baldaia[1,2], Carlos Freitas[1], Rui Palma[1], Rui Marinho[1,2], Mariana Machado[1,2].
[1]Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Gastroenterology, Lisbon, Portugal; [2]Faculdade de Medicina, Lisbon University, LIsbon, Portugal
Email: carolinabaptistasimoes@gmail.com

Background and Aims: The management of patients with acute liver injury (ALI) requires precise selection of patients who will likely die without urgent liver transplantation. The differentiation between ALI and acute liver failure (ALF) is hampered by very subtle signs of encephalopathy in acute disease. We aimed to compare the value of ALF early dynamic (ALFED) model, King's College criteria (KCC) and MELD score to predict poor prognosis (death or liver transplantation) in patients with severe ALI.

Method: A retrospective study was conducted on adult patients with severe ALI admitted to an intensive care unit, between 2005 and 2018. Patients were grouped according to their outcome as "alive" or "death or liver transplanted (LT)." The ability of the scores KCC, ALFED and MELD to predict adverse outcomes were evaluated.

Results: Forty-six patients with ALI, 26 female (56%), with mean age 46 ± 17 years were included. ALF developed in 32 patients (70%). Ten patients were LT (22%) and 17 died (37%) during their hospital stay. Causes of ALI were: drug-induced liver injury in 12 (26%), 3 of which acetaminophen related; viral hepatitis in 7 (15%), ischemic hepatitis in 6 (13%), *Amanita phaloides* poisoning in 5 (11%), and undetermined in 10 (22%). Invasive mechanical ventilation (VMI), vasopressors and renal replacement therapy were required in 11 (30%), 13 (28%), and 8 (17%) patients, respectively. The outcome LT or death associated with liver failure and severity of encephalopathy, higher age, INR, factor V, fibrinogen, albumin and creatinine serum levels, cardiovascular shock and respiratory failure, as well KCC and MELD, but not ALFED. Up to 1/3 of patients without encephalopathy died or required LT. MELD>29 was the only independent risk factor (OR 35.7 [3.5–368.8]). The performances of the different scores for discriminating the outcome LT or death were: MELD>29 AUROC 0.83 [0.68–0.99], p = 0.001, sensitivity (Se) 85%, specificity (Sp) 75%, positive predictive value (VPP) 85% and negative predictive value (NPV) 21%; KCC AUROC 0.75 [0.57–0.92], p = 0.020, Se 67%, Sp 79%, PPV 82% and NPP 37%; ALFED AUROC 0.62 [0.42–0.82], p = 0.244, Se 31%, Sp 93%, PPV 83% and NPV 56%. MELD>29 was superior than other scores even in patients with definitive ALF.

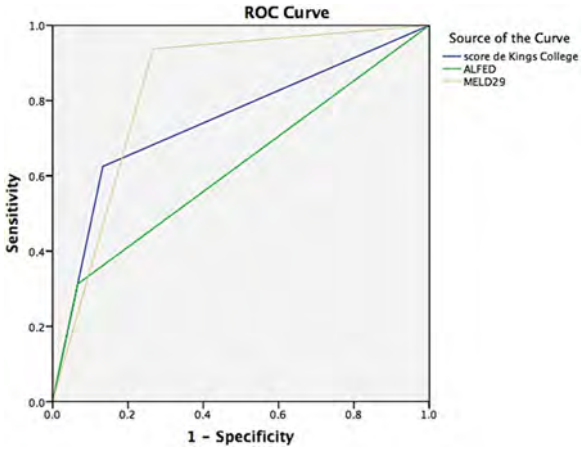

Figure: ROC Curve: Performances of the different scores for discriminating the outcome.

Conclusion: MELD score is superior to KCC and ALFED scores in predicting death or LT in severe ALI patients. MELD>29 accuracy is independent of the presence of encephalopathy. ALFED score has, however, an excellent Se and PPV.

THU160

Ketamine for maintenance sedation in critically ill burned patients is associated with liver dysfunction and acute kidney injury

Christian de Tymowski[1], Emmanuel Dudoignon[2], Nabila Moreno[3], Francois Depret[2], Matthieu Legrand[2,4], Alexandre Mebazaa[2], Vincent Mallet[5]. *[1]Hopital Bichat, Department of Anesthesiology and Surgical Critical Care Unit, Paris, France; [2]Hopital Saint-Louis,*

Department of Anesthesiology and Critical Care and Burn Unit, Paris, France; [3]Hopital Saint-Louis, Biochemestry laboratory, Paris, France; [4]University of California, Department of Anesthesiology and Peri-Operative Care, San Francisco, United States; [5]Hospital Cochin, Hepatology Service, Paris, France
Email: chrisdetymowski@gmail.com

Background and Aims: Intravenous ketamine is given for maintenance sedation of critically ill burned patients. Ketamine has been associated with drug-induced liver injury (DILI), including cholangiopathy. Cholestasis has been associated with mortality in critically ill burned patients(1). We investigated the relationship between ketamine exposure and outcomes, including liver dysfunction (LD) and acute kidney injury (AKI), in critically ill burned patients.
Method: We conducted a retrospective, single-center cohort study among consecutive patients admitted for burn injury in our burn intensive care unit (BICU) between December 2014 and December 2018. We included only patients admitted within the 3 first days following the burn injury and with a BICU stay ≥ 10 days. Drug exposure was defined as the total amount of drug received during the BICU stay divided by the numbers of days of exposure. Exposition to midazolam, a drug without any reported DILI, used as an alternative to ketamine for sedation, served as control. Primary endpoint was LD defined by total bilirubin ≥ 2 upper limits of normal (ULN). Continuous variables were expressed as medians with interquartile ranges (IQRs). We used cox models adjusted for severity of illness to measure the associations between ketamine exposure, LD, and KDIGO-defined AKI.
Results: A total of 307 patients were included LD was observed in 46 (15%) patients and was associated with severity of illness at admission, including burned body surface area ($p < 0.001$), Abbreviated Burn Severity Index ($p < 0.001$), Simplified Acute Physiology Score II ($p < 0.001$). Ketamine and midazolam exposure were also higher in patients with LD compare to patients without LD: respectively 312 mg/d [40–1139] vs 20 mg/d [0–68,8], ($p < 0,001$) and 95 mg/d [36–156] vs 0 mg/d [0–64], ($p < 0,001$). Adjusted for severity of illness, ketamine exposure was still associated with liver dysfunction and not midazolam (Figure 1). Ketamine, and not midazolam, was associated [adjusted hazard ratio (95% confidence interval) of 1.6 (1.1, 2,4), ($p = 0,018$)] with AKI only in the subgroup of patients with liver dysfunction.
Conclusion: In this cohort of critically ill burned patients, a population at high risk of liver dysfunction and exposed to a large amount of ketamine for sedation maintenance, Ketamine appears as a risk factor of liver dysfunction and may account for other organ failures, including AKI.

THU161

The therapeutic role of iNOS-expressed myeloid derived suppressor cells in acetaminophen induced acute liver failure

Chen-Yu Hsu[1], Yung-Chang Lin[2], Chien-Hao Huang[2], Chun-Yen Lin[3].
[1]Chang Gung University, Graduate Institute of Biomedical Sciences, Taoyuan, Taiwan; [2]Chang Gung Memorial Hospital, Hematology and Oncology, Taoyuan, Taiwan; [3]Chang Gung Memorial Hospital, Hepatology and Gastroenterology, Taoyuan, Taiwan
Email: chunyenlin@gmail.com

Background and Aims: An overdose of acetaminophen (N-acetyl-p-aminophenol or APAP) is one of major causes of acute liver failure. The toxic metabolites of APAP induce hepatocyte necrosis and activate the inflammatory responses to exacerbate liver injury. Myeloid-derived suppressor cells (MDSCs) increase in inflammatory diseases to regulate immune responses and are proposed to be used as adoptive immune cell therapy. Our aim is to investigate the therapeutic role of MDSC in APAP-induced acute liver failure.
Method: The BLAB/c mice were injected with a sublethal/lethal dose of APAP as the murine model. The MDSCs were defined as $CD11b^+Gr\text{-}1^+$ cells with suppressive ability on $CD8^+$ T cell proliferation. iNOS knockout mice were also used to investigate the role of iNOS in the protection functions of MDSC.

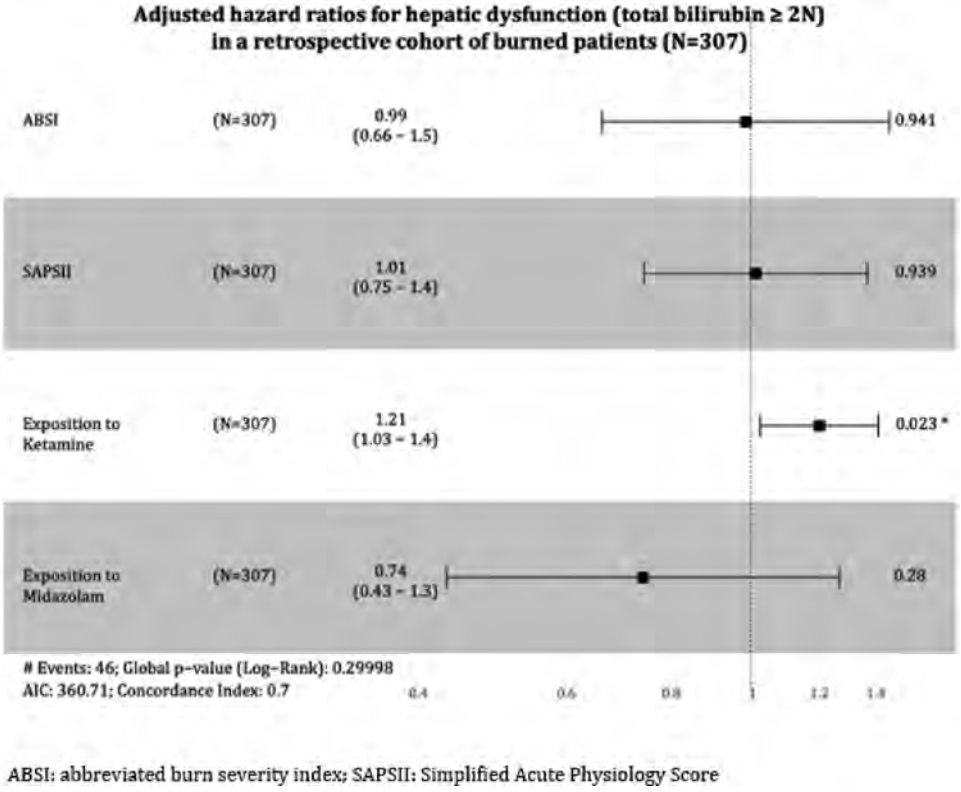

Figure: (abstract: THU160)

Results: A sublethal challenge of APAP could cause the intra-hepatic MDSCs accumulation and protect mice from subsequent lethal challenge of liver injury induced by APAP. This protection was lost if MDSC was depleted, and inducible nitric oxide synthase (iNOS) was the key molecule in this MDSC-mediated protection. Taking advantage of these observations, different bone marrow-derived MDSCs (BM-MDSCs) were generated and the TNF-α/LPS-primed BM-MDSCs had dominant iNOS expression and with the strongest liver protection ability after adoptive transfer of these BM-MDSCs into mice with APAP-induced acute liver failure. Similarly, iNOS was the key molecule for protection functions of these TNF-α/LPS-primed BM-MDSCs and induced a decrease influx of intrahepatic neutrophil infiltration that explained the therapeutic role of these MDSCs.
Conclusion: We demonstrated the protective role of MDSCs and therapeutic effect of *in vitro*-generated BM-MDSCs in APAP-induced liver failure. This protection is mediated by iNOS. Moreover, we also generated MDSCs from human peripheral blood mononuclear cells (PBMCs) with similar phenotype. These findings suggest the potential role of MDSCs as a cell-based therapy for APAP-induced liver failure.

THU162

Prevalence, incidence, and characteristics of hepatorenal syndrome-related acute kidney injury in the United States

Augustina Ogbonnaya[1], Manfred Bilzer[2], Michael Cooreman[3], Vishal Saundankar[1], Yum Lina Yip Sonderegger[4]. *[1]Xcenda LLC, Palm Harbor, United States; [2]Ferring Pharmaceuticals A/S; [3]Ferring Pharmaceuticals Inc; [4]Ferring International Center S.A.*
Email: lina.yipsonderegger@ferring.com

Background and Aims: Hepatorenal syndrome (HRS) type 1 is a severe form of acute renal failure that is common in patients (pts) with decompensated cirrhosis (DC). In 2015, the International Ascites Club (IAC) newly defined HRS as a subset of acute kidney injury (AKI) to enable early identification based on dynamic changes of serum creatinine (sCr), and expected better outcome with earlier therapy. We assessed the prevalence and incidence of HRS-AKI stages 2 and 3 and HRS type 1 as well as the practicability of the new IAC 2015 criteria.
Method: HRS was identified among hospitalized pts (≥ 18 years) with DC in 1/1/14 – 12/31/17 from a large United States (US) electronic medical record database (Explorys). HRS-AKI stages 2 and 3 and HRS type 1 were defined according to IAC 2015 and ICA 2005 criteria.
Results: Prevalence and incidence of HRS-AKI and HRS type 1 were assessed in 2017 with a starting population of 12,207 pts with DC. Of these, pts with hospitalization in 2017, sCr at baseline and during hospitalization, continuous activity in the database in 2016–2017, and no prior diagnosis of HRS-AKI or HRS type 1 (incidence assessment only) were selected. In hospitalized DC pts, the 2017 prevalence of HRS type 1 was 6.2% (70/1,135) and the incidence was 5.7% (62/1,083). By contrast, 33% higher prevalence (8.3%; 94/1,135) and incidence (7.6%; 79/1037) rates were found using the new HRS-AKI criteria. To characterize HRS-AKI pts, 552 pts who met the study criteria were identified from a starting population of 42,322 pts with DC in 2014–2017. Of these, 74.6% and 25.4% had stage 2 and stage 3 AKI, respectively. Mean (± standard deviation [SD]) baseline sCr values were 1.0 ± 0.6 and 0.9 ± 0.6 mg/dL in stage 2 and 3, respectively, and increased to 2.4 ± 1.5 and 5.2 ± 8.2 mg/dl, respectively, at hospitalization. Mean age was 60 years and 57.4% were male. Race was 74.5% Caucasian and 9.6% African American. Most frequent liver diseases assessed were chronic hepatitis C (23.9%), alcoholic hepatitis (9.6%), and non-alcoholic fatty liver disease (13%). Other top comorbidities were hypertension (54%), diabetes (31.7%), chronic obstructive lung disease (20.3%), and chronic kidney disease (19%).
Conclusion: The new HRS-AKI criteria can be easily applied to the US population because baseline sCr values important for the diagnosis and treatment of HRS-AKI are available. This will lead to diagnosis of more pts as expected and could facilitate earlier therapy.

THU163

Bioenergetics defect of CD14+ monocytes are associated with increased mortality in acute liver failure

Dhananjay Kumar[1], Ashini Hidam[1], Jitendra Kumar[1], Deepanshu Maheshwari[1], Mojahidul Islam[1], Nidhi Nautiyal[1], Viniyendra Pamecha[1], Rakhi Maiwall[2], Anupam Kumar[1], Shiv Kumar Sarin[3]. *[1]Institute of Liver and Biliary Sciences, MCM, Delhi, India; [2]Institute of Liver and Biliary Sciences, Hepatology, India; [3]Institute of Liver and Biliary Sciences, Hepatology, Delhi, India*
Email: shivsarin@gmail.com

Background and Aims: Increase systemic inflammatory response as a result of massive hepatic injury is associated with development infections & high mortality in ALF though the mechanisms are unclear. We investigated the underlying cellular mechanisms for increased susceptibility to infection & high mortality in ALF
Method: A panel 31 cytokines & growth factor were analysed in ALF (N = 30). Distribution of hepatic macrophages (ALF, N = 10, Healthy (H) = 10), monocytes (ALF N = 15; H = 15) & their phagocytosis was studied by FACS. Mitochondrial respiration and glycolysis were analysed in shorted CD14+monocyte (ALF N = 18, H = 10) by Agilent–XFe24–analyzer. Expression of Glycolysis and TCA pathway gene were done by qPCR.

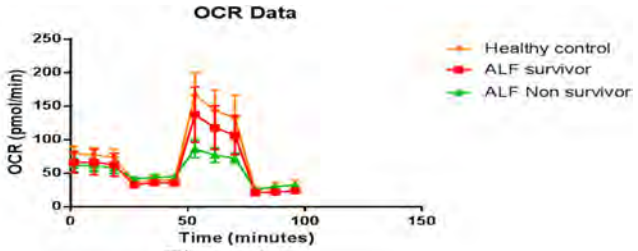

Figure A

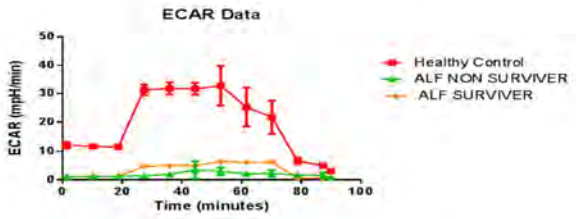

Figure B

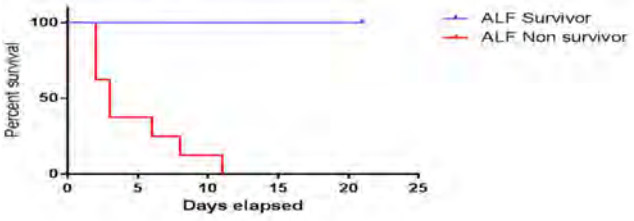

Figure C

Results: 21of 30 ALF patients died or went for liver transplant (non–survivor) and 9 patients showed spontaneous recovery (survivor). Cytokine showed reduction of innate immunity–related cytokines (MCP-3,IL-1β,IL-6,IL-10,& IL-17) in ALF non-survivors. CD68+macrophage while increased in ALF liver ($p = 0.004$),were deficient in phagocytosis($p = 0.001$) in comparison to healthy. Similarly,the CD14 +monocytes in ALF non-surviver showed reduction ($p = 0.001$) & phagocytosis ($p < 0.001$) in comparison to survivors, suggesting the

failure of mono-mac system in ALF non surviver. In comparison to healthy monocyte, the ALF monocyte showed significant decrease in mitochondrial respiration (Fig. 1A),glycolysis (fig. 1B) & showed decrease expression of enzyme associated with ATP production in glycolysis (PGK1) & TCA cycle (IDH,OGDH) in ALF non surviver, suggesting Bioenergetic failure in ALF. Further analysis of mitochondrial-respiration of monocyte in living-donor-liver-transplant donor before & after surgical resection at D3&D7 showed significant decrease in mitochondrial-respiration at D3 which recover at D7 with increase in liver mass. these data suggest the loss of hepatic mass adversely affects the energy metabolism of monocytes. In 21Ds of follow-up while9 patients discharged form ICU & survived 9 died or went for liver transplant. Baseline mitochondrial respiration of monocyte ($p < 0.001$; AUROC = 1) predict the early mortality (21 Ds) in ALF, ALF with OCR less then = 21 pM/min showed increase in mortality (Fig. 1C).

Conclusion: Broad defect in energy metabolism in ALF, lead to a compromise of mono-mac functions & associated with early mortality. Restoring the energy metabolism of monocytes may prevent the secondary infection & mortality.

THU164

Ferroptosis related regulatory protein NCOA4 and its lncRNA-mRNA co-expression network in patients witn anti-tuberculosis drug-induced liver injury

Jun Chen[1], Juan Zhou[2], Yunzhu long[3]. [1]*Third Hospital of Shenzhen, Liver Disease, Shenzhen, China;* [2]*The Affiliated Zhuzhou Hospital Xiangya Medical College, Central South University, Infectious Diseases, Zhuzhou, China;* [3]*The Affiliated Zhuzhou Hospital Xiangya Medical College, Central South University, Infectious Diseases, Zhuzhou, China*
Email: drchenjun@163.com

Background and Aims: Patients with anti-tuberculosis(anti-TB) drugs induced liver injury(DILI) greatly increased the difficulties of anti-TB treatment. Until now, the pathogenesis of anti-TB related DILI is not very clear. In this study, we aimed to investigate important signaling pathways and related genes in development of the disease and construct profile of lncRNA-mRNA co-expression network to further understand the pathogenesis.

Method: Totally 16 patients with anti-TB related DILI and 16 patients without DILI (as control) were enrolled in this study. Total serum RNA was collected, Affymetrix Human Transcriptome Array 2.0 was applied to detect the differentially expressed genes [fold change ≥ 2.0, $p < 0.05$], as well as variable splicing event [splicing index ≥ 2.0, $p < 0.05$]. The Metascape platform was applied to analysis of differentially expressed mRNAs, and gene interaction matrix was constructed based on Pearson correlation coefficient to explore the non-coding RNA related to the disease. Finally, total RNA was extracted from serum, and the selected important genes were verified by real-time fluorescent quantitative PCR.

Results: Contrast to control group, there were 568 deferentially expressed coding genes, most of which exhibited differential alternative splicing, and 845 non-coding transcripts involved in anti-TB DILI. KEGG enrichment on significantly different mRNAs highlighted the ferroptosis involving in anti-TB DILI that presenting as one of the top 20 signaling pathways, which referred to FTH1(Log FC = 2.05),FTL(Log FC = 2.94),NCOA4(Log FC = 1.65),PCBP1(LogFC = 2.5),PCBP2(Log FC = 2.32) and SAT1 (Log FC = 1.97). Co-expression analysis of mRNAs and ncRNAs showed that NCOA4, which was closely related to FTH1 (correlation P = 0.97) probably involved in the process of anti-TB DILI. In addition, the network suggested that mRNAs related to ferroptosis can be linked to each other by non-coding RNAs, such as FTH1P3(Log FC = 1.27) contemporary connecting to FTH1, FTL and NCOA4($p = 0.97$,0.97 and 0.96, respectively) (Figure 1). Furthermore, RT-PCR results confirmed both expression of NCOA4 and FTH1P3 were significantly higher in anti-tuberculosis patients with DILI than no DILI patients($p < 0.05$).

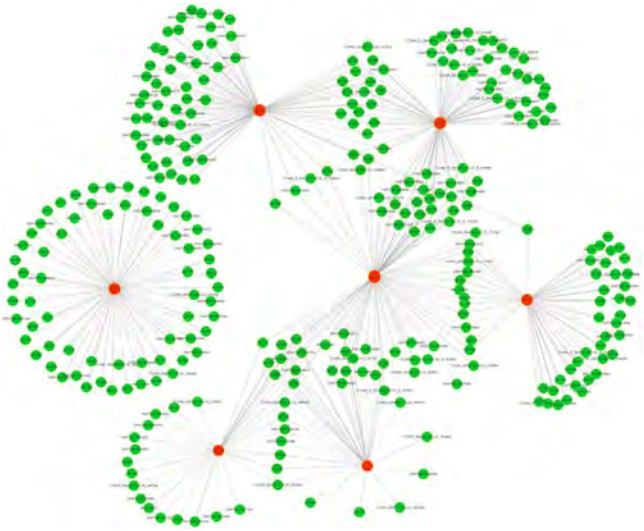

Figure 1: Non-coding RNA co-expressed with seven ferroptosis-related genes, red for ferroptosis-related genes, green for non-coding RNA; solid line for positive correlation, and dashed line for negative correlation.

Conclusion: Patients with anti-TB DILI have obviously altered gene expressions and alternative splicing events compared with the control. NCOA4 acting as a selective cargo receptor for autophagic turnover of ferritin (ferritinophagy) and FTH1P3, have a co-expression relationship with NCOA4 may play an important role in anti-TB DILI, worthy to be further studied.

THU165

AARC score has better accuracy at predicting 90-day mortality in drug induced acute-on-chronic liver failure (DILI - ACLF)

Karan Kumar[1], Sushrut Singh[1], Ashok Choudhury[1], Shiv Kumar Sarin[1], Manoj Kumar[1], Vikram Bhatia[1], Rakhi Maiwall[1], Ankur Jindal[1], Vijayraghavan Rajan[1], Vinod Arora[1]. [1]*Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: karanbjmc93@gmail.com

Background and Aims: Of the various acute insults in Acute on chronic liver failure(ACLF) patients, Drug induced liver injury(DILI) is one of the major culprit. We compared disease severity and outcome in those having Drug induced acute on chronic liver failure versus those having other acute hepatic insults.

Method: Consecutive ACLF patients registered in APASL-ACLF research consortium were included. Demography and outcome of those having Drugs as an acute insult(DILI-ACLF) were compared to rest of other patients (non-DILI ACLF). Predictors of mortality in those having Drug induced liver injury as an acute insult were identified using Cox regression.

Results: Of the Total 3132 patient studied,262(8.4%) had Drugs as an acute insult. Among Drugs, Complementary and Alternative Medicines was major culprit (5.6%) followed by Anti Tubercular drugs(2.8%). Mean age of patients having DILI as an acute insult was 47.35 ± 13.75 years which was comparable to other group 44.22 ± 12.21 years. In 28% of patients having Drugs as an acute insult the underlying chronic insult remain unknown. Baseline MELD (30.5 ± 27.2) was higher in patients of ACLF having DILI as an acute insult as compared with other acute insults (28.86 ± 7.02). Other severity score CTP, SOFA,CLIF-SOFA and AARC score at baseline were comparable among 2 groups. 91.8% of patient having DILI as an acute insult have one or more organ failure at presentation as compared to 86.1% of non-DILI acute insult($p = 0.003$). 30 days mortality (39.7%) was significantly higher in DILI group as compared to other acute insults (28.6%) ($p = 0.004$). Mean survival in DILI-ACLF was 49.99 ± 2.49days which was significantly lower than non DILI ACLF 58.94 ± 0.74 days ($p = 0.005$). MELD Score greater than 30 at baseline predict 90 days mortality with 69.2% sensitivity and 71% specificity whereas AARC

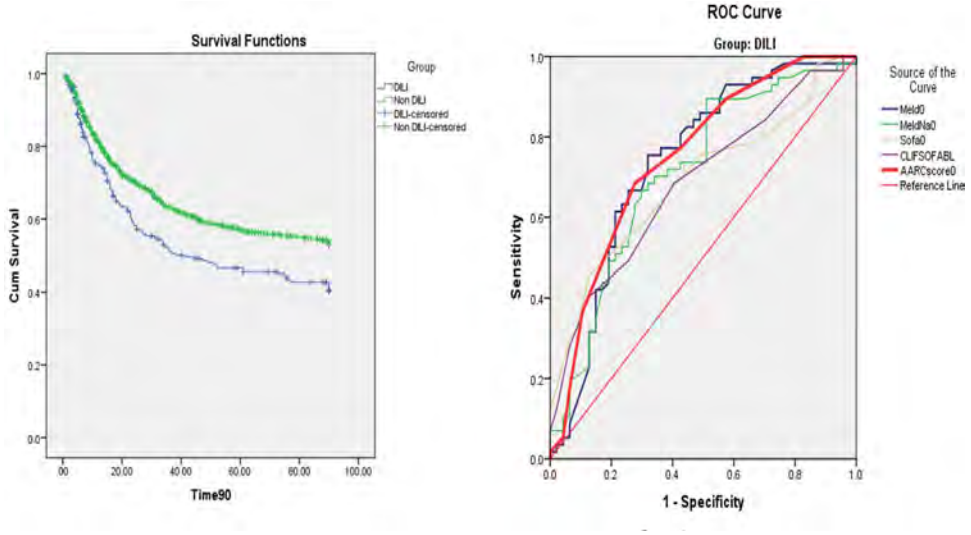

Figure: (abstract: THU165)

score greater than 10.5 predicts 90 days mortality with 68.4% Sensitivity and 73% specificity. ROC comparing MELD,CTP,SOFA, CLIF-SOFA and AARCscore at baseline revealed significantly higher area under curve for AARC score (0.75, $p < 0.001$)

Conclusion: Patients having Drugs as an acute insult in Acute on Chronic Liver Failure have poor outcome as compared to those having other acute insults. Baseline AARC score more than 10.5 has highest AUROC to predict 90 days mortality in DILI-ACLF patients

THU166

Clinical characteristics and prognostic risk factors for patients with hepatic sinusodial obstruction syndrome caused by gynura segetum

Jing Zhang[1], Zhenli Liu[1], Haibin Yu[1], Yali Liu[1]. [1]*Beijing Youan Hospital, Capital Medical University, Department of Hepatitis C and Drug–Induced Liver Disease, Beijing, China, China*
Email: drzhangjing@163.com

Background and Aims: Hepatic sinusoidal obstruction syndrome (HSOS) induced by Gynura segetum is associated with a notable mortality due to the absence of prompt diagnosis and effective therapy. The risk factors influencing the prognosis have still remained elusive. To describe clinical features and evaluate effects of anticoagulants on survival rate in patients with Gynura segetum-induced HSOS, and identify independent prognostic risk factors as well.
Method: Patients' clinical data, including medical history, symptoms, signs, imaging characteristics, laboratory test results, anticoagulant therapy and outcomes were collected. The prognostic risk factors of HSOS were analyzed by cox regression model.
Results: In this study, 49 patients from 5 hospitals were included, and the median duration of follow-up was 36 months. The main clinical manifestations were ascites (98.0%), abdominal distension (91.8%), hepatomegaly (51.0%), lower limb edema (49.0%), esophageal and gastric varices (42.9%), and splenomegaly (42.9%). The majority of patients had typical map-like or mottle-like radiographic imaging findings. The 1-, 3-, 6-, and 36-month survival rates were 91.8%, 85.7%, 81.6%, and 75.5%, respectively. Anticoagulants were administered to 27 patients (55.1%), and among them, 24 patients (88.9%) survived. The survival rate in anticoagulation group was significantly higher than that of control group (13/22, $\chi^2 = 5.821$, $p = 0.016$). White blood cell count, total serum bilirubin level, and albumin level were the independent prognostic factors of HSOS.

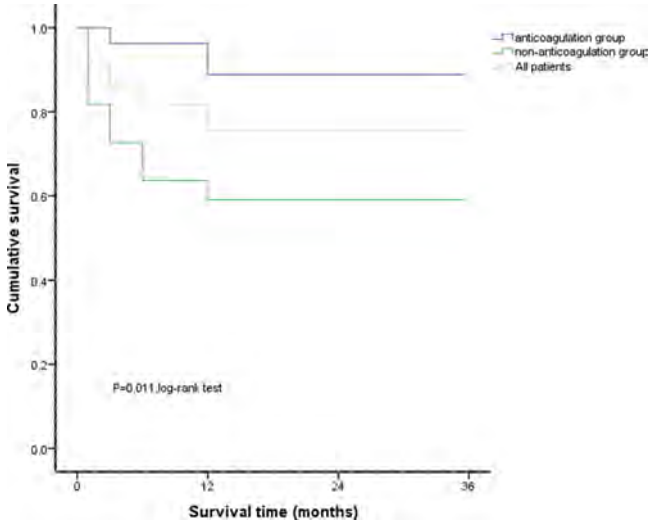

Figure: (abstract: THU166)

Conclusion: White blood cell count, total serum bilirubin level, and albumin level were the independent prognostic factors of HSOS induced by Gynura segetum. Although the mortality rate was high, however, anticoagulation therapy was effective to improve the clinical outcome.

THU167

Umbilical cord-derived mesenchymal stem cells regulate ferroptosis via the activation of NRF2 are signaling pathway for the treatment of acute liver failure

Cong Du[1], Lijie Pan[2], Qi Zhang[2]. [1] *The Third Affiliated Hospital, Sun Yat-sen University, Organ Transplantation Institute, Department of Hepatic Surgery and Liver Transplantation Center, Guangzhou, China;* [2] *The Third Affiliated Hospital, Sun Yat-Sen University, China Cell-Gene Therapy Translational Medicine Research Center, Biotherapy Center, Guangzhou, China*
Email: keekee77@126.com

Background and Aims: Acute liver failure (ALF) is characterized by widespread hepatocyte death and sudden severe liver dysfunction, which can even lead to multi-organ failure and death. However, the manner of hepatocyte death is still not fully clear. Emergency liver

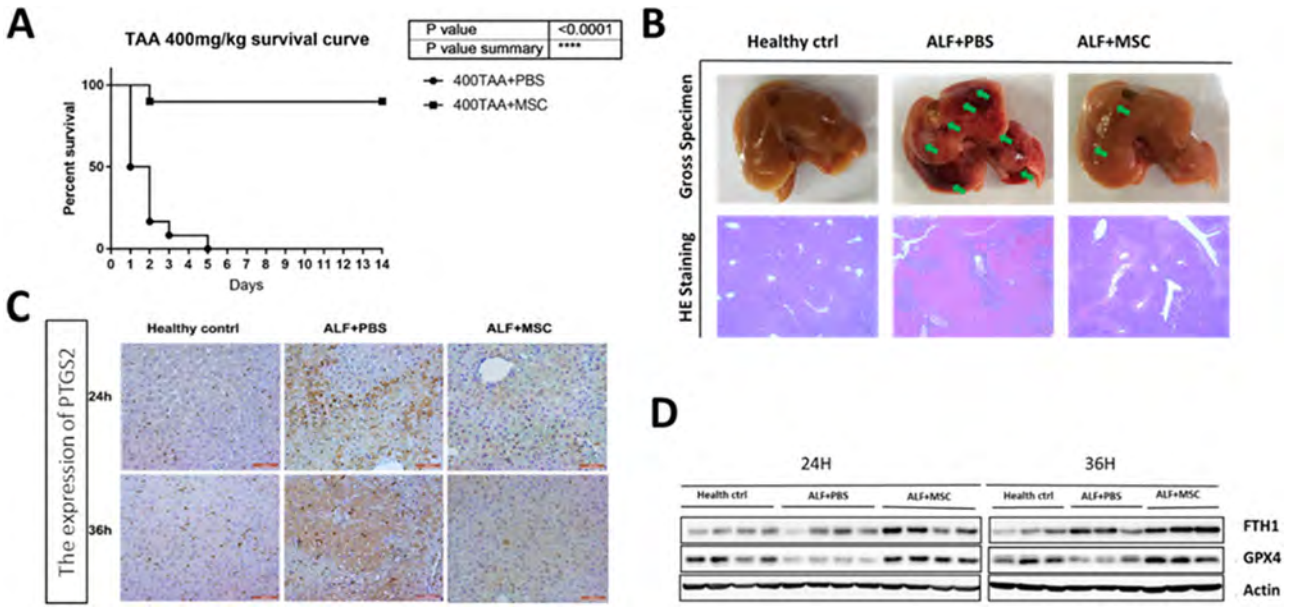

Figure: (abstract: THU167)

transplantation as an optimal treatment for ALF is greatly hampered by the critical shortage of liver grafts. Worse still, the survival rates are inferior to those patients undergoing elective transplantation for chronic liver disease. Therefore, it is urgent to clarify the exact pathogenesis of ALF and develop effective treatments based on it. This study was to investigate the therapeutic effects and possible mechanism of human umbilical cord-derived mesenchymal stem cells (hUC-MSCs) on ALF in murine models.

Method: In the present study, a murine ALF model was established by intraperitoneal injection of thioacetamide (TAA) at lethal dose (at least 400 mg/kg). Human UC-MSCs (2 × 10*6 per mouse) was infused via tail vein to those mice with ALF. Hepatocyte cell line or primary hepatocytes were treated with thioacetamide and RSL3 (Ferroptosis inducer) with or without Liproxstatin-1(Ferroptosis inhibitor) to mimic liver injury and co-cultured with UC-MSCs or MSC conditional medium (UC-MSCs-CM) for in vitro analyses.

Results: Ferroptosis were observed in mice suffering from TAA-induced ALF, including smaller mitochondria with increased mitochondrial membrane density and reduction of mitochondria crista, intracellular iron accumulation, lipid peroxidation with higher ROS level, decreased expression of GPX4 and FTH1, characteristically increased expression of PTGS2 and SLC7A11. This type of cell death is significantly different from other cell death in terms of morphology, genetics and biochemistry. All these pathological changes were revered following a tail venous transfusion of UC-MSCs (2 × 10*6 per mouse). As expected, hUC-MSCs significantly improved liver function and decreased the mortality rate of mice with ALF. To validation, our results showed that the Ferroptosis phenotype induced by thioacetamide and RSL3 can be reversed by Liproxstatin-1 and MSCs. Furthermore, we found that the expression level of P62, Nrf2 and its targeted genes (such as Nqo-1, Txn, Gsr and so on) were upregulated upon MSCs treatment. The rational mechanism could be the accumulation of P62 in cytoplasm and its competitive combination with Keap1, which leaded to more Nrf2 translocate to nucleus and then bind to ARE for transcription of cytoprotective genes.

Conclusion: Our study revealed that UC-MSCs were effective for the treatment of ALF via inhibiting Ferroptosis through the activation of Nrf2-ARE signaling pathway.

Background and Aims: Most information about hepatocyte-derived exosomes and extracellular vesicles (EVs) and their role in health and disease derives from cell culture experiments, which do not represent the complexity of whole organisms. The lineage reporter mT/mG mouse strain allows the generation of mice that express the Tomato-dye protein in the plasma membrane of all cells except in Cre-recombinase expressing cells, which express the Green Fluorescent Protein (EGFP). Our Aim was to evaluate the lineage reporter mT/mG mouse strain in experimental liver disease as a novel approach for the in vivo identification of circulating EVs according to the cell of origin.

Method: The mT/mG mouse strain (Stock 07676, Jackson Lab) was crossbred with mice expressing Cre-recombinase under the control of the Lysozyme-C (LysMCrexmT/mG mice, EGFP in myeloid-derived cells) or the Albumin promoters (AlbCrexmT/mG mice, EGFP in hepatocytes). Non-fluorescent mice (C57Bl6/J) and the original mT/

mG mouse strain were used as controls. Hepatic damage was induced by acetaminophen administration (APAP, 300 mg/kg bw ip). EVs were isolated by immune-magnetic separation (Mouse Exosome Isolation Kit Pan [CD9, CD63 and CD81 proteins] or GFP Isolation Kit, Miltenyi) from mouse plasma, and by ultracentrifugation of culture media from primary hepatocyte cultures from each mouse strain. EVs were analyzed by flow cytometry (FACS, MACSQuant16), Nanoparticle Tracking Analysis (NTA), Dynamic Light Scattering (DLS), transmission electron microscopy (TEM) and Western Blotting.
Results: The plasma concentration of EGFP-positive EVs was low in Vehicle-treated AlbCrexmT/mG mice but it largely increased in APAP-treated mice, as assessed by FACS. In contrast, APAP treatment did not change the plasma concentration of EGFP-positive EVs in LysMCrexmT/mG mice. EGFP-positivity of EVs from AlbCrexmT/mG mice was confirmed by FACS in plasma and hepatocyte culture media samples, and by Western blotting in exosomes isolated from both sources. In mouse plasma samples, the immune-magnetic isolation of hepatocyte-derived and myeloid cell-derived EGFP-positive EVs was also confirmed by FACS and Western blotting. The characteristics of exosome population were confirmed in all EVs isolates.
Conclusion: The circulating concentration of hepatocyte-derived EVs is low in normal animals, but it considerably increases after acute hepatic insults. The lineage reporter mT/mG mouse strain allows the evaluation and isolation of hepatocyte-derived and myeloid cell-derived EVs in murine models of liver disease. This highly valuable new approach for the in vivo study of the cell-type of origin of EVs overcomes a major limitation in EVs research, being also applicable to fields other than Hepatology.

THU169
Markers of neutrophil extracellular traps are associated with poor outcome in patients with acute liver failure

Fien von Meijenfeldt[1], Richard Todd Stravitz[2], Jingwen Zhang[3], Jelle Adelmeijer[1], Valerie Durkalski-Mauldin[3], William M. Lee[4], Ton Lisman[1]. [1]*University Medical Center Groningen, Surgical Research Laboratory, Department of Surgery, Groningen, Netherlands;* [2]*Hume-Lee Transplant Center of Virginia Commonwealth University, Richmond, United States;* [3]*Medical University of South Carolina, Public Health Sciences, Charleston, United States;* [4]*University of Texas-Southwestern Medical Center, Dallas, United States*
Email: f.a.von.meijenfeldt@umcg.nl

Background and Aims: Acute liver failure (ALF) is characterized by significant changes in the hemostatic system and by systemic inflammation. The formation of neutrophil extracellular traps (NETs), in which an activated neutrophil expels its DNA, histones and granular enzymes, to form web-like structures, has been discovered as a new feature of the immune system, and has been associated with immune-mediated - and thrombotic diseases. Intrahepatic NET formation coupled to activation of coagulation has been shown to drive a variety of liver diseases in animal models. In clinical studies, markers for NETs, notably cell-free DNA and the more specific myeloperoxidase (MPO)-DNA, a neutrophil-specific enzyme attached to cell-free DNA, have been indicated to have prognostic utility, but have not been studied in acute liver failure before. We hypothesized that formation of NETs occurs in patients with ALF, and further hypothesized that NETs contribute to progression of disease, promote hemostasis and could have prognostic value in ALF.
Method: A total of 676 patients with ALF (INR >/ = 1.5) or severe acute liver injury (ALI; INR >/ = 2.0) were recruited from the US ALF Study Group Registry between 2011 and 2018, of which 308 patients (45.6%) had acetaminophen-induced ALF. Bleeding occurred in 50 patients (7.4%), and 483 patients (71.4%) survived without liver transplantation. Levels of cell-free DNA and MPO-DNA complexes, were measured using enzyme-linked immunosorbent assays in plasma samples obtained at admission and compared to levels in healthy controls.
Results: Levels of cell-free DNA were 6.8-fold and MPO-DNA complexes 2.5-fold higher in patients with ALF compared to healthy controls. Cell-free DNA levels were not associated with 21-day transplant-free survival, nor with bleeding complications, but were higher in those patients with acetaminophen induced liver failure and in those patients requiring renal replacement therapy. MPO-DNA levels were 30% higher in patients with ALF who died or required urgent liver transplantation. MPO-DNA complex levels were not associated with bleeding complications.
Conclusion: Plasma levels of cell-free DNA and MPO-DNA complexes were significantly elevated in patients with ALF. Levels of MPO-DNA complexes, but not of the much less specific NET marker cell-free DNA, were associated with death or (urgent) liver transplantation, suggesting that increased NET formation might contribute to disease progression and ultimately death.

Activation ot the aryl hydrocarbon receptor sensitizes to acetaminophen-induced acute liver failure

Fenja Schuran[1], Christoph Lommetz[1], Steudter Andreas[1], Wieschendorf Björn[1], Dorothee Schwinge[1], Christoph Schramm[1], Ansgar W. Lohse[1], Johannes Herkel[1], Antonella Carambia[1].
[1]*Universitätsklinikum Hamburg Eppendorf, I. Medizinische Klinik und Poliklinik, Hamburg*
Email: f.schuran@uke.de

Background and Aims: Acetaminophen (APAP)- induced liver damage is one of the most common causes of acute liver failure. However, the risk factors determining hypersensitivity to APAP remain poorly defined. The transcription factor aryl hydrocarbon receptor (AhR), which can be activated by environmental, dietary, microbial and metabolic ligands, is a direct inducer of CYP1A2, one of the major enzymes involved in the generation of toxic APAP metabolites. Therefore, we hypothesized that AhR activation might contribute to APAP-induced hepatotoxicity.
Method: Wildtype or conditional AhR knockout mice lacking AhR in hepatocytes ($Alb^{\Delta/\Delta AhR}$) were subjected to a combined treatment with APAP and the non-toxic gut-derived AhR ligand 2-(1'H-indole-3'-carbonyl)-thiazole-4-carboxylic acid methyl ester (ITE).
Results: Administration of ITE together with a normally sublethal APAP overdose (350 mg/kg) caused 80% mortality within 8 hours, whereas all vehicle-treated control mice survived ($p = 0.0002$). Accordingly, we found vast necrotic areas in liver tissue ($p < 0.0001$) and strongly elevated serum transaminase levels (ALT: 7616 vs 812 U/L, $p < 0.0001$) in mice, which were co-treated with ITE and APAP, as compared to controls receiving vehicle and APAP. Of note, even at APAP doses equivalent to the recommended therapeutic range in humans, AhR activation by ITE induced substantial liver damage as compared to vehicle treatment (ALT: 1488 vs 117 U/L, $p = 0.0043$). In contrast, $Alb^{\Delta/\Delta AhR}$ mice were largely protected from ITE-induced disease aggravation. Indeed, serum ALT levels (1063 vs 3247 U/L), $p = 0.0012$) were significantly lower as compared to littermate controls. Moreover, TUNEL staining of liver sections revealed greatly reduced hepatocyte death in $Alb^{\Delta/\Delta AhR}$ mice following combined APAP and ITE treatment ($p = 0.007$). Mechanistically, AhR activation by ITE fueled hepatic accumulation of toxic APAP metabolites by up-regulating expression of the APAP-metabolizing enzymes CYP1A2 ($p < 0.0001$) and CYP2E1 ($p = 0.0077$).
Conclusion: AhR activation in hepatocytes induces accumulation of toxic APAP metabolites aggravating APAP hepatotoxicity. Thus, AhR activating ligands, which can originate from various sources, such as nutrition or gut microbiota, might be a risk factor sensitizing to APAP-induced acute liver failure.

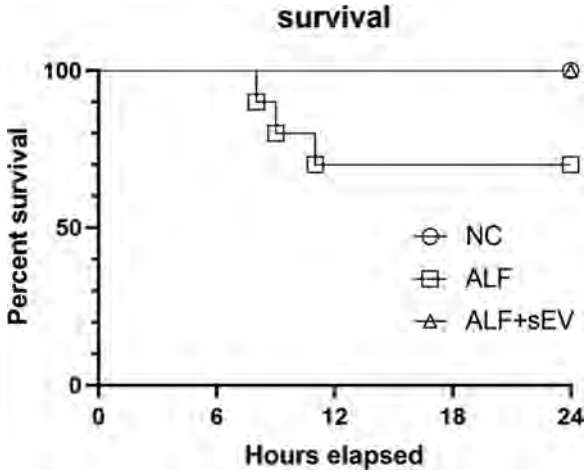
Human bone marrow mesenchymal stem cell's small extract vesicles promote hepatocyte regeneration in acute liver failure

Juan Gao[1], Jing Zhang[1], Dengna Lin[1], Jing Xiong[1], Bingliang Lin[1]. [1]*The Third Affilirated Hospital, Sun Yat-Sen University, Department of Infectious Diseases, Guangzhou, China*
Email: lamikin@126.com.

Background and Aims: Acute liver failure (ALF) is a severe, life-threatening syndrome with high mortality due to a shortage of effective agency. How to promote hepatocyte regeneration is the key to rescue ALF. Previous studies have confirmed that mesenchymal stem cells (MSCs) derived small extract vesicles (sEVs) can regulate the proliferation and apoptosis of endogenous cells, but whether it can promote the proliferation and apoptosis of hepatocytes in acute liver failure is unclear.
Method: To establish the ALF cell model of L02 cell line induced by H_2O_2 and ALF mouse model induced by GalN/LPS, collect and identify hBMSC-sEVs, and co-culture with ALF hepatocytes, then detected the proliferation and apoptosis of hepatocytes in ALF cell model by fluorescent labeling technique, meanwhile, detected the hepatocytes activity of by CCK8. Injected hBMSC-sEVs into ALF mouse by tail vein to evaluate the effect on ALF mouse. To test the molecules and genes of proliferation and apoptosis by Western Blotting and qPCR.
Results: The hBMSC-sEVs were fused with ALF cell model, and the activity of hepatocytes in ALF cell model was increased. In vivo tracing showed that hBMSC-sEVs were aggregated in liver of ALF mouse. The levels of ALT, AST and TB reduced, and 24-hour mortality of hBMSC-sEVs infusion mouse was lower than that in the control group, and the liver inflammatory infiltration, hyperemia decreased, meanwhile, hepatocyte proliferation increased. hBMSC-sEVs could upregulate pAKT and pSer9-GSK3 β, CCND1 and Bcl-2 expression increased, and p53, Bax and cMyc expression decreased.



Conclusion: hBMSC-sEVs can improve the prognosis of acute liver failure by promoting hepatocyte proliferation and reducing apoptosis in vitro and in vivo.

Cut-off level of serum cytokeratin 18 for diagnosis of acute-on-chronic liver failure in chronic hepatitis C cirrhosis

Hany Shabana[1], Sayed abd Elmaqsood[1], Mohamed El-Saadany[1], Shymaa Aleraky[1], Mohammed Al Arman[2]. [1]*Specialized Medical Hospital, Mansoura University, Internal Medicine, Mansoura, Egypt;* [2]*Faculty of Medicine, Mansoura University, Clinical Pathology, Mansoura, Egypt*
Email: hanyshabanahanyshabana@yahoo.com.

Background and Aims: Acute on chronic liver failure (ACLF) is a new form of liver failure that has unacceptable high rates of mortality. There is evidence of hepatocyte cell death in ACLF either by necrosis or apoptosis. The caspase-cleaved cytokeratin18 fragments (M30) is a marker of caspase-mediated apoptosis. The aim is to evaluate the value of serum cytokeratin 18 level in diagnosis of ACLF in chronic HCV cirrhotic patients and its correlation with ACLF severity.
Method: This study included 60 chronic HCV cirrhotic patients with ACLF (Group 1), 15 chronic HCV compensated cirrhotic patients (Group 2), and 15 healthy controls (Group 3). Laboratory investigations and radiological examination with calculation of CTP, MELD, CLIF-OF (CLIF Consortium Organ Failure Score) and calculation of CLIF-C ACLF score using EASL CLIF ACLF calculator, were done for all enrolled individuals. Serum level of caspase cleaved CK 18 (M30) using ELISA kits, was measured for all enrolled individuals.
Results: The most common precipitating factor of ACLF was infection which represented 61.7% and the most common infection was SBP (30%). The most common organ failure was renal failure (81.7%). MELD score was significantly higher in Group 1 (32.32 ± 6.76) compared to Group 2 (7.67 ± 2.06) (p = <0.001). CLIF OFs score was 13.02 ± 1.97 and CLIF C ACLF was 61.67 ± 9.31 in Group 1. In Group 1, 3.3% had single organ failure, 41.7% had two organs failure and 55% have three or more organs failure. Serum level of CK 18 (M30) was significantly higher in Group 1 [13.1 ng /ml (2–31.8 ng /ml)] compared to Group 2 [5.7 ng /ml (3.0–13.6 ng/ml)] and Group 3 [3.0 ng/ml (1.6–4.1 ng/ml)] (p = 0.017, p = <0.001). The area under the receiver operating characteristic curve (AUC) for serum CK 18 (M30) in diagnosis of ACLF was 0.902 (95% CI = 0.833–0.970) at cut off level of 3.45 ng/ml. The sensitivity was 85%,the specificity was 93.3%, positive predictive value was 98.1%, negative predictive value was 60.8%and accuracy was 86.7%. There was significant positive correlation between serum level of CK 18 (M30) and CLIF C ACLF score (r = 0.331,p = .01). Logistic regression analysis showed that serum CK 18 (M30) level was independently associated with ACLF (OR = 2.72, 95% CI = 1.14–6.5). There was no significant difference in serum CK 18 (M30) level between infection precipitated ACLF and all other causes of ACLF (p = 0.476).
Conclusion: Serum cytokeratin 18 (M30), a marker of caspase-mediated apoptosis, at cut off value of 3.45 ng/ml can diagnose acute on top of chronic liver failure in chronic HCV cirrhosis with high accuracy regardless of the precipitating insult. Its serum level is positively correlated with ACLF severity as evaluated by CLIF C ACLF score.

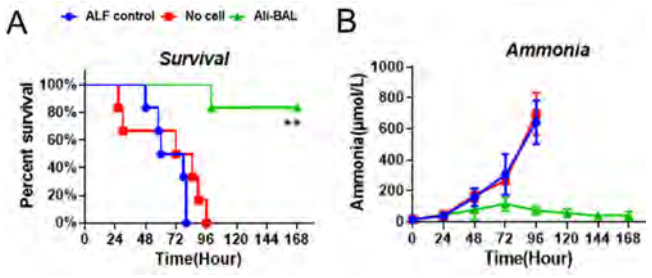
THU173

Air-liquid interactive bioartificial liver embedded with 3D-layered human hepatocyte-derived liver progenitor-like cells rescues pocine acute liver failure

Hexin Yan[1]. [1]*Renji Hospital Shanghai Jiaotong University School of Medicine, Department of Anesthesiology and Critical Care Medicine, Shanghai, China*
Email: hexinyw@163.com.

Background and Aims: Clinical advancement of bioartificial liver is hampered by the lack of expandable functional human hepatocytes and appropriate bioreactor/carriers supporting their three-dimensional (3-D) constructs. Here we developed a novel air-liquid interactive 3-D bioartificial liver (Ali-BAL) with the use of immortalized human hepatocyte-derived liver progenitor-like cells (iHepLPCs) and evaluated the safety and effectiveness of the device in a porcine model of drug-overdose acute liver failure (ALF).
Method: HepLPCs were immortalized and then functionally enhanced by selective screening of hepatic transcription factors. The cells were expanded in microfiber network on a large scale in Ali-BAL in which cells grew into 3-D structures on macroporous carriers and were alternately exposed to aeration and nutrition. Animals received infusion of hepatotoxin D-galactosamine and then were treated with Ali-BAL. Blood ammonia, liver function and coagulation index were measured every 24 h. Cytokine arrays were used to determine the proinflammatory cytokines. Hematoxylin and eosin

(H&E) staining and immunohistochemistry were used to examine liver injury and regeneration.
Results: iHepLPCs exhibited efficient expansion without growth arrest. Overexpression of FOXA3 significantly improved the synthesis, secretion and detoxification functions of iHepLPCs. When cultured on macroporous carriers in Ali-BAL, not only sufficient cell yield was obtained, but the cells formed 3-D constructs, leading to further enhanced liver functions. After Ali-BAL treatment, ALF porcine had markedly improved survival (83%, n = 6) compared to ALF control (17%, n = 6, p = 0.02) and No-cell device therapy (0%, n = 6, p = 0.003). The blood ammonia levels, as well as biochemical and coagulation indices were significantly reduced in Ali-BAL-treated pigs. Ali-BAL treatment attenuated liver damage, ameliorated inflammation and enhanced liver regeneration.



Conclusion: Novel air-liquid interactive bioartificial liver embedded with 3D-layered iHepLPCs can improve ALF porcine survival. The Ali-BAL might be considered as a new therapeutic device for ALF treatment.

THU174

Outcomes following deceased and live donor liver transplantation for the indication of acute liver failure: a multicenter experience

Ilker Turan[1], Murat Aladag[2], Murat Harputluoglu[2], Sezai Yilmaz[3], Genco Gencdal[4], Kamil Yalçin Polat[5], Figen Özçay[6], Mesut Akarsu[7], Tarkan Unek[8], Zeki Karasu[1], Murat Zeytunlu[9], Hale Gokcan Sumer[10], Erdal Birol Bostanci[10], Aysun Caliskan Kartal[11], Deniz Balci[12], Murat Dayangac[13], Dinc Dincer[14], Haydar Adanir[14], Hakan Dursun[15], Murat Taner Gulsen[16], Feyza Gunduz[17], Hatice Yasemin Balaban[18], Gökhan Kabaçam[19], Murat Akyildiz[20], Fulya Günsar[1], Ulus Akarca[1], Ahmet Gurakar[21], Ramazan Idilman[11], Acute Liver Failure and Liver Transplantation Special Interest Group Tasl[22]. *[1]Ege University School of Medicine, Gastroenterology, Izmir, Turkey; [2]Inonu University, Liver Transplant Institute, Gastroenterology, Malatya, Turkey; [3]Inonu University, Liver Transplant Institute, General Surgery, Malatya, Turkey; [4]Atasehir Memorial Hospital, Liver Transplantation Center, Gastroenterology, Istanbul, Turkey; [5]Atasehir Memorial Hospital, Liver Transplantation Center, General Surgery, Istanbul, Turkey; [6]Baskent University Faculty of Medicine, Pediatric Gastroenterology, Ankara, Turkey; [7]Dokuz Eylul University Faculty of Medicine, Gastroenterology, Izmir, Turkey; [8]Dokuz Eylul University Faculty of Medicine, General Surgery, Izmir, Turkey; [9]Ege University Organ Transplant Research and Training Center, Izmir, Turkey; [10]Ankara City Hospital, Gastroenterology, Ankara, Turkey; [11]Ankara University Faculty of Medicine, Gastroenterology, Ankara, Turkey; [12]Ankara University Faculty of Medicine, General Surgery, Ankara, Turkey; [13]Istanbul Medipol University, General Surgery, Istanbul, Turkey; [14]Akdeniz University Faculty of Medicine, Gastroenterology, Antalya, Turkey; [15]Ataturk University Faculty of Medicine, Gastroenterology, Erzurum, Turkey; [16]Gaziantep University Faculty of Medicine, Gastroenterology, Gaziantep, Turkey; [17]Marmara University Faculty of Medicine, Gastroenterology, Istanbul, Turkey; [18]Hacettepe University Faculty of Medicine, Gastroenterology, Ankara, Turkey; [19]Guven Hospital, Gastroenterology, Ankara, Turkey; [20]Koc University Hospital, Gastroenterology, Istanbul, Turkey; [21]Johns Hopkins University School of Medicine, Gastroenterology and Hepatology, Baltimore, United States; [22]Turkish Association for the Study of the Liver, TASL – Istanbul, Turkey*
Email: ilkerturan@gmail.com.

Background and Aims: The aim of the present study was to evaluate the characteristics of patients with acute liver failure (ALF) who underwent liver transplantation (LT) at 14 centers in Turkey and to determine factors associated with mortality.
Method: Between 2002 and 2019, adult and pediatric patients who have received LT with the diagnosis of ALF were enrolled into the study. Data was transferred into the electronic case report form on the web site of Acute Liver Failure and Liver Transplantation Special Interest Group (SIG) of Turkish Association for the Study of the Liver (TASL). The recipients were followed in the outpatient setting with regular intervals. Physical examination was performed and laboratory tests were obtained.
Results: Among 6944 recipients with LT, 335 patients (5%) were transplanted for ALF: 238 (144 female and 94 male) were adult, and the remaining 97 (45 female and 52 male) were pediatric cases. Mean age of adults was 36.8 ± 13.6 years, whereas it was 7.7 ± 5.4 years for pediatrics. Most common etiologies among adults were: i) viral hepatitis (32.0%, of which, 88.0% were due to acute HBV), ii) indeterminate (27.3%), and iii) drugs/toxins (26.1%, of which 29.0% were mushroom poisoning). Among children, etiologies were: i) indeterminate (37.1%) and ii) drugs/toxins (30.0%). Living-donor liver transplantation (LDLT) was performed among 221 patients (66%), whereas deceased donor liver transplantation (DDLT) was performed in 114 patients (34%). Overall survival was 70% (235/335) with a median (range) follow-up of 110 (0–884) weeks. Survival was better among the patients who underwent LDLT than those of patients who underwent DDLT (mean 675.2 ± 26.3 vs 395.5 ± 36.7 weeks, respectively, p < 0.001). Survival was slightly better in the adult group compared to the pediatric group (568.2 ± 24.1 vs 550.7 ± 50.0 weeks, respectively, p = 0.15). A multiple cox regression analysis showed that patient age at diagnosis, number of days waiting for LT, donor type (DDLT vs LDLT), pre-transplant high sodium level, high MELD and the presence of hepatic encephalopathy (grade II-IV) were associated with mortality.
Conclusion: Based on the early results of the present multicenter study, hepatitis B virus infection is still major cause of liver-related morbidity and mortality in Turkey. Long-term post-transplant survival is favorable in patients with ALF. LDLT may have improved the overall survival among recipients for ALF.

THU175

Expression of microRNA-124 in Kupffer cells modulates liver injury

Jinyu Wang[1], Xueyun Zhang[1], Zhongliang Shen[1], Pu Zhou[1], Xueping Yu[1], Sisi Yang[1], Richeng Mao[1], Mengji Lu[2], Jiming Zhang[1]. *[1]Fudan University Affiliated Huashan Hospital, Department of Infectious Diseases, Shanghai, China; [2]University Hospital of Essen, Institute of Virology, Essen, Germany*
Email: jmzhang@fudan.edu.cn.

Background and Aims: MicroRNA-124 (miR-124) is related to liver injury subjected to chronic hepatitis B (CHB) and hepatitis B virus related acute-on-chronic liver failure (HBV-ACLF). However, the mechanisms of miR-124 regulating liver inflammation are largely unknown. In this study, we tested the hypothesis that miR-124 highly expresses in Kupffer cells and modulates liver inflammation through effects on the interleukin (IL)-6 pathway.
Method: The role of miR-124 in acute liver injury was assessed in Concanavalin A (ConA) induced mice model. Four hepatic nonparenchymal cells were isolated from liver tissues of mice. Expression of IL-6, signal transducer activator of transcription 3 (STAT3), and phosphorylated-STAT3 (p-STAT3) was investigated in Kupffer cells of mice. miR-124 expression was determined in CHB and HBV-ACLF patients, with miRNA array and quantitative real-time PCR. Biological functions of miR-124 were studied using immunohistochemical.

Luciferase reporter assays and Western blots were performed to identify miR-124 targets.
Results: miR-124 expression was significantly elevated in CHB and HBV-ACLF patients and mice with acute liver injury. Besides, miR-124 was highly expressed in Kupffer cells both in human and mice. While IL-6 expression was dramatically decreased by miR-124 overexpressed plasmid injection in mice. Moreover, mRNA levels of STAT3 and protein levels of pSTAT3 were inversely correlated with those of miR-124. miR-124 inhibited IL-6-mediated proinflammatory effects in vitro and liver inflammation in vivo, through a mechanism involving direct targeting of the 3'-untranslated region of STAT3.
Conclusion: Our findings suggest that upregulation of miR-124 relieve liver inflammation through the IL-6/STAT3 pathway.

THU176
Predictors of acute liver failure and death among patients with dengue-induced severe hepatitis

Tongluk Teerasarntipan[1], Roongruedee Chaiteerakij[1], Piyawat Komolmit[1], Sombat Treeprasertsuk[1]. [1]*Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand*
Email: battan5410@gmail.com.

Background and Aims: Liver injury is common however severe hepatitis is rare in dengue viral infection. We aimed to identify prognostic predictors of acute liver failure (ALF) and death of patients with dengue-induced severe hepatitis (DISH).
Method: We retrospectively reviewed 2,311 serology-confirmed adolescent and adult dengue patients who were hospitalized during the 12-year study period (between 2007 and 2019). Patients with DISH [n = 134 (5.80%)], defined as baseline transaminase ≥ 10 times, and DISH with subsequent ALF, defined by the EASL 2017 criteria, [n = 17 (0.74%)] were included. Predictors of ALF and in-hospital death were identified using logistic regression analysis.

Table: Multivariate analysis of factors associated with acute liver failure and death from dengue-induced severe hepatitis

	Acute liver failure			Death		
Factors	Adjusted Odd ratio	95% confidence interval	p-value	Adjusted Odd ratio	95% confidence interval	p-value
INR	2.40	0.37–15.46	0.36	7.03	1.20–41.12	0.031
Albumin	0.48	0.11–2.13	0.34	0.35	0.07–1.81	0.21
Creatinine	0.81	0.42–1.57	0.53	1.20	0.63–2.27	0.58
MELD score	1.23	1.01–1.49	0.039	0.96	0.79–1.17	0.70
Presence of liver co-morbidities	0.59	0.06–5.45	0.64	0.21	0.01–4.51	0.32

Results: Of the 151 patients, 53% were female, with a median age of 23 years. Capillary leakage syndrome (CLS) occurred in 64.2% of DISH and 100% of ALF patients. The mortality rate was low in DISH (0.7%), but was remarkably high if ALF developed (58.5%). By univariate analysis, age, sex, hematocrit, white blood count, atypical lymphocyte count, platelet count, INR, SGOT, SGPT, ALP, albumin, creatinine, MELD score, alcohol consumption, presence of liver co-morbidity and presence of CLS, were identified as potential prognostic parameters for ALF or death. By multivariate analysis (Table), MELD score was the only factor that remained associated with ALF with adjusted odd ratio (AOR) of 1.23 (95% confidence interval (CI) 1.01–1.49), p = 0.039. Regarding mortality prediction, the deterioration of liver function to ALF was the most significant factor related to death in DISH patients (AOR 394.00, 95%CI 4.01–38845.94, p = 0.011). Other independent factors associated with death included baseline INR (AOR 7.03, 95%CI 1.20–41.12, p = 0.031). INR ≥ 1.5 predicted death from DISH with AUROC of 0.832, 81.8% sensitivity and 86.8% specificity.
Conclusion: High MELD score was the best predictor of ALF in dengue viral infection. The presence of ALF was the major risk of death from DISH.

THU177
Clinical and radiological features for early identification of malignancy induced acute liver failure

Liane Rabinowich[1], Pablo Solis-Munoz[1], Praveen Peddu[2], Pauline Kane[2], Georg Auzinger[3], Julia Wendon[3], William Bernal[3]. [1]*Kings College Hospital, Institute of Liver Studies, London, United Kingdom;* [2]*Kings College Hospital, Department of Radiology, London, United Kingdom;* [3]*Kings College Hospital, Liver Intensive Therapy Unit, London, United Kingdom*
Email: liane.rabinowich@gmail.com.

Background and Aims: Acute Liver failure (ALF) caused by malignant infiltration (ALF-M) as the first presentation of a neoplastic disease is an extremely rare cause of ALF. It is crucial to reach a correct diagnosis for consideration of appropriate treatment and to avoid liver transplantation (LT). We sought to identify features enabling earlier diagnosis of ALF-M in patients with ALF without a clear initial cause.
Method: Analysis of clinical, laboratory and radiologic features of patients presenting to King's College Hospital with ALF-M between 1999–2019 compared to patients with LF of indeterminate cause (ALF-I). All patients had liver imaging with a CT scan, US or both. For patients with available CT scans, observed and predicted liver volume (LV) was determined.
Results: Of the 35 ALF-M patients, 51% were male with median age 54 years (range 19–73). Among 50 patients presenting with ALF-I, 32% were male with median age was 46 years (range 20–70, p = 0.04). Hematological malignancies were diagnosed in 63% of ALF-M, most commonly lymphoma (68%). Among those with solid malignancy, 58% were poorly differentiated adenocarcinoma. ALF-M diagnosis was made post-mortem in 31%, one patient with ALF-M underwent LT and was diagnosed on explant. In both groups the most common presentations were jaundice (65%) and abdominal pain (35%). Nausea, vomiting and pruritus were more common among patients with ALF-I; fever, weight loss and night sweats were more frequent with ALF-M. Mortality in ALF-M patients was 91% vs. 22% in ALF-I (p < 0.001), with median interval from admission to death 7 days (range 1–70). In patients with ALF-M median predicted LV was 1591 cm^3 and 88% of the patients had a larger then expected LV. Observed LV was 2331 cm^3 (range 1132–6347 cm^3), 149% of expected (range 71–411%); in comparison to the ALF-I group where liver volume was reduced with median LV of 1112 cm^3 (range 445–2910 cm^3, p = 0.001), 70% of predicted LV (range 28–260%, p < 0.001). ALF-M patients also had higher Alkaline-phosphatase, CRP (P < 0.001), ferritin (P < 0.05) and Lactate Dehydrogenase (P < 0.01) levels. On multivariate logistic regression, LV remained an independent predictor of ALF-M over ALF-I (P < 0.001).
Conclusion: ALF-M may be differentiated from indeterminate disease by clinical features of age, gender and systemic symptoms. It has characteristic laboratory findings and is strongly associated with hepatic enlargement.

THU178
Deletion of XBP1 in liver parenchymal cells ameliorates acetaminophen (APAP)-induced hepatotoxicity via activation of IRE1alpha-JNK1-ATG5-dependent autophagy

Hui Ye[1,2], Kang Zheng[1,2], Yulia Nevzorova[2,3,4], Beatriz Martin[1,2], Leonard J Nelson[5], Manuel Gómez del Moral[6], Iris Asensio[7,8,9], Javier Vaquero[7,8,9], Rafael Bañares[7,8,9], Eduardo Martínez-Naves[1,2], Francisco Javier Cubero[1,2]. Email: fcubero@ucm.es.

Background and Aims: Drug-induced liver injury (DILI) is a leading cause of acute liver injury, including acetaminophen (APAP) overdose. APAP-mediated hepatotoxicity induces the unfolded protein response (UPR), a signalling cascade that triggers endoplasmic reticulum (ER) stress and splicing of the X-binding protein 1 (Xbp1). However, the mechanisms underlying ER stress remains poorly understood, thus dampening the chances of pharmacologic therapy for DILI patients.
Method: Mice harboring a conditional floxed allele of Xbp1 ($Xbp1^{f/f}$) were crossed with Alb-Cre expressing strain to obtain a liver specific knockout of Xbp1 ($Xbp1^{\Delta hepa}$). For these experiments, fasting male mice aged 10–12 weeks, were challenged with APAP (500 mg/kg, i.p.). APAP was first dissolved in DMSO and then diluted into 50 mg/ml (final concentration of DMSO was 0.09%). Control mice received an equivalent volume of PBS with DMSO. Mice were sacrificed 0–48 h later and tissues collected. Histopathological examination of livers, immunofluorescence (IF) and immunohistochemistry (IHC), Western blot, Real Time (RT)-qPCR studies and transmission electron microscopy (TEM) were performed.
Results: Mice with deletion of Xbp1 in liver parenchymal cells (LPC) showed significantly less mortality to APAP than floxed littermates. Twenty-four hours later, $Xbp1^{\Delta hepa}$ animals displayed a significant dramatic decrease in serum ALT, AST and LDH levels in response to 500 mg/kg of APAP, compared with $Xbp1^{f/f}$ mice. Concomitantly, reduced necrotic foci in the liver parenchyma, TUNEL-detected hepatocyte death and maintenance of hepatocyte polarity – evaluated with ZO-1 IF - was characteristic of $Xbp1^{\Delta hepa}$ animals. Less hepatic lipid accumulation evidenced by Oil Red O (ORO) staining alongside triglyceride and cholesterol levels were dramatically reduced in livers of $Xbp1^{\Delta hepa}$ mice. Transcription of CYP2E1 was drastically diminished in $Xbp1^{\Delta hepa}$ mice, associated with significantly lower oxidative stress (e.g.: 4-HNE and DHE). Next, we investigated the UPR in these conditions. Increased mRNA and protein expression of pIREα, associated with decreased BIP, CHOP were observed in $Xbp1^{\Delta hepa}$ group. TEM analysis showed abundance of lipid bodies and autophagosomes in $Xbp1^{\Delta hepa}$ animals. Interestingly, ablation of Xbp1 in LPC triggered JNK1 and ATG5 overexpression, and downregulation of p62.
Conclusion: Our study overall demonstrated that Xbp1 deficiency in LPC ameliorates APAP-derived DILI via activation of autophagy in an IRE1α-JNK1-ATG5-dependent mechanism. This novel finding provides the basis for therapies targeting the restoration of LPC function after acute liver injury.

THU179

Larazotide acetate reduces the frequency of bacterial translocation in the thioacetamide-induced liver failure in rats

Ali Riza Caliskan[1], Muhsin Murat Harputluoglu[1], Baris Otlu[2], Mehmet Gul[3], Elif Ozerol[4], Nuray Uremis[4], Ramazan Dertli[5], Murat Aladag[1], Ulvi Demirel[6], Jay Madan[7], Balasinghman Radhakrishnan[7]. *[1]Inonu University Medical Faculty, Gastroenterology, Malatya, Turkey; [2]Inonu University Medical Faculty, Microbiology, Malatya, Turkey; [3]Inonu University Medical Faculty, Histology, Malatya, Turkey; [4]Inonu University Medical Faculty, Biochemistry, Malatya, Turkey; [5]Van Education and Research Hospital, Gastroenterology, Van, Turkey; [6]Firat University Medical Faculty, Gastroenterology, Elazig, Turkey; [7]Innovate Biopharmaceutical, Inc, Raleigh, United States*
Email: murat.harputluoglu@inonu.edu.tr.

Background and Aims: Increased mucosal permeability is one of the possible mechanisms that could increase bacterial translocation (BT) in liver failure. Intestinal epithelial barrier function relies on tight junction proteins, such as occludin and Z0–1, which may be regulated in part by endogenous zonulin release. Larazotide acetate (LA) (Innovate Biopharmaceuticals, Inc., Raleigh, NC, USA) is a synthetic octapeptide that reduces tight junction permeability by blocking zonulin receptors, although other mechanisms are being explored. Presently, LA is being studied in Phase 3 clinical trials for treatment of Celiac disease. In this study, we aimed to investigate the effect of LA on BT in a thioacetamide-induced liver failure model in rats.
Method: A total of 48 rats were divided 6 groups (n = 8 rats/group) as follows: Group I (Control), 0.1 ml i.p. 0.9% NaCl for 7 days; Group II (TAA), 300 mg/kg/day i.p. thioacetamide (TAA) every 24 h for 3 days; Group III (TAA + LA), 300 mg/kg/day i.p. TAA 3 days + 0.01 mg /ml LA in the drinking water for 7 days, initiated before the first dose of TAA; Group IV (LA): LA in the drinking water for 7 days with no TAA treatment; Group V (TAA + gavaged LA): 300 mg/kg/day i.p. TAA for 3 days + gavaged LA (300 μl of 0.1 mg/ml) twice a day for 7 days initiated before the first dose of TAA; Group VI (gavaged LA): Gavaged LA twice a day for 7 days (300 μl of 0.1 mg/ml). BT was defined as positive bacterial cultures from mesenteric lymph nodes, liver, or spleen samples. Liver and intestine samples were taken for histopathological examination.
Results: Significant intestinal and liver damage was observed in the TAA group when compared with control, LA-drinking water, and LA-gavaged groups. Serum AST, ALT and ammonia levels in the TAA group were significantly higher than those in the other groups. The frequency of BT in the TAA+LA-drinking water group was significantly lower than in the TAA group (28.5% and 62.5%, respectively, $p < 0.05$). Intestinal damage scores in the TAA+LA-drinking water was lower than in the TAA group ($p < 0.05$). In the TAA + LA-drinking water and TAA + LA-gavage groups, close apposition between the villus epithelial cells in the region of the tight junctions was observed.
Conclusion: Our results suggest that Larazotide reduces the frequency of bacterial translocation by reducing intestinal barrier breakdown as compared to the TAA-induced liver failure rats in the absence of LA. These studies reveal a potential therapeutic benefit of LA for important liver diseases such as NASH and NAFLD.

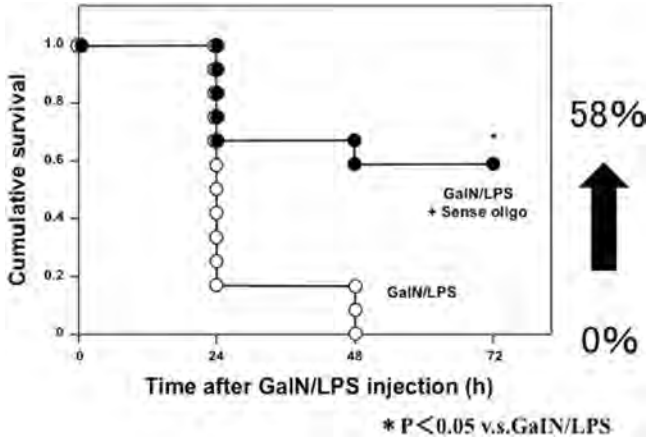
THU180

The protective effects of a sense oligonucleotide drug targeting inducible nitric oxide synthase for a rat model of acute liver injury

Richi Nakatake[1,2], Tetsuya Okuyama[3], Masaki Kaibori[1], Tadayoshi Okumura[1,4], Mitsugu Sekimoto[1], René Tolba[2], Mikio Nishizawa[3]. *[1]Kansai Medical University, Department of Surgery, Osaka, Japan; [2]RWTH-Aachen University, Institute for Laboratory Animal Science and Experimental Surgery, Aachen, Germany; [3] Ritsumeikan University, Department of Biomedical Sciences, College of Life Sciences, Shiga, Japan; [4]Ritsumeikan University, Research Organization of Science and Technology, Shiga, Japan*
Email: nakatakr@hirakata.kmu.ac.jp.

Background and Aims: From rat, mouse, and human genes that encode inducible nitric oxide synthase (iNOS), natural antisense transcripts (asRNAs) that do not encode proteins are transcribed. iNOS catalyzes the production of the inflammatory mediator nitric oxide (NO), which is excessively produced in hepatocytes and macrophages in septic shock. The iNOS asRNA stabilizes iNOS mRNA by interacting with the iNOS mRNA. We found that single-stranded sense oligonucleotides corresponding to the sequence of iNOS mRNA decreased iNOS mRNA levels by interfering with the mRNA-asRNA interactions in hepatocytes. The iNOS sense oligonucleotides that were substituted with locked nucleic acids and phosphorothioate bonds and efficiently reduced the levels of iNOS

mRNA and iNOS protein. Here, we investigated in vivo effects of the iNOS sense oligonucleotides in acute liver injury model rats.
Method: Each iNOS sense oligonucleotide (SO1 or its derivatives) was introduced into primary cultured rat hepatocytes, and the expression levels of iNOS mRNA were measured in the presence of interleukin 1beta and compared to the cells transfected with control DNA. A sepsis model was prepared by the administration of D-galactosamine (GalN) and bacterial lipopolysaccharide (LPS) with or without the injection of an iNOS sense oligonucleotide to rats. Survival of the treated rats was recorded by 72 h after GalN/LPS injection, and the expression of iNOS and cytokine mRNAs in the liver were analyzed. Liver tissues of the treated rats were pathologically examined.
Results: Among prepared iNOS sense oligonucleotides, which include chemically modified derivatives, SO1 was the most effective oligonucleotide for decreasing expression level of iNOS mRNA in rat hepatocytes. When SO1 was simultaneously administered with GalN and LPS to rats (GalN/LPS+SO1 group), their survival rate was markedly increased (58%) compared to the rats administered with GalN and LPS alone (GalN/LPS group)(Fig). The expression of the iNOS and TNF-alpha mRNAs was decreased, and the number of apoptotic hepatocytes were also significantly suppressed in the livers of GalN/LPS+SO1 group compared to that of GalN/LPS group.



Conclusion: Administration of an iNOS sense oligonucleotide inhibited the induction of iNOS and TNF-α in sepsis model rats and showed hepatoprotective effects by the improvement of the pathological findings in the liver. These data imply that natural antisense transcript-targeted regulation (NATRE) technology using the iNOS sense oligonucleotide may be applied to treat human sepsis with acute hepatic failure.

THU181
Hasi-iquest: investigating viral etiologies of acute liver failure of unknown cause

Nicolas Gille[1], Anne Marie Roque-Afonso[1], Mylène Sebagh[1], Celine Piedvache[1], Helene Agostini[1], Jean-Charles Duclos-Vallée[1], Didier Samuel[1], Audrey Coilly[1]. [1]*Hôpital Paul-Brousse Ap-Hp, Villejuif, France*
Email: nicolasgille.78@gmail.com.

Background and Aims: In France, 18% of acute liver failure (ALF) are of unknown cause (ALFUC). Some ALFUC could be due to non-tested viruses. Furthermore, other ubiquitous viruses, such as EBV and TTV, whose viral loads change with immunosuppression state, could impact patients' prognosis. The main objective of our study was to describe the virological screening performed at admission for ALF in France. We also aimed to search for viral causes which had not been previously found, to describe patients' characteristics, to determine prognostic factors and to evaluate the prognostic role of ubiquitous viruses.

Method: HASIPRO is a national prospective cohort studying ALFUC. Between 2013 and 2016, 70 patients with ALFUC from 15 centers were included. Inclusion criteria were: age ≥ 18 years, severe ALF defined by INR>1.5, absence of identified cause at admission or chronic liver disease. Viral tests were performed via real-time PCR and serologies on a biobank. A blind histological review was completed to evaluate the probability of a viral cause, according to the presence of histological lesions compatible with a viral hepatitis.
Results: Hepatotropic viruses (HAV, HBV, HCV, HEV) were investigated in more than 90% of cases, versus only 19% to 69% for non-hepatotropic viruses (Table 1). Viral screening methods were heterogenous and did not follow EASL guidelines: HSV-1 and HSV-2 were investigated both via PCR and serology in only 25% of patients. Six ALFUC cases (8.5%) were reconsidered viral (HEV, n = 3; dengue, n = 1; Parvovirus B19, n = 2). Among them, one died (17%) and another one underwent liver transplantation (17%). Their characteristics were not different from those with non-viral ALFUC.

Table 1: Percentage of methods used to detect viruses in 70 patients with ALFUC

	PCR	IgM	IgG	Other method
HBV	36	94		100
HAV	3	**99**		
HCV	44	**99**		
HEV	46	**90**		
CMV	**69**	73	91	
HSV-1	**57**	54	63	
HSV-2	**56**	49	57	
EBV	**49**	79	89	
HHV-6	**40**	14	14	
VZV	**26**	36	46	
Parvovirus B19	**19**	33	34	
Rubella	**1**	6	11	

In bold: baseline diagnostic method.

The probability of a viral cause based on histological review was considered "Possible" in 14 cases (56%) on liver biopsies and 15 cases (75%) on explanted liver samples. Necrosis percentage ($p = 1.0$) and fibrosis score ($p = 0.77$) were not prognostic factors of mortality or liver transplantation.
Ubiquitous viruses EBV and TTV were detected in 49% and 78% of cases respectively but were not prognostic factors of mortality or liver transplantation ($p = 0.06$ and $p = 0.97$).
Conclusion: This is the first study to prospectively search for a viral cause in patients with ALFUC. Even though cases of ALFUC later reclassified as viral are rare (8.5% of patients), the viral investigations conducted in French centers are heterogenous and do not fully respect international guidelines. Liver biopsies do not provide supplementary information when a viral cause is suspected. Ubiquitous viruses do not seem to play a prognostic role in patients with ALFUC.

THU182
Poly(adp-ribose) polymerase plays a critical role in oxidative stress- and hypoxia/reoxygenation-induced programmed cell death in mouse liver cells

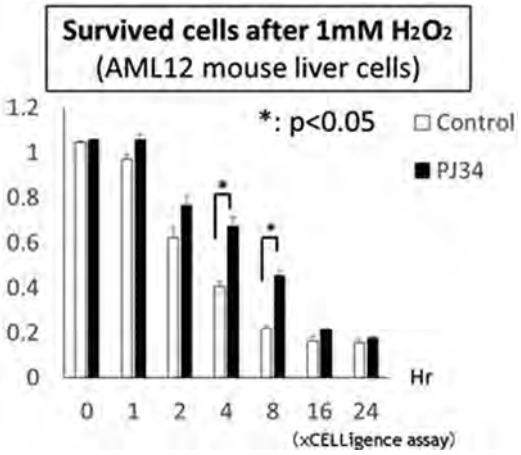
Michitaka Ozaki[1], Sanae Haga[1], Mami Asano[1], Naoki Morita[2]. [1]*Hokkaido University, Faculty of Health Sciences, Sapporo, Japan;* [2]*National Institute of Advanced Industrial Science and Technology (AIST), Bioproduction Research Institute, Sapporo, Japan*
Email: ozaki-m@med.hokudai.ac.jp

Background and Aims: Ischemia/reperfusion (I/R) of liver is an unavoidable event in liver surgery and transplantation, which sometimes causes serious post-operative liver failure, leading to life-threatening complications. The mechanism of I/R-induced liver injury, however, seems to be complicated so that we have not elucidated yet. Recently, various types of programmed cell death have been newly reported, including ferroptosis, necroptosis, pyroptosis,

and parthanatos. In the present study, we investigated the roles of PARP [Poly(ADP-ribose) polymerase] on oxidative stress- and hypoxia/reoxygenation (H/R)-induced programmed cell death in AML12 mouse liver cells.

Method: The mouse liver cells (AML12) were used for the experiments. AML12 cells were cultured in high-glucose DMEM supplemented with 10% FBS. H2O2 were administered directly to the culture medium for oxidative stress. Cellular hypoxic conditions were created and maintained in a chamber by flushing with a 95% N2/5% CO2 gas mixture for 10 min and then sealing the chamber. Following 6 h of hypoxia, AML12 cells were reoxygenated by opening the chamber and replacing the hypoxic medium with oxygenated medium. Protein and gene expressions were measured by western blot analysis/capillary-based immunoassay and RT-PCR, respectively. Cell survival and death were determined by plating the cells in the xCELLigence System (Roche) and the LDH release from hepatocytes into culture medium.

Results: H/R-induced cell death was inhibited significantly by PJ34, a specific inhibitor of PARP. Because an oxidative stress is one of the major causes of H/R-induced cell death, we challenged 1 mM H2O2 to AML12 liver cells. H2O2 induced cell death, PAR [Poly(ADP-ribose)] production and nuclear translocation of AIF (apoptosis inducing factor), which were suppressed significantly by the pre-treatment of PJ34 (Figure). H2O2 also induced Receptor-Interacting Protein (RIP)1/RIP3 binding, which indicates the involvement of necroptosis in H2O2-induced cell death. Interestingly, H2O2-induced RIP1/RIP3 binding was also inhibited by PJ34. These facts indicate that H/R and oxidative stress potentially induce parthanatos and necroptosis in hepatocytes.



Conclusion: PARP is potentially involved in H/R- and oxidative stress-induced cell death in mouse liver cells, by inducing parthanatos and necroptosis.

THU183

Investigation into the cut-off point for chronicity of drug-induced liver injury through metabolomic profiling

Jia-bo Wang[1], Lu-ge Wei[1], Yue-Cheng Yu[2], Xiao-He Xiao[1], Zhengsheng Zou[1]. [1]*Fifth Medical Center of Chinese PLA General Hospital, Institute of Chinese Medicine & Institute of Integrative Medical*

Research, Beijing, China; [2]General Hospital of Eastern Theater Command, Liver Diseases Center, Nanjing, China
Email: pharm_sci@126.com

Background and Aims: Chronicity is an unsolved problem and a challenge in the field of drug-induced liver injury (DILI). Since there are discrepancies in the cut-off point for the definition of chronicity in DILI, it inevitably leads to incomparability among different studies.
Method: In this study, we divided the involved DILI cases into Group 1 (0~6 months), Group 2 (6~12 months) and Group 3 (>12 months) based on the duration of liver injury, and then performed high-resolution mass spectrometry-based serum metabolomic profiling. All of the differential metabolites with statistical significance within every two groups were selected as the potential biomarkers of duration-related characteristics.
Results: By using these 2,554 characteristic metabolites, the unsupervised principal component analysis represented a two-cluster pattern of the aforementioned three groups with 6 months as a rough separatrix. The following linear discrimination analysis showed that the cut-off point at 6 months was better than that at 12 months. The cut-off of 6 months was then validated independently in the prospective cohort at an external center.

Conclusion: Taken together, our results provided the first experimental evidence to support the duration of 6 months as the rational cut-off point in defining chronicity in DILI.

THU184

Hepatic steatosis predicts fibrosis in long-term methotrexate use

Marcel Tomaszewski[1], Monica Dahiya[2], Amir Mohajerani[1], Hin Hln Ko[1], Hanaa Punja[3], Alnoor Ramji[2]. *[1]UBC, Gastrointestinal Research Institute, Vancouver, Canada; [2]UBC, Vancouver, Canada; [3]UBC, GIRI, Vancouver, Canada*
Email: marcel.a.tomaszewski@gmail.com

Background and Aims: Methotrexate (MTX) is effective for dermatologic and rheumatologic conditions such as psoriasis (Ps), psoriatic arthritis (PsO) and rheumatoid arthritis (RA). Long-term MTX use may be complicated by hepatic fibrosis, although patient, disease factors and the mechanism remain unclear. Transient elastography (TE) is a non-invasive measure of hepatic fibrosis that is often used as surveillance in this patient population.
Patients with Ps and PsO have higher rates of non-alcoholic fatty liver disease. The controlled attenuation parameter (CAP) measurement is a non-invasive test that correlates with histologic degree of steatosis. To our knowledge, no studies have evaluated hepatic steatosis via CAP scores in MTX use.
The aim was to determine the prevalence of hepatic steatosis and predictors of hepatic steatosis and fibrosis in persons on MTX.
Method: A single centred retrospective cohort study was performed. Patients on >6 months of MTX for a dermatologic or rheumatologic disease who had undergone TE from January 2015 to September 2019 were included. Demographic variables, laboratory investigations, TE and CAP scores were collected. Multivariate analysis was performed to determine predictors of steatosis and fibrosis.
Results: A total of 177 patients on methotrexate were included. Ps was the most frequent diagnosis (n = 52) followed by RA (n = 50) and PsO (n = 38). Steatosis (CAP>245 dB/m) was present in 73.9% of patients. Patients with steatosis had significantly more fibrosis and a higher BMI than those without steatosis (CAP < 245 dB/m). Higher CAP score was correlated with increased lifetime dose of methotrexate by Pearson correlation analysis (r = 0.48, p = 0.001) (n = 85 patients). Multivariate regression analysis revealed that diabetes mellitus (OR 10.5, 95% CI 1.38–80.60), hypertension (OR 4.97, 95% CI 1.66–14.84), and BMI>30 (OR 10.1, 95% CI 1.88–37.14) were predictors of steatosis (CAP>245 dB/m). Predictors of METAVIR>F2 (TE>8.0 kPa) by multivariate regression analysis included CAP score of >270 (OR 8.36, 95% CI 1.88–37.14), diabetes mellitus (OR 2.85, 95% CI 1.09–7.48), hypertension (OR 5.4, 95% CI 2.23–13.0), dyslipidemia (OR 3.71, 95% CI 1.50–9.18) and alcohol use (OR 3.06, 95% CI 1.2–7.49).
Conclusion: In patients on MTX for rheumatologic and dermatologic diseases, hepatic steatosis was prevalent and predicted higher grades of fibrosis. Additionally, increasing MTX exposure is correlated with steatosis. Features of the metabolic syndrome including diabetes, hypertension and obesity were predictors of both steatosis and fibrosis. Further study is needed to evaluate if steatosis is a mechanism by which fibrosis occurs in patients on MTX, or if it due to other patient factors.

Email: rrodriguez@cicbiogune.es

Background and Aims: The liver has a major role in maintaining homeostasis and is in charge of xenobiotic metabolism. Acetaminophen (paracetamol or APAP) is commonly used to treat pain and fever worldwide. Its overdose is the most common cause of Drug-Induced Liver Injury (DILI) and Acute Liver Failure (ALI) in the United States and in the majority of Europe, being Acetylcysteine (NAC) the standard treatment for acetaminophen overdose. However, its use is limited, as NAC is effective at 8 h after ingestion, so alternative approaches are needed. It is known that Glycine N-methyltransferase (GNMT) expression is reduced in different liver diseases. It is known that GNMT, the main enzyme implicated in S-adenosylmethionine catabolism in the liver, is reduced in different liver diseases. Further, we have recently identified that miR-873-5p mediated repression of GNMT compromises hepatocyte and mitochondrial functionality. The aim of this work is to study the implication and potential therapeutic targeting of miR-873-5p/GNMT axis in APAP-induced liver injury.
Method: Analysis of miR-873-5p was performed in human serums from patients with different DILI scores (n = 40). Primary hepatocytes were transfected with anti-miR-873-5p or anti-miR-Control and the response was evaluated 1, 3 and 6 hours after APAP administration (10%). Besides, C57BL/6J mice were exposed to 300 mg/kg APAP and treated with anti-miR-873-5p (60 µg/mice) or anti-miR-Control (60 µg/mice) at 6 (n = 5) and 24 hours (n = 5) after APAP overdose. Mice were sacrificed after 48 h of APAP administration.
Results: The protective role of anti-miR-873-5p in DILI has been characterised, both *in vivo* and *in vitro*, via methionine and polyamine cycles refeeding. Higher levels of miR-873-5p were detected in serum samples from DILI patients. Anti-miR-873-5p treated mice showed significantly reduced levels of liver transaminases and ROS, increased GSH/GSSG and decreased concentration of TNF in serum in the 24h-group. The metabolomic analysis of liver tissue revealed higher levels of spermidine in anti-miR-873-5p treated mice (24 h-group).

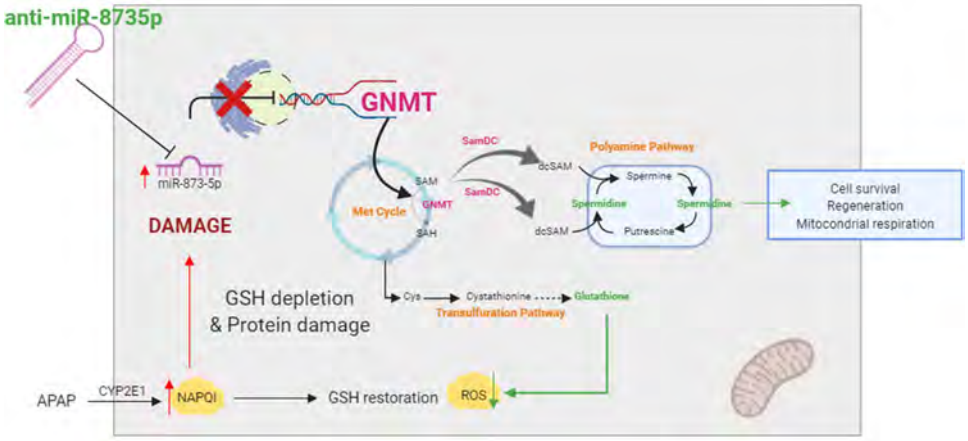

Figure: (abstract: THU185)

Spermidine levels correlate with enhanced mitochondrial functionality, respiration and regeneration via GSK3β/β-catenin/cyclin-D1 pathway. ATP and mitochondrial respiration were also significantly higher in hepatocytes with anti-miR-873-5p (at 1 h).
Conclusion: During APAP-induced liver injury, GNMT expression is downregulated by miR-873-5p. The present study showed that 1- miR-873-5p could be a potential biomarker in DILI and 2- anti-miR-873-5p could be a suitable therapeutic agent as protects the mitochondria, reduces inflammation and induces liver regeneration by restoring GNMT levels. Overall, anti-miR-873-5p treatment prevents APAP-induced liver injury, even long time after the overdose, then, 3- this therapy could be an alternative at times in which NAC is not efficient.

THU186

A novel HER2-targeted liposomal formulation for reducing the risk of liposome-induced hepatotoxicity

Sara De Martin[1], Samantha Sarcognato[2], Daniela Gabbia[1], Elena Canato[1], Martina Colognesi[1], Nora Cazzagon[3], Maria Guido[2], Gianfranco Pasut[1]. Email: sara.demartin@unipd.it

Background and Aims: Stealth immunoliposomes (SILs) are nanosystems obtained by conjugating monoclonal antibodies or antibody fragments to fractions of poly-ethylene-glycol (PEG)-phospholipids present in stealth liposomes. It has been shown that these nanosized materials can accumulate into the liver, causing drug-induced liver injury. The aim is to improve the pharmacokinetic and toxicological profile of encapsulated drugs and permit targeted therapy.
Method: We evaluated the pharmacokinetics and hepatotoxicity of two HER2-targeted SILs obtained by conjugating trastuzumab Fab' with classic PEG-phospholipids (SIL) or with a novel mPEG-branching-(phospholipid)$_2$ ($SSIL_2$). Both formulations were loaded with doxorubicin. 2.5 mg/kg of doxorubicin equiv. SIL or $SSIL_2$ was administered via caudal vein to Sprague-Dawley rats (n = 6 per group). Vehicle-administered rats were used as controls. Rats were sacrificed 48 hours after treatment. Hepatotoxicity was assessed by 1) standard histological analysis (H&E) performed on liver sections; 2) full blood count and plasma liver function tests; 3) hepatic mRNA level for IL-1β, TNF-α, IL-10, CCL2 and CXCL2; 3) reactive oxygen species (ROS) production in liver tissue. Data were compared by one-way ANOVA followed by Tukey *post-hoc* test.
Results: $SSIL_2$ showed an improved pharmacokinetic profile compared to SIL, since elimination half-life increased ($p < 0.05$), while systemic clearance of doxorubicin tended to drop. SIL caused hepatotoxicity, as indicated by the decrease of plasma albumin ($p < 0.05$ *vs* controls), the presence of several hepatic granulomatous lesions, granulocytes, and macrophages, and confirmed by increased hepatic CXCL2 and IL-10 mRNA levels ($p < 0.001$ *vs* controls). Accordingly, IL-1β and TNF-α mRNA expression and ROS concentration increased significantly ($p < 0.001$) in these rats. At variance, histological analysis revealed only few isolated granulomas in $SSIL_2$-treated animals, and the other parameters were similar to those of controls. Immunohistochemical staining for α-SMA excluded the presence of fibrosis in all rats.
Conclusion: The conjugation of SILs with mPEG-branching-(phospholipid)$_2$ represents an effective strategy to improve the pharmacokinetic profile of drugs and prevent the hepatoxicity associated to PEG-derived nanosystems, thus improving the efficacy and tolerability of innovative cancer therapy.

THU187

Combination of sivelestat and n-acetylcysteine alleviates the inflammatory response and exceeds standard treatment for acetaminophen-induced liver injury

Sarah Raevens[1], Sanne Van Campenhout[1], Pieter-Jan De Backer[1], Sander Lefere[1], Xavier Verhelst[1], Anja Geerts[1], Hans Van Vlierberghe[1], Isabelle Colle[1], Lindsey Devisscher[1,2]. [1]*Ghent University, Gastroenterology and Hepatology, Gent, Belgium;* [2]*Ghent University, Basic and Applied Medical Sciences, Gut-Liver Immunopharmacology Unit, Gent, Belgium*
Email: sarah.raevens@ugent.be

Background and Aims: Hepatocyte death during acetaminophen (APAP) intoxication elicits a reactive inflammatory response, with hepatic recruitment of neutrophils and monocytes, which further aggravates liver injury. Neutrophil elastase (NE), secreted by activated neutrophils, has degradative and cytotoxic functions and sustains a pro-inflammatory state. We investigated NE as a therapeutic target in APAP-induced liver injury.
Method: C57BL/6 mice were administered a toxic dose of APAP (300 mg/kg intraperitoneally (IP)), 2 hours prior to receiving the NE inhibitor sivelestat (150 mg/kg IP), N-acetylcysteine (NAC, 200 mg/kg IP) or a combination therapy, and were euthanized after 24 and 48 hours. Serum and liver tissue were harvested for analyses. In additional *in vitro* experiments, the chemotactic properties of NE were evaluated using peripheral blood mononuclear cells (PBMCs).
Results: Upon APAP overdose, life $CD45^+CD11b^+Ly6C^{int}Ly6G^+$ neutrophils and life $CD45+Ly6G^-$ $CD11b^+Ly6C^{hi}Tim4^-$ monocytes

infiltrated the injured liver, accompanied by increased levels of NE (p = 0.0006 versus control mice, ELISA). Combination therapy of NAC and sivelestat significantly limited liver damage, as evidenced by lower serum transaminase levels and less hepatic necrosis compared to APAP-overdosed mice without treatment, and this to a greater extent than NAC monotherapy. Only the combination of NAC and sivelestat was able to reduce the expression of hepatic pro-inflammatory markers and liver monocyte infiltration in APAP overdosed mice. Indeed, additional *in vitro* experiments confirmed the chemotactic activity of NE. Importantly, sivelestat did not impair hepatic repair in APAP-intoxicated mice as transaminase levels and hepatic necrosis were decreased at 48 hours compared to 24 hours post APAP overdose in sivelestat-treated mice.

Conclusion: Combination of NE inhibition, by using sivelestat, together with NAC dampens the inflammatory response and reduces liver damage following APAP overdose. This strategy exceeds the standard of care and might represent a novel therapeutic option for APAP-induced acute liver injury.

THU188

GSDMD inhibitor necrosulfonamide protects mice from galactosamine/lipopolysaccharide-induced acute liver failure via pyrotosis pathway

Yi-Long Wu[1], Weijie Ou[1], Su Lin[1], Mingfang Wang[1], Jiaofeng Huang[1], Yueyong Zhu[1]. [1]*The First Affiliated Hopital of Fujian Medical University, Liver Research Center, Fuzhou*
Email: sumer5129@163.com

Background and Aims: Acute liver failure (ALF) is a critical disease characterized by severe liver dysfunction and high mortality. There is no specific cure for ALF so far. Pyroptosis, with Gasdermin-D (GSDMD) being the executioner, is involved in the pathophysiological process of immune dysregulation in ALF. Necrosulfonamide (NSA) is a direct inhibitor of GSDMD and has been demonstrated to alleviate sepsis and monosodium urate crystal-induced cell death. The aim of this study was to examine the potential therapeutic role of NSA in ALF.

Method: ALF model was established by lipopolysaccharide/D-galactosamine (LPS/D-GalN) challenged in C57BL/6 mice. A dose of 20 mg/kg NSA was intraperitoneally injected 0.5 h before LPS/D-GalN challenged. The survival rate was monitored every 30 min for 24 h. Liver damage was determined by hematoxylin and eosin (HE) and serum alanine aminotransferase (ALT). Possible mechanisms involved were explored by quantitative real-time PCR, western blot and enzyme-linked immunosorbent assay (ELISA).

Results: Mice in ALF group all died within 10 h. The prognosis of mice treated with NSA was greatly improved with a 24h-survival rate of 60% (p = 0.0001, Fig. A). The liver injury features in histology, including hepatic structure collapse, hepatocytes necrosis, coagulation necrosis and inflammation, were attenuated in NSA treatment group (Fig. B, C). ALT level was significant decreased in NSA treatment group compared with ALF group (232.0 vs. 468.3; p < 0.001, Fig. D). The mRNA levels of the upstream molecules of GSDMD, including caspase-1 and caspase-11, increased in ALF group while significantly decreased after NSA pretreatment (Fig. E, F). IL-1β gene expression decreased after NSA treatment compared with ALF group (Fig. G). The protein level of GSDMD, as well as NLRP3, cleaved caspase-1, cleaved caspase-11, and IL-1β was higher in ALF than control, and significantly decreased after NSA pretreatment (Fig. H). Serum IL-1β level examined by ELISA was significant decreased in NSA treatment group compared with ALF group (55.63 vs. 110.9; p < 0.01, Fig. I).

Conclusion: Pyroptosis is activated in LPS/D-GalN induced ALF. NSA might alleviate ALF via pyroptosis pathway.

Administration of lactobacillus alleviates experimental NASH by reducing miR-21 in the liver

André A. Santos[1], Marta B. Afonso[1], André Simão[1], Rui E. Castro[1], Cecília M. P Rodrigues[1]. [1]*Research Institute for Medicine (iMed. ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, Portugal, Lisbon- Portugal*
Email: afasantos@ff.ulisboa.pt

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a widely spread disease mostly associated to the Westernized diet, rich in fat and sugar with strong impact on gut microbiota. The dysbiotic effect contributes to liver disease onset and progression. Recent advances in the study of gut-liver axis have exposed the importance of gut microbiota modulation through the use of probiotics for the treatment of NAFLD. Particularly, *Lactobacillus* species improved liver disease in experimental NALFD. We have shown that miR-21KO mice are protected from gut dysbiosis and liver disease due to increased levels of *Lactobacillus sp.* in an inflammatory mice model. Here, we aim to understand how the therapeutic use of a probiotic strain of *Lactobacillus reuteri* may modulate the expression of mir-21 in the liver and ameliorate non-alcoholic steatohepatitis (NASH) pathogenesis.
Method: Five-month-old male C57BL/6N mice were fed either normal diet or a methionine and choline-deficient diet (MCD) supplemented with 10^9/mL *Lactobacillus reuteri* DSM17938 in sterile water for 8 weeks. Mice were sacrificed, and liver and small intestine recovered for further histological and molecular analyses. Serum was collected for biochemical analyses.
Results: Our results show that therapeutic supplementation with *Lactobacillus* reduced weight loss and ameliorated MCD-induced liver and small intestine damage. In particular, liver histology was improved with less steatosis and inflammation. Consistently, NLRP3, TNF-α, IL-1β and TLR-4 mRNA expression levels were significantly reduced in liver tissue. In small intestine, mRNA expression levels of Lgr-5 and Olfm4 were reduced, while Muc-2, JAM-A and ZO-1 were increased. FXR mRNA was also decreased in the intestine. Importantly, expression levels of miR-21 were reduced in the liver after *Lactobacillus* treatment.
Conclusion: The use of *Lactobacillus* as a preventive strategy in the MCD model of NASH improved gut damage as well as liver steatosis and inflammation via reduced liver mir-21 expression. These results reinforce the importance of the gut-liver axis in protecting the liver.

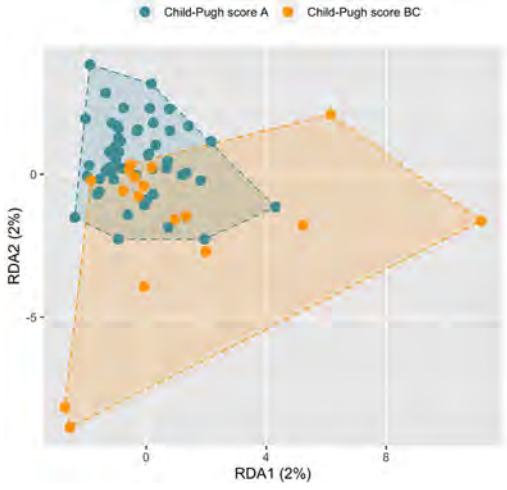
THU190

Disease severity and proton pump inhibitor use impacts strongest on faecal microbiome composition in cirrhosis

Vanessa Stadlbauer[1], Irina Komarova[2], Ingeborg Klymiuk[3], Marija Durdevic[3], Alexander Reisinger[2], Andreas Blesl[1], Florian Rainer[1], Angela Horvath[1]. [1]*Medical University of Graz, Department of Gastroenterology and Hepatology, Graz, Austria;* [2]*Medical University of Graz, Intensive Care Unit, Graz, Austria;* [3]*Medical University of Graz, Center for Medical Research, Graz, Austria*
Email: vanessa.stadlbauer@medunigraz.at

Background and Aims: Compositional changes of the faecal microbiome in cirrhosis are well described and have been associated with complications and prognosis. However, it is less well known, which disease or treatment-related factors affect microbiome composition most distinctively. We aimed to investigate which factors influence microbiome composition in cirrhosis the most by analysing a well characterized cirrhosis cohort with an extensive set of metadata.
Method: 16S rDNA sequencing data of 88 cirrhotic outpatients were investigated. Factors influencing microbiome composition were analysed by univariate and multivariate redundancy analysis. The association of the identified factors with changes in diversity and taxonomic composition was studied in depth using Analysis of Composition of Microbiome, LDA-effect size and Least Absolute Shrinkage and Selection Operator Regularized Regression. Network analysis was performed to understand overlaps of effects.
Results: Disease severity, proton pump inhibitor use, etiology of liver disease, nutritional status, age and C-reactive protein are significant explanatory variables for faecal microbiome composition in liver cirrhosis on redundancy analysis. (Figure). Each of these factors are associated with distinct taxonomic differences. However, since those variables are not entirely independent of each other, the results of taxonomic analyses show large overlaps.
Conclusion: In the analyses and interpretation of descriptive microbiome studies, all possible influencing variables must be taken in account. Especially in chronic diseases, with high morbidity,



Variable	Variance	F-statistic	P-value	Signif.

Figure: (abstract: THU190): Redundancy analysis based on Bray-Curtis dissimilarity (PPI: proton pump inhibitor, SGA: subjective global assessment, CRP: C reactive protein, Lac/Man lactulose/mannitol ratio in urine, MELD Model of end stage liver disease, PZINR: International normalized ratio, sMR: soluble mannose receptor, sCD163 soluble CD163).

such as liver cirrhosis, precise patient metadata documentation is of utmost importance. Disease and drug effects are difficult to distinguish. Therefore, detailed analysis of influencing factors on microbiome composition as well as longitudinal studies will allow the identification of potential modifiable factors.

THU191

Patients with alcoholic hepatitis present strong Th1 cellular immune responses to alcohol dehydrogenase related to impairment of the PD-1/PD-L1 pathway due to high circulating levels of soluble PD-1

Laura Blackmore[1], Brandon Turner[1], Xiaohong Huang[1], Munther Hussain[1], Debbie L. Shawcross[1], Yun MA[1]. [1]*Institute of Liver Studies and Transplantation, King's College London, King's College Hospital, London, United Kingdom*
Email: laura.blackmore@nhs.net.

Background and aims: Alcoholic hepatitis (AH) is characterised by florid hepatic inflammation, liver failure and high short-term mortality. We have previously reported that AH patients present strong cellular immune responses to alcohol dehydrogenase (ADH), with a predominant Th1 and a limited Th2 response. We have also observed that AH patients have a reduced frequency of suppressive PD-1 expressing CD4 T cells. The imbalanced cellular immune response to ADH is related to a defect in the PD-1/PD-L1 pathway, which negatively regulates T cells and is essential for the maintenance of peripheral tolerance. In this study, I aimed to evaluate the role of circulating soluble PD-1 (sPD-1) in patients with AH.

Method: PBMC and plasma were collected from 29 AH patients (20 female, median age: 43, range 25-63), 12 alcohol-related cirrhosis (ARC) patients (4 female, median age: 61, range 37-74), 9 pathological controls (PC) (NASH, PSC; 4 female, median age: 58, range 39-70), and 14 healthy controls (HC) (6 female, median age: 38.5, range 28-64). $1x10^5$ cells/well were cultured with T cell stimulator and IL-2, with and without 10μM of 8 antigenic ADH peptides. Cells were cultured for 8 days in the presence or absence of anti-PD-1, anti-PD-L1 or combined anti-PD-1/PD-L1 neutralising antibodies. Cells were harvested and FACS used to determine T cell phenotype and frequency of cytokine producing T cells. Duplicate cell cultures were pulsed with 0.25 μCi/well ^{3}H-thymidine for 18 hours and harvested onto glass-fibre lined membranes. Thymidine incorporation was measured using a β-counter and expressed as the stimulatory index (SI). Proliferative responses were positive when SI ≥ 2.5. Plasma (100 μl/well) was used to measure concentrations of soluble PD-1 using a sandwich ELISA according to the manufacturers standard protocol (DuoSet ELISA for human sPD-1, R&D Systems).

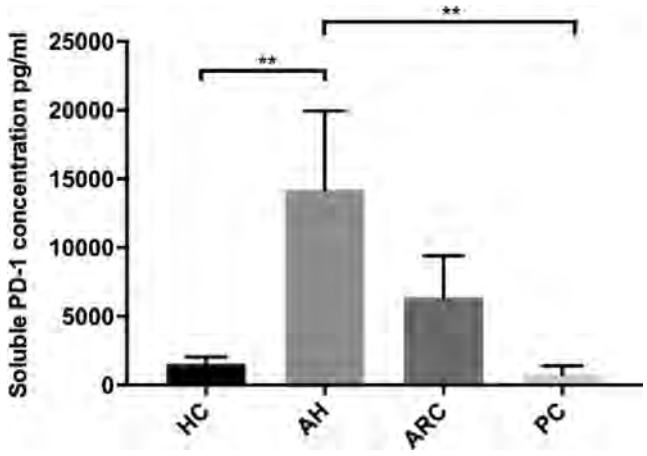

Figure:

Results: In AH, positive PBMC proliferative responses were observed in the presence of ADH peptides, but not in their absence. Frequency of PD-1^{+ve}CD4^{+ve} lymphocytes was significantly higher in the presence of ADH peptides and no PD-1/PD-L1 blockade in HC than in AH (4.40 ± 0.54 versus 1.90 ± 0.26, p=0.003). Mean baseline soluble PD-1 concentration was significantly higher in AH than in HC (14,205 ± 5741 versus 1536 ± 521.4 pg/ml, p=0.0075) and PC (14,205 ± 5741 versus 755.9 ± 658.6 pg/ml, p=0.0032). No other significant differences in sPD-1 were identified between groups.

Conclusion: Soluble PD-1 has been shown to counteract PD-L1 mediated suppression of CD4^{+ve} T cell proliferation in a number of autoimmune diseases. We have identified significantly higher levels of sPD-1 in patients with AH, who demonstrate inappropriate proliferative cellular immune responses to ADH. This may explain some of the beneficial effects of immune suppression in the treatment of AH. Further investigation of the role of sPD-1 is warranted in AH.

THU192

Alteration of the gut microbiota in patients with primary sclerosing cholangitis and concomitant dominant strictures

Luca Ambrosy[1], Sebastien Boutin[2], Petra Kloeters-Plachky[1], Peter Sauer[3], Karl Heinz Weiss[1], Konrad Bode[2,4], Christian Rupp[1,3]. [1]*University Hospital Heidelberg, Department of Gastroenterology, Heidelberg, Germany;* [2]*University Heidelberg, Department of Infectious Diseases, Medical Microbiology and Hygiene, Heidelberg;* [3]*University Hospital Heidelberg, Interdisciplinary Endoscopy Unit, Heidelberg;* [4]*MVZ Dr. Limbach Labor und Kollegen, Heidelberg*
Email: christian_rupp@med.uni-heidelberg.de

Background and Aims: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease often leading to end-stage liver disease. Its pathogenesis remains largely unknown, although frequent concomitant inflammatory bowel disease (IBD) hints towards common factors underlying gut and bile duct inflammation. Considering the mounting evidence on the involvement of the intestinal microbiota in initiating and determining IBD phenotype, we investigated intestinal microbiota composition in patients with PSC and compared it to patients with IBD.

Method: Stool samples of patients with PSC (n = 49) were collected and compared with samples derived from IBD patients (n = 56) during the time period July 2016 till November 2018 at the University Hospital Heidelberg. At the time of collection all patients were in stable clinical condition without overt signs of infection and without antibiotic treatment for at least three months. Samples were prepared for DNA-isolation and sequenced by ILUMINASeq method. In PSC patient subgroups depending on the presence of dominant strictures (DS) or IBD were analyzed. Clinical and laboratory data were collected by chart review.

Results: The alpha-diversity is significantly higher in PSC patients due to a higher richness of the microbiome while the dominance is not significantly different. We also observed a significant change in the structure of the microbiome (R^2 = 2%; p-value: 0.016). This change is due to a significant decrease of Firmicutes and increase of Bacteroides in the PSC group. There was no influence of the underlying IBD on the structure. However, the alpha diversity was significantly increased in patients with PSC only compared to PSC patients with concomitant CU ($p < 0.01$) and CD ($p < 0.05$) indicating a strong effect of the underlying disease on the microbiome. In subgroup analyis of PSC patients with DS we observed no major impact of the stricture on the alpha and beta-diversity level indicating no changes in the overall structure of the microbiome. There was was a slight change in the structure (R^2 = 0.05, p-value = 0.012) and several species showed a significant difference related to the presence of stricture indicating a mild effect on the biosphere of the microbiome.

Conclusion: Gut microbiota composition in PSC patients showes disease specific alterations compared to IBD patients. Differences in the colonic microbiome depending on concomitant IBD or the

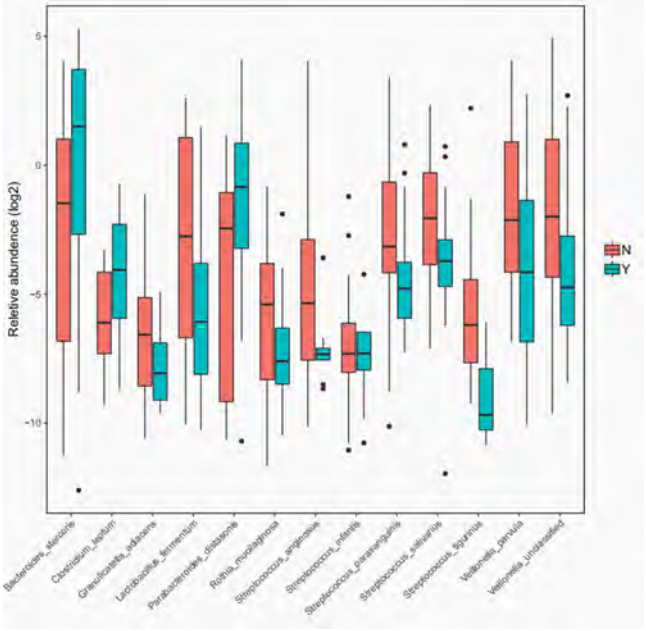
presence of DS in PSC might be a contributing factor in PSC pathogenesis.

THU193

Gut microbiota and metabolites associated with response to ursodesoxycholic acid in patients with primary biliary cholangitis

Bingliang Lin[1,2,3], Bin Gao[3], Jing Xiong[3], Weizhen Weng[3], Hui Juan Cao[3], Jun-Feng Chen[3], Shao Quan Zhang[3]. *[1]The Thrid Affiliated Hospital of Sun Yat-Sen University, GuangDong Provincial Key Laboratory of Liver Diseases, Guangzhou, China; [2]Ministry of Education, Key Laboratory of Tropical Disease Control (Sun Yat-Sen University), Guangzhou, China; [3]The Thrid Affiliated Hospital of Sun Yat-Sen University, Department of Infectious Diseases, Guangzhou, China*
Email: lamikin@126.com

Background and Aims: Ursodeoxycholic acid (UDCA) is the first line drug for primary biliary cholangitis (PBC), which forty precent was inadequate response. The gut microbiota plays an important role in pathogenesis and progress of PBC, but whether affected the responese of UDCA for PBC is unclear,so we compared gut microbiotas and their related metabolites in PBC patients with adequate response and inadequate response after UDCA therapy.
Method: This was a cross-sectional study. According to Paris standard, sixty-one PBC patients were divided to adequate response group (n = 29) and inadequate response group (n = 32). Fecal samples were collected and analyzed by macrogenomic sequencing. Bile acids (BAs) and short chain fatty acid in serum and faeces were measured using UPLC-MS.



Results: The individual diversity (alpha-diversity) of the gut microbiota in UDCA-inadequate patients was no significant change, but the overall microbial diversity (beta-diversity) increased dramatically compared with the UDCA-adequate response (p = 0.009). At the phylum level, the proportion of Firmicutes was higher in the UDCA-inadequate group than that in UDCA-adequate group (p = 0.01). The changes of species level characterized by decreased abundance of three species (Bacteroides_stercoris, Clostridium_leptum and Parabacteroides_distasonis) and increased abundance of ten species (Granulicatella_adiacens, Lactobacillus_fermentum, Rothia_mucilaginosa, Streptococcus anginosus, Streptococcus_infantis, Streptococcus_parasanguinis, Streptococcus_salivarius, Streptococcus_tigurinus, Veillonella_parvula and Veillonella_unclassified) strongly correlated with the effect of UDCA response, the area under curve was 0.838. The fecal BAs of the UCDA-inadequate patients were lower than that in UDCA-adequate patients, but the serum BAs were higher, especially in GCDCA, TUDCA and GUDCA. There was a obvious correlation between the gut microbiota and BAs. In particular, Streptococcusus_tigurinus positively correlated with serum total BAs, GCDCA and TCDCA, and Veillonella_unclassified was negatively related with faeces total secondary BAs and LCA.
Conclusion: The gut microbiome and bile acid metabolism were disordered in the UDCA-inadequate response PBC, which further affected the UDCA efficacy, so altering gut microbiota may a effective approach to improve the response of UDCA for PBC patients.

THU194

Gut microbiota are associated with minimal hepatic encephalopathy (MHE) in cirrhosis regardless of country of origin

Aldo Torre[1], Mayra Rojas Lara[1], Andrew Fagan[2], Edith Gavis[2], Ivvone Escalona Nandez[1], Melanie White[2], Sara McGeorge[2], Omar De Leon Osorio[1], Masoumeh Sikaroodi[3], Patrick Gillevet[3], Michael Fuchs[2], Jasmohan S Bajaj[2]. *[1]Instituto Nacional de la Nutrición, Mexico; [2]Virginia Commonwealth University and McGuire VA Medical Center, United States; [3]George Mason University, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: Cirrhosis is associated with altered gut-brain axis that can predispose to hepatic encephalopathy (HE). Diet, ethnicity and microbiota composition vary, but their impact on different cohorts is unclear. *Aim*: Define differences in gut-brain axis in cirrhosis cohorts from US & Mexico (MX)
Method: Age-matched controls and cirrhotic pts from US & Mexico underwent dietary recall, stool microbiota (16srRNA) analysis and cognitive testing using psychometric hepatic encephalopathy score (PHES, low is better, MHE worse than –4 score). Interactions between microbiota, cognition, and diet in US vs Mexico were compared. Microbial diversity, key taxa and cirrhosis dysbiosis ratio (CDR). CDR is [(Lachno+Rumino+Veillo)/(Enterobact+Bacteroidaceae)]; high ratio indicates lower dysbiosis. Logistic regression for determinants of MHE were performed in the entire group and then only in cirrhosis using cohort origin, diet, demographics, cirrhosis, CDR and other microbiota as variables.
Results: 120 total subjects (60/cohort, 20 controls, 20 compensated & 20 decompensated) were enrolled from tertiary care centers in US & MX. Age and PPI use were similar but there were less men in MX cohort. MELD scores, prior HE (65% each; all on lactulose), MHE were greater & PHES was worse in decomp pts regardless of US/MX.
Diet: MX subjects consumed lower protein and higher carbohydrates vs the US. US subjects consumed more coffee, tea, pork, milk, eggs, cheese and yogurt, and lower fish compared to MX.
Microbiota: Shannon diversity was similar between US/MX. Only MX cohorts had Prevotellaceae with highest in controls and compensated, which reduced in decomp pts; none were found in US. MX pts had higher Enterobacteriaceae, Veillonellaceae, Strep and lower Lactobacillaceae vs US. As expected, advancing cirrhosis had lower beneficial taxa (Lachno, Rumino). CDR was lower in MX decomp vs US decomp pts.
Regression: In the entire group, MHE was associated positively with decomp (OR 3.1, p < 0.001) and negatively with CDR (OR:0.56, p = 0.02). When only cirrhotics were considered, MHE was associated with MELD (OR 1.2,p = 0.04), decomp (OR 4.3, p = 0.05) and cheese (OR 6.9, p = 0.01), while CDR was protective again (OR: 0.6 p = 0.04) independent of cohort, demographics, diet and other clinical factors.
Conclusion: A favorable gut microbial profile (high CDR) is associated with protection from cognitive impairment (MHE) independent of cohort of origin, diet and cirrhosis severity in a multi-center study from USA and Mexico. Efforts to improve dysbiosis could beneficially impact brain function in cirrhosis.

Microbiota modulates ischemia-reperfusion injury in mouse liver transplantation

Shoichi Kageyama[1], Kojiro Nakamura[2], Takahiro Ito[1], Hirofumi Hirao[1], Kentaro Kadono[1], Hidenobu Kojima[1], Kenneth J Dery[1], Ronald Busuttil[1], Jerzy Kupiec-Weglinski[1]. [1]*Dumont-UCLA Transplant Center, Surgery, Los Angeles, United States;* [2]*Nishi-Kobe Medical Center, Surgery, Kobe, Hyogo, Japan*
Email: jkupiec@mednet.ucla.edu

Background and Aims: Ischemia-reperfusion injury (IRI) is a major risk factor in orthotopic liver transplantation (OLT). As host microbiota may associate with health or disease, antibiotics (Abx) and fecal microbiota transplantation (FMT) can manipulate microbial profile to improve disease status. We have reported on benefits of Abx in IRI-OLT via PGE2/EP4 pathway in mouse and humans. Here, we evaluated the effects of Abx/FMT on taxonomical composition/outcomes in mouse OLT.

Method: In IRI-OLT arm (n = 6/gr), mice (C57BL/6) pretreated±10d amoxicillin (AMPC; 50 g/L in drinking water) were transplanted with 18 h cold-stored liver allografts (Balb/c), followed by OLT/blood sampling (6 h). In FMT group, AMPC-treated recipients received FMT from naïve donors + OLT. In fecal analysis arm, cage-controlled mice were divided into: 1) control, 2) AMPC, 3) AMPC+FMT, 4) OLT groups. To ensure the selective effect of anaerobe bacteria on OLT, metronidazole (MNZ; 1 g/L in drinking water for 10d) was given±FMT (n = 4/gr).

Results: In OLT recipients, AMPC alleviated IRI, evidenced by decreased sALT (3359 ± 1574 vs. 7383 ± 1501 U/L, $p < 0.05$), Suzuki's histological score, frequency of TUNEL+ cells, infiltrating neutrophils/macrophages and enhanced EP4 (IHC). Adjunctive FMT restored hepatic IRI (sALT: 7485 ± 847.6 U/L, $p < 0.05$ vs. AMPC) and reduced EP4 expression. In fecal 16S q-PCR analysis, there were no changes in absolute microbiota levels between groups; while 16S rRNA-amplicon sequencing showed decreased species richness, abundance, and diversity in AMPC vs. control (Faith's, Shannon and Chao1; $p < 0.005$ in each index). FMT abrogated this pattern ($p < 0.005$ vs. AMPC, ns vs. control); and day 1 post-OLT microbiota was comparable with controls. Levels of Akkermansia and Bacteroidetes were increased in AMPC group vs. control; while Ruminococcaceae, Turicibacter, and Clostridium were reduced. Remarkably, MNZ pretreated OLT experienced severe IRI, with increased sALT (8853 ± 353.5 vs. 5486 ± 1345 U/L, $p < 0.05$), Suzuki's score, TUNEL+ cells, and graft-infiltrating neutrophils/macrophages, and decreased EP4 expression vs. controls. FMT adjunct in MNZ-treated OLT restored hepatocellular function to control levels (sALT: 4301 ± 2145 U/L, ns vs. control, $p < 0.05$ vs. MNZ group).

Conclusion: This study documents striking benefits of microbiota modulation in a clinically-relevant mouse OLT model; and identifies a specific microbiota genus profile as a target for novel therapeutic manipulation in IRI-OLT.

THU196

Gut microbiota composition is difference between HCV mono-infection and HCV/HIV co-infection

Natthaya Chuaypen[1], Salyavit Chittmittrapap[1], Anchalee Avihingsanon[2], Pisit Tangkijvanich[1]. [1]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, Bangkok;* [2]*The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), Bangkok, Thailand, Bangkok*
Email: pisittkvn@yahoo.com

Background and Aims: Alteration of gut microbiome has been linked to the pathogenesis of hepatitis C virus (HCV) infection. However, little is known about the effect of human immunodeficiency virus (HIV) infection on gut dysbiosis in HCV/HIV co-infected patients. This study aimed at investigating the difference of gut microbiota composition between patients with chronic HCV mono- and co-infection.
Method: Fecal specimens from patients were collected and extracted for DNA. Gut microbial compositions were analyzed using 16S ribosomal RNA (V3-V4) sequencing by Illumina MiSeq sequencing platform. The alpha and beta diversity were calculated with QIIME pipeline.
Results: This study included 58 patients with HCV mono-infection and 28 patients with HCV/HIV co-infection, who were age and gender-matched. There were no differences in taxonomic diversity (alpha and beta index) and Unifrac-based principle coordinates analysis (PCoA) between groups. The co-infected group showed significantly lower in the relative abundance of genus Faecalibacteria (6.34 ± 5.96 vs. 8.57 ± 6.24, P = 0.043) and Blautia (1.66 ± 1.19 vs. 2.71 ± 2.29, P = 0.044) when compared to the mono-infected group. Patients with cirrhosis showed significant increase in Agathobacter and decrease in Lachnoclostridium when compared to patents without cirrhosis (3.10 ± 3.08 vs. 2.47 ± 5.46, P = 0.043 and 0.60 ± 0.87 vs. 1.15 ± 1.73, P = 0.029, respectively). The abundance of Agathobacter was also increased in patients with F3–4 when compared with patients with F0–2 (3.27 ± 4.35 vs. 2.29 ± 5.34, P = 0.024). In subgroup analysis, Lachnospira was significantly higher in co-infected cirrhotic patients when compared with cirrhotic patients with mono-infection (2.55 ± 1.83 vs. 1.15 ± 1.64, P = 0.012).
Conclusion: This is the first report that compares gut microbiome profiles between patients with HCV mono- and HCV/HIV co-infection. The presence of HIV was accompanied by changes in gut microbiota composition, which might be associated with an increased risk of disease progression in co-infected patients.

Email: ngoikoetxea@cicbiogune.es

Background and Aims: Enhanced activity of mitochondria complex I by deletion of the methylation controlled J (MCJ) protein has proved to avoid liver lipid accumulation. Due to the role of gut microbiota (GM) in non-alcoholic fatty liver disease (NAFLD) development, adaptations induced by MCJ-deficiency could be related to microbiota composition changes. This work aims to evaluate the outcomes of a choline-deficient high-fat diet (CDA-HFD) in MCJ-knockout (KO) mice and to determine if the effects linked to the genotype could be transferred to germ-free mice (GFm).
Method: MCJ-KO and wild type (WT) mice were fed with control (C) diet and CDA-HFD for 6 weeks. Donor mice with a specific metabolic phenotype were selected based on markers related to NAFLD. GFm were colonized with GM from these donors and fed with C and CDA-HFD for 3 weeks. NAFLD activity score (NAS) besides gut-liver axis, fibrosis and inflammation markers were measured.
Results: Mice fed with CDA-HFD showed an increase in fibrosis, inflammation and gut-liver axis alteration parameters. MCJ-KO was related to an improvement of these inflammatory and fibrotic patterns. Based on these results, donors were selected from WT and MCJ-KO mice fed with C and CDA-HFD. CDA-HFD-fed GFm receivers displayed hepatic damage proved by increased plasma transaminases levels, NAS and hepatic triglyceride content. This diet was also associated with enhanced fibrosis, gut-liver axis alteration and hepatic inflammatory response activation. GM transplantation-derived phenotypes evidenced specific functionalities in GFm receivers associated to the donor genotype. CDA-HFD-fed GFm receivers from MCJ-KO donors showed an improvement in signalling pathways related to fibrosis progress, independently of the donor diet. In contrast, only CDA-HFD-fed GFm transplanted with microbiota from CDA-HFD-fed MCJ-KO donor showed a downregulation of inflammatory markers that corresponds with the hepatic histological findings, resulting in a reduced NAS in these receivers. This microbiota profile linked to MCJ-KO genotype and CDA-HFD feeding in GFm triggered an improvement in transaminases and hepatic triglycerides levels.
Conclusion: Our results demonstrate that some beneficial effects of MCJ-KO related to NAFLD development can be transferred by cecal microbiota transplantation, suggesting that GM may be involved in the mechanisms underlying its protective effect. Supported by BFU2017-87960-R and GRS 1888/A/18. CIBERehd is funded by ISCIII. Effects of anti-TNF? treatment on Crohn's disease induced hepatic steatosis

Paul Peter Manka[1], Svenja Sydor[2], Ulrike von Arnim[2], Alexander Link[2], Ramiro Vilchez-Vargas[2], Annika Helbeck[1], Malte Brandenburg[1], Sonja Kinner[3], Yan Li[3], Ali Canbay[4], Alisan Kahraman[1], Heiner Wedemeyer[1], Lars Bechmann[4]. [1]*Essen University Hospital, Gastroenterology and Hepatology, Essen, Germany;* [2]*Otto-von-Guericke University Magdeburg, Gastroenterology, Hepatology and Infectiology, Magdeburg, Germany;* [3]*Essen University Hospital, Department of Diagnostic ant Interventional Radiology and Neuroradiology, Essen, Germany;* [4]*Ruhr-University Bochum, University Hospital Knappschaftskrankenhaus Bochum GmbH, Department of Internal Medicine, Bochum, Germany*
Email: paul.manka@uk-essen.de

Background and Aims: Even in the absence of metabolic risk factors, non-alcoholic fatty liver disease (NAFLD) occurs in up to one-third of patients with inflammatory bowel disease (IBD). To date, little is known about the mechanisms leading to hepatic steatosis in IBD nor how anti-Tumor Necrosis Factor-alpha (anti-TNFα) treatment affects steatosis. However, we and others have shown that NASH in patients with Crohn's disease (CD) is associated with an increased susceptibility for acute-on-chronic liver failure. Multivariate logistic regression analyses have shown that ongoing anti-TNFα therapy was the only independent protective factor. Therefore, we aimed to analyze and compare non-invasive predictors of liver disease paying special

attention to the role of the gut-liver axis and bile-acid (BA) metabolism.
Method: We included patients with established CD with and without anti-TNFα treatment and analyzed serum markers of liver injury, transient elastography as well as controlled attenuation parameter (CAP) and MRI proton density fat fraction to assess hepatic steatosis. Additionally, we analyzed gut microbiota composition and mediators of BA signaling in the absence or presence of treatment with anti-TNFα through analysis of stool and serum.
Results: Patients on anti-TNFα treatment expressed less hepatic steatosis as assessed by CAP and MRI. Serum FGF-19 levels were significantly higher in patients on anti-TNFα treatment and associated with less steatosis as well as lower LFT-levels. Group-specific alterations in gut microbiome were found for several bacteria involved in BA metabolism and FGF-19 regulation, including Bacteroides and Firmicutes.
Conclusion: In this Crohn's disease cohort, anti-TNFα treatment is associated with less steatosis, reduced circulating FGF19 levels, and specific alterations in the composition of gut microbiota and BA metabolism.

Investigation of microbiome metabolites and mitochondrial function in non-alcoholic fatty liver disease
Paula Boeira[1], Charles Affourtit[1], Daniel Felmlee[1], David Sheridan[1].
[1]*University of Plymouth, Faculty of Health: Medicine, Dentistry and Human Sciences, Plymouth, United Kingdom*
Email: paula.boeira@plymouth.ac.uk

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a hepatic feature of the metabolic syndrome associated with obesity, type 2 diabetes, and increased risk of developing cardiovascular disease (CVD). Intestinal bacteria are increasingly recognised players in metabolic diseases, but it is not yet fully understood how the gut microbiome affects liver function. Trimethylamine N-oxide (TMAO) and phenylacetic acid (PAA) are microbiome-derived metabolites that have been associated with CVD and the early onset of NAFLD, respectively. Hypothesising that these metabolites may contribute to lipid deposition in the liver by altering hepatic mitochondrial function, we are currently assessing how TMAO and PAA affect hepatocyte bioenergetics in cell models of liver steatosis.
Method: HepaRG cells were used because of their ability to differentiate into fully functional hepatocyte-like cells, forming bile canaliculi and presenting CYP450 activity, and potential utility for drug toxicology studies. HepaRG cells were cultured under standard conditions, and steatosis was established by overnight exposure to oleate and palmitate (2:1 molar ratio). Lipid accumulation was quantified by BODIPY™ fluorescence. Mitochondrial bioenergetics were measured in real-time by extracellular flux (XF) analysis in intact control cells and in cells that had been exposed to PAA (100 µM or 200 µM) or TMAO (20 µM, 50 µM, 100 µM and 200 µM).
Results: HepaRG cells responded as expected to bioenergetic effectors as their respiratory activity decreased in the presence of the ATP synthase inhibitor oligomycin, and increased after subsequent addition of a mitochondrial uncoupling agent. These responses demonstrate good coupling efficiency of oxidative phosphorylation and significant spare respiratory capacity. PAA and TMAO lowered spare respiratory capacity dose-dependently in HepaRG cells. Interestingly, removal of these metabolites 48 h post-exposure restored spare respiratory capacity indicating that PAA and TMAO effects are reversible.
Conclusion: Our data indicate that microbiome-derived compounds alter hepatic mitochondrial function and exacerbate lipid deposition. Such effects might suggest that involvement of microbiome-derived compounds with metabolic liver disease is mediated by mitochondrial dysfunction.

THU200
Veillonella as a bile acid-sensitive bacteria and a microbiome-based biomarker for aldafermin (NGM282) in patients with non-alcoholic steatohepatitis
Rohit Loomba[1], Lei Ling[2], Duy Dinh[3], Bryan Baxter[4], Alex DePaoli[4], Hsiao Lieu[4], Stephen Harrison[5], Arun Sanyal[6]. [1]*University of California, San Diego;* [2]*NGM Biopharmaceuticals, South San Francisco, United States;* [3]*Diversigen;* [4]*NGM Biopharmaceuticals;* [5]*Pinnacle Clinical Research;* [6]*Virginia Commonwealth University*
Email: lling94080@yahoo.com

Background and Aims: Recent studies have shown that the gut microbiome of elite athletes is enriched in *Veillonella*, a performance-enhancing microbe that functions via lactate metabolism (Scheiman et al., Nat Med 2019;25:1104). *Veillonella* is selectively induced in NASH patients treated with aldafermin (previously known as NGM282), a non-tumorigenic FGF19 analogue that significantly inhibits bile acid (BA) synthesis. We hypothesize that *Veillonella* may be a bacteria genus sensitive to BAs. Here we assessed the correlation of *Veillonella* with BA species in a pooled analysis of phase 2 aldafermin trials in NASH.
Method: 144 NASH subjects, with NAS ≥ 4 (at least 1 point in each component), stage 1–3 fibrosis and absolute liver fat content by MRI-PDFF ≥ 8%, received aldafermin 0.3 mg, 1 mg, 3 mg, 6 mg or placebo daily for 12 weeks (W12), and had both baseline (BL) and W12 stool samples collected. Stool microbiota was analyzed using 16S rRNA method (Diversigen). Serum BA was measured with LC/MS (Mayo Clinic). We performed a linear mixed-effect model to account for non-independence of the data set with the following model: *Veillonella*_abundance ~ treatment_type + visit + (1|subject). Correlation between pre- and post-treatment in the relative abundance of *Veillonella* and BA species was determined by Spearman's rank correlation coefficient.
Results: Subjects treated with aldafermin had stable gut microbial composition and diversity. No taxonomic changes were observed among 12 phyla or the top 30 most abundant genera over time or between aldafermin and placebo, except for an increase in the low abundance genus *Veillonella* in subjects who received aldafermin. Enrichment of *Veillonella* from BL to W12 was observed in the aldafermin groups, but not in the placebo group (Figure 1). At W12, the appearance of *Veillonella* was associated with a reduction in BA levels. The relative abundance of *Veillonella* was negatively correlated with concentrations of BAs, and the more hydrophobic, toxic BAs in particular (GDCA: $r = -0.45$, $p < 0.0001$; GCDCA: $r = -0.38$, $p < 0.0001$; DCA: $r = -0.38$, $p < 0.0001$; GCA: $r = -0.37$, $p < 0.0001$).

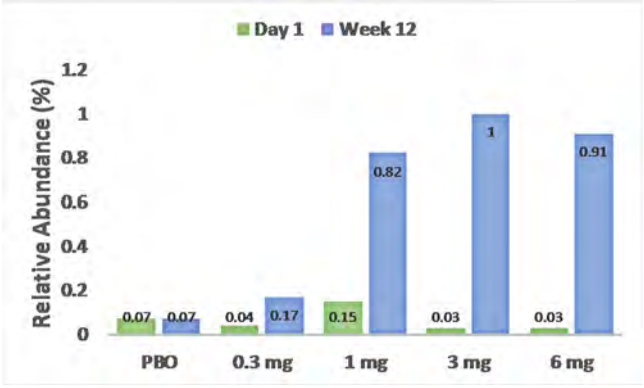

Figure 1: Aldafermin enriches the lactate-consuming *Veillonella* in patients with NASH.

Conclusion: The lactate-fermenting *Veillonella* may serve as a microbiome-based biomarker for aldafermin activity. *Veillonella* appear to be sensitive to BAs, and especially the more hydrophobic, toxic BA species. Given that levels of lactate are elevated in patients with cirrhosis and predict organ failure and mortality, the ability of

aldafermin to enrich lactate-consuming *Veillonella* in the gut could have a protective effect in advanced liver disease.

Novel metagenomic signature of fungal mycobiome in NAFLD-cirrhosis with validation in a geographically independent cohort

Tae Gyu Oh[1], Susy Kim[2], Bassirian Shirin[2], Seema Singh[2], Richele Bettencourt[2], Lisa Richards[2], Annette Atkins[1], Ruth Yu[1], Brenner David[2], Claude Sirlin[2], Michael Downs[1], Ronald Evans[1], Rohit Loomba[2,3]. [1]*Salk Institute for Biological Studies, San Diego, United States;* [2]*UC San Diego School of Medicine, San Diego, United States;* [3]*NAFLD Research Center, UCSD, Medicine, La Jolla, United States*
Email: roloomba@ucsd.edu

Background and Aims: Gut bacteria derived metagenomic signature has been associated with NAFLD-Cirrhosis (Caussy et al. 2019 Nature Communications) However, there are limited metagenomic data regarding the role of fungal mycobiome in NAFLD Cirrhosis. The aim was to examine the association between fungal mycobiome in NAFLD Cirrhosis and then validate fungal alteration in an independent racially and geographically distinct cohort of patients from China.
Method: Shotgun metagenomics profiling were performed on stool samples from well-characterized participants ($N = 163$) comprising NAFLD-cirrhosis ($N = 27$) and non-NAFLD controls ($N = 54$) as well as their first-degree relatives or twins. Then, we utilized an independent cohort of Chinese patients with and without cirrhosis (Qin et al. Nature 2014) as a validation cohort.
Results: Using a uniquely phenotyped cohort of NAFLD-cirrhosis ($N = 27$) and non-NAFLD controls ($N = 54$), we identified significant alteration of microbial fungi. We found *Saccharomycetaceae* was significantly enriched and uniquely associated with NAFLD-cirrhosis at the family level. Our metagenomic analysis enabled to identify that subclass of *Saccharomycetaceae, Candia glabrata,* was increased in NAFLD-cirrhosis at species level (mean 3.57-fold up). Furthermore, we identify that a unique strain of *Candia glabrata* highly enriched in NAFLD-cirrhosis is *GCA 000002545*. In order to identify common or unique fungi signatures, we utilized 237 participants (114 controls and 123 cirrhosis) from Chinese cohort and examined change of fungal composition. Importantly, we observed *Saccharomycetaceae* was consistently enriched in cirrhotic samples from the Chinese cohort. Surprisingly, *Candia glabrata* (strain: *GCA 000002545*) was also consistently more enriched in Chinese cirrhotic samples (Wilcox $P < 0.0057$). Notably, we found a unique alteration that *Saccharomyces cerevisiae* was the most enriched in Chinese cirrhosis samples (Wilcox $P < 0.01$). Meanwhile, we found *Candia glabrata* is the most significant enrichment in the UCSD cohort, suggesting *Candia glabrata* is a potential biomarker for NAFLD-cirrhosis.
Conclusion: We have identified significant alteration of fungal composition that accurately represents liver NAFLD-cirrhosis, consistent with enteric dysbiosis observed in disease progression. The utility of this pattern change (e.g. *Saccharomycetaceae* [family], *Candia glabrata* [species], *GCA 000002545* [strain]) is demonstrated as it is also altered in cirrhotic samples from a Chinese cohort. This external validation is unique to cirrhosis since previous studies have mainly focused on bacterial profiling and alteration of fungi has not been demonstrated or validated using a geographically independent cohort. Further studies are needed to better understand the pathogenetic role of these alterations in fungal mycobiome in cirrhosis and its complications.

THU202

Lactobacillus rhamnosus GG improve fungal dysbiosis on liver cirrhotic rats

Ding Shi[1], Lanjuan Li[1]. [1]*The First Affiliated Hospital, College of Medicine, Zhejiang University, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Collaborative Innovation Centre for Diagnosis and Treatment of Infectious Diseases, Hang ZHOU, China*
Email: shidingzju@126.com

Background and Aims: Cirrhotic patients are susceptible to fungal infection with high mortality. While infected cirrhotics have bacterial dysbiosis, the role of fungi is unclear. Gut microbiota regulation are considered a potential treatment strategy to protect liver injury. This study aimed to evaluate the functional role of *Lactobacillus rhamnosus* GG (LGG) in fungal structure and liver inflammation on cirrhotic models
Method: Thirty-eight SD rats were randomly divided into healthy control (NC group, $n = 8$) and experimental groups ($n = 15$). Each group was administrated with LGG or normal saline once daily during the induction of liver cirrhosis by CCl_4. Subcutaneous injection of 50% (V/V) CCl4 solution in olive oil was used to induce liver cirrhosis at a dose of 2 ml/kg twice a week for 13 weeks. A PC group treated with normal saline during cirrhosis induction as positive control ($n = 15$). Animals were euthanised one week after the last injection of CCl_4 solution, with liver tissue and caecal contents taken for the subsequent biochemical and molecular analyses.
Results: Rats in PC group displayed an unfavourable intestinal fungal signature, mainly in the increase of common pathogenic fungi, and the reduction of symbiotic and beneficial fungi. Compared with healthy control group, at the family level, the abundance in the PC group was significantly reduced in the yeast family *Saccharomycetaceae* and *Trichomeriaceae*. At the genus level, the abundance of PC group was significantly increased by *Candida* and *Zygosaccharomyces*, and *Nakaseomyces* and *Knufia* were significantly decreased in NC group. LGG administration could increase the fungal diversity and change the intestinal fungal structure during cirrhosis induction. The structure of intestinal fungi in LGG group was similar to that of normal group flora, and the population difference between the groups was small. Compared with the PC group, at the genus level, the LGG group significantly reduced *Candida* and increased the abundance of *Nakaseomyces*. At the species level, the LGG group significantly reduced *Candida. Catenulata* and significantly increased *Candida. glabrata* abundance. LGG treatment significantly reduced the translocation of fungal β-glucan into systemic circulation and attenuated liver inflammation, which was correlated with the decreased abundance of *Candida.*
Conclusion: There is a significant fungal dysbiosis in cirrhotic rats. LGG can improve the intestinal fungal structure of cirrhosis, reduce the proliferation of pathogenic fungi, and ameliorate liver inflammation. Probiotics intervention suggest novel strategies for the prevention of fungal infection in liver cirrhosis.

THU203

Protective effects of akkermansia muciniphila against non-alcoholic fatty liver disease through modulation of gut microbiota

Wenrui Wu[1], Lanjuan Li[1]. [1]*State Key Laboratory for Diagnosis and Treatment of Infectious Disease, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China*
Email: ljli@zju.edu.cn

Background and Aims: There exists gut microbiota dysbiosis in NAFLD (Nonalcoholic Fatty Liver Disease), and the imbalance may be related to stages of liver injury. However, the dynamic changes of intestinal flora during the development of NAFLD are still poorly understood. Akkermansia muciniphila can regulate host's immune

and metabolic functions. This study intends to use a high-fat diet-induced NAFLD mouse model and explore the effects of Akkermansia muciniphila on NAFLD as well as its underlying mechanisms.
Method: C57BL/6 mice were fed with high-fat diet for five months to induce nonalcoholic fatty liver disease. During the experiment, mice were either administered with 3 * 10^9 CFU of Akkermansia muciniphila by oral gavage every day or given the same amount of PBS. We measured the intestinal barrier function, metabolic biomarkers, liver injury, inflammation, lipid metabolism, and gut-liver FXR-FGF15 axis. Besides, the alteration of intestinal bile acids and gut microbiota was also measured.
Results: Akkermansia muciniphila reduced HFD-induced weight gain, improved insulin resistance and glucose tolerance, and alleviated liver injury. Akkermansia muciniphila significantly inhibited the hypertrophy of visceral fat, improved dysbiosis of the metabolic factors like leptin and resistin, and reduced the uptake of fatty acids and triglyceride deposition of liver. Akkermansia muciniphila maintained the gut barrier function and reduced endotoxin translocation. In addition, the up-regulation of gut-liver FXR-FGF15 axis inhibited the expression of CYP7A1 in the liver. The structure of intestinal microbiota changed during the development of NAFLD which was improved by Akkermansia muciniphila.
Conclusion: This study found that Akkermansia muciniphila has a protective effect on NAFLD induced by high-fat diet. It can inhibit intestinal barrier permeability and endotoxin translocation, reduce abnormal synthesis of adipokines, and regulate the balance of gut bile acids and the intestinal FXR-FGF15 axis. These effects may be related to the significant modulation of intestinal microbiota by Akkermansia muciniphila.

THU204
Identification of gut bacterial candidates involved in hepatic encephalopathy by the analysis of feces DNA from patients administered rifaximin

Yoshimi Muto[1,2], Norifumi Kawada[1], Naoko Ohtani[2]. [1]*Osaka City University, Graduate School of Medicine, Dept. of Hepatology, Osaka, Japan;* [2]*Osaka City University, Graduate School of Medicine, Dept. of Pathophysiology, Osaka, Japan*
Email: ohtani.naoko@med.osaka-cu.ac.jp

Background and Aims: The gut microbial dysbiosis has been discussed as a cause of hepatic encephalopathy (HE) where hyperammonemia is one of the major causes of the disease. However, the key gut microbial species that could cause the pathophysiology of HE remain to be elucidated. Therefore, our research focused on identifying gut bacterial species that functionally causing the pathophysiology of HE, based on the analysis of the gut microbiota profile of HE patients' feces DNA before and after RFX administration.
Method: From April 2017, we consulted 26 patients with liver cirrhosis who had been administered with RFX (1200 mg/day). In 19 of 26 cases, we analyzed the blood ammonia levels as well as gut microbial profile before and every two weeks after RFX administration, and categorized the patients as effective (n = 10) and non-effective cases (n = 9) judging by the reduction level of blood ammonia. We performed 1) the comparison of the gut microbiota profile using 16SrRNA gene sequence analysis and LEfSe (Linear discriminant analysis effect size) before and after RFX administration, 2) the oral administration of the identified gut bacterial species in CCl_4 treated cirrhosis mouse models to see the enhancement of blood ammonia levels, and 3) the isolation of bacteria which could contribute to HE pathophysiology from fecal samples derived from the non-effective cases.
Results: 1) Clear differences were detected in the gut bacterial profile between the two groups. LEfSe analysis identified the candidate bacterial species that were significantly abundant in the effective cases as ammonia-producing bacteria, and the amount of bacteria decreased with RFX administration. 2) Significant enhancement of blood NH_3 levels was observed ($p = 0.049$) in mice with oral administration of the candidate bacterial species, confirming the relationship between this bacterial species and hyper-ammonemia in mouse models. 3) RFX-resistant bacteria, that were highly competent to produce ammonia, were successfully isolated from the feces of non-effective patients.
Conclusion: We identified strong candidates of bacterial species involved in the pathophysiology of HE.

Liver development, physiology and regeneration

THU205
Modulation of native decellularized liver matrix enhances hepatic cells proliferation, viability and functions on 3D-bioscaffolds

Abhishak Gupta[1], Dinesh Mani Tripathi[2], Savneet Kaur[2], Preety Rawal[2], Sumati Rohilla[2], Shiv Kumar Sarin[2]. [1]*Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, India;* [2]*Institute of Liver and Biliary Sciences*
Email: abhigupta78@gmail.com

Background and Aims: The Extracellular matrix (ECM) provides various physicochemical cue in directing cells behaviour, proliferation and functions. Liver stiffness acts as a vital cue affecting liver regeneration and repair. 3D In-vitro models that mimic the liver stiffness corresponding to various stages of disease progression might help to elucidate the role of cellular responses. Here, we developed 3D-bioscaffolds with solubilized decellularized liver (DCL) containing matrices with tunable mechanical properties and investigated the effect of substrate stiffness on the behaviour of hepatic cells.
Method: DCL was developed by portal vein cannulation and perfusion with detergents and characterized by histology and DNA content. Enzymatically digested DCL matrix was mixed with commercially available hydrogel to create 3D-bioscaffolds. To recreate physiologically relevant stiffness, we designed soft (4–6 kPa) to represent the healthy liver and stiff (15–20 kPa) liver matrix by mixing of varied DCL matrix concentration with hydrogel. Hepatic cells were cultured on stiff and soft 3D scaffolds till 14 days. Phenotypic and functional analysis was done by cell morphology, cell viability, hepatic gene expression, immunostaining and albumin secretion at day 3, 7 and 14 of cultured hepatic cells.
Results: DCL histology and DNA content (less than 50 ng/ml) confirmed the intact matrix and complete removal of hepatic cells from the native liver. More than 90% hepatic cells viability was observed in cultured conditions. However, at day 14, proliferation of hepatic cells was significantly increased on 3D-soft bioscaffolds than stiff ($p < 0.05$). Gene expression of hepatocyte specific markers, Asialoglycoprotein Receptor 1(ASGR-1), Cytokeratins CK-18 and 19 was increased more than 2 and 4 folds at day 7 and 14 in 3D- soft scaffolds than stiff ($p < 0.05$). Liver-specific (ASGR-1) immunostaining also showed significantly enhanced expression in 3D-soft scaffolds at day14 than the stiff ($p < 0.05$). Secretory albumin levels from hepatic cells were significantly increased in the culture supernatants at day 7 and 14 in 3D-soft bioscaffolds ($p < 0.05$).
Conclusion: Our results showed that 3D bioscaffolds supports enhanced hepatic cell viability and functionality. Mechanical factors in 3D-liver bioscaffolds have important implications for understanding the development and progression of liver disease and for new drug screening.

Hepatocyte-targeted R-spondin mimetic for liver regeneration

Zhengjianzhang Zhang[1], Caroline Broderick[1], Marni Shimoto[1], Teppei Yamaguchi[1], Sung-Jin Lee[1], Zhong Wang[1], Haili Zhang[1], Hui Chen[1], Jay Ye[1], Helene Baribault[1], Wen-Chen Yeh[1], Yang Li[1].
[1]*Surrozen, South San Francisco, United States*
Email: helene@surrozen.com

Background and Aims: Wnt signaling plays a central role in hepatocyte expansion during development and tissue repair. R-spondins (RSPOs) amplify Wnt signaling via stabilization of Frizzled and LRP co-receptors and their function depends on the presence of Wnt ligands, which are upregulated in injured tissue. A major limitation to the potential therapeutic use of Wnts and RSPOs is their widespread effect on several organs, and in liver, on non-hepatocyte cells. To leverage the Wnt regenerative potential for parenchymal mass expansion, we generated a hepatocyte-targeted antibody-based R-spondin mimetic. We named this molecule, SWEETS-1, for Surrozen Wnt Enhancer Engineered for Tissue Specificity.
Method: *In vitro*, Wnt signaling activity was measured using the Huh-7 hepatic or HEK293 non-hepatic cell lines containing a luciferase gene controlled by a Wnt-responsive promoter (Super Top Flash reporter assay, STF). *In vivo*, SWEETS-1 (0.01–30 mg/kg), RSPO (0.01–10 mg/kg) or the negative control anti-beta-galactosidase (0.01–10 mg/kg) were injected intraperitoneally. Liver samples were collected 48 hours later for gene expression analysis of the Wnt target gene, Axin2, and for immunofluorescence analysis with the proliferation marker, Ki67 and the hepatocyte differentiation marker, HNF4-alpha. To examine the tissue-specific activity of SWEETS-1, expression of Axin2, was measured by qPCR in kidney, salivary gland, intestine, heart, lung, pancreas, skin and spleen.
Results: SWEETS-1 enhanced Wnt signaling in the Huh-7 hepatic cell line to a level similar to that of RSPO. In contrast to RSPO, which induced Wnt signaling in the Huh-7 hepatic and HEK293 non-hepatic cell lines, SWEETS-1 activity was limited to Huh-7 cells. SWEETS-1 enhanced the expression of the Wnt target gene, Axin 2, to a level similar to that of RSPO. In contrast to RSPO which induced Wnt signaling in kidney, salivary gland, intestine, heart and pancreas, SWEETS-1 induced Axin2 expression in liver only. Immunofluorescence analysis revealed that SWEETS-1 induced Ki67 positive nuclei specifically in HNF4-alpha-hepatocytes.
Conclusion: These results show that SWEETS-1 can stimulate hepatocyte-specific cell regeneration. This approach may be beneficial for the treatment of liver diseases.

THU207

Primed liver regeneration in protein convertase subtilisin/kexin type 9 knockout mice is associated with increased lipids uptake and hypercholesterolemia

Jacopo Gavini[1], Dana Leuenberger[1], Daniel Sanchez-Taltavull[1], Riccardo Tombolini[1], Vanessa Banz[1], Daniel Candinas[1], Deborah Stroka[1]. [1]*Department of Biomedical Research, Visceral Surgery and Medicine, Bern, Switzerland*
Email: jacopo.gavini@dbmr.unibe.ch

Background and Aims: Liver regeneration is a complex and well-orchestrated process following partial hepatectomy (PH). Proprotein Convertase Subtilisin/Kexin Type 9 (PCSK9) has an important role in the regulation of plasma low-density lipoprotein cholesterol (LDLc) levels by shuttling liver LDL receptors (LDLR) for degradation, which in fact mediates hepatic clearance of LDLc from the circulation. Transient hepatic steatosis following PH indicates a functional relationship between lipid metabolism and hepatocyte proliferation, all phenomena not well defined yet. Herein, we studied the regenerative potential of PCSK9 knockout (KO) mice after PH in order to determine the functional significance of PCSK9 in the context of hepatic lipid metabolism during liver regeneration.
Method: A single-cell RNA sequencing (scRNA-seq) database of murine liver cells isolated following a standard two-thirds PH was examined for gene expression analysis. LDLR expression, Oil Red O-stained hepatic lipid droplets accumulation and lipid parameters in the serum were deeply analyzed after PH, as well as hepatocyte proliferation and liver regeneration capability in PCSK9 KO and control mice.

Results: scRNA-seq data showed that PCSK9 was mainly expressed in cholangiocytes and hepatocytes, where exclusively in the latter its expression was regulated by PH. mRNA and protein expression levels of LDLR were increased in PCSK9 KO mice before PH and after liver resection. Greater intrahepatic transient lipid droplets accumulation and lower cholesterolemia were observed in the KO animals compared to the controls, with a markedly reduced cholesterol biosynthesis rate (3-Hydroxy-3-Methylglutaryl-CoA Reductase – HMGCR gene expression). There were no histological alterations in liver morphology and architecture between the two groups, whereas an increased liver/body weight ratio together with a higher proliferation index and pro-proliferative genes upregulation were observed 30–36 h after PH in PCSK9 KO mice.
Conclusion: We observed increased hepatocellular cholesterol uptake and enhanced liver regeneration in PCSK9 KO mice. The increase of LDLR expression as well as the higher transient liver steatosis and hypocholesterolemia seem to be crucial factors and events in priming the compensatory hyperplasia of the liver after PH.

Targeting the embryonic liver with ultrasound-guided in utero nano-injection to manipulate gene expression during liver development and hematopoiesis

Jingyan He[1], Noémi K. M. Van Hul[2], Jan Mašek[2], Niklas Björkström[3], Emma Andersson[1,2]. *[1]Karolinska Institutet, Department of Cell and Molecular Biology, Solna, Sweden; [2]Karolinska Institutet, Department of Biosciences and Nutrition, Huddinge, Sweden; [3]Karolinska Institutet, Department of Medicine, Huddinge, Sweden*
Email: jingyan.he@ki.se

Background and Aims: In order to understand developmental principles in liver, gain of function, loss of function, and lineage tracing studies in vivo are undertaken to decipher gene function during stem cell proliferation, commitment, and differentiation. Manipulation of gene expression in liver cells typically relies on liver-specific cre-drivers (eg AFP-cre) or AAV specific to liver cell types (eg AAV8 for hepatocytes). However, traditional mouse genetics approaches are slow and expensive, while AAV approaches are more rapid, but limited by viral tropism. Furthermore, the fetal liver is home to both future liver cells (hepatocytes and cholangiocytes), as well as the future hematopoietic system. We therefore aimed to develop a technique to rapidly and flexibly manipulate gene expression in fetal liver stem cells and hematopoietic stem cells (HSCs).
Method: We adapted ultrasound-guided in utero nano-injection to achieve gene manipulation in embryonic liver (Fig 1). To determine the optimal parameters to target liver cells and HSCs, we tested different injection volumes, viral titers, injection sites, and developmental stages. Developmental stages tested include E7.5 (exocoelomic cavity), E10.5 (liver bud) and E13.5 (liver). Analysis of targeted cells is performed by qPCR, scRNA seq, FACS, and immunocytochemistry/immunohistochemistry on liver sections.

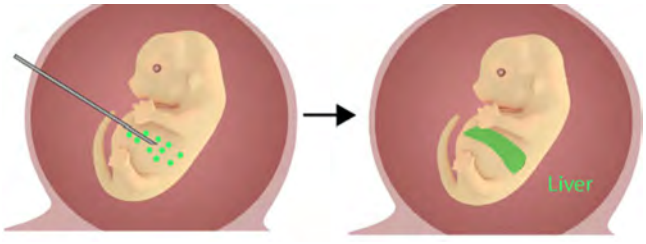

Figure: Ultrasound-guided nano-injection with GFP-encoding lentivirus (or cDNA/shRNA/sgRNA of interest) to target the liver.

Results: In utero nano-injection with GFP-encoding lentivirus results in successful viral integration in embryonic liver cells and HSCs, allowing gain of function, loss of function or lineage tracing. GFP+ cells are detectable in liver as early as E10.5, and can be detected in blood cells at postnatal stages.
Conclusion: Ultrasound-guided in utero nano-injection is a feasible, powerful method to investigate gene functions in liver development and hematopoiesis. It requires fewer mice, is faster and cheaper compared to using genetically engineered mice. With the help of this technique, we are now investigating gene function in liver and hematopoietic development.

Development and automation of 3D innovative hiPSC-based liver organoids including the microenvironment for phenotyping screening - application on metabolic diseases

Roudaut Méryl[1,2], Caillaud Amandine[1,3], Girardeau Aurore[1], Mikael Croyal[1,4], Aurélie Thedrez[1], Wieneke Dijk[1], Matthieu Pichelin[1,3], Lucie Arnaud[1], Cédric Le May[1], Elodie Vandenhaute[2], Zied Souguir[2], Nathalie Maubon[2], Bertrand Cariou[1,3], Karim Si-Tayeb[1,3]. *[1]l'institut du thorax INSERM UMR 1087/CNRS UMR 6291 / IRS-UN, Team IV- Dyslipidemia and Lipotoxicity, Nantes, France; [2]HCS Pharma, Siège de Lille, Loos, France; [3]Nantes University Hospital Hotel-Dieu, Nantes, France; [4]CRNHO, Inra UMR 1280, Nantes, France, Plateforme de Spectrométrie de Masse, Nantes, France*
Email: karim.si-tayeb@univ-nantes.fr

Background and Aims: We previously showed that urine-derived human pluripotent stem cells (hiPSCs) provide a suitable model to study metabolic diseases, such as familial hypercholesterolemia, upon hepatocyte-like cell (HLC) differentiation. While the direct link between hiPSCs and patients, as well as the abundance of HLCs provide promising advantages, it is impaired by the neonatal characteristic of HLCs and the difficulty to perform high-throughput studies for pharmacological investigations.
To overcome these burdens, we chose to 1. Design a 3D hiPSCs differentiation procedure to enhance their maturation. 2. Adapt our setup to a 96-well format compatible for drug screening.
Method: To reach our goals, we established a partnership with HCS Pharma, which produces an innovative 3D hydroscaffold, BIOMIMESYS®, composed of modified Hyaluronic Acid that can be biofunctionalized with extracellular matrix derivatives, with adjustable stiffness and porosity.
Results: Our strategy allowed us to generate liver organoïds in a 96-well plate format, through a unique and common procedure, without separated cell culture mixed thereafter. We performed a global gene expression analysis throughout their differentiation, and a head-to-head comparison between 2D and 3D showing an enhanced expression of most hepatic genes and non-parenchymal cells such as stellate cells. Immunofluorescence data confirmed, among others, the co-localization of albumin-positive hepatocytes, desmin-positive stellate cells and LYVE1 positive sinusoidal endothelial cells in liver organoids. At the functional level, liver organoids showed several CYP activities including CYP3A4, at the basal level and increased upon induction, the ability to accumulated lipids upon amiodarone or ethanol treatment and to activate stellate cells into myofibroblasts.
Conclusion: We can produce patient-specific metabolically functional liver organoids in Biomimesys™ in a format adapted for molecular screening and/or metabolic target identification.

Dynamic characterization of revascularization in decellularized whole-liver scaffold

Beibei Guo[1], Qian Zhou[1], Jing Jiang[1], Jiaxian Chen[1], Xi Liang[2], Jiaojiao Xin[1], Dongyan Shi[1], Keke Ren[1], Xingping Zhou[1], Hozeifa Mohamed Hassan[1], Jun Li[1]. *[1]The First Affiliated Hospital, Zhejiang University School of Medicine, State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China; [2]Taizhou Central Hospital, Taizhou University Hospital, Precision Medicine Center, Taizhou, China*
Email: lijun2009@zju.edu.cn

Background and Aims: Vascular reconstruction of decellularized whole-liver scaffold is a major challenge for in vivo transplantation of functional recellularized whole-liver. We aimed to reendothelialize whole-liver scaffold, and characterize the biological process to evaluate degrees of revascularization.
Method: We reendothelialized the scaffold with 1.5×10^7 human umbilical vein endothelial cells (HUVECs), followed by 3 weeks of continuous perfusion using the self-developed bioreactor. Native, decellularized and reendothelialized (days 1, 3, 7, 14 and 21) livers were collected for histological analysis and further proteomic analysis with LC-MS/MS technique. Functional enrichment analysis was performed with the DAVID database.
Results: HUVECs were gradually migrated and adhered to form an endothelium after reendothelialization. Dynamic histological analysis on reendothelialized samples harvested at days 1, 3, 7, 14 and 21 shown revascularization process. Revascularization reduced blood leakage and platelet adhesion upon blood perfusion. The positive staining with VE-cadherin further confirmed the integrity of endothelial barrier. Principal component analysis shown that the samples of day 14 and 21 are significantly different from those at other time points. Proteomic analysis shown that numbers of human-derived proteins were gradually increased from day 1 and synthesized extracellular matrix (ECM) proteins participated in ECM reorganization. 114 proteins, mainly participate in the process of cell adhesion, protein synthesis and energy metabolism, were always expressed in the process of three-week revascularization. Compared with day 1, proteins associated with the regulation of vasoconstriction were significantly differentially expressed at day 14 and 21. Three differential proteins (MYBPC, MYH1 and alpha-SMA), associated with cytoskeleton regulation and cell phenotype transition, were validated by immunohistochemistry.

Conclusion: This study successfully achieved the reendothelialization of whole-liver scaffold for up to 3 weeks. Further proteomic analysis revealed that stable and mature vessels were formed after two-week culture. Overall, revascularization dynamic characteristics will better promote transplantation of functional recellularized whole-liver.

Optimal liver metabolism and proliferation require the tight junction protein claudin-3

Felix Alexander Baier[1], Daniel Sanchez-Taltavull[1], Fadi Jebbawi[2], Adrian Keogh[1], Nicolas Melin[1], Mariana Mota Castro Dias[3], Urban Deutsch[3], Britta Engelhardt[3], Mikio Furuse[4], Adolfo Odriozola[5], Benoit Zuber[5], Daniel Candinas[1], Deborah Stroka[1]. *[1]University of Bern, Inselspital Bern, Visceral Surgery Research Laboratory, Department for Biomedical Research, Bern, Switzerland; [2]University of Basel, Department of Pharmaceutical Sciences, Switzerland; [3]Theodor Kocher Institute, University of Bern, Immunobiology Research Group, Bern, Switzerland; [4]National Institute for Physiological Sciences, Division of Cell Structure, Okazaki, Japan; [5]University of Bern, Institute of Anatomy, Bern, Switzerland*
Email: mr.rock@web.de

Background and Aims: The expression of hepatic tight junction proteins and their contribution to homeostasis and regeneration remained largely unexplored. Here, we determine the cell type specific expression of tight junction genes in murine livers. We further explore the regulation and functional importance of the transmembrane protein CLDN3 in normal and regenerating livers.

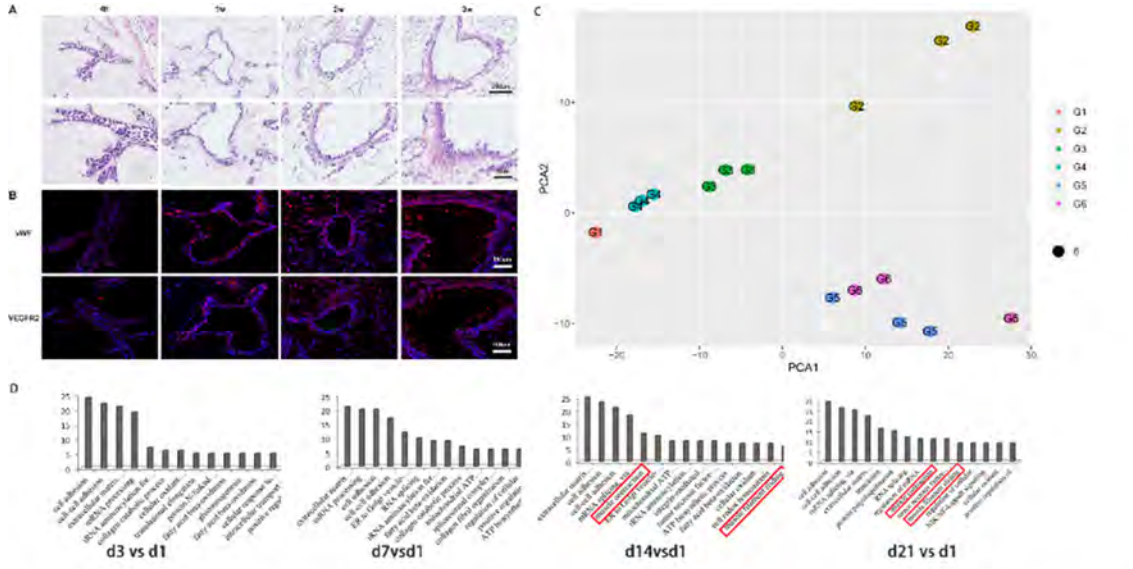

Figure1: Results of re-vasculaturation in vitro and dynamic proteomic analyses. (A) H&E staining of re-vascularization in different phases. (B) Immunofluorescence staining of markers of endothelial cell ,vWF and VEGFR 2. (C) Principal omponent analysis G2-G6 respectively represent d1,3,7,14,21.. (D)Go Ontology enrichment analyses on different

Figure: (abstract: THU210)

Method: Murine livers were used for tissue- and single cell RNA-seq. CLDN3 localization was determined by immunofluorescence. CLDN3 +/+ or CLDN3−/− livers were analysed by electron microscopy, fluorescence-activated cell sorting and liquid chromatography mass spectrometry. Lipid content was quantified with oil-red. Mice were subjected to 2/3 partial hepatectomy. Proliferation was quantified with Ki67 and pHH3 stainings. Cell cycle gene expression was determined by RT-qPCR. Barrier impairments were assessed with total bile acid measurements. Differential gene expression was analysed by tissue RNAseq with DESeq2.
Results: We determined the profile of tight junction gene expression in the main liver cell types, showing that tight junction transcripts can be found in hepatocytes and cholangiocytes but also on non-parenchymal cell populations. CLDN3 was among the highly expressed- and regulated genes in native and regenerating livers. CLDN3 had a zonated expression pattern. CLDN3−/− mice had microscopically intact tight junctions, but showed significantly downregulated hepatic energy metabolism and suboptimal cell proliferation in the regeneration model.
Conclusion: Our data suggests a functional role of CLDN3 for maintenance of energy homeostasis and optimal regeneration, proving that the function of hepatic tight junction proteins extends beyond basic membrane sealing.

THU213

Serum transferrin levels reflect hepatocyte nuclear factor 4 alpha activity in the liver

Nurdan Guldiken[1], Josepmaria Argemi[2], Berivan Gürbüz[1], Stephen Atkinson[3], Karim Hamesch[4], Joaquin Cabezas[5,6], Sheng Cao[7], Philippe Mathurin[8], Vijay Shah[7], Christian Trautwein[9], Mark Thursz[10], Ramon Bataller[11,12], Pavel Strnad[9]. *[1]University Hospital RWTH Aachen, Medical Clinic III, Gastroenterology, Metabolic Diseases and Intensive Care, Germany; [2]University of Pittsburgh Medical Center, Pittsburgh Liver Research Center, United States; [3]Imperial College London, Department of Hepatology, United Kingdom; [4]University Hospital RWTH Aachen, Germany, Medical Clinic III, Gastroenterology, Metabolic Diseases and Intensive Care, Germany; [5]University of North Carolina at Chapel Hill, Liver Center, United States; [6]University Hospital Marqués de Valdecilla, Gastroenterology and Hepatology Unit; [7]Mayo Clinic, Division of Gastroenterology and Hepatology; [8]Hôpital Claude Huriez, Services des Maladies de l'Appareil Digestif, CHRU Lille, and Unité INSERM 995; [9]University Hospital RWTH Aachen, Germany, Medical Clinic III, Gastroenterology, Metabolic diseases and Intensive Care; [10]Imperial College London, Department of Hepatology; [11]University of Pittsburgh Medical Center, Pittsburgh Liver Research Center; [12]University of North Carolina at Chapel Hill, Liver Center*
Email: pstrnad@ukaachen.de

Background and Aims: Decreased serum transferrin (TF) levels constitute an independent predictor of short term mortality in patients with alcoholic hepatitis (AH), decompensated liver cirrhosis and acute-on-chronic liver failure (ACLF). The aim of this study was to evaluate the pathomechanisms underlying the prognostic usefulness of serum transferrin in individuals with chronic liver disease.
Method: Factors regulating transferrin expression were assessed via transcriptomic and methylomic analysis in human livers with/without severe AH (sAH). The biological relevance of identified candidates was tested in primary mouse hepatocytes. An *in silico* analysis of transcriptomic data from alcoholic cirrhosis liver specimen was complemented by assessment of dual serum-mRNA samples from 33 patients with chronic liver disease of different etiologies.
Results: Hepatic transcriptome analysis of sAH samples revealed a strong positive relationship of *TF* with the nuclear factor *HNF4a* ($r = 0.74$, $p < 0.0001$) and negative associations with the cytokines TGFb1, TNFa, IL1b, and IL6. Hypermethylation of the *TF* gene in patients with sAH appears to be of regulatory importance. In primary hepatocytes, treatment with TGFb1 or the HNF4a inhibitor BI6015 suppressed *TF* production, while exposure to TNFa, IL1b, and IL6 had no effect. *In silico* data demonstrated a correlation between *TF* and *HNF4a* mRNA levels in patients with alcoholic cirrhosis. In patients with different chronic liver diseases, serum TF levels moderately correlated with hepatic *TF* ($r = 0.51$, $p = 0.004$). Immunohistochemical und biochemical analysis confirmed reduced HNF4a and TF protein levels in individuals with liver cirrhosis.

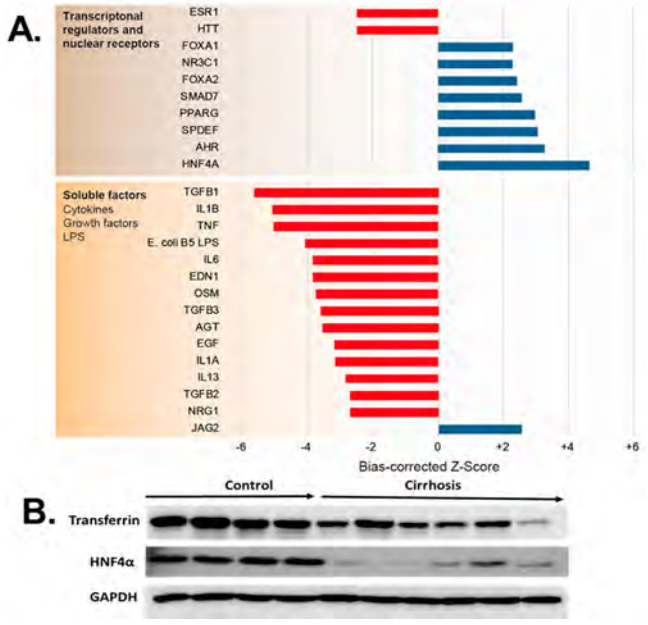

Figure: **Regulation of transferrin production in human liver disease.** (A) Ingenuity Pathway Analysis was used to identify factors predicted to control the Transferrin-correlated transcriptome in individuals with alcoholic hepatitis (B) immunoblotting was used to determine transferrin and HNF4α levels in patients with and without alcoholic cirrhosis. GAPDH was used as a loading control.

Conclusion: Decreased TF serum levels indicate impaired intrahepatic *HNF4a* signaling and may therefore predict the development of hepatocellular failure.

THU214

Macrophage regulation of PKM2 during liver regeneration process

Nicolas Melin[1], Zindel Joel[1], Giulio Loforese[1], Isabel Büchi[1], Tess Brodie[1], Daniel Sanchez-Taltavull[1], Daniel Candinas[1], Deborah Stroka[1]. *[1]University of Bern, Departement for BioMedical Research, Visceral and Transplantation Surgery, Bern, Switzerland*
Email: nicolas.melin@dbmr.unibe.ch

Background and Aims: The pyruvate kinases (PKs) are responsible for the last and limiting step of the glycolytic pathway. Four PKs proteins, PKL, PKR, PKM1, and PKM2, are differentially expressed depending on cell type and metabolic need, with PKL being the hepatocyte-specific PK. PKM2 is expressed in proliferative cells such as cancer cells and stem cells, as well as immune cells. In macrophages, the polymerization state dictating the nuclear or cytoplasmic localization of PKM2 has been shown to change depending on their polarization. The tetrameric protein complex is enzymatically active in the cytoplasm, and the nuclear dimeric complex acts as a transcriptional activator via binding to HIF1a, promoting proinflammatory cytokine production.
Method: Liver regeneration was induced by 60% partial hepatectomy and inhibited using shikonin or adenovirus delivered shPKM2. PKs expression was evaluated by qPCR, single-cell RNA-Seq, mass cytometry, and immunostaining. Isolated human hepatocytes were exposed to recombinant PKM2 was produced in bacteria and isolated by affinity chromatography.

Results: Analysis of PKs expression during liver regeneration, revealed a decrease of PKL and a parallel increase of PKM2 as early as 3 h post-PH and sustained through the regenerative process up to 7 days. Interestingly, PKM2 inhibition by shikonin or shPKM2 resulted in a decrease in liver regeneration markers. The identification of PKM2 expressing cells revealed that PKM2 was increased in the bone marrow-derived macrophage but not in the Kupffer cells. The PKM2 polymerization state was change between 12 h and 24 h post-PH (also observable in the serum), which was accompanied by a macrophage polarization shift.
Careful examination of PKM2 immuno-staining and mass cytometry showed that pericentral hepatocytes have a moderate level of cytoplasmic PKM2. This increased PKM2 at 3 h and 6 h post-PH proved the presence of PKM2 protein besides the lack of hepatocyte PKM2 RNA expression. In vitro, we could show that hepatocytes can uptake recombinant PKM2 suggesting the possible macrophage origin of the hepatocyte PKM2.
Conclusion: PKM2 is increased in macrophages shortly after PH and is necessary for liver regeneration. The evolution of the macrophage polarization during liver regeneration coincides with a shift in PKM2 polymerization. Finally, the release of PKM2 in the extracellular space may allow its uptake by hepatocyte, suggesting compensation mechanism for the loss of PKL activity.

THU216
Diploid hepatocytes drive physiological liver renewal in adult humans

Paula Heinke[1], Fabian Rost[2], Julian Rode[3], Thilo Welsch[4], Kanar Alkass[5], Joshua Feddema[1], Mehran Salehpour[6], Daniel Primetzhofer[6], Henrik Druid[5], Göran Possnert[6], Lutz Brusch[3], Olaf Bergmann[1,7]. *[1]TU Dresden, Center for Regenerative Therapies, Dresden, Germany; [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany; [3]TU Dresden, Center of Information Services and High Performance Computing, Dresden, Germany; [4]University Hospital Carl Gustav Carus, TU Dresden, Visceral-, Thoracic- and Vascular Surgery, Dresden, Germany; [5]Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden; [6]Uppsala University, Department of Physics and Astronomy, Ion Physics, Uppsala, Sweden; [7]Karolinska Institutet, Department of Cell and Molecular Biology, Stockholm, Sweden*
Email: paula.heinke@tu-dresden.de

Background and Aims: The liver is an organ with an enormous regenerative capacity and current studies aim to understand this extraordinary property. Specific aspects of hepatocyte renewal in humans remain unclear, as the direct exploration of these processes is difficult due to methodological restrictions. Detailed knowledge about the age distribution of human hepatocytes and the dynamics of hepatocyte renewal is still lacking.
Method: We used retrospective radiocarbon (^{14}C) birth dating to establish the age of hepatocytes in healthy, adult humans. This technique utilizes the incorporation of nuclear-bomb-test-derived ^{14}C into genomic DNA to quantify cellular ages. A mathematical model was built, using a kinetic equation that accounts for cell division, cell death as well as changes in ploidy, to characterize human hepatocyte turnover from experimental ^{14}C data.
Results: To establish the dynamics of cell renewal in the human liver with ^{14}C birth dating we analyzed liver tissues from n = 32 healthy subjects aged 20–82 years. Our observations indicate that hepatocytes are renewed throughout adulthood and that there is no evidence for a quiescent population in homeostasis. Instead, by analyzing the different ploidy classes in the human liver, we found diploid hepatocytes to show a turnover rate of 45% per year and an average life-span of one year in mid-aged individuals. On the contrary, hepatocytes of higher ploidy classes display much slower turnover dynamics of seven per cent per year and live around eight years. These findings support the view that in contrast to rodents, the physiological liver renewal in humans is mainly dependent on diploid hepatocytes, whereas polyploid cells are compromised in their ability to divide. Moreover, polyploid hepatocytes do not frequently reverse to a diploid state under homeostatic conditions.
Conclusion: In our study, we utilize ^{14}C dating to provide a new integrated model of hepatocyte generation in humans that gives fundamental insights on their turnover dynamics. We show that the age distribution of human hepatocytes is highly dependent on the ploidy level, which increases substantially with aging. Our data indicate that age-related liver diseases might at least partly be related to impaired hepatocyte renewal in polyploid hepatocytes.

Imaging human liver regeneration by multiphoton microscopy

Scott Davies[1,2], Dean Kavanagh[3], Gary Reynolds[1,2], David Hodson[4], Zania Stamataki[1,2]. *[1]University of Birmingham, Centre for Liver and Gastrointestinal Research, Institute of Immunology and Immunotherapy, Birmingham, United Kingdom; [2]NIHR Birimingham Biomedical Research Centre, University Hospitals, NHS Foundation Trust, United Kingdom; [3]University of Birmingham, Institute of Cardiovascular Sciences, Birmingham, United Kingdom; [4]University of Birmingham, Institute of Metabolism and Systems Research (IMSR), Birmingham*
Email: s.p.davies.1@bham.ac.uk

Background and Aims: The combination of mouse models and intravital microscopy has provided unique insight into liver disease pathogenesis. However, mouse models do not accurately represent human inflammatory disease pathogenesis. We aimed to adapt methods commonly associated with intravital microscopy to image live human liver disease tissue ex vivo, to study liver regeneration in the context of drug discovery.
Method: Using 3D-printing, we developed *in situ* perfusion systems and fluorescence labelling strategies which reproducibly permit the imaging of live human tissue using multiphoton microscopy (MPM). We have access to tissue from over 250 liver transplants a year at the Queen Elizabeth hospital, Birmingham, UK. In both non-cirrhotic donor livers and end stage disease explants, we assessed tissue viability using reporters of mitochondrial membrane potential, enzymatic activity and endocytosis. We identified regions of collagen-rich fibrosis using second harmonic generation (SHG). Finally, we observed cellular responses in the tissue in response to acute injury by cauterisation.
Results: Sinusoidal and parenchymal architecture was identified in *ex vivo* liver tissues using MPM and commercially available contrast dyes. These tissues displayed evidence of viability and regeneration up to 48 hr following perfusion. We could track the migration of infused fluorescence-labelled leukocytes within the tissue in three dimensions to a depth of >100 µm. We documented areas of necrosis, regeneration, and hepatocyte phagocytosis proximal to cauterisation injury.
Conclusion: Our methodology provides a new platform to study authentic human liver disease; it permits the observation of regeneration in response to injury, as well as the assessment of pharmacological compounds, in real time.

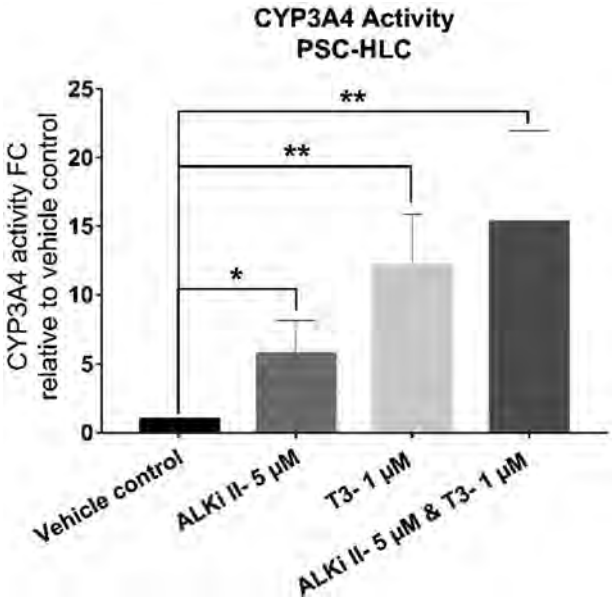
THU218
Thyroid hormone and TGF-? inhibition drive functional maturation of human pluripotent stem cell-derived hepatocytes

Sarah Withey[1,2], Dave Gerrard[3], Hannah Leeson[1], Rebecca Atkinson-Dell[4], Sean Harrison[4], Melissa Baxter[2], Ali Al-Anbaki[2], Karen Piper Hanley[2], Ernst Wolvetang[1], Neil Hanley[2]. *[1]The University of Queensland, Australian Institute for Bioengineering and Nanotechnology, Brisbane, Australia; [2]The University of Manchester, Division of Diabetes, Endocrinology & Gastroenterology, Manchester, United Kingdom; [3]The University of Manchester, Division of Evolution & Genomic Sciences, Manchester, United Kingdom; [4]The University of Manchester, Division of Diabetes, Endocrinology & Gastroenterology, United Kingdom*
Email: neil.hanley@manchester.ac.uk

Background and Aims: The usefulness of pluripotent stem cell-derived hepatocytes (HLC) for modeling hepatotoxicity, human disease, or therapy depends on their ability to recapitulate the many functions of the adult liver. This includes expression of nuclear receptors, transcription factors and activity of the adult-specific cytochrome P450 (CYP450) enzymes which metabolize xenobiotics. We have previously demonstrated by transcriptome, proteome, and functional analyses that current HLCs from multiple labs are most similar to fetal rather than adult liver, hindering their use as a reliable hepatocyte cell model. We aimed to identify and target gene pathways that would advance hepatic maturation in iPSC derived HLCs.

Method: We undertook RNA-sequencing of HLCs throughout differentiation and compared their transcriptomes to human adult liver, fetal liver and multiple other human fetal tissues. We used differential gene expression and advanced pathway analysis tools to identify key sub-optimally expressed transcription factor networks in HLC which we hypothesized were limiting their ability to functionally mature. We identified and screened a number of small molecules predicted to target these suboptimal networks to successfully advance hepatic maturation. Quantitative PCR, Western blot, albumin secretion and CYP3A4 enzyme expression (luciferase detection) were used to measure maturation state.

Results: We identified HNF4A and CEBPA as limiting factors in hepatic maturation. Their expression and that of their multiple downstream targets is sub-optimally expressed in HLC, at levels most similar to fetal liver. We further predicted TGF-β overexpression in HLCs was inhibiting HNF4A. We therefore treated differentiating cells with thyroid hormone (T3) and ALK5i II (TGF-β receptor inhibitor) to significantly increase CEBPA and HNF4A expression, respectively, and confirmed this by QPCR and Western blot. On average, combined treatment increased hepatic gene expression (including ALB, A1AT, CYP3A4, CYP2C9, CYP2C19 and CYP3A7) by 10 to over 100-fold compared to published protocols. CYP3A4 enzyme activity increased by 15-fold on average. We also detected significant increases in Albumin secretion. We confirmed that the maturation promoting effects of these treatments were reproducible across multiple cell lines and with multiple common HLC differentiation protocols.



Conclusion: HNF4A and CEBPA transcriptional networks are sub-optimally expressed in HLCs. TGF-β signaling is over-represented in PSC-derived HLC generated by multiple labs. Treatment of HLC with T3 and ALK5i II during the differentiation protocol promotes significant increases in both transcription factors and their downstream targets. CYP450 gene expression and activity is restored to values more similar to adult liver.

THU219

Nicotinamide riboside promotes liver regeneration by enhancing mitochondrial fatty acid oxidation

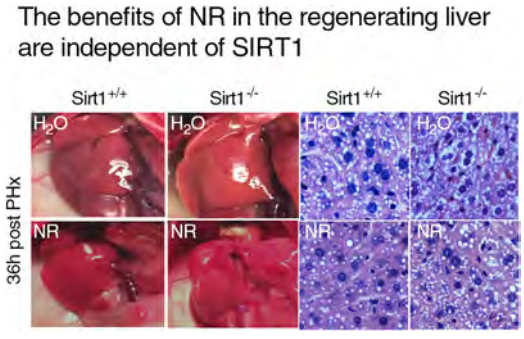
Sarmistha Mukherjee[1], Karthikeyani Chellappa[1], James Mo[1], Lauren Paolella[2], Timothy Luongo[1], Qingwei Chu[1], Qiang Tong[3], Joseph A Baur[1]. *[1]University of Pennsylvania, Department of Physiology and Institute for Diabetes, Obesity and Metabolism, Philadelphia, United States; [2]University of Pennsylvania, Department of Physiology and Institute for Diabetes, Biochemistry and Molecular Biophysics Graduate Group, Philadelphia, United States; [3]Baylor College of Medicine, Pediatrics-Nutrition, Medicine, Molecular Physiology & Biophysics, Houston, United States*

Email: baur@pennmedicine.upenn.edu

Background and Aims: The regenerative capacity of the liver is essential for the replacement of hepatocytes that are lost due to injuries, surgical resection, or chronic disease processes. Nicotinamide adenine dinucleotide (NAD) levels markedly decline during liver regeneration, which may result from metabolic competition for common precursors required for DNA synthesis. We have previously showed that augmenting NAD synthesis, either genetically or by supplementing with the precursor nicotinamide riboside (NR), is sufficient to accelerate liver regeneration in mice. However, the underlying mechanisms have remained unclear. NAD deficiency in the injured liver could plausibly slow regeneration through direct effects on metabolism and bioenergetics, or indirectly through changes in the activity of the signaling enzymes such as Sirtuins. Here, we aimed to understand the molecular mechanisms underlying this improved liver regeneration.

Method: We examined the effects of NR supplementation on mitochondrial function and respiratory capacity in isolated hepatocytes and in isolated mitochondria. We employed genetic models of liver-specific deletion of Sirtuin 1 (SIRT1) and mitochondrial Sirtuin 3 (SIRT3), both NAD-dependent enzymes that have been implicated in liver regeneration and fatty acid oxidation.

Results: NR treatment enhanced the fatty acid oxidation capacity of mitochondria isolated from regenerating livers and increased circulating levels of ketone bodies, suggesting increased beta oxidation of fatty acids *in vivo*. Deletion of hepatic SIRT1 or SIRT3 impaired liver regeneration, however NR supplementation still improved regeneration in these models. Treating primary hepatocytes with NR for 5 hours was sufficient to increase fatty acid oxidation, glucose output, and production of beta-hydroxybutyrate, demonstrating that NR rapidly increases anabolic capacity.



Conclusion: Increasing NAD concentration fuels anabolic processes in hepatocytes by promoting mitochondrial oxidation of endogenous lipid stores in a SIRT1 and SIRT3-independent manner. Improved respiratory capacity is observed even in isolated mitochondria. Our data support a direct metabolic role of NAD in promoting

mitochondrial fatty acid oxidation from lipid substrates during liver regeneration. Thus, providing supplemental NAD precursors and lipid substrates may be effective strategies to promote recovery from liver injuries.

Email: andrea.perra@unica.it

Background and Aims: Although the hepatomitogenic activity of 3,5,3'-triiodothyronine (T3) is well established, the wide range of harmful effects exerted by this hormone precludes its use in regenerative therapy. The aim of this study was to investigate whether two novel agonists of thyroid hormone receptor-beta (TRbeta), the prodrug TG68 and the active compound IS25, could exert a mitogenic effect in the liver in the absence of T3/TRalpha-dependent side effects.
Method: Three different doses of both compounds (12.5, 25 and 50 mcg/100 g body weight) dissolved in drinking water were given to F-344 male rats for 1 week. Activation of TRbeta was assessed by qRT-PCR. The proliferative effect was measured by immunohistochemistry, qRT-PCR and western blot.
Results: The results showed that, at all the employed doses, both drugs displayed a significant increase in bromodeoxyuridine incorporation (from 14 to 28% vs. 5% of controls), which was associated with increased mitotic activity. Hepatocyte proliferation was preceded by up-regulation of *Dio1* and *Spot14*, two classical TRbeta target genes. No significant signs of liver toxicity, as showed by lack of increased serum transaminase levels, was observed following the administration of IS25 and TG68. No change in the serum levels of free fraction of thyroid hormones was detected after treatment with the two agonists. Noteworthy, while cardiac hypertrophy typical of T3 was not observed, beneficial effects, such as lowering blood triglyceride levels, were associated to TG68 administration. Importantly, no proliferation of pancreatic acinar cells, such as that observed after T3 treatment, was detected, suggesting the hepato-specificity of these novel TRbeta agonists.
Conclusion: Here we show that TG68 and IS25 induce hepatocyte proliferation without obvious toxicity. Hence these agents may be useful for regenerative therapies in liver transplantation or other surgical settings.

Liver transplantation and hepatobiliary surgery: Clinical aspects

Parenchyma-sparing hepatectomy improves salvageability and survival for solitary small intrahepatic cholangiocarcinoma

Hui Li[1], Jinjiu Wang[1], Bo Ren[1], Jiaxin Li[1], Lin Xu[1], Genshu Wang[2], Hong Wu[1]. [1]*West China Hospital, Liver Surgery & Liver Transplantation, Chengdu, China;* [2]*The Third Affiliated Hospital of Sun Yat-sen University, Hepatic surgery, Guangzhou, China*
Email: 445613487@qq.com

Background and Aims: Previous study has reported comparable survival outcomes and increased perioperative morbidity for major hepatectomy in comparison to minor resection for intrahepatic cholangiocarcinoma (ICC). However, their conclusion was draw on patients with heterogeneous tumor characteristics, for part of which major resection was inevitable due to large tumor size. This study aimed to investigate the prognostic impact of parenchyma-sparing hepatectomy (PSH) on solitary small ICC.
Method: A total of 184 patients who underwent hepatectomy for solitary small ICC (≤5 cm in size) from 2009 to 2017 were identified. Short- and long-term outcomes were compared between PSH and Non-PSH approach.
Results: 95 (51.6%) patients underwent PSH and 89 (48.4%) patients underwent Non-PSH for solitary small ICC. Baseline tumor characteristics were comparable between two groups. PSH was associated with less intraoperative blood loss (212.9 mL versus 363.5 mL, p = 0.038), lower transfusion rate (7.4% versus 16.9%, P = 0.048), without increasing the frequency of tumor recurrence (60.0% versus 58.4%). No significant differences were observed in overall survival (OS), recurrence-free survival (RFS) and liver RFS (p = 0.627, 0.769 and 0.538, respectively). 109 (59.2%) patients experienced recurrence, of them, 67 (36.4%) were intrahepatic recurrence. Subgroup analysis of patients with liver-only recurrence demonstrated an increased opportunity of repeat hepatectomy for PSH compared to Non-PSH (21.2% versus 2.9%, p = 0.031), thus resulting in improved liver OS (p = 0.016). Multivariate analysis identified PSH approach and repeat resection for recurrent lesion as independent favor factors for liver OS.
Conclusion: PSH was associated with improved perioperative outcomes while did not increase liver recurrence in comparison to Non-PSH. PSH offered an increased rate of salvage hepatectomy for recurrent tumor, thus improving long-term survival in case experienced liver recurrence.

THU222

Reducing length of stay in patients following a liver transplant

Abdulrhman Alamr[1], Karim Qumosani[1], Anouar Teriaky[1], Anton Skaro Skaro[1], Kelly Thomas Thomas[2], Sandy Williams Williams[2], Lynne Sinclair Sinclair[2], Corinne Weernink Weernink[2], Peggy Kittmer Kittmer[2], Melanie Dodds Dodds[2], Sanjay Patel Patel[1], Mayur Brahmania Brahmania[1]. [1]*Western University, London, Canada;* [2]*University Hospital- London Health Sciences Centre, Medicine, London, Canada*
Email: abdulrhman-alamr@hotmail.com

Background:

- There are seven liver transplant centers in Canada, however, data on length of stay (LOS) has not been analyzed in any center.
- Some United States transplant centers have suggested a target of 18 days.
- Prolonged LOS in hospital can result in increased rates of infection, malnutrition, and increased healthcare resource utilization thus a multidisciplinary effort to reduce LOS may improve patient outcomes and reduce costs.
- London health Sciences Centre had a median LOS of 18 days from January 2015–August 2017.

Aims:

1. The aim of the current project was to reduce the median LOS by 3 days over a 16-month period.

Method: Improvement:

2. We used the model for continuous improvement and instituted four Plan-Do-Study-Act (PDSA) cycles to achieve our aim.
3. The 1st PDSA cycle (n = 23) included educational sessions among liver transplant team members.
4. The 2nd PDSA cycle (n = 9) included development of a liver transplant clinical pathway.
5. The 3rd PDSA cycle included institution of a clinical order set (n = 14).

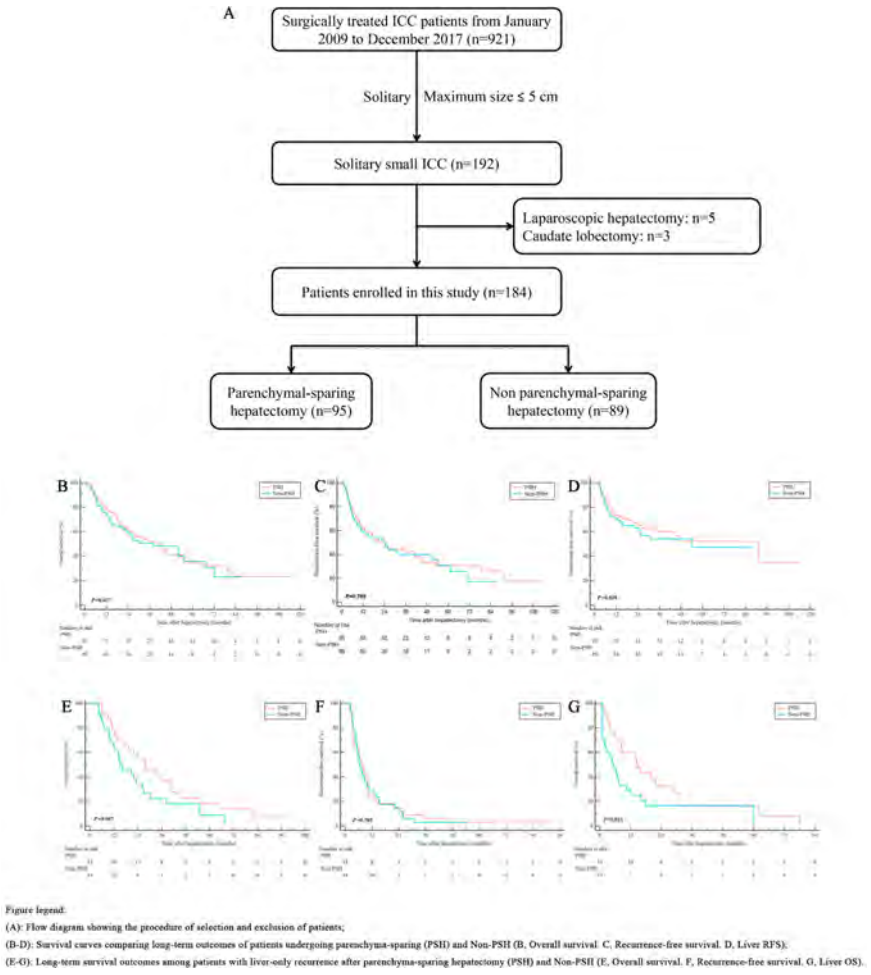

Figure legend:
(A): Flow diagram showing the procedure of selection and exclusion of patients;
(B-D): Survival curves comparing long-term outcomes of patients undergoing parenchyma-sparing (PSH) and Non-PSH (B, Overall survival. C, Recurrence-free survival. D, Liver RFS);
(E-G): Long-term survival outcomes among patients with liver-only recurrence after parenchyma-sparing hepatectomy (PSH) and Non-PSH (E, Overall survival. F, Recurrence-free survival. G, Liver OS).

Figure: (abstract: THU221)

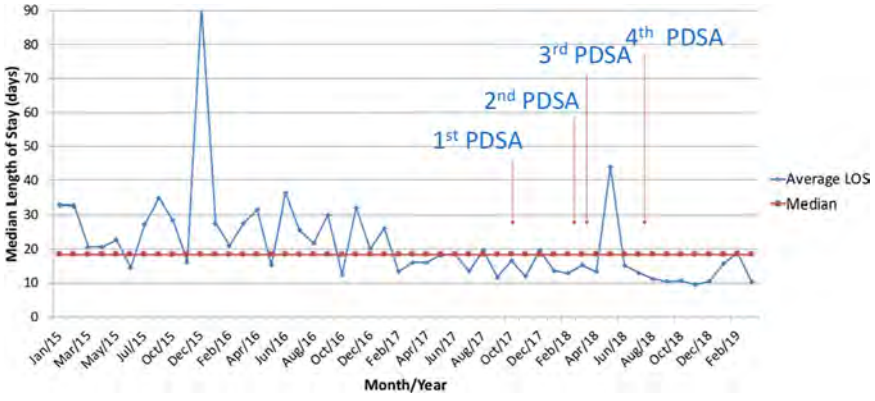

Figure: (abstract: THU222): Run chart rules satisfied over the study period as more than six points were below the median and there was also a trend for more than five consecutive points of improvement.

6. The 4th PDSA cycle (n = 19) involved a patient oriented clinical pathway instrument.

Information gathered/Approach Taken

6. The study took place at University Hospital in London, Ontario from August 2018 – February 2019.
7. 1st PDSA – awareness/education among healthcare professionals.
8. 2nd PDSA – Initiate clinical pathway for patients and healthcare professionals to follow (if applicable).
9. 3rd PDSA – Initiate HUGO Care Set to help facilitate mandatory orders and transfers from ICU.
10. 4th PDSA – Clinical pathway individualized to the patient placed in patient rooms.

Results: Current Status of Project/Project Impact:

6. Over a 16-month period we had 49 liver transplants discharged from hospital with a median LOS of 10 days.

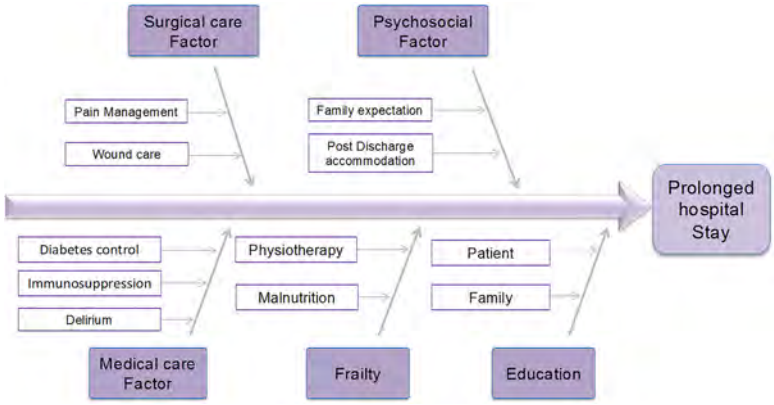

Figure: (abstract: THU222): Ishikawa diagram showing factors relating to Prolonged Hospital Stay.

7. We also analyzed balancing measures and found 30 day and 90 readmission rates to be 18.4% and 22.4%, respectively, which was not significantly different from the 2015–2017 rates of 15.4% and 22.7%.
8. Over this brief study period, $540,000 hospital dollars were saved, which is put toward the global hospital budget.

Conclusion: Development of a multidisciplinary care pathway with patient engagement led to improved discharge rates within a target of ten days.

- Balancing measure of increased readmission rates were not clinically significant.
- During the project period we found further areas of intervention that were preventing patient discharges within target times:
  a. Education/Managing patient expectations
  b. Psychosocial/family support
  c. Frailty (lack of rehabilitation homes/hospital transfer facilities)
  d. Discharge planning
- Macro hospital level issues will be a future barrier to further improvement.

THU223

The presence and outcome of biliary sphincter disorders in liver transplant recipients according to the Rome IV classification

Alejandro Fernandez Simon[1,2], Oriol Sendino[2,3], Karina Chavez Rivera[2], Jordi Colmenero[3,4], Gonzalo Crespo[3,4], Yilliam Fundora[3,5], Pablo Ruiz[3,4], Constantino Fondevila[3,5], Miguel Navasa[3,4], Andres Cardenas[2,3,4]. *[1]Hospital Moises Broggi, Gastroenterology Department, Barcelona, Spain; [2]Institut de Malalties Digestives i Metaboliques, Hospital Clinic, GI Unit, Barcelona, Spain; [3]Institut d'Investigacions Biomèdiques August Pi-Sunyer (IDIBAPS) and Ciber de Enfermedades Hepáticas y Digestivas (CIBEREHD), Barcelona, Spain; [4]Institut de Malalties Digestives i Metaboliques, Hospital Clinic, Liver Transplant Unit, Barcelona, Spain; [5]Institut de Malalties Digestives i Metaboliques, Hospital Clinic, Hepatobiliary and Transplant Surgery, Barcelona, Spain*
Email: acardena@clinic.cat

Background and Aims: Biliary sphincter disorders after liver transplantation (LT) are poorly described. The aim of this analysis was to describe the presence and outcome of patients with papillary stenosis (PS) and functional biliary sphincter disorders (FBSD) after LT, according to the updated Rome IV criteria (Cotton et al. Gastroenterology 2016; 150:1420–29).
Methods: We reviewed all endoscopic retrograde cholangiopancreatographies (ERCP) performed in LT recipients with duct-to-duct biliary anastomosis from 01/2003 to 01/2018. Information on clinical and endoscopic findings was obtained from electronic health records and endoscopy databases. Laboratory and clinical findings were collected at the time of ERCP and 1-month after ERCP.
Results: 1162 patients underwent LT between 01/2003 and 01/2018. 271 LT recipients underwent 691 ERC's during this time period. Twenty patients met the updated Rome IV criteria for PS (former sphincter of Oddi dysfunction (SOD type I) (20/1162, 1.7%). Twelve patients (1.03%) met the Rome IV criteria for FBSD (former SOD type II). Biliary sphincterotomy was performed in 20 (PS group) and 8/12 (FBSD group) respectively. One month after sphincterotomy, bilirubin, ALP and GGT levels decreased in 60%, 70% and 45% of patients respectively in the PS group and in 42%, 58% and 42% of patients respectively in the FBSD group. Thirty-five percent (7/20) of patients with PS had an additional diagnosis on top of PS during follow-up whereas all of the patients initially suspected of having a FBSD group turned out to have a different diagnosis after the ERCP.
Conclusion: PS alone or in combination with other diagnosis can account for a small proportion (1.7%) of LT recipients undergoing ERCP due to cholestasis. Our data does not support the existence of a FBSD after LT. Sphincterotomy is a safe and effective procedure in LT recipients with PS.

THU224

Impact of sarcopenia in patients awaiting simultaneous liver and kidney transplantation: a cohort of study on clinical outcomes

Alessandra Mazzola[1], Raffaele Brustia[2], Bianca Magro[1], Muhammad Atif[3], Nassera Ouali[4], Jerome Touret[5], Benoit Barrou[5], Yvon Calmus[1], Olivier Scatton[2], Filomena Conti[1]. *[1]APHP, Sorbonne université, Unité Médicale de Transplantation Hépatique Hôpital Pitié Salpêtrière, Paris, France; [2]APHP, Sorbonne université, Unité de Chirurgie Hépatobiliaire et Transplantation hépatique, Hôpital Pitié Salpêtrière, Paris, France; [3]APHP, sorbonne Université, Centre d'immunologie et maladies infectieuses, Hôpital Pitié Salpêtrière, Paris, France; [4]APHP, Sorbonne Université, Department of Nephrology and Transplantation, Tenon Hospital, Paris, France; [5]APHP, Sorbonne Université, Service de Transplantation rénale, Pitié Salpêtrière, Paris, France*
Email: alessandra.mazzola3@gmail.com

Background and Aims: Little is known on the impact of sarcopenia in patients undergoing simultaneous liver and kidney transplantation (SLKT). The aim of this single center cohort study was to focus on sarcopenia impact on SLKT recipient's clinical outcomes: patients and grafts survival, infections and complications free-survival at 6 and 12 months.
Methods: Between 2003 and 2018, 79 consecutive patients underwent to SLKT at Pitié Salpêtrière department. Sarcopenia was assessed only in 43 patients through the total psoas muscle area (TPA) at the level of the 3rd lumbar vertebra, measured on a CT scan realized either during the pre-SLKT workup (up to 4 months before SLKT) or in the first 7 days following transplantation. Sarcopenia was defined by TPA <1460 mm^2 in women and <1560 mm^2 in men. Post-operative

complications included biliary and vascular complications. A survival analysis was performed by Kaplan Mayer method with log rank test.
Results: We included 43 SLKT recipients (56% male, median age of 58 (53–63) years). The liver disease was cirrhosis in 74% (n = 32) with a median MELD-score of 21 (20–22), and polycystic liver disease in 26% (n = 11) of patients. Unknown end-stage renal disease was observed in 12 36.2% (n = 12) of patients, with 54,8% (n = 23) of them requiring dialysis before transplantation. Median TPA was 1138 (926–1510) mm^2, and sarcopenia was observed in 72% patients (n = 31). No difference was observed in 6 and 12 months patients or grafts survival censored for death in sarcopenia-group vs. non-sarcopenia-group (overall p = 0.76; liver graft p = 0.8; kidney graft p = 0.83, respectively). Six months post-operative complications free survival was not significantly different in the sarcopenia vs. non-sarcopenia-group respectively, 50% (95%CI: 0.284–0.880) vs. 53%, (95%CI: 0.3791–0.745), (p = 0.61). No difference in infection free survival was observed between two groups at 6 months: 52% (95%CI: 0.213–0.787) vs. 65% (95%CI: 0.4643–0.536), (p = 0.088).
Conclusions: In this cohort of patients, no difference was observed among patients, grafts, complications or infection-free survival among SLKT sarcopenic or none patients. Future studies including more patients are needed to confirm and clarify these results.

THU225

Recent trends and intention-to-treat survival of liver transplantation for non-alcoholic steatohepatitis: an Italian liver transplant registry study. On behalf of AISF, FIRE, SITO and CNT

Alessandro Vitale[1], Silvia Trapani[2], Patrizia Burra[1], Alessandra Bertacco[1], Renato Romagnoli[3], Silvia Martini[3], Paolo De Simone[4], Paola Carrai[4], Matteo Cescon[5], Maria Cristina Morelli[5], Luciano De Carlis[6], Luca Saverio Belli[6], Salvatore Gruttadauria[7], Riccardo Volpes[7], Michele Colledan[8], Stefano Fagiuoli[8], Giorgio Rossi[9], Maria Francesca Donato[9], Fabrizio Di Benedetto[10], Nicola De Maria[10], Umberto Tedeschi[11], Antonio Colecchia[11], Andrea Ricci[2], Massimo Cardillo[2], Umberto Cillo[1]. *[1]Azienda Ospedaliera di Padova; [2]Centro Nazionale Trapianti; [3]AOU Città della salute, PO S.G Battista, Torino; [4]AOU Pisana, Pisa; [5]AOU Sant'Orsola Malpighi, Bologna; [6]AO Niguarda Ca' Granda, Milano; [7]Is.Me.T.T, Palermo; [8]Ospedale Papa Giovanni XXIII, Bergamo; [9]Ospedale Maggiore Policlinico, Milano; [10]Azienda Ospedaliera Policlinico, Modena; [11]Ospedale Civile Maggiore, Verona*
Email: bertaccoale@gmail.com

Background and Aims: A recent European Liver Transplant registry study showed that the proportion of liver transplants performed for nonalcoholic steatohepatitis (NASH) in Europe has increased from 2002 through 2016, and that the post-transplant outcome in patients with NASH is comparable to that of other disease indications. There are few data on recent trends in waiting list inscriptions/dynamics, and on intention-to-treat transplant survival of NASH patients, however.
Method: We analysed data from adult patients listed for primary LT for chronic end-stage liver disease between January 2012 and December 2018 using the Italian Liver Transplant Registry database. We evaluated annual trends of waiting list inscriptions according to main liver disease aetiologies. Moreover, we compared data of patients with NASH with that of other aetiologies in terms of patient characteristics and intention-to-treat survival outcome.
Results: Among 8,567 adults listed for first LT in Italy in the study period, 494 (5.8%) had NASH. The proportion of NASH patients significantly increased from 3.6% in 2012, to 8.9% in 2018 (p < 0.001). The proportion of patients with alcohol related–liver disease similarly increased from 11.6% in 2012, to 19.2% in 2018 (p < 0.001). Conversely, the proportion of hepatitis C patients significantly decreased from 46.8% to 33.5% (p < 0.001), while that of hepatitis B patients remained stable during the study period around 13%.
NASH patients were older than no-NASH patients (59 vs. 55 years, p < 0.001), and more often had associated hepatocellular carcinoma (51% vs. 45%, p = 0.005). The 1-, 3- and 5-year intention-to-treat survival rates were 81%, 70% and 65% in the no-NASH group vs. 74%, 64% and 56% in the NASH group, p = 0.004. The presence of NASH was a significant risk factor for death (hazard ratio [HR] 1.30; 95% CI 1.07–1.56) also at multivariable Cox survival analysis.

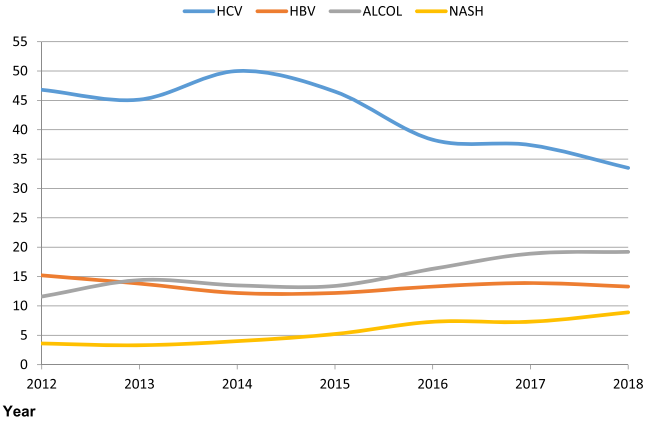

Figure 1: Recent trends of waiting list inscriptions for LT in Italy according to main liver disease etiologies.
Conclusion: The proportion of NASH patients listed for LT in Italy has significantly increased from 2012 to 2018. This preliminary analysis suggests a significant negative impact of NASH aetiology on intention-to-treat transplant survival.

THU226

The application of immunoglobulins after liver transplantation influences the occurrence of donor-specific antibody associated complications

Alexandra Frey[1], Katharina Willuweit[1], Anne Achterfeld[1], Peter A. Horn[2], Andreas Heinold[2], Heiner Wedemeyer[1], Kerstin Herzer[1]. *[1]University Hospital Essen, Department of Gastroenterology and Hepatology, Essen, Germany; [2]University Hospital Essen, Institute for Transfusion Medicine, Essen, Germany*
Email: alexandra.frey@uk-essen.de

Background and Aims: Human immunoglobulins (IGs) are used after liver transplantation (LT) e.g. for hepatitis B recurrence prophylaxis and for therapy of cytomegalovirus infection. In addition to their primary function, an overarching immunomodulatory function may have further effects on the course of the disease after transplantation. The occurrence of donor-specific antibodies (DSA) plays a pathophysiological role after solid organ transplantation and leads to complications such as transplant rejection. Subject of this study is the investigation of a relation between the application of human immunoglobulins (Hepatect, Zutectra, Cytotect) and the occurrence of DSA or associated complications after LT.
Method: The DSA status, as well as further clinical and laboratory chemical data after LT were retrospectively collected from 427 patients and statistically evaluated. Detection of DSA was performed by lymphocyte toxicity test and antibody specification by Luminex® technology. Data was statistically analysed by Fisher-Exact test and Chi-square test.
Results: In the cohort, 15.5% of the patients (n = 66) received immunoglobulins after LT. In the course after IG application, 13 of these patients (19.7%) became DSA positive. Of the 361 patients who did not receive IG, 18% developed DSA (P < = 0.864). Regardless of IG administration, complications occurred in both groups in approximately 74% of patients (P < = 0.887). The overall occurrence of complications was neither with nor without IG administration dependent on the DSA status (P > 0.5). However, there was a reduced risk of graft rejection after IG administration, regardless of DSA status (n = 6/66; 9% versus n = 50/361; 14%; P < = 0.424). In addition, patients with IG application had a significantly lower risk of

developing DSA-associated *de novo* autoimmune hepatitis (*de novo* AIH) after LT (P < = 0.043).
Conclusion: The application of immunoglobulins after LT appears to reduce the risk of transplant rejection regardless of DSA status. Likewise, the risk for DSA-associated *de novo* AIH is significantly reduced. An extension of the evaluations will provide further insights into the influence of human immunoglobulins in the long-term course after liver transplantation.

THU227

A new score including anthropometric measurement for weight improved prediction of mortality in adolescents on the liver transplantation waiting list: a US nationwide study

Abdel-Aziz Shaheen[1], Sahar Khorsheed[2], Kelly Burak[1], Mark G Swain[1], Stephen Martin[2]. [1]*University of Calgary, Department of Medicine, Division of Gastroenterology and Hepatology, Calgary, Canada;* [2]*University of Calgary, Department of Pediatrics*
Email: azshaheen@me.com

Background and Aims: The Model for End-Stage Liver Disease (MELD) was adopted for liver transplant (LT) allocation to adolescents with chronic liver disease (CLD) without published validation in children. Pediatric CLD is associated with poor growth that may affect implementing MELD in adolescent patients. Therefore, we assessed the performance of MELD, MELD Na, and the Pediatric End-Stage Liver Disease (PELD) score in predicting adolescent LT wait list mortality. In addition, we evaluated incorporating height and weight into MELD at the time of registration to improve the prediction of mortality in listed adolescents for LT.
Method: Adolescents (12–17 years of age) registered for their first LT in the United States between January 2003 and December 2015 were identified using the united network for organ sharing (UNOS) database. Patients listed for multiple organs, Status 1A or 1B, and those who were granted exception points, were excluded from the analysis. Area under receiver operating curve (AUROC) and C-statistics were used to evaluate the discrimination of MELD, MELD Na, and PELD for the prediction of wait list mortality at 6 and 12 months. Weight, height, and their Z scores at time of registration were examined by univariate analysis and later incorporated into a multivariate regression analysis to obtain a new model termed Adolescent PELD.
Results: A total of 946 adolescent patients fulfilled our eligibility criteria. The cohort was randomized into derivation (n = 473) and validation cohorts (n = 473). Both cohorts had similar age (median 15 for both, p = 0.56), sex (female, 54% vs. 52%, p = 0.27), weight (56 vs. 57 kg, p = 0.52), and height (161 vs. 160 cm, p = 0.66), respectively. Z scores for weight, height, and laboratory variables (Na, creatinine, INR, bilirubin) were similar between cohorts. Median follow-up was 6 months (IQR 1–21) for both cohorts. Overall 100 patients (11%) died while waiting for LT (50 in each cohort), while 437 patients (46%) had LT (209 in derivation cohort and 228 in validation cohort). Only Z score for weight was a significant predictor in univariate and multivariate analysis to predict 6 month mortality on the LT waitlist. Therefore, we created a new prediction model incorporating Z score for weight with MELD score (Adolescent MELD). In the derivation cohort, Adolescent MELD performed better than PELD, MELD, and MELD Na to predict 12 month mortality (AUROC: 0.78 [0.71–0.86], 0.67 [0.59–0.75], 0.74 [0.66–0.83], and 0.75 [0.65–0.84]; p < 0.05 for all comparisons, respectively). Similarly, Adolescent MELD performed significantly better than the other scores in predicting 6 month and 12 month mortality in our validation cohort.
Conclusion: Incorporating the anthropometric measurement Z score for weight improved the accuracy of MELD and the prediction of mortality on the LT waiting list.

THU228

Post-transplant lymphoproliferative disease after adult liver transplantation has a higher incidence after primary sclerosing cholangitis and can be prevented by surveillance of Epstein-Barr viral load with a pre-emptive strategy - a long-term study

Mitchell Hew[1], Bastian Ruijter[1,2], Naftalie Francisco[1], Herold J. Metselaar[2], Ron Wolterbeek[3], Jeroen Dubbeld[4], Ann C.T.M. Vossen[5], Bart Van Hoek[1]. [1]*LUMC, Gastroenterology&Hepatology and Transplantation, Leiden, Netherlands;* [2]*Erasmus University Medical Center, Gastroenterology&Hepatology, Rotterdam, Netherlands;* [3]*LUMC, Medical Statistics, Leiden, Netherlands;* [4]*LUMC, Transplantation & Surgery, Leiden, Netherlands;* [5]*LUMC, Microbiology, Leiden, Netherlands*
Email: b.van_hoek@lumc.nl

Background and Aims: Epstein-Barr virus (EBV) primary infection or reactivation can occur after liver transplantation (LT). An infrequent but serious complication after LT is post transplant lymphoproliferative disease (PTLD). In paediatric LT recipients -with more primary infection- it has been reported that peripheral blood EBV-DNA surveillance in the first year after LT, with a pre-emptive strategy in case of positivity including reduction of immunosuppression (IS), has led to a lower incidence of PTLD. For adult LT recipients, with less primary EBV infection and a lower PTLD incidence, the value of EBV surveillance is unknown. The aim of this two-centre study was to examine the impact of a strategy based on EBV-DNA monitoring on the incidence of PTLD in adult LT recipients, comparing both a contemporary and a historic control group without EBV-DNA surveillance to a group with EBV-DNA surveillance.
Method: From 3/2003 on in adult LT in Leiden EBV-DNA surveillance was used in the first year with lowering of immunosuppression in case of persistent positivity; the LTs from 3/2003 through 2018 formed the EBV monitoring group, and the LTs from 9/1992 till 3/2003 formed the historic control group without EBV monitoring. A third group was a contemporary control group of LTs without EBV monitoring transplanted 2003–2018 in Rotterdam with immunosuppression similar to the Leiden EBV monitoring group. Data were retrieved from the local transplant databases and patient charts. Kaplan-Meier survival analysis with exact Poisson regression analysis was used, p < 0.05 was considered significant.
Results: In the historic non-EBV-monitoring group 8/117 (6.8%) recipients developed PTLD, in the EBV monitoring group none of 322 developed PTLD (p = 0.0004 with an estimated incidence rate ratio of 18.59). In the contemporary non-EBV-surveillance group 10/606 (1.7%) recipients developed PTLD (p = 0.0084 with an estimated incidence rate ratio of 8.37). PSC was a risk factor for PTLD in both the historic and contemporary control cohorts (p < 0.01). Treatment of PTLD was successful in 7/8 cases in the historic controls and in 5/10 cases in the contemporary controls without EBV surveillance.
Conclusion: PSC is a risk factor for PTLD in adult LT and EBV-DNA surveillance in the first year after first LT in adult recipients, with IS reduction in case of persistently detectable EBV-DNA, can prevent occurrence of PTLD. It thereby can prevent morbidity and mortality.

THU229

De novo metabolic syndrome after liver transplantation: a prospective, longitudinal study

Chiara Becchetti[1,2], Nicola Zeni[1], Francesca D'Arcangelo[1], Alberto Ferrarese[1], Alberto Zanetto[1], Salvatore Sciarrone[1], Sarah Shalaby[1], Monica Pellone[1], Marco Senzolo[1], Martina Gambato[1], Francesco Paolo Russo[1], Umberto Cillo[3], Patrizia Burra[1], Giacomo Germani[1]. [1]*Multivisceral Transplant Unit, Padua University Hospital, Department of Surgery, Oncology and Gastroenterology, Padua, Italy;* [2]*Hepatology, Inselspital, DBMR, University of Bern, Bern, Switzerland;* [3]*Hepatobiliary Surgery and Liver Transplantation, Padua University Hospital, Department of Surgery, Oncology and Gastroenterology, Padua, Italy*
Email: becchettichiara@tiscali.it

Background and Aims: *De novo* metabolic syndrome (MS) is an emerging complication after liver transplantation (LT). This longitudinal, prospective study aimed to assess the prevalence and incidence of MS post-LT and its components and potential risk factors.
Method: patients without MS undergoing LT between April 2013 and October 2017 were prospectively included. Metabolic variables were collected at LT and at 6, 12 and 24 months post-LT. MS was defined according to the modified NCEP-ATP III criteria. In a sub-group of patients, CT-scan images were analysed by calculating skeletal muscle index (SMI), visceral adipose tissue index (VATI) and subcutaneous adipose tissue index (SATI) as predictors of post-LT MS.
Results: 63 patients were included (76% male, mean age 53.6 ± 9.5 years). The most common indication to LT was alcoholic liver disease (ALD) (38%). The prevalence of MS was 46%, 43% and 49% at 6, 12, and 24 months after LT, respectively, while its incidence was 46%, 57% and 68%. Among MS components, the prevalence of type 2 diabetes (T2DM) significantly increased after LT (33% at 6, 12 and 24 months post-LT vs. 16% pre-LT, p = 0.003), as well as hypertension (HT) (38% vs. 13%, p < 0.001; 37% vs. 13%, p = 0.001; 30% vs. 13%, p = 0.013, at 6, 12 and 24 months vs. pre-LT, respectively) and hypertriglyceridemia (31 vs. 14%, p = 0.035; 38% vs. 14%, p = 0.006, at 6 and 12 months vs. pre-LT, respectively). The incidence rates of T2DM, HT and obesity at 6, 12 and 24 months were 32%, 36% and 41%, 38%, 46% and 49% and 14%, 25% and 29%, respectively. At multivariate analysis, ALD was an independent risk factor for MS (HR 2.65, CI 1.12–6.29, p = 0.03) and obesity (HR 13.91, CI 1.57–122.77, p = 0.02), while high BMI pre-LT was predictive for HT (HR 1.11, CI 1.03–1.20, p = 0.007) and obesity (HR 1.82, CI 1.24–2.66, p = 0.002). Pre-LT impaired fasting glucose resulted predictive of T2DM (HR 1.02, CI 1.01–1.03, p = 0.001), conversely, the use of MMF was protective for T2DM (HR 0.18, CI 0.04–0.87, p = 0.03). In the sub-group undergoing body composition analysis (36 patients) sarcopenia was found in 23/36. High VATI was independently associated to the development of MS (HR 1.02, CI 1.00–1.04, p = 0.02) and HT (HR 1.02, CI 1.01–1.04, p = 0.01) after LT.
Conclusion: *de novo* MS is a frequent complication after LT showing a progressive increase overtime. A strict metabolic follow-up is mandatory starting early after LT, with particular attention for patients with established risk factors.

THU230
Phase angle is a prognostic nutritional marker in patients on the waiting list and after liver transplantation

Berenice M. Román-Calleja[1], Ana Monserrat Montaña Duclaud[1], Daniela Campuzano Guerrero[1], Aline Huerta Álvarez[1], Nayelli C. Flores-Garcia[1], Ignacio Garcia Juarez[1], Ricardo Macias-Rodriguez[1], Astrid Ruiz-Margain[1]. [1]*Instituto Nacional De Ciencias Médicas y Nutricion Salvador Zubirán, Department of Gastroenterology, Ciudad de México, Mexico*
Email: ruizm.astrid@gmail.com

Background and Aims: Liver transplantation (LT) is the only curative treatment for end stage liver disease. Recently pre-LT assessment of nutritional status and functionality has gained attention given its prognostic implications; mainly CT scan and liver frailty index (LFI) have been used and validated, however, given the need for specialized software for CT scan and radiation exposure, and the lack of aplicability of LFI in patients with hepatic encephalopathy and bed-bound patients, more bedside and aplicable markers are available. Phase angle (PhA), a nutritional marker derived from bioelectrical impedance, is a portable, non-invasive, inexpensive method that can be performed in outpatients and hospitalized patients, as well as in those with hepatic encephalopathy, that could be useful in this population. The aim was to evaluate the association between PhA and the development of pre- and post-LTcomplications, and thus obtain a specific cut-off value for this population.
Method: Retrospective cohort study conducted at a tertiary care center (INCMNSZ) in Mexico City Patients with liver cirrhosis, of any etiology, that had PhA measurement were included. Patients with pacemakers, limb amputation and patients whose PhA measurement had been performed after LT were excluded. For the statistical analysis the Kolmogorov-Smirnov tests, descriptive statistics, ROC with Youden curves, Kaplan-Meier curves and Cox regression were used. SPSS v19 and MedCalc Version 19.0.5 were used. The study was approved by the Institutional Ethics Committee.
Results: 141 patients were included, 55% women, with an average age of 53 ± 13 years, AF of 4.5 ± 2.1, MELD of 17 ± 7 and the majority in Child-Pugh C stage (45.4%). The median follow-up was 224 (83–301) days, where at least one hospitalization was observed in 49.1%, the waiting list mortality was 35.7%; being the main cause septic shock (36.3%). 20.6% underwent LT, observing a post-LT mortality of 13.8% and 65.5% presented some complication, mainly of infectious origin (25%). According to the ROC curves, an AF <3.8 ° was associated with hospitalizations, and infectious complications before and after LT with AUC of 0.703, 0.683 and 0.704 respectively (p = <0.001). The Kaplan-Meier curves showed a greater survival in those patients with AF>3.8 ° vs with AF <3.8 ° 322 ± 17 vs 223 ± 24 days (p = 0.001). And finally, two multivariate models were created (to avoid collinearity) where the phase angle showed a higher risk of mortality HR = 1.98 (1.02–3.84) regardless of the severity of the disease according to MELD score and equally higher risk HR = 2.01 (1.02–3.94) regardless of the Child-Pugh stage.
Conclusion: A value of PhA less than 3.8 ° is associated with pre- and post-liver transplantation complications, mainly infectious, as well as hospitalizations and higher mortality, so this marker could be used in clinical practice as part of the pre LT nutritional assessment.

THU231
Differences of bile microbiology and antibiotic susceptibilities in liver transplant recipients from a non-transplant population with acute biliary infection

Sukwon Suh[1], Yoo Shin Choi[1]. [1]*Chung-Ang University, Surgery, Seoul, Korea, Rep. of South*
Email: bumboy1@cau.ac.kr

Background and Aims: Because of immunosuppression, signs and symptoms of biliary infection in liver transplantation (LT) recipients are frequently subtler than those of non-transplant population that infection progresses easily to bacteremia, therefore the usage of effective antibiotics is important. However, there has been little study of bile microbiology and antibiotic susceptibilities in LT recipients with acute biliary infection that antibiotics recommended for non-transplant population is mostly administered to LT recipients in current situation and it sometimes do not effectively control the infection. Therefore, it is helpful to have an information of commonly isolated microorganisms and its antibiotic susceptibilities, especially in LT recipients with acute biliary infection to improve their clinical outcome that we investigated its differences between LT recipients and non-transplant population.
Method: We performed a comparative analysis of 376 positive bile cultures between LT recipients with biliary complication (n = 127, LT group) and non-LT population who underwent cholecystectomy for acute cholecystitis (n = 249, non-LT group) from January 2009 to December 2018 at multiple centers.
Results: There were significant differences of incidences of commonly isolated microorganisms between LT and non-LT group (P < 0.001); *Enterococcus* (31.5% vs. 26.5%), *Klebsiella* (18.1% vs. 12.4%), *Pseudomonas* (14.2% vs. 4.0%), *Escherichia* (11.0% vs. 29.3%), and *Enterobacter (*3.9% vs. 8.4%). Extended-spectrum beta-lactamase (ESBL) producing Gram-negative bacteria was significantly more common in LT group than non-LT group (62.9% vs. 13.0%, P < 0.001). Frequently isolated microorganisms were significantly changed over time after LT; *Enterococcus* (35.8%), *Klebsiella* (26.4%), and *Pseudomonas* (13.2%) within 6 months of LT and *Enterococcus* (28.4%), *Escherichia* (17.6%), and *Pseudomonas* (14.2%) after 6 months of LT (P = 0.029). Many of the commonly used antibiotics with a good effectiveness in non-LT group provided inadequate

coverage for frequently encountered microorganisms in LT group, except amikacin and imipenem against commonly isolated Gram-negative microorganisms and linezolid, streptomycin, and teicoplanin against *Enterococcus* including vancomycin-resistant *Enterococcus* sp. (VRE).
Conclusion: Differences of bile microbiology and antibiotic susceptibilities in LT recipients should be considered before selection of antibiotics in acute biliary infection.

THU233
Safety of marginal grafts in liver transplantation:a single-center experience
Hui Tang[1], Qing Yang[1], Binsheng Fu[1], Shuhong Yi[1], Yang Yang[1], Guihua Chen[1]. [1]*The Third Affiliated Hospital of Sun Yat-sen University, Liver Transplantation Center, Guangzhou, China*
Email: chenux@aliyun.com

Background and Aims: With the shortage of donors, the use of marginal donors has become more common in liver transplantation (LT). We aimed to assess the outcomes and experiences of LT from these marginal donors in a single centre study.
Method: We retrospectively analyzed all the database of LTs performed at our institution from January 2015 to October 2018. According to 2015 EASL clinical practice guidelines, the marginal grafts are defined as livers from donors >60 years of age, livers from donors with serum sodium levels >155 mEq, graft steatosis >30%, livers with cold ischemia time ≥ 12 hours, livers from donors who were hepatitis B or C virus positive, livers recovered from donation after cardiac death, and livers split between 2 recipients. Patients receiving marginal grafts (marginal group) were compared with patients receiving standard grafts (standard group).
Results: There were 356 patients in the standard group and 237 patients in the marginal group. No significant differences were found in terms of age, sex, Model for End-Stage Liver Disease score, underlying liver disease, presence of hepatocellular carcinoma, and hospital stay between the 2 groups. The incidence of acute cellular rejection, cytomegalovirus infection, and postoperative complications was similar between the 2 groups. But the incidence of early allograft dysfunction was higher in the marginal group. Patient overall survival and graft survival (death-censored) were significantly lower in the marginal group ($P < 0.05$). On multivariate analysis, receiving a marginal graft was significantly associated with worse patient overall survival($P < 0.01$). Also, when factors associated with marginal graft were analyzed separately, graft steatosis >30% and cold ischemia time ≥ 12 hours were independently associated with survival ($P < 0.05$).
Conclusion: Marginal grafts could be a acceptable way for LT because of shortage of donors, but the standard limit should be under critical assessment, such as graft steatosis >30% and cold ischemia time ≥ 12 hours may not suitable for LT.

THU234
Severe obesity increases death and dropout from liver waiting list: French liver transplant cohort
Claire Delacôte[1], Mathilde Favre[2], Helene Montialoux[3], Eric Nguyen Khac[4], Alexandre Louvet[1,2], Emmanuel Boleslawski[5], Gilles Lebuffe[6], Valérie Canva[2], François-Rene Pruvot[5], Philippe Mathurin[1,2], Sebastien Dharancy[1,2], Lassailly Guillaume[1,2]. [1]*INSERM U995-LIRIC, Lille;* [2]*Service des maladies de l'appareil digestif et de la nutrition, CHU Lille, Lille, France;* [3]*Service d'hépatogastroentérologie, CHU Rouen, Rouen, France;* [4]*Service d'hépatogastroentérologie, CHU Amiens-Picardie, Hôpital Sud, Amiens;* [5]*Service de chirurgie digestive et de transplantation, CHU Lille, Lille, France;* [6]*Anesthésie-Réanimation, CHU Lille, Lille, France*
Email: claire.delacote@inserm.fr

Background and Aims: As obesity is increasing, new challenges are emerging in the management of severe obese (BMI>35 kg/m²) on the liver transplant waiting list. Indeed, severe obesity is related to increased morbidity after transplant and a reduced access to liver transplantation (LT) in the US. We studied the outcomes of severe obese patients on the French liver waiting list (WL) and the reason of graft refusal.
Method: Analyses were performed in adult candidates listed between January 2007 and December 2017 (MELD era). Data were extracted from the prospective national database of the French Transplant Agency. The study was conducted in two steps. First, competing risk analyses were performed to evaluate predictors of receiving a LT. The outcomes of death/waitlist removal due to disease aggravation and waitlist dropout owing to improvement were considered as competing events. Patients still on the WL or dropped-out due to personal decision were censored. Second, we evaluated the potential link between severe obesity and graft propositions, and then the causes of graft refusal.
Results: 15 184 registrations occurred between 2007 and 2017. At time of analysis, 10 813 patients were transplanted, 2 847 were dead or dropout from the list for disease aggravation, 748 were redirected for disease improvement and 776 censored.
Characteristics of patients were: age 56 ± 10.4, male gender 74.2%, BMI 26.2 ± 5.3 kg/m² (6.3% of severe obesity), MELD 15.8 ± 10.7. Severe obese patients were older (55.8 ± 8.5 vs. 54.2 ± 10.5) more diabetic (36.9 vs. 22.2%), higher MELD (16.6 ± 11.3 vs. 15.7 ± 10.7) and were frequently registered for HCC (39.2 vs 32.4%).
After adjustment in multivariate analysis, severe obesity, higher age, hepatic encephalopathy and ascites were independent predictors of death and drop out due to disease aggravation. In addition, severe obesity was reducing access to LT.
At least one graft has been proposed to the included patients in 82.6% of cases. Before LT or waiting list dropout, 4.4 ± 7.7 grafts were proposed per patients. There was no difference in terms of number of propositions between severe obese and non-severe obese patients. However in severe obesity, grafts were more frequently refused especially for "morphological incompatibility."
Conclusion: Severe obese patients are disadvantaged on the WL with lower access to LT and higher drop out of the WL. Indeed, in this subgroup graft refusal is more frequent, in particular for morphological reasons.

THU236
Liver transplantation assessment: what are the factors associated with contraindication for listing or delayed activation on waiting list?
Domitille Erard-Poinsot[1,1], Veyre Florian[1], Sylvie Radenne[1], Fanny Lebosse[1], Jean-Yves Mabrut[2], Mickael Lesurtel[2], Dr Mokham Kayvan[2], Dr Bonnet Aurélie[3], Dr Guichon Céline[3], Teresa Antonini[1], Jérôme Dumortier[1]. [1]*Lyon, Hepatology, Hopices Civils de Lyon, lyon, France;* [2]*Hospices Civils de Lyon, Hepatobiliary Surgery, Lyon, France;* [3]*Hospices Civils de Lyon, Intensive Care unit, Lyon, France*
Email: domitille.poinsot@gmail.com

Background and Aims: LT assessment is a challenge for patients with Alcohol-Related Liver Disease (ALD) and Nonalcoholic Fatty Liver Disease (NAFLD) with multiple comorbidities (metabolic syndrome and cardiovascular disease (CVD)). The aim of this study was to evaluate the factors associated with a contraindication for LT listing and delayed activation on waiting list.
Method: From 2014 to 2019, all patients (n = 895) with an indication for LT were retrospectively screened for inclusion. A total of 588 (65.7%) cirrhotic patients were assessed for LT: 143(24.3%) patients were contraindicated, and 445(75.7%) patients were listed for LT. On the list, 275(61.8%) were activated with no delay and 170(38.2%) with delay (Figure).
Results: The main causes of contraindication were CVD (n = 36;25.2%), active alcohol consumption (n = 34;23.8%) and advanced hepatocellular carcinoma (HCC) (n = 29;20.3%). In univariate analysis, the factors significantly associated with contraindication for LT listing were: age>60 years (53.8%*vs.*39.3%, p = 0.002), ALD (74.1%*vs.*64.7%, p

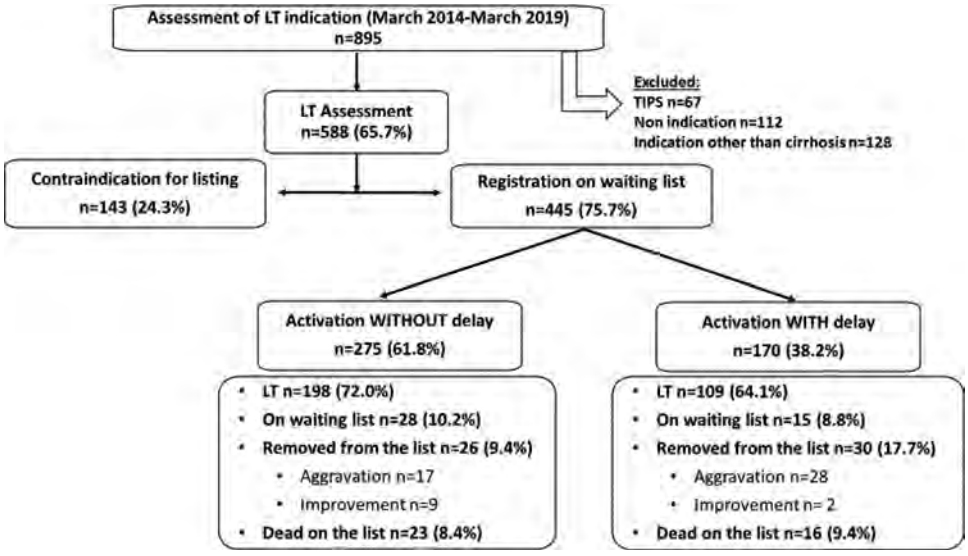

Figure: (abstract: THU236): Flow Chart of the study.

= 0.04), hypertension (49.7% *vs.*38.4%, p = 0.02), dyslipidemia (21.7% *vs.*13.5%, p = 0.02), MELD score ≥ 30 (20.3% *vs.*8.8%, p = <0.0001). Factors not associated with LT contraindication were metabolic syndrome, BMI>30 kg/m^2, male sex, NAFLD and active smoking. In multivariate analysis, age>60 years old (OR = 1.9; IC95:1.27–2.79), ALD (OR = 1.6; IC95:1.02–2.42) and MELD score ≥ 30 (OR = 3.0; IC95:1.75–5.15) were significantly associated with LT contraindication. The main causes of delayed activation on the list were the need for specific investigations (38.8%), infection (27.6%), and interventions (coronary stenting)(24.1%). In univariate analysis, factors significantly associated with delayed activation on the list were: hepatitis C (21.8%*vs.*12.4%, p = 0.009), metabolic syndrome (25.9% *vs.*17.5%, p = 0.033), registration for MELD exception (24.7%*vs.*13.5%) or HCC (46.5%*vs.*40.4%) (*vs.* MELD score (28.8%*vs.*46.2%)) (p < 0.0001), and antiplatelet therapy (25.3%*vs.*5.8%, p < 0.0001). In multivariate analysis, factors associated with delayed activation on waiting list were: hepatitis C (OR = 2.4; IC95:1.4–4.3), antiplatelet therapy (OR = 6.9; IC95:3.6–13.7), MELD score<30 (OR = 6.7; IC95:2.1–21.5), registration for MELD exception (OR = 2.2; IC95:1.2–3.8) or HCC (OR = 2.2; IC95:1.2–3.9).

Conclusion: Assessment before LT leads to contraindication or delayed activation on waiting list in a large proportion of cirrhotic patients, because of associated co-morbidities and complications of cirrhosis.

Anticoagulation in liver transplant candidates: a case control study

Domitille Erard-Poinsot[1], Jeanne-Marie Giard[2], Willems Philippe[2], Alissa Chehade[2], Bergere Michel[3], Marc Bilodeau[2], Catherine Vincent[2], Julien Bissonnette[2], Jérôme Dumortier[3], Genevieve Huard[2]. [1]*Hospices Civils de Lyon, Hepatology and Liver Transplantation Unit, Lyon, France;* [2]*Centre Hospitalier Universitaire de Montréal, Hepatology and Transplantation, Montreal, Canada;* [3]*Hospices Civils de Lyon, Hepatology and Liver transplantation Unit, Lyon, France*
Email: domitille.poinsot@gmail.com

Background and Aims: In liver transplant candidates, indication for anticoagulation are diverse, including portal vein thrombosis (PVT), and anticoagulation can be associated with bleeding complications. The aim of this study was to evaluate the safety of anticoagulation in a large series of liver transplant candidates.

Method: In two tertiary care centers, all patients listed for liver transplantation (LT) from January 2010 to March 2018 were screened for anticoagulation treatment. All patients treated with anticoagulation were compared to liver transplant candidates with no anticoagulation. The two groups were matched on: age, year of registration, MELD score, cause of cirrhosis and gender. Patients' clinical characteristics, indication for anticoagulation, bleeding events, hospitalisation, transfusion requirements and surgical complications during LT were collected.

Results: Of the 852 patients listed for LT, 70 (8.2%) were treated with an anticoagulant (PVT n = 61 (87.1%)). Bleeding events occurred in 28 patients (40.0%) treated with anticoagulation and in 11 patients (15.7%) in the control group, mostly related to portal hypertension in both groups (Figure 1). The median time from the beginning of anticoagulation to bleeding event was 2.7 months (IQR: 0.9–7.7) Ten patients (35.7%) patients had a definitive withdrawal of anticoagulation. In univariate analysis the factors associated with bleeding events were: anticoagulation (p = 0.01), PVT (p = 0.04), MELD score ≥ 18 (p = 0.03) and decompensated cirrhosis (p = 0.06). In the anticoagulation group, in univariate analysis, male sex was the only factor associated significantly with a higher risk of bleeding events (p = 0.03) while the type of anticoagulant (VKA or LMWH) (p = 0.34), the extension of PVT (p = 0.67) and platelets count <70 Giga/L (p = 0.65) were not associated with a significant risk of bleeding. In multivariate analysis, anticoagulation was the only factor significantly associated with bleeding events (HR = 3.5; IC95: 1.7–6.9; p < 0.001). Anticoagulation was not associated with a higher wait list mortality (p = 0.14). At LT, 37 patients had PVT and 92.8% had end to end portal anastomosis. Blood loss was significantly more important in the anticoagulation group (p = 0.03) but there was no difference in blood transfusions (p = 0.14).

Conclusion: In liver transplant candidates, anticoagulation is associated with a high risk of bleeding events on waiting list mainly related to portal hypertension.

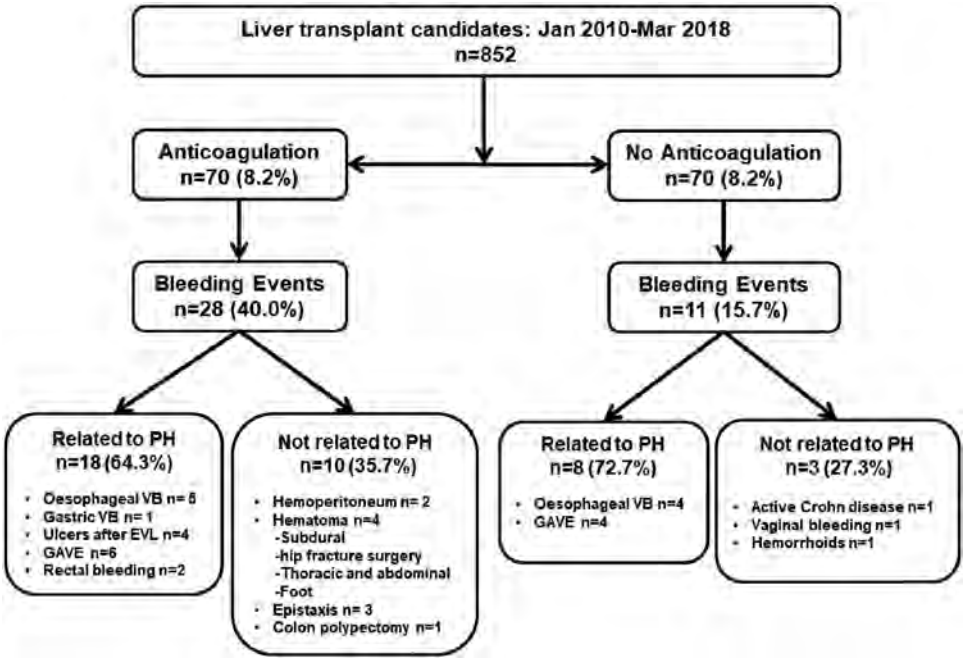

Figure: (abstract: THU237): Flow Chart of the study; *Abbreviations*: PH: Portal Hypertension; GAVE: Gastric antral vascular ectasia; VB: variceal bleeding.

Pre-transplant sarcopenic obesity worsens the survival after liver transplantation: a meta-analysis and systematic review

Péter Jenő Hegyi[1], Alexandra Soós[1,2], Péter Hegyi[1], Zsolt Szakács[1,3], Lilla Hanák[1], Erika Pétervári[1], Gabriella Pár[4], Márta Balaskó[1], Bálint Pár[5]. [1]*Institute for Translational Medicine, Medical School, University of Pécs, Pécs, Hungary;* [2]*Clinical Medicine Doctoral School, University of Szeged, Szeged, Hungary;* [3]*University of Pécs, János Szentágothai Research Centre, Pécs, Hungary;* [4]*Department of Gastroenterology, Medical School, University of Pécs, Pécs, Hungary;* [5]*Medical School, University of Pécs, Division of Gastroenterology, First Department of Medicine, Pécs, Hungary*
Email: drdunajskastreda@gmail.com

Background and Aims: Sarcopenic obesity (SO) - loss of skeletal muscle mass with an increased fat mass - is a common complication of end-stage liver disease and is considered among the predictive factors for increased morbidity and mortality in several diseases. Our aim was to evaluate the effect of pre-transplant SO on the outcomes of liver transplantation (LT).
Method: A comprehensive search was performed on 27th March 2019 in seven medical databases for studies which discussed patients subjected to LT and compared the effect of pre-transplant radiologically-proven SO to that of non-SO. The primary outcome was overall mortality at short- (1–2 years), intermediate- (2–5 years), and long-term (>5-years). In the meta-analysis, pooled relative risks (RRs) with 95% confidence intervals (CIs) were calculated. Heterogeneity was quantified with I2-statistics.
Results: Altogether, 4 articles were eligible for inclusion. Based on the analysis of 1515 patients, SO increased overall mortality compared to non-SO at short-, intermediate-, and long-term (RR = 2.06, 95% CI: 1.28–3.33; RR = 1.67, 95% CI: 1.10–2.51; and RR = 2.08, 95% CI: 1.10–3.93, respectively), without significant between-study heterogeneity. The amount of data did not allow us to compare SO to normal or other pathological body compositions.
Conclusion: Pre-transplant radiologically-proven SO proved to be a risk factor of mortality after LT. Further research is called for to investigate the effect of SO in relation to other body compositions and by underlying etiology of liver diseases.

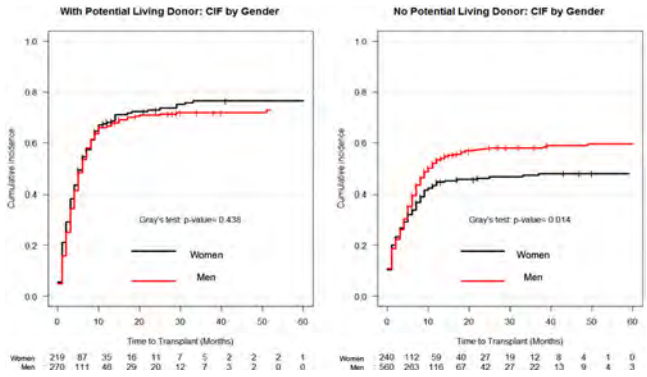
THU239

Women benefit more from having a potential living liver donor than men

Ravikiran Sindhuvalada karnam[1], Shiyi Chen[2], Anand Ghanekar[1], Markus Selzner[1], Gonzalo Sapisochin[1], Sayed Blayne[1], Zita Galvin[1], Nazia Selzner[1], Ian McGilvray[1], Trevor Reichman[1], Leslie Lilly[1], Mark S Cattral[1], Mamatha Bhat[1]. [1]*Toronto General Hospital and University Health Network, Multiorgan Transplant Program, Toronto, Canada;* [2]*University Health Network, Toronto, Canada*
Email: drskravikiran@gmail.com

Background and Aims: It is well recognized that there is a disparity in liver transplantation (LT) rates between men and women. Several factors account for this disparity, including smaller body size and lower muscle mass leading to lower serum creatinine in women. We sought to determine whether the presence of a Potential Living Donor (PLD) helps women gain better access to LT.
Method: We performed a retrospective analysis of data on adult patients above the age of 18 listed for LT from November 2012 till December 31, 2018. Patients were followed till the time of dropout from the waiting list and LT. Subgroup analysis was done based on gender and type of LT. Patients with acute liver failure and those requiring exception points for listing were excluded. Variables that would potentially influence listing and LT were identified based on a-priori clinical relevance. A PLD referred to an individual who had stepped forward for living donation and had completed the initial assessment as well as imaging assessment.
Results: 783 of 1289 listed patients (573 deceased donor LT, 210 living donor LT) underwent LT during the study period. In the group with no PLD at assessment: a) 46.13% failed to attract LT and NaMELD score did not differ between men and women at the time of listing or drop out, b) in patients eventually receiving deceased donor LT, women had both a higher NaMELD at listing ($p = 0.0004$) and at LT ($p < 0.0001$) compared to men. In the group with PLD, NaMELD score did not differ between gender at time of listing, LT or drop-out. Fine and Gray model suggested that in the no PLD group, the cumulative incidence curve for time to LT was higher in men than women ($p = 0.014$) (Figure 1), whereas there was no gender difference detected in the PLD group ($p = 0.44$). Cox PH model revealed a trend of higher overall survival in

men than in women (p = 0.08) in the no PLD group and no difference was found in the PLD group (p = 0.93). Also, among women with no PLD, taller women were associated with higher chances of LT (HR 1.04, 95%CI 1.01–1.07, p = 0.01).



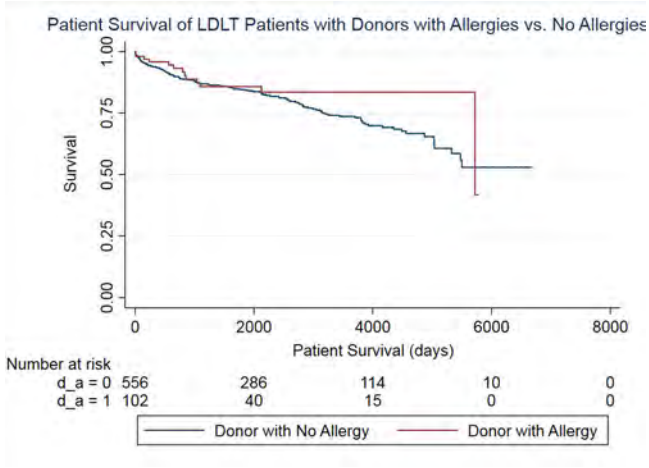
Conclusion: With no PLD during assessment, women were at potential risk of lower survival and were significantly disadvantaged at receiving LT compared to men. Women receiving LT were much sicker than their male counterparts both at time of listing and at time of LT, and were taller than other women who failed to receive LT. When PLD were identified at time of assessment, access to LT and overall survival improved for women and their results became comparable with men.

THU240

Transmission and impact of donor allergies in living donor liver transplantation

Ravikiran Sindhuvalada karnam[1], Sayed Blayne[1], Anand Ghanekar[1], Markus Selzner[1], Gonzalo Sapisochin[1], Mark S Cattral[1], Ian Mcgilvray[1], Trevor Reichman[1], Mamatha Bhat[1], Nazia Selzner[1], Leslie Lilly[1], Zita Galvin[1]. [1]*Toronto General Hospital and University Health Network, Multiorgan Transplant Program, Toronto, Canada*
Email: drskravikiran@gmail.com

Background and Aims: The transmission of donor allergies at time of liver transplant (LT) has been clearly documented in the literature. However, there is lack of large studies or case series regarding the frequency of transfer of drug allergies, in addition to clear data regarding the impact, if any, on rejection or graft and patient outcomes.
The aim of this study was to identify the number of living liver donors with allergies, to estimate the risk of post-transplant transmission of donor allergies and to assess if the presence of donor allergies had an impact on incidence of rejection or graft and patient survival after living donor liver transplantation (LDLT).
Method: This was a retrospective, single-centre analysis of adult patients who received a LDLT from 2000–2018. Donor allergies were classified according to World Allergy Organization Systemic Allergic Reaction Grading System. Transmission of allergies was assessed by individual chart review. The incidence of post LT rejection and patient/graft survival outcomes (graft from an allergic donor versus non-allergic donor) were compared.
Results: 667 recipients had a LDLT during study period (418 had LDLT from related donor). 103 donors had documented >/ = grade 3 allergy (79 donors had grade 3 allergy and 24 had grade 4/5 (history of anaphylaxis)). All recipients were followed in our program and there was no documented transfer of allergies from the donor to recipient. There was no significant difference in the rejection rates and overall survival in the LDLT group receiving liver from donors 24 with severe allergies.



Conclusion: The presence of a donor allergy does not adversely affect the outcome of the recipient of a LDLT

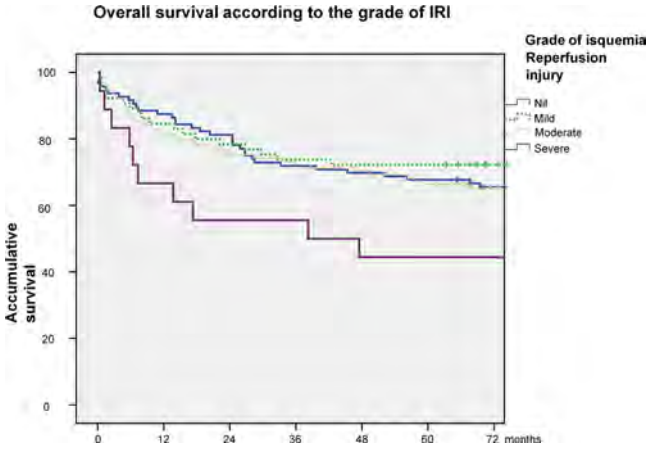
THU241

Postreperfusion biopsy as predictor of outcomes after liver transplantation

Esteban Fuentes Valenzuela[1], Rodrigo Najera[1], Javier Tejedor Tejada[1], Carlos Maroto Martín[1], Laura Sanchez Delgado[1], Beatriz Madrigal Rubiales[2], Carmen Alonso Martin[1], Fátima Sánchez Martín[1], Félix García Pajares[1], Carolina Almohalla Alvarez[1], Gloria Sánchez Antolin[1]. [1]*Hospital Universitario Rio Hortega, Hepatology and Liver Transplantation Unit., Valladolid, Spain;* [2]*Hospital Universitario Rio Hortega, Department of Pathology, Valladolid, Spain*
Email: estebanfuentes_2@hotmail.com

Background and Aims: Postreperfusion liver biopsy (PRB) assess the degree of ischemia reperfusion injury (IRI) after liver transplantation (LT). There are few studies about Its influence on the graft outcomes and overall survival. The aim of our study was to know the correlation between the severity of IRI in the PRB, the overall graft and patient survival and the predictor factors.
Method: We performed a retrospective study in all LT patients with a PRB, between January 2001 and June 2014 in our center. The independent predictor factors and the survival analysis were determined with Cox regression and Kaplan Meier, respectively. The early primary graft dysfunction (EPGD) was defined by the presence of one or more of the following: total bilirubin >10 mg/dl, INR >1,6 or ALT > 2000 U/l within the first week after LT. The initial poor graft function (IPGF) was determined as AST > 1,500 U/l or ALT > 1,000 U/l. The primary nonfunction (PNF) was defined as the need for urgent transplant or death. The severity of IRI on the PRB was graded as nil, mild, moderate, and severe.
Results: Out of 433 LT performed during this period, 280 patients with PRB were included in our study (64.9%), 77.5% were males. The main LT indication was decompensated cirrhosis 47.9%. The median MELD score was 13.0 (IQR 10–17). The donors' average age was 57.9 (SD+/–17.5). The cold ischemia average time was 402.3 (SD +/–91.9). The PRB were graded as follows: nil (34.3%), mild (23.2%), moderate (66.3%), and severe (5.4%). The incidence of IPGF, PNF and EPGD was 32.5%, 3.9%, and 18.6%, respectively. The severe IRI was associated with higher incidence of IPGF (p = 0.04), but no statistically significant differences were found in the incidence of PNF (p = 0.52) and EPGD (p = 0.27). Although patients with severe IRI tended towards higher incidence of EPGD (33.2% vs 18.6). Only the cold ischemic time was an independent predictor factor of severe IRI HR 1.006 (95% CI 1.001–1.011). The severe IRI was associated with poor 1 and 5-year overall survival rates (67% and 44%, compared with 84 and 68%). Patients with severe IRI had worse overall survival, although not

statistic significant (Figure 1) (p = 0.06). Patients who developed EPGD had worse overall survival (p = 0.002).



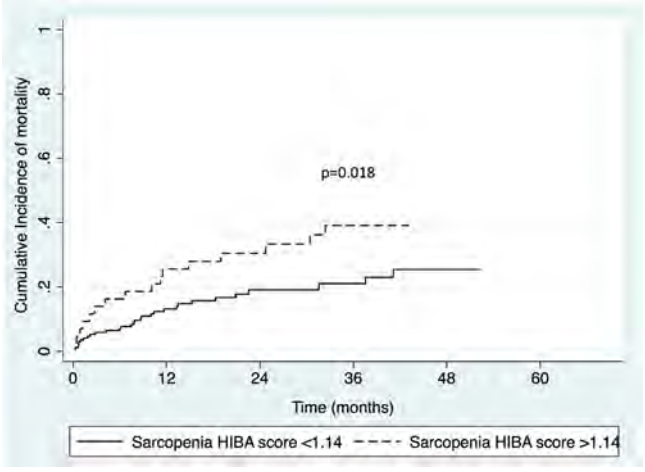
Conclusion: Cold ischemia time predicts the development of severe IRI. Patients with severe IRI tended towards a worse overall survival and higher incidence of EPGD. Moreover, the development of EPGD itself could be predictor of overall survival.

THU242

Sarcopenia HIBA score predicts the presence of sarcopenia and mortality in patients on the waiting list for liver transplant

Ezequiel Mauro[1], Juan Manuel Diaz[1], Maria Nelly Gutierrez Acevedo[1], Lucrecia Garcia Olveira[1], Fernanda Zalazar[1], Agustina Martinez Garmendia[1], Lorena Savluk[2], Julia Saidman[2], Jorge Ortiz Patron[1], Carla Bermudez[1], Adrian Narvaez[1], Gonzalo Crespo[3], Juan Carlos Spina[2], Adrian Gadano[1]. *[1]Hospital Italiano de Bs As, Liver and Liver Transplant Unit, Buenos Aires, Argentina; [2]Hospital Italiano de Bs As, Radiology Department, Buenos Aires, Argentina; [3] Hospital Clínic, IDIBAPS, CIBERehd, University of Barcelona, Liver Transplant Unit, Liver Unit, Barcelona, Spain*
Email: ezequiel.mauro@hospitalitaliano.org.ar

Background and Aims: Sarcopenia is a prevalent condition that predicts an unfavourable prognosis in patients with cirrhosis included on the waiting list (WL) for liver transplant (LT). The gold standard for the diagnosis of sarcopenia is based on the assessment of the muscular area at L3 with CT scan (Skeletal Muscle Index, SMI). Since the routine use of CT scan is limited in clinical practice due to cost and exposure to radiation, Sarcopenia HIBA Score has recently been postulated as an indirect score to predict the presence of sarcopenia by SMI. Our aim was to evaluate the capability of Sarcopenia HIBA Score to predict mortality in patients on the WL
Method: Monocentric retrospective study in which a cohort of patients with cirrhosis was included in the WL for LT (January 2014 to April 2019). The sarcopenia HIBA score was defined by the following formula: Male * 2.344 + BMI*(−0.372) + Alkaline Phosphatase * (−0.005) + Child Pugh * (0.308) + Creatinine/Cystatin-C * (−4.547) + 9.057. All the variables, including the presence of sarcopenia by skeletal muscle index and sarcopenia HIBA score were collected at the time of the inclusion on the WL. The predictive factors of mortality in the WL were evaluated with competing risk regression analysis (with LT as the competing risk of mortality in WL). We described the 80-percentile threshold of Sarcopenia HIBA score to rule in sarcopenia (>1.14) for the analysis of cumulative incidence of mortality.
Results: A total of 215 patients with cirrhosis listed for LT were included: 38% female, median age 59 years, main etiologies were liver disease alcohol, HCV and NASH. The main indication of LT was decompensated cirrhosis (85%). The prevalence of sarcopenia by SMI was 43%. The median follow-up was 11.7 (4.9–25.8) months. During the follow-up 77 (36%) patients underwent LT, 46 (21%) died and 92 (43%) remained alive. After adjusting for MELD-Na, Sarcopenia HIBA score was an independent predictor of mortality in the WL (sHR1.19; 95% CI 1.01–1.40; p = 0.042).



Conclusion: Higher values of Sarcopenia HIBA score are independently associated with mortality in WL. The assessment of this risk factor may improve the prognostic evaluation and allow identifying a group of patients with a risk of death while awaiting LT.

THU243

A novel nomogram based on liver stiffness to predict the comprehensive complication index after liver resection in patients with hepatocellular carcinoma

Federico Ravaioli[1], Matteo Serenari[1], Kwang-Hyub Han[2], Seung Up Kim[2], Alessandro Cucchetti[1], Dai-Hoon Han[2], Federica Odaldi[1], Matteo Ravaioli[1], Davide Festi[1], Antonio Pinna[1], Matteo Cescon[1]. *[1]University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [2]Yonsei University College of Medicine, 2 Department of Internal Medicine, Seoul, Korea, Dem. People's Rep. of*
Email: f.ravaioli@unibo.it

Background and Aims: Liver stiffness measurement (LSM) assessed by transient elastography (FibroScan®) has been demonstrated to predict post-hepatectomy liver failure (PHLF) in patients undergoing hepatic resection for hepatocellular carcinoma (HCC). However, other complications, besides PHLF, can be related to the underlying grade of liver fibrosis. This study aimed to identify predictors of postoperative complications calculated by the comprehensive complication index (CCI) and to build and develop a novel nomogram able to identify patients at risk of developing severe postoperative complications.
Method: Data of patients treated by hepatectomy for HCC between 2006 and 2016 at two referral centres, were retrospectively reviewed. All surgical complications were recorded and scored using the CCI, ranging from 0 (uneventful course) to 100 (death). A CCI ≥26.2 was used as a threshold to define patients having severe complications.
Results: During the study period, 471 patients underwent hepatic resection for HCC. Among them, 50 patients (10.6%) had a CCI ≥ 26.2. Age, MELD score and LSM values together with serum albumin were independent predictors of high CCI. The nomogram built on these variables was internally validated and showed good performance (C-statistic = 0.797). A regression equation to predict the CCI was also established by multiple linear regression analysis: [LSM (kPa) × 0.254] + [age(years) × 0.118] + [MELD score(pt.) × 1.050] – [albumin (g/dL) × 2.395] – 3.639.
Conclusion: This novel nomogram, combining LSM values, age and liver function tests provided an excellent preoperative prediction of high CCI in patients with resectable HCC. This predictive model could be used as a reference for clinicians and surgeons to help them in clinical decision-making.

Physical frailty predicts liver transplant waiting list mortality: United Kingdom experience

Felicity Williams[1,2], Alice Freer[2], Florence Hockey[3], Natasza Klas[3], Jonathan Quinlan[4], Samantha Mann[2], Jennifer Towey[2], Laura Nicholson[2], Jill Johnson[2], Peter Nightingale[5], Neil Rajoriya[6], Matthew Armstrong[6]. *[1]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom; [2]University Hospitals Birmingham, Therapy Services, Birmingham, United Kingdom; [3]University of Birmingham, College of Medical and Dental Sciences, Birmingham, United Kingdom; [4]University of Birmingham, Sport and Exercise Science, Birmingham, United Kingdom; [5]University Hospitals Birmingham, Birmingham, United Kingdom; [6]University Hostials Birmingham, Liver Transplantation, Birmingham, United Kingdom*
Email: f.williams@bham.ac.uk

Background and Aims: Patients awaiting liver transplantation (LT) have reduced physiological reserve and increased vulnerability to health stressors – known as physical frailty (Lai et al., 2017). Physical frailty is associated with poorer clinical outcomes, however there remains paucity of data on physical frailty in European populations. We aimed to prospectively investigate the incidence and impact of physical frailty in patients awaiting LT in the United Kingdom (UK).
Method: From 2018–2019, patients were consecutively recruited from the LT assessment and waiting list clinics at the University Hospital Birmingham, UK. The Liver Frailty Index (LFI) (hand grip, chair stands, balance; https://liverfrailtyindex.ucsf.edu) and Duke Activity Status Index (DASI) (predicted VO_2 peak) were used to evaluate physical frailty. Clinicians were blinded to the results omitting any influence on organ allocation or LT waiting list status. Patients were prospectively followed up for a minimum of 4 months.
Results: 307 patients (57% male; median age 54 years; 46% ALD/NAFLD) were recruited. The median UKELD and MELD were 52 (IQR 49–55) and 13 (IQR 9–16), respectively. 37% (114/307) were obese (BMI > 30 kg/m^2) and 27% (82/307) had metabolic syndrome. During follow-up, 40% (123/307) underwent LT and 4.6% (14/307) died whilst waiting.

Median LFI was 3.76 (IQR 3.31–4.29), with 20% (60/307) classified as robust, 65% (201/307) pre-frail and 15% (46/307) frail. These parameters are similar to that reported in North America (Figure 1) (Lai et al., 2017). Median VO_2peak was 21.9 (IQR 16.6–31.2) ml/kg/min. LFI (alive 3.77 vs. death 4.22; $p = 0.017$) and VO_2peak (22.6 vs. 16.4 ml/kg/min; $p < 0.001$) were significantly associated with waiting list mortality. Furthermore, both LFI and VO_2peak were associated with increased intensive care length of stay post-LT ($p = 0.03$).

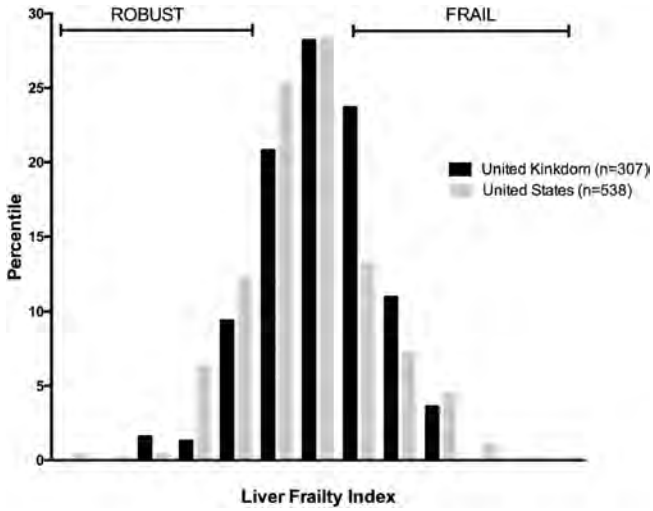

Figure: A comparison of Liver Frailty Index scores in the UK and US

Female sex, age, BMI, hyponatraemia, INR, encephalopathy and ≥ 2 metabolic co-morbidities were significantly ($p < 0.05$) associated with higher LFI (*physical frailty*). VO_2 peak significantly correlated with LFI ($r = -0.56$; $p < 0.001$). Older age ($p = 0.003$) and hyponatraemia ($p = 0.016$) were independent predictors of physical frailty (LFI) on multiple linear regression analysis.
Conclusion: A significant proportion of patients awaiting LT are physically frail. Risk factors include female sex, older age, obesity,

metabolic syndrome and encephalopathy. Markers of physical frailty, LFI and DASI, predict LT waiting list mortality.

THU245

Early versus late hepatocellular carcinoma (HCC) recurrence after liver transplantation for HCC: patterns and long-term outcome

Email: faouzi.saliba@aphp.fr

Background: Hepatocellular carcinoma (HCC) is the most common indication of liver transplantation (LT). HCC recurrence is the main complication affecting short and medium term outcome after liver transplantation (LT). The aim of this study is to analyze the patterns and outcome of patients who developed HCC recurrence according to post-transplant time of recurrence.
Method: Consecutive patients who underwent LT for HCC between 2000 and 2017 at our center were recruited. Characteristics of patients, recurrence, modalities of treatment and outcome were collected retrospectively. Patients were divided according to time of recurrence: early (≤2 years post-transplant) and late (>2 years post-transplant).
Results: 433 patients (mean age: 57.8 ± 8.5 years; 83.8% were males) underwent LT for HCC. Mean follow-up was 74.6 ± 58.6 months. Seventy-five patients (17%) developed HCC recurrence with a mean time to recurrence of 29.7 ± 31.8 months. Patient who developed recurrence had as expected more tumors outside Milan and UCSF criteria, a significantly high AFP score and microvascular invasion at pathology. Recurrence site at diagnosis was intrahepatic only (16.0%), extrahepatic only (61.3%) and intrahepatic and extrahepatic (22.7%). 71.2% of the recurrent HCC cases were treated by systemic chemotherapy. The mean AFP level at the time of diagnosis of early HCC recurrence 1061 ± 3545 ng/mL and 292 ± 805 ng/mL in the late HCC recurrence group. Early recurrence developed in 46 patients (61.3%) and late recurrence occurred in 29 patients (38.7%). The median survival times from the diagnosis of the HCC recurrence were similar 15 months and 17 months respectively in the early and late recurrence groups (p = 0.12). The 5,10 and 15-year patient survival of the whole cohort were respectively 74.6%, 59.0% and 48.6%. The overall 5, 10 and 15-year recurrence free survival rate was 70.6%, 55.4% and 46.3%. Among the patients who developed an early HCC recurrence the overall 5, 10 and 15-year survival rates were similar 6.7% and significantly shorter than those patients with late recurrence respectively at 5,10 and 15 years, 64.0%, 27.1% and 0% (log rank p < 0.0001).
Conclusion: In this large cohort with long-term follow-up, late HCC recurrence has been associated with a good long-term survival. Early HCC recurrence is associated with very bad prognosis, in relation to more aggressive tumor and either tumor progression or bad selection criteria at time of transplant.

Epidemiology, features and outcome of patients transplanted for hepatocellular carcinoma in the last decade: a single-center experience

Federica Invernizzi[1], Massimo Iavarone[1], Daniele Dondossola[2], Barbara Antonelli[2], Arianna Zefilippo[2], Tullia De Feo[3], Marco Maggioni[4], Angelo Sangiovanni[1], Pietro Lampertico[1], Giorgio Rossi[2], Maria Francesca Donato[1]. *[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, CRC "A. M. and A. Migliavacca" Certer for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Fondazione IRCCS Cà Granda Ospedale Maggiore Hospital, University of Milan, HBP Surgery and Liver Transplantation Unit, Milan, Italy; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, North Italy Transplant Program, Coordinamento Trapianti, Milan, Italy; [4]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Nuclear Medicine Department, Milan, Italy*
Email: federica.invernizzi@policlinico.mi.it

Background and Aims: Hepatocellular carcinoma (HCC) represents an increasing indication for liver transplantation (LT) world-wide but the burden and clinical implications of post-transplant HCC recurrence is still debated. Aim of this study was to identify recurrence rate, survival and predictors of recurrence in HCC patients consecutively transplanted in the last 10-years.
Method: retrospective, single center study including all consecutive LT patients with HCC from 01/2010 to 07/2019. HCC-recurrence surveillance was performed with CT-scan and AFP every 6 months for the first 5-yrs after LT. Immunosuppression was CNI-based.
Results: 182 HCC out of 449 transplanted patients (41%) were studied: 84% males, median age 58-yrs, 60% HCV, 25% MELD ≥ 15, median AFP at LT 9 ng/ml; median time-lag between HCC diagnosis and LT was 17 months, pre-LT bridging/down-staging therapy in 74%. At explant pathology: 16% showed micro-satellitosis, 27% micro-vascular invasion (mVI), 50% Edmonson score = G3/4; 76% were "Milan"-in, 11% were "Milan"-in and "Up to 7"-in while 13% "Up to 7"-out. During a median follow-up of 42 months, HCC recurred in 29 patients (16%) after a median time of 9 (2–46) months. Probability of recurrence at 1-, 3-, 5-yrs was 5%, 11% and 15%, respectively. By multivariate analysis, independent risk-factors for HCC recurrence were micro-satellitosis (HR = 0.31, p = 0.023) and microvascular invasion (HR = 0.38, p = 0.04). Overall probability of survival at 1-, 3- and 5-yrs was 94%, 87% and 77%, respectively; being 95%, 89% and 85% in the recurrence-free patients vs 89%, 76% and 43% in the recurrence-group (p < 0.005). Those patients who were transplanted after 2015 (n = 108), significantly differed from those transplanted before 2015 (n = 74), since they were older (p = 0.04), more frequently males (p = 0.02), with lower MELD (p = 0.0001) at transplant, more frequently treated by locoregional therapies for bridging/down-staging purposes (p = 0.002) and with higher rates of G3/4-HCC (p = 0.001) at explant pathology, however with similar post-transplant overall survival [100.9 (95%CI 90.16–111.8) vs 91.4 81.7–101.1) months (p = 0,15)].
Conclusion: Our study confirms tumor-related features at explant pathology as predictors of HCC recurrence. Moreover, in the last few years we have transplanted older patients with less severe disease but with more advanced tumors, while maintaining survival figures well fitted with a transplant benefit.

THU247

Early recurrence of hepatocellular carcinoma after liver transplantation can be predicted by FDG-PET and microvascular invasion at explant pathology

Federica Invernizzi[1], Massimo Iavarone[1], Daniele Dondossola[2], Alberta De Monti[1], Stefano Mazza[1], Umberto Maggi[2], Barbara Antonelli[2], Tullia De Feo[3], Luigia Florimonte[4], Pietro Lampertico[1], Giorgio Rossi[2], Maria Francesca Donato[1].

Migliavacca" Certer for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Fondazione IRCCS Cà Granda Ospedale Maggiore Hospital, University of Milan, HBP Surgery and Liver Transplantation Unit, Milan, Italy; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, North Italy Transplant Program, Coordinamento Trapianti, Milan, Italy; [4]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Nuclear Medicine Department, Milan, Italy
Email: federica.invernizzi@policlinico.mi.it

Background and Aims: Hepatocellular carcinoma (HCC) may recur early after liver transplantation (LT), because of pre-transplant dissemination of primary tumor cells, mainly through blood vessels. One of the main driver for recurrence is microvascular invasion, which is not always detectable by pre-operative imaging examination, as CT-scan and contrast enhanced-MRI, however the role of F-18 fluorodeoxyglucose positron emission tomography (FDG-PET) is poorly investigated in this setting. Our study aimed to identify predictors of the recurrence of HCC after LT, including FDG-PET, with particular attention to early recurrence (≤12 months) risk.
Method: This is a single center, retrospective study including all consecutive patients who underwent LT for HCC as the main indication since 01/2010. Epidemiological, clinical, radiological and histological data were collected and analysed.
Results: Between 01/2010 and 07/2019 449 patients have been transplanted in our center, 182 (41%) with HCC: 158 (84%) males, median age 58 (36–71) years, 60% HCV-Ab positive, 25% MELD-score ≥15, 54% Child-Pugh stage A, median AFP at LT 9 (1–60,500) ng/mL, 29% resulted FDG-PET positive. The histopathological evaluation of the native liver revealed: 86% explanted liver with at least one active HCC nodule [median number per liver 2 (1–22)] with a median size of 32 (3–239) mm; 16% with micro-satellitosis and 27% with micro-vascular invasion (mVI). During a median follow-up of 42 (2–118) months, HCC recurred in 29 (16%) patients (Probability of recurrence at 1–3–5-yrs was 5–11–15%, respectively): 13 recurred within 12 months after LT (early recurrence group) and 16 >12 months. By univariate analysis, the risk-factors for early-recurrence were micro-satellitosis, mVI, G3/4, FDG-PET positive, Milan-out criteria, however only mVI and FDG-PET positivity were confirmed by multivariate analysis as independent predictors for early-recurrence (HR 0.22, p = 0.019 and HR 0.11, p = 0.09). The over-all survival in our cohort was 96 months (95%CI:20–89), being 49 months (95%CI:20–78) in the 13 early-recurrent patients, 64 (95%CI:39–89) in the 16 late-recurrent ones and 104 (95%CI:21–85) in non-recurrent ones.
Conclusion: The FDG-PET in the pre-LT setting and microvascular invasion at explant pathology may help to identify those patients at high risk of early HCC recurrence, deserving of aggressive surveillance or pre-emptive systemic treatment after LT.

THU248

Re-establishing abstinence after alcohol relapse after early transplant (LT) for alcoholic hepatitis (AH) provides survival advantage

Email: gtherapondos@ochsner.org

Background and Aims: Alcohol relapse after early LT for AH is the strongest predictor of post-LT death. To inform post-LT alcohol interventions, using the ACCELERATE-AH (American Consortium of Early Liver Transplantation for Alcoholic Hepatitis), we sought to identify factors associated with establishing abstinence in patients with harmful alcohol relapse after early LT for AH, and to determine whether re-establishing abstinence after alcohol relapse can abrogate the effects of alcohol relapse on survival.
Method: Detailed post-LT alcohol use data in 3-month intervals was retrospectively obtained from 11 ACCELERATE-AH sites. Consecutive patients with clinically-diagnosed severe AH and no prior diagnosis of liver disease who underwent LT from 2006–2018 were included. Latent class analysis and Cox regression identified longitudinal harmful patterns of alcohol relapse, defined as alcohol use patterns associated with increased risk of post-LT death. Patients with harmful relapse post-LT were classified as "established abstinence after relapse" vs. "continued use" as determined by the alcohol use during the last interval of follow-up. Logistic regression examined associations of pre-LT and post-LT variables with establishing abstinence after relapse, adjusted for center clustering.
Results: A total of 146 AH patients underwent LT [67% male, median pre-LT abstinence 59 days) with a median of 3.0 years (IQR 2.0–4.6) post-LT follow-up: 18% for ≥5 years. Median post-LT hospital stay was 14 days (IQR 9–24). 34 patients had harmful relapse: 22 had

continued use after relapse, whereas 12 re-established abstinence after relapse. There were 17 post-LT deaths, of which 10 were alcohol-related. 11 post-LT deaths occurred in patients with continued use after relapse, whereas only 1 post-LT death occurred in patients who re-established abstinence after relapse (p = 0.008). In multivariable analysis, compared to abstinence/non-harmful use, establishing abstinence after relapse was associated with similar risk of death (HR 4.1, p = 0.25), whereas continued harmful alcohol use was associated with increased risk of death (HR 23.2, p < 0.001) (Figure 1). In multivariable analysis, compared to patients with continued alcohol use, length of post-LT hospital stay (OR 1.11 [per day], p = 0.02), and non-Medicaid insurance (OR = 16.3, p < 0.001) were associated with establishing abstinence after post-LT alcohol relapse.

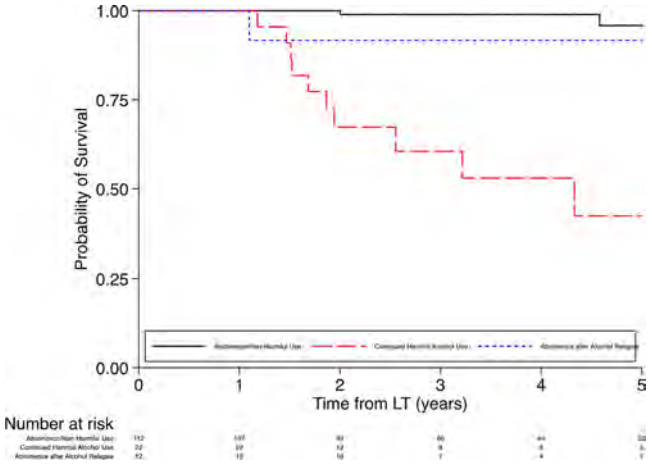

Figure 1. Kaplan-Meier Estimates of Survival in Patients with Abstinence/ Non-Harmful Alcohol Use Post-LT vs. Continued Harmful Use vs. Abstinence after Alcohol Relapse

Conclusion: Re-establishing abstinence after alcohol relapse appears to abrogate the deleterious effects of alcohol use on patient survival after early LT for AH. Our data suggest that encouraging AH LT recipients to enter treatment even after relapse may restore survival.

THU249

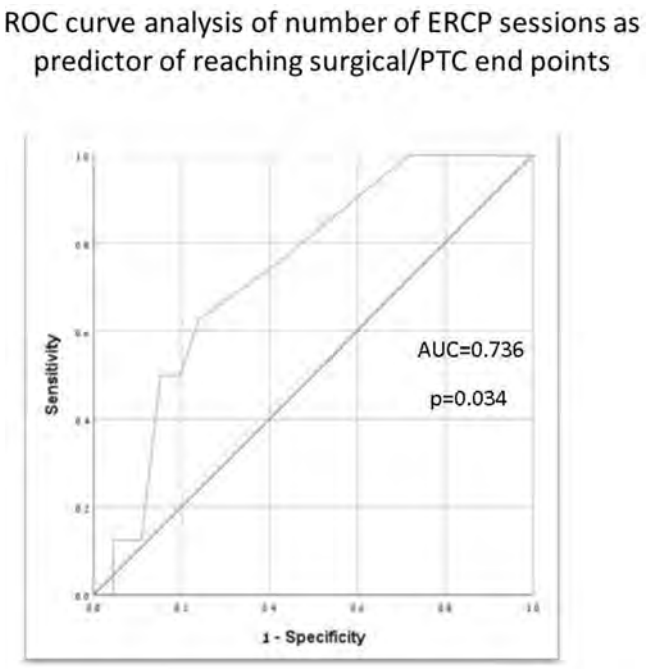
Predictors of success in the treatment of anastomotic biliary stricture after liver transplantation

Ophir Gilad[1,2], Adam Phillips[1,2], Sharon Levy[1,2], Nir Lubetsky[2,3], Yakov Goihkman[2,3], Ido Nachmani[2,3], Oren Shibolet[1,2], Helena Katchman[1,2]. *[1]Tel Aviv Sourasky Medical Center, Gastroenterology, Tel Aviv, Israel; [2]Tek Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel; [3]Tel Aviv Sourasky Medical Center, Surgery, Tel Aviv, Israel*
Email: hkatchman@gmail.com

Background and Aims: Anastomotic bile duct stricture is a common complication following liver transplantation (LT). Endoscopic retrograde cholangiopancreatography (ERCP) is first-line choice for diagnosis and treatment of this complication, followed by percutaneous transhepatic cholangiography (PTC) or surgery in case of failure. We aimed to determine the effectiveness and safety of ERCP for anastomotic biliary strictures, and find predictors of ERCP treatment failure and complications.

Method: A retrospective cohort study; demographic, clinical data, number of ERCP sessions, number and type of stents, need for PTC or surgery, complications and mortality were recorded.

Results: Out of 242 patients that underwent LT between 2003–2019 sixty nine patients underwent ERCP, in 54 of them biliary stricture was diagnosed. Median time from LT to ERCP was 54 days (IQR 16–227.5). Overall, 223 ERCPs were performed, with an average of 4.1 ± 3.7 sessions per patient until resolution of stenosis or switch to other treatment modality. In 32 patients (59.2%) ERCP was definitive treatment, 8(14.8%) required PTC or surgery and 9(16.6%) died with stent in place. Five patients (9.2%) are still in treatment. Roc curve analysis has shown that need for more than four ERCP sessions predicts reaching of PTC/surgery end point with 75% sensitivity and 59% specificity (Figure). Fourteen (25.9%) patients developed complications (pancreatitis (12.9%), cholangitis (14.8%) and bleeding (1.8%)).



Plastic, metal or plastic followed by metal stent on the next sessions were used in 40(74.1%), 4(7.4%) and 10(18.5%) patients respectively. No correlation between stent characteristics and outcome or development of complications was found.

Metal stents were introduced in the routine use in 2013. Patients were divided into 2 groups, before and after 2013 (27(50%) in each group). The outcomes in both groups were similar, but patients in the latter group underwent significantly less ERCPs to get outcome (p = 0.03 for cut off 4 or less ERCPs).

Conclusion: Our experience confirms that ERCP is highly effective and safe treatment for anastomotic biliary strictures after LT. We demonstrated that performing more than 4 ERCPs had no added benefit and was significant predictor of need for surgery/PTC. Increased center experience in the recent years resulted in reaching the same outcomes in less ERCP sessions. Prospective data collection is needed to evaluate possible advantages of different type of stents.

THU250

Survival after liver transplant in recipients of different age groups: a systematic review and meta-analysis

Ho Ming Cheng[1], Wai-Kay Seto[1], Cheuk Kin Kevin Cheng[1], Albert CY Chan[2], Man-Fung Yuen[1], Yan Yue James Fung[3]. *[1]The University of Hong Kong, Medicine, Hong Kong; [2]The University of Hong Kong, Surgery, Hong Kong; [3]Queen Mary Hospital, Medicine, Hong Kong*
Email: wkseto@hku.hk

Background and Aims: An increasing number of elderly patients are undergoing liver transplantation for end-stage liver disease and hepatocellular carcinoma. However, there is a paucity of data on the risk of mortality post-liver transplantation with respect to increasing age.

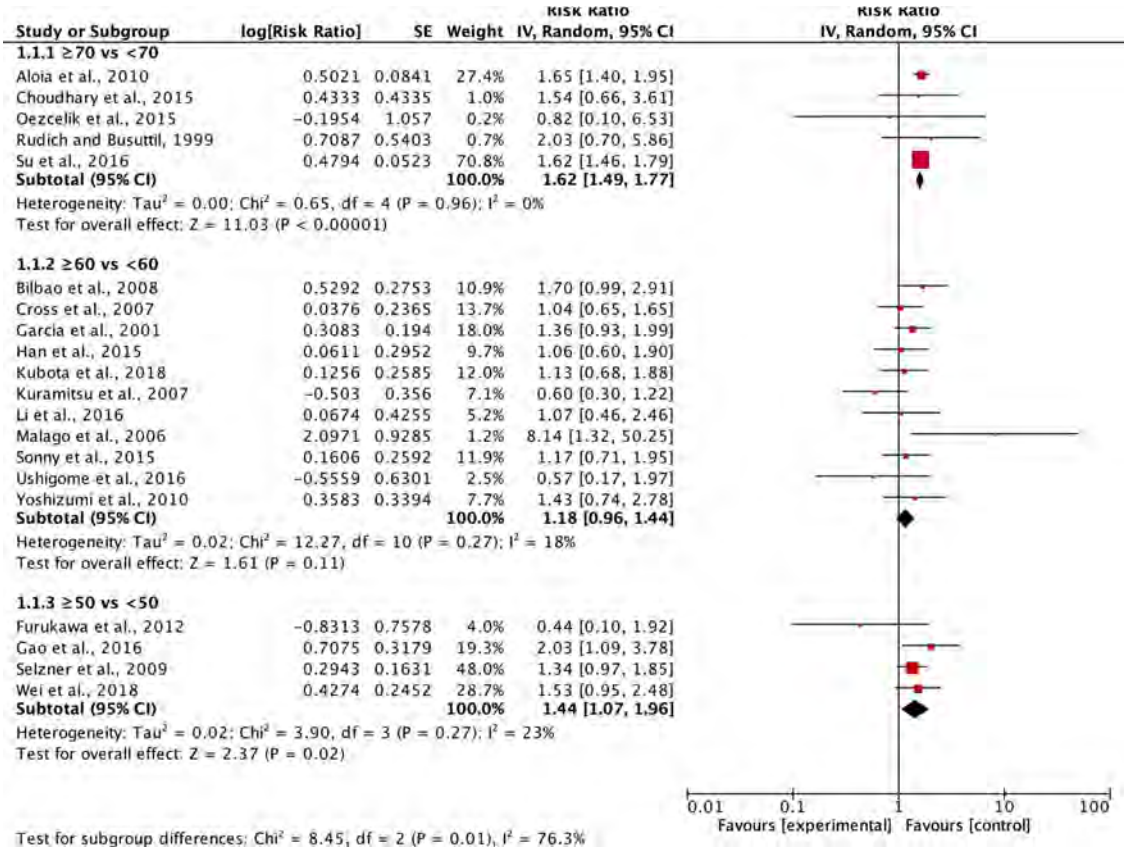


Figure: (abstract: THU250)

Method: We performed a systematic review and meta-analysis to assess the effect of older age on mortality after liver transplantation. A comprehensive literature review was conducted utilizing the PUBMED, MEDLINE, SCOPUS and EMBASE databases through July 2019 to identify all cohort studies that compared the long-term survival outcome between patients who underwent liver transplantation at the age of older recipients versus younger recipients. Effect estimates from each study were extracted and combined using the random-effect.

Results: Of 686 potentially eligible articles, a total of 20 studies with 19,412 participants fulfilled the eligibility criteria and were included in the meta-analysis. With respect to transplant mortality, subgroup analysis showed age ≥70 years compared to younger recipients had the pooled RR of 1.62 (95% CI, 1.49–1.77, $p < 0.0001$) (Figure); age ≥60 years compared to younger recipients had the pooled RR of 1.18 (95% CI, 0.96–1.44, $p = 0.11$) and age ≥50 years compared to younger recipients had the pooled RR of 1.44 (95% CI, 1.07–1.96, =0.02) (Figure). Between-group comparisons, recipients age ≥70 years were significantly increase risk of mortality post-liver transplantation ($p =$ 0.01).

Conclusion: There was a significantly increased risk of mortality post-liver transplantation among recipients age ≥70 years. This suggests that the age of 70 years could be the deflection point where the rate of mortality starts to accelerate, with risks outweighing benefits beyond this age group.

THU251

Prophylactic rifaximin use in liver transplant candidates is associated with false positive results of the alcohol biomarker, ethyl sulphate

Ian Webzell[1], Nicholas Beckley-Hoelscher[2], David R Taylor[3], Vishal C Patel[1,4,5], Debbie Shawcross[1], Nigel Heaton[1]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom;* [2]*School of Population Health and Environmental Sciences, King's College London, London, United Kingdom;* [3]*Department of Clinical Biochemistry, King's College Hospital, London, United Kingdom;* [4]*Foundation for Liver Research, Institute of Hepatology, London, United Kingdom;* [5]*King's College London, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, London, United Kingdom*
Email: ianwebzell@nhs.net

Background and Aims: A key component during assessment for liver transplantation (LT) is assessment of alcohol use and abstinence. LT candidates can be toxicologically screened for the direct alcohol metabolites, ethyl glucuronide (ETG) and ethyl sulphate (ETS). At King's College Hospital, we observed ETS results that provided an anomaly to the reviewed literature which we described as "weak positive" ETS. We sought to explore this discrepancy.

Method: A cross-sectional study reviewed demographic, clinical and laboratory data, including medications. We studied 243 patients who were assessed for LT from December 2017 – November 2018 and provided a urine specimen analysed for ETG/ETS. Chi-square tests of association measured crude relationships between categorical status of urine specimen results and highlighted medications, and multiple logistic regression assessed relationships adjusted for potential confounding variables.

Results: Majority of patients were male (60%) with mean age of 52 years. Aetiology of liver disease was mainly alcohol-related liver disease (34%), non-alcoholic steatohepatitis (16%) and viral hepatitis

(8%). Of the 243 patients, 67% had negative urine ETG/ETS, 7% were positive for both ETG/ETS and 26% were positive for only ETS which was the anomalous result further explored. No samples were ETG positive/ETS negative.
Quantification of the ETS positive/ETG negative results found a mean result of 313 µg/L and median 228 µg/L. The positive range for ETS is 100 µg/L – >80,000 µg/L. We defined these results as "weak positive" ETS.
When comparing the study variables using chi-square tests and multiple regression analyses, only one association was significant. "Weak positive" ETS was strongly associated with concurrent Rifaximin therapy ($p < 0.001$) even after adjusting for Lactulose co-therapy ($p < 0.001$).
Conclusion: During LT assessment, urinalysis for ETG and ETS provides objective evidence of recent alcohol use. Reliability is important given the implications of false positive (or negative) results. Caution should be applied in interpreting urine ETG/ETS results in patients treated with Rifaximin, given the high probability of an anomalous "weak positive" ETS result, which may be falsely interpreted as evidence of covert drinking. We hypothesise that this finding is driven by alterations in the microbiome and the ability for bacteria to degrade urinary ETG but not ETS as is reported in the literature, with Rifaximin modulating this effect.

THU252
Predictive factors of symptomatic nodular regenerative hyperplasia after liver transplantation
Ilias Kounis[1,2,3], Manon Evain[1], Mylène Sebagh[2,3,4], Bruno Roche[1,2], Eleonora De Martin[1,2,3], Rodolphe Sobesky[1,2,3], Eric Vibert[1,2,3], Jean-Charles Duclos-Vallée[1,2,3], Cyrille Feray[1,2,3], Didier Samuel[1,2,3], Audrey Coilly[1,2,3]. *[1]AP-HP Hôpital Paul Brousse, Centre Hépato-Biliaire, Villejuif, France; [2]Université Paris-Sud, Université Paris Sud Saclay, UMR-S 1193, Villejuif, France; [3]DHU Hepatinov, Villejuif, France; [4]AP-HP Hôpital Paul Brousse, Department of Pathology, Villejuif, France*
Email: ilias.kounis@aphp.fr

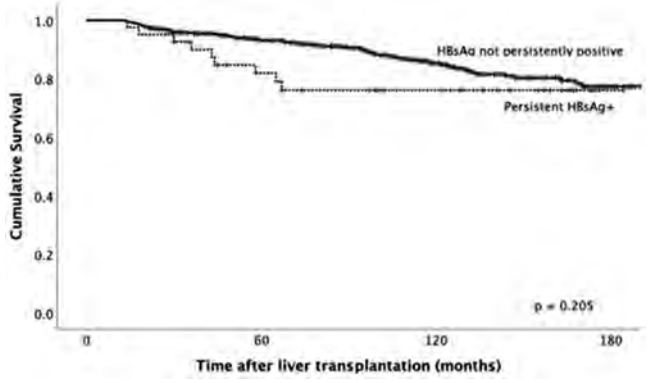
Background and Aims: In the context of liver transplantation (LT), nodular regenerative hyperplasia (NRH) could occur on the graft, responsible for portal hypertension that may lead to death or re-transplantation. To date, no study specifically focuses on predictive factors of events due to NRH. The primary objective of this study is to identify predictive factors of symptomatic NRH after LT.
Method: In this monocenter retrospective study, inclusion criteria were: liver transplant recipients > 18 years (y) and a diagnosis of histologically proven NRH on the graft. All biopsies showing NRH after LT were collected from 2008 to 2018. Patients with NRH recurrence were excluded. Symptomatic forms of NRH were defined as the presence of ascites, esophageal varices with or without bleeding, hepatic encephalopathy, portal thrombosis, retransplantation or death related to NRH.
Results: 115 patients were included. The mean follow-up between LT and diagnosis of NRH was 7.5 ± 8.6 y. The mean age at diagnosis was 53 ± 14 y. Main indication of LT was alcoholic cirrhosis (16.1%). Symptomatic form occurred in 27(23.1%) patients. Symptoms were 18(15.3%) ascites occurrence, 12(10.2%) esophageal varices and 7 (5.9%) variceal bleeding, 3(2.5%) hepatic encephalopathy and 8(6.8%) portal thrombosis. The meantime to onset of symptoms was 1.3 ± 2.9 y after diagnosis. Seven (6%) patients were treated with portocaval shunt including 6 TIPS procedure with a meantime of 0.7 ± 1.9 y after diagnosis. Six (5.2%) and 4(3.5%) patients were retransplanted or died for symptoms related to NRH. Overall survival was 71% versus 92% ($p = 0.012$) and graft survival was 51% versus 89% ($p < 0.0001$), between groups with or without symptoms related to NRH, respectively. In multivariate analysis, the factors associated with symptomatic NRH were low hemoglobine level at diagnosis (OR 0.68, IC95%, $p = 0.027$)) and the ratio spleen size at diagnosis/spleen size before LT (OR 9.57, IC95%, $p = 0.039$).
Conclusion: NRH after LT is a serious condition that leads to symptomatic portal hypertension in 23.1% of patients. Although overall prognosis is good, symptomatic patients experienced significantly lower transplant free survival. Patients who have an increase in spleen size or decrease of hemoglobin rate should be strongly monitored to symptomatic NRH.

THU253
Transplanting livers from hepatitis C positive donors: is it worth the risk?
Jacobus Mensink[1,2], Bart Van Hoek[3,4], Brigitte Schaefer[2], Marieke van Rosmalen[5], Ian Alwayn[1,3], Andries Braat[1]. *[1]Leiden University Medical Center (LUMC), Transplant Surgery, Leiden, Netherlands; [2]Dutch Transplant Foundation, Organ and Tissue Donation, Leiden, Netherlands; [3]Leiden University Medical Center (LUMC), LUMC Transplant Center, Leiden, Netherlands; [4]Leiden University Medical Center (LUMC), Gastroenterology and Hepatology, Leiden, Netherlands; [5]Eurotransplant International Foundation, Organ Allocation, Leiden, Netherlands*
Email: j.w.mensink@lumc.nl

Background and Aims: Before the introduction of Direct-Acting Antivirals (DAAs), only selected organs from Hepatitis C virus (HCV) positive donors were successfully transplanted into HCV positive recipients. Since HCV infection is now curable in a large percentage of cases (>95%) it may be possible to transplant organs from HCV positive donors to HCV negative recipients. In this study we aim to analyse current utilization of livers of HCV positive donors in the Eurotransplant (ET) region and its future potential.
Method: All reported post-mortem organ donors with age ≥16 years in the ET region between January 2007 and December 2018 were included. Donors from outside the ET region were excluded. Segmental liver transplantations were excluded as well. First, donor demographics were evaluated for all reported donors by HCV status. Then, utilization and graft survival were analysed for both groups.
Results: A total 22,474 donors were reported in the ET region and 287 (1.3%) donors were tested positive for HCV antibodies (ab), with a range of 0.0–1.7% per country in the ET region. A total of 141 (49%) livers of the HCV ab positive donors were transplanted, 74/141 (53%) in HCV ab positive recipients. Graft failure occurred in 25/141 (18%) recipients directly or later after transplantation. In 5/141 (3.5%) it was due to recurrence of HCV. Of the 21,998 HCV ab negative donors 17,745 (81%) livers were transplanted, 2,245/17,745 (13%) in HCV ab positive recipients. In 2,585/17,745 (15%) recipients graft failure occurred directly or later after transplantation. Recurrence of HCV as cause of graft failure was in 77/17,745 (0.4%) of the recipients with graft failure.
Conclusion: Liver utilization is much higher in HCV ab negative donors as compared to HCV ab positive donors. However, graft failure overall and specifically due to HCV infection occurs in 18% and 3.5% respectively in the HCV ab positive donors. Therefore, the absolute risk is slightly higher in recipients of a HCV ab negative graft. Although the number of HCV ab positive donors is not very high in the ET region, with the new DAAs there is an opportunity to improve utilization of HCV ab positive donors and outcome after liver transplantation. With the increasing waiting lists and relatively stable number of donors, transplant centers should consider all liver grafts of HCV positive donors for transplantation.

THU254
Long-term outcomes of persistently positive hepatitis B surface antigen after liver transplantation for chronic hepatitis B
Yan Yue James Fung[1], Albert CY Chan[2], Tiffany Wong[2], Wing-chiu Dai[2], Sui-ling Sin[2], Lung Yi Mak[1], Wai-Kay Seto[1], Man-Fung Yuen[1], Chung Mau Lo[2]. *[1]The University of Hong Kong, Medicine, Hong Kong; [2]The University of Hong Kong, Surgery, Hong Kong*
Email: jfung@gastro.hk

Background and Aims: Antiviral therapy alone without hepatitis B immune globulin (HBIG) has been shown to be effective after liver transplantation for chronic hepatitis B (CHB). However, a small proportion will have persistently positive hepatitis B surface antigen (HBsAg), of which the long-term outcome is unclear. We aim to determine the long-term outcome of recipients with persistently positive HBsAg.
Method: Consecutive patients with CHB and liver transplantation from January 2003 to December 2017 were considered. All patients received HBIG-free regimen as prophylaxis with oral antiviral therapy alone. Graft survival and outcome were determined.
Results: A total of 630 CHB patients were transplanted, of which 582 (92%) had over one year of follow-up and were included. Of these, 486 (84%) were male, and 250 (43%), 212 (36%), and 120 (21%) were transplanted for decompensated cirrhosis, hepatocellular carcinoma (HCC), and severe flares respectively. The median follow-up was 104 months (range, 13–199). Forty-one (7%) had persistently positive HBsAg without evidence of seroclearance, with higher rates observed in severe flares compared to cirrhosis and HCC patients (13.3% vs. 6.8% vs. 3.8% respectively, p = 0.005). The graft survival for persistently positive HBsAg was 81.9%, 76.1% and 76.1% at 5, 10, and 15 years post-transplant respectively, compared to 93.1%, 85.3% and 77.3% respectively for those patients that were not persistently positive for HBsAg (p = 0.205), as shown in the figure. There were 9 graft losses during the follow up period for persistently positive HBsAg patients, of which 4 were due to HCC recurrence, 2 from lymphoma, 2 from extra-hepatic malignancies, and 1 from sepsis. There were no cases of graft loss due to *de novo* HCC or reactivation of hepatitis B virus infection. At the time of last follow-up, all active patients had undetectable HBV DNA.

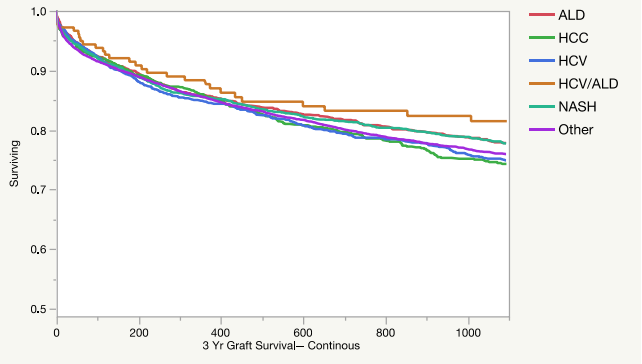


Conclusion: Despite a persistently positive HBsAg after liver transplantation for CHB in patients receiving HBIG-free prophylaxis, there was excellent long-term graft survival, which was comparable to patients who had evidence of HBsAg loss. Importantly, there was no graft loss from *de novo* HCC or hepatitis B reactivation in persistently positive HBsAg patients.

THU256
NASH is the leading indication for liver transplantation in elderly patients

Justin Steggerda[1], Ju Dong Yang[2], Irene Kim[1], Nicholas Nissen[1], Tsuyoshi Todo[1], Shelly C. Lu[2], Walid Ayoub[2], Vinay Sundaram[2], Naim Alkouri[3], Mazen Noureddin[2]. [1]*Cedars-Sinai Medical Center, Surgery, Los Angeles, United States;* [2]*Cedars-Sinai Medical Center, Hepatology, Los Angeles, United States;* [3]*University Hospital, Gastroenterology, San Antonio, United States*
Email: justin.steggerda@cshs.org

Background and Aims: Non-alcoholic steatohepatitis (NASH) is an increasingly prevalent cause of end-stage liver disease (ESLD) and indication for liver transplantation (LT) in the United States and around the world.
Method: United Network for Organ Sharing (UNOS) databases for waitlisted and transplanted patients were evaluated between 2006 and 2018. Pediatric patients (<18 years old) were excluded. Elderly recipients defined as ≥ 65 years old. Chi-square and Wilcoxon rank-sum analyses were used to compare groups. Logistic regression analyses were performed to assess likelihood of transplantation with odds ratios (OR) and 95% confidence intervals (CI) reported. Three-year graft survival was assessed with Kaplan-Meier (KM) survival analysis. P-values <0.05 were considered significant.
Results: 129,839 patients were waitlisted for LT during the study period, of which 22,897 (14.9%) had NASH as primary diagnosis. Patients waitlisted with NASH were the oldest (median 60 years, IQR 54–65 years, p < 0.0001), and predominantly male (n = 12,091, 50.7%). NASH became the most common primary diagnosis amongst candidates ≥ 64 years old, at which point it accounted for 25.6% of waitlisted patients. Interestingly, NASH was the most common primary diagnosis amongst waitlisted women ≥ 60 years old, while in in men it did not become the most common until ≥ 70 years old. The median age at transplant for candidates with NASH was 64 years (IQR 59–67 years). NASH became the most common diagnosis amongst transplanted recipients ≥ 62 years old (≥59 years old in women and ≥ 69 years old in men). Multivariable analysis showed that patients with NASH were more likely to be transplanted than those with HCV (OR 1.13, 95% CI 1.09–1.18, p < 0.001) and ALD (OR 1.06, 1.01–1.11, p < 0.001). Amongst elderly recipients, patients with NASH were more likely to be transplanted than those with HCV (OR 1.13, 1.07–1.18, p < 0.001), but there was no difference between NASH and ALD (OR 1.03, 0.99–1.09, p = 0.15). KM survival analyses showed no difference in 3-year graft survival across etiologies of ESLD overall, or amongst elderly recipients alone (Figure 1).



Conclusion: NASH is the most common indication for waitlisting and transplantation in elderly patients. Despite being a disease of the elderly, there is no difference in graft survival amongst recipients with NASH.

THU257
Hepatitis B immunoglobulin prophylaxis for prevention of de novo Hepatitis B infection from hepatitis B core antibody-positive donors

Kyeongdeok Kim[1], Jinsoo Rhu[1], Jong Man Kim[1], Gyu-Seong Choi[1], Jae-Won Joh[1]. [1]*Samsung Medical Center, Department of Surgery, Seoul, Korea, Rep. of South*
Email: yjongman21@gmail.com

Background and Aims: Recently, hepatitis B core antibody (anti-HBc) positive liver grafts are used as extended criteria donor organs. However, prophylaxis methods to prevent de novo hepatitis B virus (HBV) infection after liver transplantation (LT) are still controversial. Thus, the purpose of our study is to evaluate the risk and outcomes of

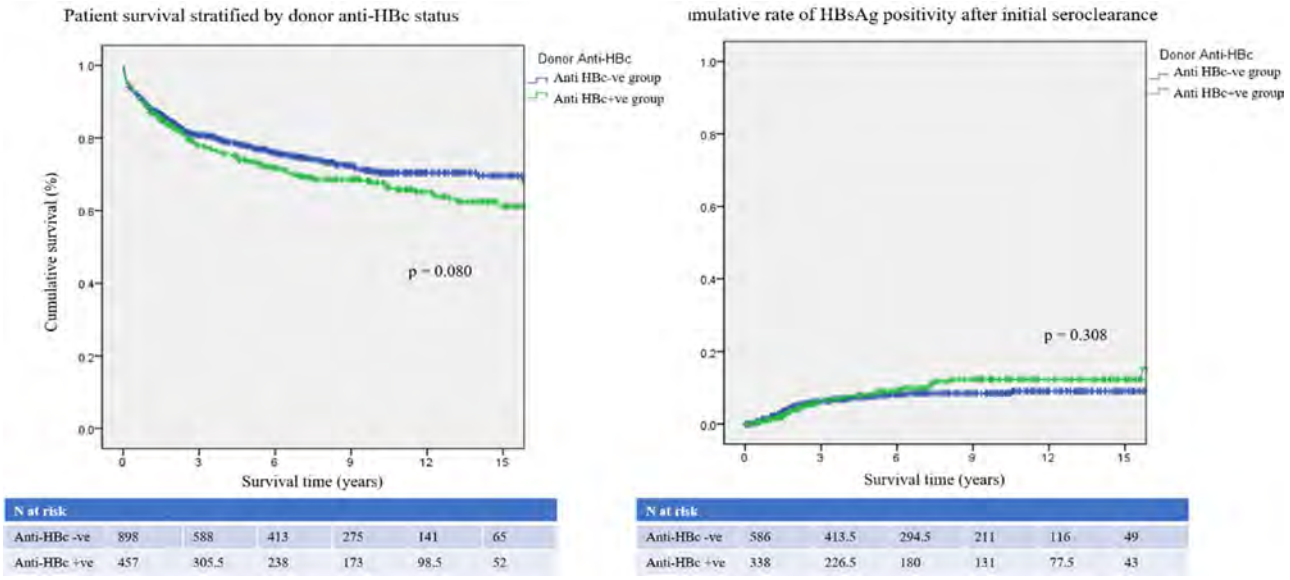


Figure: (abstract: THU257)

receiving anti-HBc positive grafts with prophylactic HBIG monotherapy.

Method: All adult patients who underwent LT at Samsung Medical Center in Seoul, Korea, between January 2001 and December 2018 were gathered from a prospectively maintained database and reviewed retrospectively. HBV patients received the combination treatments with antiviral prophylaxis and hepatitis B immunoglobulin (HBIG). Prophylactic HBIG monotherapy was given for patients without HBV receiving grafts from anti-HBc positive donors.

Results: A total of 1355 patients underwent LT during this period. Among them, 457 (33.7%) were anti-HBc positive and 898 (66.3%) were anti-HBc negative donors, who underwent follow-up for a median time of 5.7 years. Perioperative outcomes (mortality in 30 days, complications and postoperative ICU stay period) were similar between the two groups. Also, there were no significant difference in the 1-, 5-, 10- and 15-year patient survival rates between the anti-HBc positive (87.5%, 73.5%, 67.7% and 61.2%) and the anti-HBc negative groups (88.5%, 77.7%, 70.7% and 69.6%, p = 0.080). All of the 117 recipients who were HBsAg negative and received anti-HBc positive grafts were given prophylactic HBIG monotherapy. Only one patient (0.9%, 1/117) developed de novo HBV during follow-up. There were 972 HBsAg-positive patients and 348 (35.8%) received anti-HBc positive grafts. The risk of HBV recurrence was similar between 2 groups (p = 0.308). The donor anti-HBc status did not have a significant influence on the long-term survival or the risk of de novo or recurrent HBV infection after LT.

Conclusion: De novo HBV was very rare especially with HBIG prophylaxis in non-HBV patients received anti-HBc positive liver graft. There was no significant influence of anti-HBc positive grafts on the perioperative and long-term outcomes after LT.

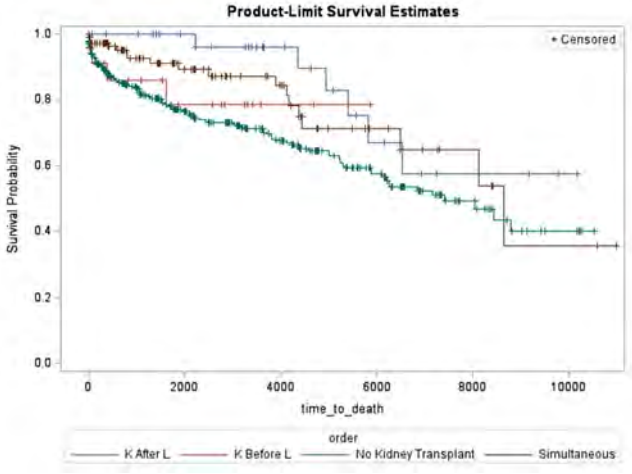
THU258

Improved patient and graft survival from kidney transplantation in liver transplants for congenital hepatic fibrosis and Caroli's disease

Khalid Khan[1], Tandy Agostini[2], Sameer Desale[3], Arul Thomas[1].
[1]*MedStar Georgetown University Hospital, Transplant Institute, Washington, United States;* [2]*MedStar Washington Hospital Center, Internal Medicien, Washington, United States;* [3]*MedStar Health Research Institute, Washington, United States*
Email: khalid.m.khan@gunet.georgetown.edu

Background and Aims: Congenital hepatic fibrosis (CHF) and Caroli's disease (CD) have a common etiology, arising as ductal plate malformations, and can include autosomal recessive polycystic kidney disease. The natural history of the liver disorders either alone or in combination appears highly variable with little data on outcomes, particularly in liver transplantation. We aimed to determine whether there are differences in patient survival and graft failure between patients with CHF and CD after liver transplantation and how this is impacted by kidney disease leading to kidney transplantation.

Method: We evaluated liver transplant outcomes of CHF versus CD, from 1987 to 2018, using the entire United Network of Organ Sharing dataset that incorporates transplantation in the United States. Using standard software, data are presented as mean + standard deviation or median and analysed with the student t test and Chi square. Kaplan-Meier curves were constructed, and log-rank tests were applied to test for differences in graft failure and patient survival. A $p < 0.05$ was considered statistically significant.



Results: A total of 626 unique patients diagnosed with either CHF, n = 363, CD, n = 243 or both diagnoses, n = 20 were identified from the SRTR data. Patients with CHF were primarily transplanted as children

or young adults while the CD group is evenly spread throughout the age groups. This resulted in a difference of 24 years in the median age (16 years versus 40 years) at transplantation (p = 0.000). There was also differences amongst racial groups with black patients being twice as common in the CD as compared to the CHF group (p = 0.013). There was a statistically significant difference in patient (p = 0.020) and graft survival (p = 0.003) between patients with CHF versus CD. A total of 305 kidney transplants were performed in 235 individuals with either CHF or CD;172 received 1 graft, 56 received 2 grafts and 7 received 3 grafts. Patient survival was better with simultaneous (p = 0.020) and kidney transplant after liver transplant (p = 0.034), Figure 1. Liver graft survival was significantly better with simultaneous liver and kidney transplant (p = 0.015). Multivariate analysis confirmed age, race, CHF versus CD and simultaneous kidney transplantation as significant for graft survival; The same factors were also significant for patient survival apart from simultaneous kidney transplantion.

Conclusion: Patients with CHF and CD, although related etiologies, have diverse outcomes for liver transplantation. Patients with CD undergo liver transplantation across wider ages than CHF patients. CD patients have worse graft survival and higher rates of death than CHF patients. Both groups of patients benefit from kidney transplantation either simultaneously or following liver transplantation.

THU259

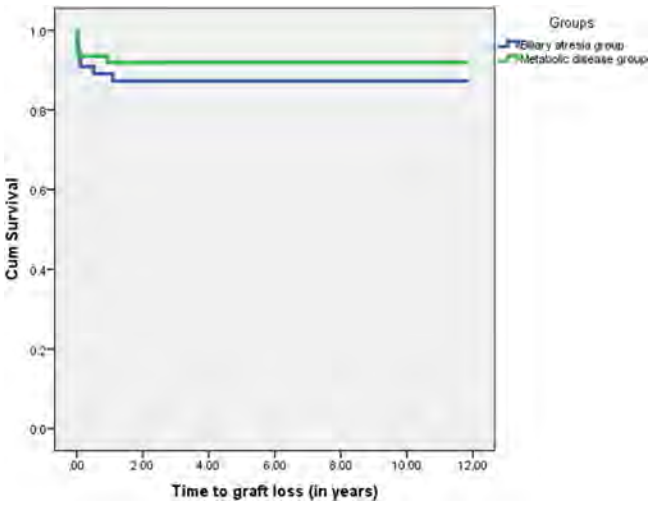
Outcomes of liver transplantation for metabolic disorders in children

Khalid Khan[1], Ahmed Elsabbagh[2], Stuart S. Kaufman[1], Nada Yazigi[1]. [1]*MedStar Georgetown University Hospital, Transplant Institute, Washington, United States;* [2]*St Vincent's Hospital, Surgery, Indianapolis, United States*
Email: khalid.m.khan@gunet.georgetown.edu

Background and Aims: The main indication for liver transplantation (LT) in children has been biliary atresia. Recent advances in surgical management and the development of new immunosuppressants have made LT a viable therapeutic option for an increasing number of disorders in this modern era. In particular LT has become an effective therapeutic modality for patients with metabolic liver diseases, especially urea cycle disorders. To be considered a treatment of choice for metabolic patients, LT must have at least equivalent outcomes to biliary atresia. As a large center for LT for metabolic disorders we are able to examine this issue.

Method: This was a retrospective analysis comparing between isolated pediatric liver transplantation for metabolic liver diseases (N = 62) versus biliary atresia (N = 55) in the period between January 2008 and December 2018. Standard statistical software was used. Proportions are compared using chi-square and continuous variable using student t-test. Kaplan-Meyer curves are constructed and compared using the log-rank test.

Results: The median age for the metabolic group was 2 (0.16–16) year versus 1 (0.4–15) year for the biliary atresia group (P = 0.0001). 41.9% were female in metabolic group versus 73.6% in biliary atresia group (P = 0.001). 14.5% were African American in the metabolic group versus 41.5% in biliary atresia group (P = 0.010). Graft types included whole liver, cadaveric split liver, living donor segmental liver (54.8%, 38.7%, 6.5% in the metabolic group versus 40%, 27.3%, 32.7% in the biliary atresia group, P = 0.001). The 1-, 3-, and 5-year patient survival for the metabolic group were identical to the biliary atresia group (95%, 95%, and 95%). The 1-, 3-, and 5-year graft survival for metabolic group was 92%, 92%, and 92% versus 87%, 87%, and 87% for the biliary atresia group (P = 0.418). Postoperative complications included biliary (14.5% in metabolic vs. 33.3% in the biliary atresia group, P = 0.017), vascular (19.4% in the metabolic group vs. 35.8% in the biliary atresia group, P = 0.047), postoperative bleeding (16.1% in metabolic group vs. 20.8% in the biliary atresia group, P = 0.522). High grade Clavien-Dindo (3B or higher) complications were significantly less in the metabolic group (25.8% vs. 48.1% in the biliary atresia group, P = 0.014). Acute rejection tended to be higher in metabolic group (37.1% versus 21.8% in the biliary atresia group, P = 0.072).



Conclusion: Pediatric liver transplantation for metabolic liver diseases in our high volume center has excellent outcomes in comparison to biliary atresia. It has similar patient and graft survival but with less postoperative complications and readmissions. Rejections tended to be higher in metabolic group.

THU260

Assessment of long-term risk of cardiovascular disease after liver transplantation

Kirsty Miles[1], Usman Ahmad[1], Alexandra Hinkson[1], Lisa Bridgeman[1], Richard Parker[1]. [1]*Leeds Teaching Hospitals NHS Trust, Leeds Liver Unit, Leeds, United Kingdom*
Email: kirsty.miles1@nhs.net

Background and Aims: The risk of cardiovascular disease (CVD) is increased in people who have undergone liver transplant (LT) and is a common cause of death in long-term follow-up studies. Risk assessment for CVD is commonplace in non-transplant cohorts but the relevance of commonly used systems of CVD risk scores in the UK have not been evaluated in liver transplant patients. This is important as accurate risk assessment can guide interventions to reduce cardiovascular risk such as statin therapy. We evaluated the accuracy of Q-RISK, Framingham-CVD and the BNF scores in a cohort of patients in Leeds.

Method: All patients who had undergone a first liver-only transplantation in Leeds from 2008–2012 were identified from a prospectively maintained database. Those patients over 25 and surviving for at least 1 year after LT were included. Baseline characteristics were noted and information about clinical outcomes was extracted from clinical notes. CVD that occurred after the first year of follow-up were noted to exclude peri-operative events. Ten-year risk scores for CVD were calculated at 12 months after LT. Test accuracy was assessed with receiver-operator curves using the "pROC" package in R.

Results: In total (367–36 deaths – 16 under 25) 315 patients were included with a maximum of 10.6 years follow-up (median 7.2 years, IQR 5.5–8.4 years). After the first year of follow-up, there were 27 patients with incident CVD (8%) – of which one event (a myocardial infarction) was fatal – giving a crude event rate of 1.1%/year. At twelve months after LT, median CVD risk scores were: Q-RISK 2 8.8 (IQR 3.5–14.4), Framingham CHD 3.4 (1.2–7.3) and BNF 2.8 (1.0–6.1). The Q-RISK score had the best performance: AUROC 0.72 (95%CI 0.62–0.82) followed by the Framingham CHD score, AUROC 0.70 (95% CI 0.61–0.79) and the BNF score, AUROC 0.69(95% CI 0.60–0.78).

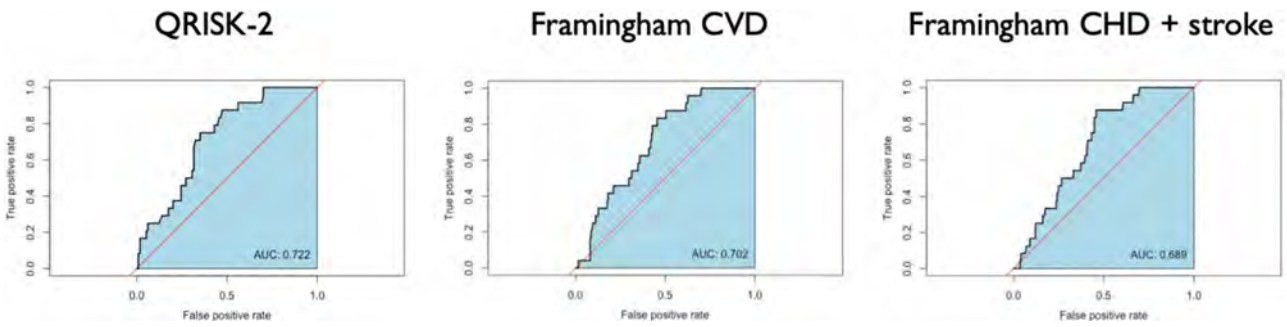


Figure: (abstract: THU260)

Conclusion: cardiovascular disease in this cohort was not a common event and was usually not fatal. The scarcity of CVD events limits this analysis. However, the Q-RISK score, recommended by NICE for non-transplant populations, was the most accurate score to predict incident CVD events.

THU262

Portal venous thrombosis and liver transplant: incidence and evolution in the 1st year after transplant

Eva Julissa Ortega Suazo[1], Patricia Abellan Alfocea[1], María Dolores Espinosa Aguilar[1], Ana Gila Medina[1], Mercedes Angeles Gonzalez Sanchez[1], Flor Nogueras López[1], Eduardo Redondo[2], Maria Angeles Lopez Garrido[1]. *[1]Hospital Universitario Virgen de las Nieves, Servicio de Aparato digestivo. Unidad de Hepatologia; [2]Hospital Universitario Virgen de las Nieves, Jefe de Servicio de Aparato digestivo. Unidad de Hepatologia*
Email: julissa.ort3ga@gmail.com

Background and Aims: Portal venous thrombosis (PVT) occurs, before and after liver transplant. There are a few studies about it. We do not know its incidence and evolution in our hospital. To determine the incidence of pre and post-transplant PVT and describe: patient characteristics, donation type, predisposing factors, treatments and mortality.
Method: It is a retrospective observational study, where we include patients who received liver transplant from 2010 to April 2019 in our center. We selected patients with pretraplant PVT diagnosed by imaging tests (Eco-Doppler, abdominal Angio-CT) and/or intraoperative diagnosis. In the post-transplant follow-up was with Eco-Doppler: 1st week and 1st, 3rd and 12th month. The clinical and demographic characteristics of the patients, type of donor, smoking, predisposing factors (atrial fibrillation, Phospholipid Syndrome), pre-transplant and post-transplant treatment, post-transplant PVT and mortality in the 1st post-transplant year were collected.
Results: 278 patients were transplanted, 65 (23%) had pre-transplant PVT. Of these, 55 were men (85%) and 10 women (15%). The average age was 56 + –8.4 years. 43% (n: 28) were non-smokers, 31% (n: 20) ex-smokers and 26% (n: 17) smokers. 94% (n: 61) had no predisposing factors and 6% (n: 4) did. 98.5% (n: 64) was a cadaveric donation and 1.5% (n: 1) asystole. The pre-transplant diagnosis was 100% (n: 65) by Eco-Doppler. 78.5% (n: 51) presented intraoperative thrombosis. 68% did not receive pre-transplant treatment and 32% did. Postransplant PVT diagnosed by Eco-Doppler was 15% (n: 10), 12% (n: 5), 8% (n: 5) and 4% (n: 3), in the 1st week, the 1st month, 3rd month and 12th month, respectively. 89% received anticoagulation after transplant. Eight patients died (12%).
Conclusion: The incidence of pre-transplant PVT was high (23%). Few patients had predisposing factors (6%) and most (57%) had been or were smokers. All patients received anticoagulation after transplant and 89% maintained it until the first year. The incidence of post-transplant PVT was low (4%) with a good response to anticoagulation (89%). Mortality in the 1st year was not related to PVT.

THU263

Utility of anticoagulation in portal venous thrombosis before and after liver transplant

Patricia Abellan Alfocea[1], Eva Julissa Ortega Suazo[1], Flor Nogueras López[1], María Dolores Espinosa Aguilar[1], Mercedes Angeles Gonzalez Sanchez[1], Ana Gila Medina[1], Eduardo Redondo[2], Maria Angeles Lopez Garrido[1]. *[1]Hospital Universitario Virgen de las Nieves, Servicio de Aparato digestivo. Unidad de Hepatologia; [2]Hospital Universitario Virgen de las Nieves, Jefe de Servicio de Aparato digestivo. Unidad de Hepatologia*
Email: patriabellan91@gmail.com

Background and Aims: Portal venous thrombosis (PVT) is a relatively common complication of liver transplant. Its prophylaxis with anticoagulants is a controversial issue currently. The objective of these work was to determine the efficacy of anticoagulation in PVT, before and after transplant, as prophylaxis in relapse of PVT.
Method: Our study included 278 patients undergoing liver transplant from January 2010 to April 2019 in our center. 65 patients with pretraplant PVT diagnosed with imaging tests (Eco-Doppler/Angio-CT) or during surgery were selected. Patients without contraindications received anticoagulation (vitamin K antagonists (VKA)/Low molecular weight heparin (LMWH)) until surgery. After this, all patients received anticoagulation (VKA/LMWH) for 6 to 12 months. Ultrasound control was performed at the 1st week and at the 1st, 3rd, and 12th month post-transplant.
Results: 23% (n: 65) of the patients had PVT before transplantation. 32% (n: 21) of these received pre-transplant anticoagulation, 15% (n: 10) with HBMP and 17% (n: 11) with VKA. In treated and untreated patients, intraoperative thrombosis was 52% (n: 11) and 91% (n: 40), respectively. Only 3 patients treated (4.6%) had hemorrhagic complications. 11% of patients (n: 7) did not receive early post-surgery anticoagulation, by contraindication, the rest 89% (n: 57) did. The overall recurrence of PVT in the 1st year was 4% (n: 3). Post-transplant recurrence of PVT was 2.5% (n: 2) in patients with LMWH and 1.5% (n: 1) in patients with VKA.
Conclusion: Our study concludes that those patients with pre-transplant PVT who received anticoagulant therapy prior to surgery had a considerable reduction in the rate of intraoperative thrombosis with respect to those who did not receive it. In turn, the number of hemorrhagic complications was very low and without fatal consequences in any case. The overall recurrence rate in the post-transplant in the first year was less than 5%, being lower in those patients who received anticoagulant therapy, therefore, our study demonstrates the efficacy of post-transplant anticoagulation to prevent recurrence.

THU264

Safety and efficacy of a cardiac risk stratification protocol based on traditional cardiac risk-factors in patients undergoing liver transplantation

Marcus Robertson[1,2], Dorothy Liu[1], Rosemary Seagar[1], William Chung[1], Tessa O'Halloran[1], Omar Farouque[3], Mark Horrigan[3], Paul Gow[1,2], Peter Angus[1,2]. *[1]Austin Health, Liver Transplant Unit, Heidelberg, Australia; [2]University of Melbourne, Department of Medicine, Heidelberg, Australia; [3]Austin Health, Department of Cardiology, Heidelberg, Australia*
Email: marcus.robertson@monash.edu

Background and Aims: Coronary artery disease (CAD) is prevalent in patients undergoing liver transplantation (OLT) and confers an increased peri-operative risk. Routine screening for CAD is recommended however data on the effectiveness of screening strategies is limited. We aimed to assess the safety and efficacy of a 3-tiered cardiac risk-assessment protocol that stratifies patients based on age and traditional cardiac risk factors (RF).
Method: Consecutive patients >18 years old undergoing OLT assessment were prospectively included from 2010 to 2017. Patients receiving multi-visceral transplant were excluded. Patients were stratified into one of 3 risk groups and received standardised investigations (Table). Primary outcome was peri- or post-operative cardiac events.
Results: 586 patients undergoing 606 OLT assessments were included. Median age was 56 years (IQR 48–60), 70% were male and median MELD score was 18 (IQR 13–25). Common indications for OLT were hepatitis C, alcohol and hepatocellular carcinoma. Cardiac RFs included: diabetes (27%), smoking (50%), hypertension (17%), hypercholesterolemia (8%), family (17%) or personal (6%) history of heart disease and obesity (28%). 61% patients had ≥2 risk factors.
80 patients were identified as low risk (LR), 269 intermediate risk (IR) and 257 high risk (HR). 11 patients were rejected following cardiac assessment: 1 LR patient (abnormal ECHO with pulmonary hypertension (PHT) at CA); 2 IR patients (cardiac amyloid and cirrhotic cardiomyopathy), and; 8 HR patients (aortic stenosis, PHT, cardiomyopathy [n = 2], multi-vessel CAD [n = 4]). Peri-operative cardiac events were observed in 8 patients (event rate 1.3%) with 2 deaths (0.3%). 4 cardiac events occurred in the IR group (Non-ST elevation myocardial infarction (NSTEMI) [n = 3], death from progressive right ventricular dysfunction post reperfusion) and 4 in the HR group (NSTEMI [n = 3], death post-operatively from cirrhotic cardiomyopathy).
Conclusion: Cardiac risk stratification based on traditional cardiac RFs with the selective use of DSE, CA and CTCA is a safe and feasible approach that results in a very low peri-operative cardiac event rate.

THU265

Projection of liver transplant activity per indication in France and United Kingdom

Mark Connolly[1,2], Melodi Kosaner Kliess[1]. *[1]Global Market Access Solutions, Health Economics, St-Prex, Switzerland; [2]University of Groningen, Department of Pharmacy, Groningen, Netherlands*
Email: mark@gmasoln.com

Background and Aims: Efforts towards eliminating hepatitis C virus (HCV) are likely to yield many patient relevant benefits and cost savings for health services. As another externality, decreasing numbers of people with HCV subsequently decreases the demand for liver transplantations (LT) due to HCV. The reductions in HCV indicated LT will make more livers available for other indications. In this analysis changes in LT were projected based on current trends to explore which liver failure conditions may benefit from eliminating HCV.
Method: The number of new registrants and first LTs per indication were identified from annual reports of the French and UK LT registries. Data were available from 2013–2018 for both countries. The proportional change in LTs was calculated per year and averaged across all years. Projections were made based on the mean proportional change within each indication with non-zero values until HCV-related first LTs constituted <1% and ≤0.5% of the dataset. The number of LTs for benign tumors were projected to increase by 2 biennially based on observed trends.
Results: Incidence-specific values were available for the full French registry; and for elective deceased donor liver only transplants for the UK. The frequency of HCV-related elective first LTs decreased to <1% and ≤0.5% by 2024 and 2026 in France; and by 2022 and 2024 in the UK. The number of LTs related to alcoholic liver disease were projected to decrease in France and increase in the UK. In both countries LTs increased noticeably for HCC and other malignant tumors, other causes of cirrhosis and pathologies. Metabolic diseases preceded first LTs with increasing numbers in the UK. In France, the proportion of patients receiving LTs to the number of registrants was higher by the end of 2018 in contrast to 2013 for HCV, other malignant tumors, sclerosing cholangitis, autoimmune cirrhosis, other causes of cirrhosis and pathologies.
Conclusion: The dynamics of receiving LTs has altered substantially with the availability of highly curative therapies for HCV. In both countries targets to eliminate HCV as an indication for LT were achieved within 8 years; leading to a higher transplantation rate and possibly shorter waiting times for indications beyond cirrhosis. The growth seen in these indications and existing waiting lists provide further motivation towards HCV elimination.

THU266

The impact of gender and comorbidity burden on liver transplant eligibility and patient survival

Scott Coppel[1], Karan Mathur[1], Lauren Nephew[2], Kavish Patidar[2], Eric Orman[2], Archita Desai[2], Eduardo Vilar Gomez[2], Burcin Ekser[3], Chandrashekhar Kubal[3], Naga Chalasani[2], Marwan Ghabril[2]. *[1]Indiana University, Medicine, Indianapolis, United States; [2]Indiana University, Gatroenterology and Hepatology, United States; [3]Indiana University, Transplant Surgery, United States*
Email: mghabril@iu.edu

Background and Aims: Disparity is reported in liver transplant (LT) waitlist mortality for females, however the reasons are not elucidated. Gender based differences in medical comorbidities have been described, but the impact of comorbidity burden on LT-free survival, LT eligibility and post-LT survival is unquantified. We aimed

Table: (abstract: THU264): Three-tiered cardiac risk stratification protocol

Risk group	Investigations	Results
Low -Age<45 *OR* Diabetic age<35 *AND* -No cardiac RF	Trans-thoracic ECHO	Normal: No further investigation (NFI) Abnormal: high-risk Cardiology clinic

to describe the comorbidity burden and its impact on survival and LT eligibility in females and males with cirrhosis.

Method: We reviewed 340 adults with cirrhosis referred to our centre for their first LT in 2012 through initial evaluation, LT selection and long-term post-LT outcomes. The comorbidity burden was assessed using the Charlson Comorbidity Index (CCI), while excluding the liver disease component and hepatocellular carcinoma (HCC) from the CCI. CCI was examined as categories (0, 1–2,>2). Cox proportional hazards analyses for study endpoint were controlled for age, model for end stage liver disease (MELD), race, aetiology of liver disease and HCC.

Results: The 340 patients (37% females) mean age 56 ± 11, and 23% had HCC. Females had lower mean MELD (15 ± 6) than males (17 ± 7), more frequent fatty liver (27% vs. 17%) and less alcohol related disease (24% vs. 30%), but similar age, CCI (0.9 ± 1.1 for both genders), race, BMI, and HCC. CCI was 0/1–2/>2 and 48%/39%/13% in females and 42%/47%/11% in males (p = 0.3). Over a median follow up of 6.5 years (IQR 6 to 6.8) the impact of CCI and gender on; (i) 90-day LT-free survival in 332 patients not undergoing LT within 90 days, (ii) LT eligibility in 177 patients reviewed in LT selection committee after complete evaluation and (iii) 1 and 5-year post-LT survival in 99 patients (median follow up 5 years) was analysed (Table). The risk of LT-free mortality in males was attenuated by CCI and other covariates.

Conclusion: Comorbidity burden is similar in females and males referred for LT and adversely impacts LT-free survival and LT eligibility in cirrhosis. If validated these data may inform mortality-risk modelling in cirrhosis. However, comorbidity burden does not explain gender-based differences in LT eligibility or post-LT survival, and further study is needed to mitigate these disparities.

THU268

Accuracy of triple echo MRI in predicting hepatic steatosis in potential liver donors

Mohammed Aljawad[1], Rehab Abdullah[1], Mohammed Alqahtani[1], Miral Mashhour[2], Amal Alawami[3], Suha Albadr[3]. *[1]King Fahad Speciliast Hospital, Liver Transplant Department, Dammam, Saudi Arabia; [2]King Fahad Speciliast Hospital, Pathology; [3]King Fahad Speciliast Hospital, Medical Body Imaging, Dammam*
Email: mshj2013@hotmail.com

Background and Aims: Living donor liver transplantation is a lifesaving procedure for patients with end stage liver disease and patients with hepatocellular carcinoma especially in regions where there is severe shortage in cadaveric liver grafts. Although there is variability in practice among transplant centres regarding the acceptable cut off value for donor hepatic steatosis, significant hepatic steatosis of >10 to 15% is considered a limitation for donation in many centres since this might affect the transplant outcome. Many centres routinely perform liver biopsy for steatosis quantification prior to transplantation. The goal of this study is to evaluate the accuracy of triple Echo MRI in predicting hepatic steatosis in potential liver donors in comparison to histopathology and if this non-invasive method could replace or limit the need for liver biopsy.

Method: This is a single centre, retrospective study including potential liver donors who underwent triple echo MRI of the liver and liver biopsy between March 2015 to November 2019. Liver fat fraction was measured by triple echo MRI as part of the donor evaluation process and compared to histopathology steatosis. Sensitivity, specificity, positive predictive value and negative predictive value of fat fraction by triple echo MRI were calculated using cut off value of > 10 hepatic steatosis. Correlation between MR fat fraction and histopathology hepatic steatosis was examined by Pearson correlation coefficient.

Results: In the study period, 163 potential liver donors were identified in our medical records. Of these 163, 35 potential liver donors met the inclusion criteria of having both triple echo MRI and liver biopsy were included in the analysis. The mean donor age was 31 years. Out of the 35 donors, 28 were male and 7 were female donors. The average weight and BMI were 71.1 kg and 25.3 respectively. The correlation coefficients of triple-echo MR imaging and histopathological hepatic steatosis was r of 0.860. For Threshold of ≥10% steatosis, triple Echo MR demonstrated sensitivity of 71.43%, specificity 92.86%, positive predictive value 71.43% and negative predictive value 92.86%.

Conclusion: This study demonstrates a good correlation between triple echo MR fat quantification and histopathological hepatic steatosis in healthy liver donors with good performance to exclude significant hepatic steatosis ≥10%. Our results suggest that triple echo MR might be enough for evaluating hepatic steatosis in potential liver donors and potentially might replace or limit the need for liver biopsy.

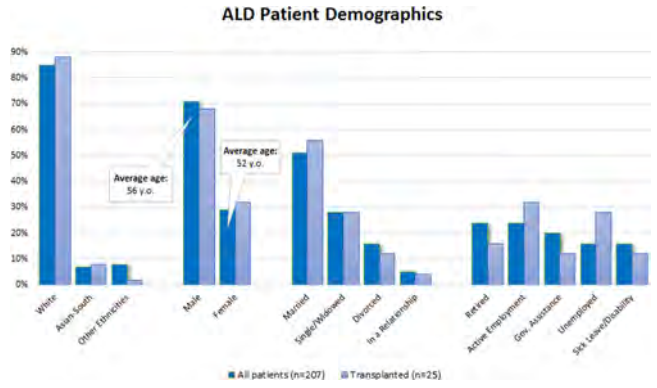
THU269

Preliminary results of a prospective pilot program for transplantation of patients with alcohol-related liver disease and less than 6 months abstinence

Lauren Carrique[1], Jill Quance[1], Isabel Sales[1], Les Lilly[1], Zita Galvin[1], Mamatha Bhat[1], Susan Abbey[1], Adrienne Tan[1], Josee Lynch[1], Nazia Selzner[1]. *[1]Toronto General Hospital, Multiorgan Transplant Institute, Toronto, Canada*
Email: nazia.selzner@uhn.ca

Background and Aims: In Canada, 6 months of abstinence for those with alcohol-associated liver disease (ALD) is typically required prior to being listed for liver transplantation (LT). This policy disadvantages

those who cannot survive this timeframe. The Ontario ALD Pilot Program was initiated in 2018 to provide access to LT for ALD patients through an in-depth examination of alcohol use history, social support and psychiatric comorbidity, as well as the provision of pre- and post-LT relapse prevention therapy.
Method: All referrals were triaged using pilot-specific inclusion criteria. Patients were assessed by a multidisciplinary team, including transplant hepatology, addiction psychiatry, social workers and a nurse practitioner. Random ethyl glucuronide (EtG) testing for alcohol and relapse prevention therapy was performed.
Results: We reviewed 390 referrals from May 2018 to November 2019, with an average NaMELD of 22. From these, 124 referrals (32%) were declined upon initial triage (72 did not meet program criteria, 52 for other reasons). The remaining patients (n = 259) were assessed. The demographic and socioeconomics of them are presented in Figure 1. Of this group, 88 (34%) did not meet ALD inclusion criteria for the following reasons: 72 had severe alcohol use disorder, 17 had a positive urine EtG, 14 had severe psychiatric comorbidity and 14 declined to participate in relapse prevention. Forty-six patients (12%) were listed for transplantation with an average NaMELD of 26. Twenty-five (6.4%) were transplanted, three of whom expired. After an average of 158.6 days post-discharge from hospital, two patients had returned to alcohol use as per positive EtG tests.



Conclusion: The high volume of declined referrals based on history of alcohol use highlight the challenge of assessing ALD patients with less than 6 months abstinence. Based on this complexity, close monitoring of potential relapse post-transplant and the provision of appropriate therapy should be integral part of transplant follow up for these patients.

THU270

Positive complement-dependent cytotoxicity crossmatch results do not influence long-term graft or patient survival following liver transplantation

Christopher Bricogne[1,2], Neil Halliday[1,2], Raymond Fernando[3], Laura De Luca[1], Manuel Rodríguez-Perálvarez[1], Emmanuel Tsochatzis[1,2], Mark Harber[4], Rachel Westbrook[1,2].
[1]University College London, Institute for Liver and Digestive Health, London, United Kingdom; [2]Royal Free London NHS Foundation Trust, Sheila Sherlock Liver Unit, London, United Kingdom; [3]Royal Free London NHS Foundation Trust, The Anthony Nolan Research Institute, London; [4]Royal Free Hospital, Kidney Unit, London, United Kingdom
Email: neilhalliday@doctors.org.uk

Background and Aims: Transplant recipients have typically been screened for the presence of pre-formed anti-donor antibodies with complement-dependent cytotoxicity (CDC) crossmatch testing, prior to kidney and other solid organ transplants. The presence of positive CDC results may guide organ allocation and inform the risk of rejection and immunosuppression choice. There are conflicting reports as to whether CDC crossmatch status is important for outcomes following liver transplantation (LT), hence testing does not routinely alter clinical practice. We aimed to assess whether the presence of a positive CDC crossmatch at the time of LT influenced long term graft outcomes.
Method: We retrospectively identified all LT operations performed at the Royal Free Hospital, London, between October 1999 and December 2016 from the hospital LT database and identified all associated CDC crossmatch assays from laboratory databases. We compared graft outcomes between those with positive and negative crossmatch results.
Results: 1125 LT were identified during the study period; 1076 (96%) LT had an associated CDC crossmatch result available. 84 (7.5%) recipients had a positive T cell CDC crossmatch, 193 (17%) a positive B cell CDC and 204 (19%) were positive for either or both T cell and B cell assays. The presence of a positive CDC crossmatch was more prevalent in female recipients (p = 0.03).
Patients were followed up for a median time of 9 years. Positive CDC crossmatch for T cell only, B cell only or either T or B cell assay was not associated with a greater risk of graft loss over time (log rank p = 0.83, 0.27 and 0.34 respectively). Similarly, the overall hazard of graft loss with a positive T and/or B CDC was not raised (HR 1.22 (95% CI 0.93–1.6, p = 0.15)). There was no increase in the rate of re-transplantation with positive crossmatch (p = 0.75) or for mortality (log rank p = 0.19) with a positive T or B cell CDC.
Conclusion: This large cohort study, reporting over 10,000 patient-years following LT, demonstrates that the presence of a positive CDC at the time of LT was not associated with greater graft loss or patient mortality in the era of modern immunosuppression protocols. Whether these patients are at higher risk for manageable acute rejection episodes or other adverse outcomes remains unclear.

THU271

Pregnancy outcomes after liver transplantation: a systematic review and meta-analysis

Nelson Valentin[1], Isabel Guerrido Martinez[1], Rachel Pinotti[2], Frederick Rozenshteyn[1], Yi Chia Wu[1], Kelsey Collins[1], Michelle Shah[1], Melissa Hershman[1], Ilan Weisberg[1]. *[1]Mount Sinai Beth Israel, Division of Digestive Diseases, New York, United States; [2]Icahn School of Medicine at Mount Sinai, Levy Library, New York, United States*
Email: nelson.feliciano@mountsinai.org

Background and Aims: Liver transplant (LT) remains the gold standard for treatment of end stage liver disease. There is an increasing number of liver transplantation in females of reproductive age. The aim of this study was to conduct a systematic review and meta-analysis to evaluate pregnancy outcomes after liver transplantation.
Method: The MEDLINE, Embase and Scopus databases were searched for relevant studies published through December 2018. Study selection, risk of bias assessment and data extraction were conducted independently by two reviewers. Estimates of pregnancy related outcomes in LT recipients were generated and pooled across studies using the random effects model.
Results: A comprehensive search of the literature identified 1,430 potential studies. Thirty-eight studies with 1,131 pregnancies from 838 LT recipients were included in the analysis. Common LT indications included autoimmune hepatitis, chronic parenchymal diseases and cryptogenic cirrhosis. The mean maternal age at pregnancy was 27.8 years with a mean interval from LT to pregnancy of 59.7 months. The live birth rate was 80.4% with a mean gestational age of 36.5 weeks. The rate of miscarriages (16.7%) was comparable to the general population (10%–20%). The rate of pre-term birth, pre-eclampsia and cesarean delivery (32.1%, 12.5% and 42.2%) among LT recipients were all higher than the rates for the general United States

population (9.9%, 4%, and 32%, respectively). The majority of the analyses were associated with substantial heterogeneity.

OUTCOME	NUMBER OF STUDIES	POOLED ESTIMATE	95% Confidence Interval	I^2
Mean Maternal Age (years)	31	27.8	26.8–28.8	88.4
Mean Gestational Age (weeks)	27	36.5	35.9–36.9	76.4
Mean Interval from Transplantation to Pregnancy (months)	29	59.7	50.7–68.6	95
Maternal Outcomes Rates				
Pre-eclampsia (%)	32	12.5	9.8–15.9	24.5
Cesarean Delivery (%)	34	42.2	35.5–49.2	73
Miscarriages* (%)	37	16.7	12.5–22	58.7
Fetal Outcomes				
Pre-term Birth** (%)	36	32.1	26.8–38	55.6
Mean Birth Weight (grams)	28	2691.9	2574–2809	85.5
Live Births (%)	38	80.4	74.8–85	58.4

*Includes elective abortion, spontaneous abortion, and stillbirth.
**Defined as live birth prior to 37 weeks gestation.

Conclusion: Pregnancy outcomes following liver transplantation are favorable but the risk of some maternal and fetal complications is increased. Large studies along with consistent reporting to national registries is necessary for appropriate patient counseling and to guide clinical management of liver transplant recipients during pregnancy.

THU272

Clostridium difficile infection in liver transplant recipients is uncommon and does not impact long-term survival: a case-control study

Nicholas Kortt[1], Cositha Santhakumar[1], Rebecca Davis[1,2], Simone Strasser[1,3], Geoff McCaughan[1,3,4], Ken Liu[1,3,4], Avik Majumdar[1,3]. [1]*Royal Prince Alfred Hospital, Australian National Liver Transplant Unit, Camperdown, Australia;* [2]*Royal Prince Alfred Hospital, Department of Infectious Disease, Camperdown, Australia;* [3]*The University of Sydney, Sydney Medical School, Camperdown, Australia;* [4]*Centenary Institute, Liver Injury and Cancer Program, Sydney, Australia*
Email: nicholas.kortt@health.nsw.gov.au

Background and Aims: *Clostridium difficile* infection (CDI) occurs in up to 14% of liver transplant (LT) recipients in the first year after transplantation. There are conflicting data on whether CDI is associated with increased mortality in LT recipients. We aimed to determine the prevalence, risk factors and patient survival associated with CDI in LT recipients.
Method: Consecutive patients who underwent deceased-donor LT from 01/01/2007 to 31/12/2017 were studied retrospectively. All patients received at least 3 days of routine prophylactic antibiotics post-LT. CDI was defined by positive enzyme immunoassay for *C. difficile* toxins A/B performed on diarrhoeal stool within 12 months post-LT. Data were extracted from microbiology and LT databases and medical records. Severity of CDI was defined by Australasian guidelines (Cheng et al. 2011). CDI cases were matched by age, sex, LT indication and year of LT to uninfected controls using a ratio of 1:2. The primary outcome of interest was patient survival.
Results: During the study period, 676 patients underwent LT, of which 32 (4.7%) were diagnosed with CDI. Most CDI cases were male (71.8%) with a median age of 55 years (IQR 51–60) and mean pre-LT MELD of 23 (±8.7). Among CDI cases, the most common LT indications were HCC (28.1%), decompensated cirrhosis from HCV (25.0%) and NASH (18.8%). Baseline characteristics were similar between cases and controls except CDI cases were less likely to receive rifaximin pre-LT (15.6% vs 35.9%, p = 0.04). The median time from LT to CDI was 28 days (IQR 14–65) with most diagnosed in hospital (ward 56.3%, ICU 12.5%, community 31.3%). In 18 (56.3%) cases antibiotics were received within the previous 7 days. There were 3 cases of severe CDI but no CDI-related deaths or colectomies. The majority responded to oral metronidazole alone (71.9%). Single recurrence of CDI occurred in 4 patients, the majority was treated with oral metronidazole alone (75.0%). Patient survival did not differ between CDI cases and controls over a median follow-up of 6.3 years (IQR 3.9–8.0) (Figure). CDI cases were more likely to have returned to theatre post-LT (34.4% vs 15.6%, p = 0.04) and have longer hospital stays after LT (35.0 vs 26.3 days, p = 0.03). Only length of hospital stay after LT was associated with CDI on binary logistic regression (OR 1.03, 95% CI 1.00–1.06, p = 0.02).

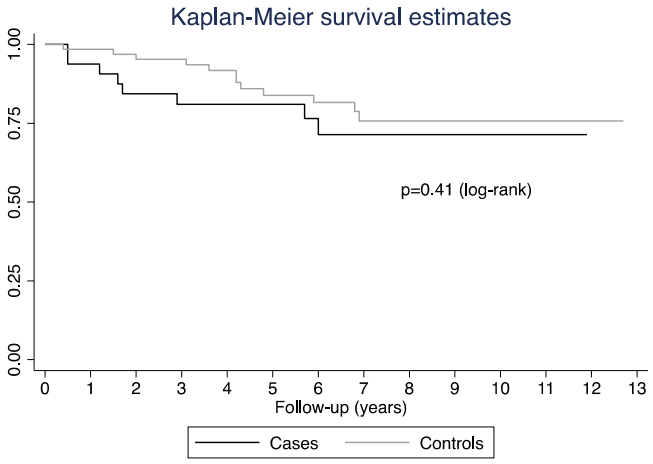


Figure: Post-transplant patient survival among *C. difficile* infection cases and matched uninfected controls

Conclusion: In this single-centre Australian study, CDI within 12 months post-LT was uncommon, of low severity and associated with longer hospital stay after LT. Contrary to previous reports, CDI did not adversely impact patient survival. The reasons for these differences warrant further study.

THU274

Patient social and lifestyle factors associated with cardiovascular risk affect decisions regarding transplant candidacy more than factors associated with psychological and financial well-being

Oliver Tavabie[1], Jeremy Nayagam[1], Deepak Joshi[1], Abid Suddle[1], Kosh Agarwal[1], Michael Heneghan[1], Varuna Aluvihare[1]. [1]*King's College Hospital, United Kingdom*
Email: oliver.tavabie@nhs.net

Background and Aims: Liver transplant (LT) assessment is a process to define not only if patients require transplantation, but the likely short- and long-term consequences to the candidate's health following LT. Whilst it is clear that patient co-morbidity affects LT outcomes, it is increasingly apparent that psychosocial factors influence long-term outcomes. In this study, we aim to evaluate if there are associations between psychosocial factors and outcomes of LT assessments.
Method: All LT assessments performed at King's College Hospital for UK based patients between 1/10/2018–1/10/2019 were included in this retrospective analysis. Patient demographics, liver disease aetiology and psychosocial history data were recorded from the clinical notes. Univariate and multivariate analysis were performed.
Results: 290 LT assessments were eligible for analysis. 30% of patients were declined for transplant with 17% found to have a contraindication to LT. Patients declined for LT were more likely to be: older (*58.8 v 54.0, U = 6780, p = 0.002*); Caucasian (*OR 3.78,* p = 0.004); a previous hazardous alcohol drinker (*OR 2.71*, p = 0.0002); and a current smoker

(*OR 2.14*, p = 0.04). Factors not associated with being declined for LTx were being: male (p = 0.10); currently employed (p = 0.06); a homeowner (p = 0.55); a parent (p = 0.58); and in a relationship (p = 0.76) or having a: history of substance misuse (p = 0.26); psychiatric history (p = 0.75); and history of opioid use (p = 0.63). 3 patients reported previous criminal convictions. Multiple logistic regression was performed using variables achieving significance as well as employment history and male sex (table 1). Caucasian ethnicity, age and being a current smoker were found to be associated with being declined for LT. Patients who were Caucasian were more likely to have a diagnosis of alcohol (ARLD) or non-alcohol related liver disease (NAFLD) than those who were not (*OR 2.08*, p = 0.04).

Table 1: Multiple logistic regression model of psychosocial factors influencing liver transplant candidacy

Variable	Beta	95% CI	p value
Caucasian ethnicity	1.24	1.36–10.67	0.016*
Age	0.04	1.02–1.07	0.002**
Current smoker	1.13	1.34–7.25	0.008**
Previous hazardous alcohol intake	0.55	0.98–3.07	0.06
Currently employed	−0.49	0.33–1.13	0.12
Male sex	0.38	0.81–2.64	0.21

Conclusion: Given the increased prevalence of ARLD/NAFLD amongst Caucasian patients, this would suggest that cardiovascular risk factors have a greater role in determining patients LTx candidacy than factors associated with psychological and financial wellbeing.

THU275

Inequality in access to liver transplant: are satellite liver transplant centres the answer?

Oliver Tavabie[1], Jeremy Nayagam[1], Talal Valliani[2], Deepak Joshi[1], Johnny Cash[3], Abid Suddle[1], Matthew Cramp[4], Kosh Agarwal[1], Michael Heneghan[1], Varuna Aluvihare[1]. *[1]King's College Hospital, United Kingdom; [2]North Bristol NHS Trust, United Kingdom; [3]Royal Victoria Hospital, United Kingdom; [4]Derriford Hospital, United Kingdom*
Email: oliver.tavabie@nhs.net

Background and Aims: It has been demonstrated that patients listed for liver transplant (LT) living further away from LT centres have worse outcomes. Although challenging to define causality, it has been hypothesised that this is due to reduced access to specialist care including LT candidacy assessment. To address this, King's College Hospital (KCH) has developed satellite LT centres (SLTC) in Northern Ireland and the Southwest and West of England. In this study, we aim to evaluate if distance from a LT centre is associated with outcomes of LT assessment and compare outcomes between KCH, SLTCs and the rest of the referral network.
Method: All LT assessments performed at KCH for UK based patients between 1/10/2018–1/10/2019 were included in this retrospective analysis. Patient demographics, clinical and laboratory data were recorded from the time of their assessment from the clinical notes. Patients referred from KCH or the non-SLTC referral network had distance and shortest driving time measured from their postcode to KCH calculated using Google maps. Patients referred from SLTCs had the same measurements calculated between patient postcode and referring SLTC. Univariate analyses were performed.
Results: 290 LT assessments were eligible for analysis. 99 patients were referred from KCH, 77 patients from SLTCs and 114 patients from the referral network. 30% of patients were declined for LT with 17% of patients having a contraindication to LT. Living greater than 60 mins drive from either KCH or a SLTC was associated with being declined for LT (*OR 1.94*, p = 0.01). There was no significant difference in risk of being declined for LT between SLTCs and KCH (p = 0.18). Patients referred from the referral network compared to KCH had a significantly higher rate of being declined for LT (OR 3.15, p = 0.0001). MELD and Child Pugh scores were significantly higher in patients referred from the referral network than KCH (*15 v 14*, *U = 2903*, p = 0.03) (*9 v 8*, *U = 2742*, p = 0.006). No significant difference was demonstrated in MELD and Child Pugh scores between SLTCs and KCH (p = 0.43) (p = 0.32).
Conclusion: Further work is required to address inequality for patients not only living further away from LT centres but those referred from non-LT centres. Developing additional SLTCs may have a role in improving access to LT.

THU276

Usefulness of phosphatidylethanol and urinary ethyl glucuronide to monitor alcohol abstinence in patients awaiting liver transplantation

Olivier Menard[1], Hakim Florian[2], Cecile Guenard[1], Jean Michel Gaulier[2], Delphine Allorge[2], Valérie Canva[3], Lassailly Guillaume[3], Olivier Cotencin[1], Alexandre Louvet[3], Philippe Mathurin[3], Sebastien Dharancy[3]. *[1]Hopital Fontan 2, CHU de Lille, Lille, France; [2]Laboratoire de toxicologie, CHU de Lille, Lille, France; [3]Service des maladies de l'appareil digestif, Hopital Huriez, Lille, France*
Email: olivier.menard@chru-lille.fr

Background and Aims: Alcohol-related liver disease (ALD) is one of the most common indication for liver transplantation (LT). A period of abstinence is widely required for being registered on the waiting list, and alcohol consumption is not allowed during the waiting time. New highly specific alcohol biomarkers such as blood phosphatidylethanol (Peth) and urine ethyl glucuronide (uEtG) have been developed recently. The aim of the present preliminary study is to assess and compare on 2 consecutive periods the rates of detection of alcohol relapse during waiting time with and without the use of the new biomarkers.
Method: Medical files for all patients registered for an LT in our institution from January 2016 to November 2019 were inspected for alcohol consumption detected either by systematic blood ethanol or patient's own declaration (period 1 from January 2016 to December 2018) or using systematic uEtG and Peth (period 2 from June to November 2019). Patients were systematically asked for alcohol consumption by the medical team.
Results: During period 1, 365 patients have been registered on LT waiting list. ALD was the main etiology for 248 patients (67.9%). Alcohol consumption was detected in 12 patients (3.2%) by blood ethanol tests. Interestingly, 3 alcohol consumptions were detected as the patients were hospitalized to undergo LT. During period 2, 74 patients attended to the liver pre-transplantation unit, 52 (70.2%) of them suffering of ALD. All patients declared to be fully abstinent. Alcohol consumption was detected in 12 (16.2%) patients, cumulating 33 visits in the unit. All markers (Peth, uEtG and blood ethanol) were available for 31 of these visits. Peth was positive (>5 ng/ml) in 25/31 visits, uEtG (>500 ng/ml) in 16/31 and blood ethanol in 2/31 (both times at 0.06 g/l). Peth concentration ranged between 19 et 1135 ng/ml, reflecting consumptions between less than 14 g/day to more than 84 g/day. On 10 visits, Peth concentrations were above 326 ng/ml, potentially reflecting daily consumption of more than 50 g/day on the last 21 days. Interestingly, CDT was available in 17 of the 25 times Peth was positive (and 8 of the 10 times it was >326 ng/ml), and reflected alcohol consumption (rate >2.5%) in only 4 times, including 3/8 times when Peth detected heaving drinking.
Conclusion: Blood ethanol, medical examination and potentially CDT may be ineffective to detect alcohol consumption in patient waiting for LT, even in case of heavy drinking. New alcohol markers might represent an interesting tool to effectively monitor alcohol abstinence, and if need be, quickly provide addiction therapy to the patients who need it.

THU277

Poor dental health is a risk factor for infections by streptococci after liver transplant

Philipp Göbel[1], Forsting Christiane[2], Knipper Petra[3], Steffen Manekeller[3], Jacob Nattermann[1,4], Jörg Kalff[3], Wahl Gerhard[2], Christian Strassburg[1,4], Philipp Lutz[1,4]. *[1]University of Bonn, Department of Internal Medicine I, Bonn, Germany; [2]University of Bonn, Department of Oral Surgery, Bonn, Germany; [3]University of Bonn, Department of Surgery, Bonn, Germany; [4]University of Bonn, German Center for Infection Research, Bonn, Germany*
Email: p.g.91@web.de

Background and Aims: Assessment of dental health in patients with cirrhosis before transplant is recommended to avoid infectious complications due hematogenous spread from dental foci after transplant. However, data to support this recommendation are scarce. We investigated liver transplant patients to clarify if dental care is necessary before transplant.
Method: Clinical, laboratory and microbiological data from patients with cirrhosis who received a liver transplant between 2010 and 2018 in our department were retrospectively analysed for oral foci of infection before transplant and infections after transplant.
Results: Data on oral health were available from 110/185 patients who received a liver transplant. Median age of patients was 53 years, 67% were male and the most frequent causes for liver transplant were alcoholic liver diseases (34%), viral hepatitis (28%) and autoimmune liver disease (14%). 35 patients showed good oral health without need for dental care, in 39 patients dental care was performed because of pretransplant assessment, 36 patients did not receive dental care despite poor oral health. The most common dental issues were caries, which affected 75% of all patients, and periodontal diseases with a prevalence of 40%. We noted that need for dental care was highest in alcoholic liver disease (95%) compared to viral hepatitis (71%) and autoimmune liver disease (73%) ($p = 0.002$). Bleeding complications due to oral care occurred in 5/13 patients, who all presented with platelets below 70 G/L and an INR above 1.5. Mortality in the first 9 months after liver transplant was similar for patients with poor oral health, after dental care and without need for dental care (19%, 11% and 14%, respectively). However, the number of infections after transplant per patient were higher in patients with poor oral health (2,9) compared to patients who had received dental care (1,9) or patients with good oral health (1,8) ($p = 0.02$). In contrast to infections by staphylococci, klebsiella or enterococci, infections by streptococci were more frequent in patients with poor oral health compared to patients without need for or after dental care (25% vs 8%; $p = 0.02$).
Conclusion: The high prevalence of dental foci of infection in liver disease patients and the increased risk for streptococci infections in patients who did not receive oral care pre-transplant suggest that assessment of oral health and oral care are important in patients awaiting liver transplant.

THU278

Pre-formed donor specific antibodies and aetiology of liver disease are associated with increased incidence of acute cellular rejections after liver transplantation

Preya Patel[1], Aaron Wetten[1], Vaughan Carter[2], Aditya Kanward[1], Paul Williams[1], Derek Manas[1], Stuart McPherson[1,3], Mark Hudson[1,3], Jessica Dyson[1,3], Steven Masson[1,3]. *[1]Liver Unit, Newcastle Freeman Hospital, High Heaton, United Kingdom; [2]NHS Blood & Transplant, Newcastle, United Kingdom; [3]Institute of Cellular Medicine, Newcastle University, Newcastle, United Kingdom*
Email: steven.masson@nuth.nhs.uk

Background and Aims: The role of donor specific HLA antibodies (DSA) in relation to clinical outcomes with liver transplantation (LT) remains debatable. This single centre UK retrospective study aimed to determine factors associated with the expression of DSA and their impact on outcomes after LT.
Method: Demographic and clinical data were collected on all consecutive adult LT recipients between January 2005 and December 2015. The detection of HLA antibodies present at the time of LT was performed using Luminex solid-phase assays and an MFI value 500 was considered positive. Multivariate logistic regression and Cox proportional hazard analysis were used to identify factors predictive of DSA expression and development of acute cellular rejection (ACR).
Results: 385 patients underwent LT and DSA data were available for 347 (90.1%). For patients with DSA data, the median age at LT was 56 years (range 17–75) and 55.6% were male. The commonest transplant indications were alcohol related liver disease (28.2%), autoimmune liver disease (AILD) (20.6%) and acute liver failure (12.8%).
Overall, 30.0% were positive for DSA with 16.1% patients having HLA class I Ab and 19% class II. Age <50 years (OR 1.93 95%CI 1.19–3.15; $P = 0.008$) and female sex (OR 2.65 95%CI 1.64–4.30; $P < 0.001$) were factors independently associated with DSA expression.
In the entire cohort, biopsy proven ACR occurred in 25.7% (99/385), of which 46.7% (43/92) had pre-formed DSAs ($p < 0.001$). This remained significant whether class I or II Ab (both $p = 0.001$). Following adjustment for age and sex, both DSA expression (OR 2.78 95%CI 1.57–4.90; $P < 0.001$) and AILD (OR 3.05 95%CI 1.52–6.10; $p = 0.002$) remained independently associated with developing ACR. Patients who express DSA were more likely to develop ACR within 6 months (Hazard Ratio 2.31 95% CI 1.47–3.64; $p < 0.001$, Figure 1). There was no significant association between the presence of pre-formed DSA and the development of biliary strictures ($p = 0.246$) or all-cause mortality ($p = 0.871$).

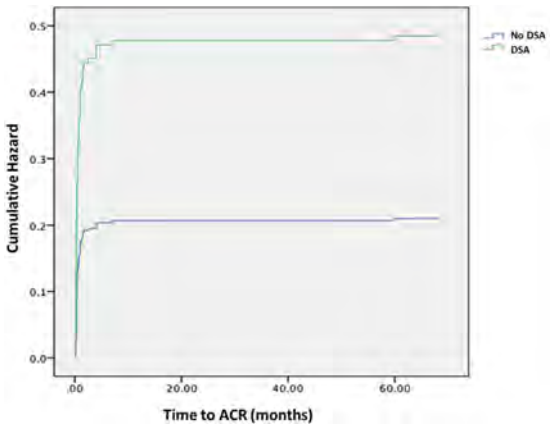

Figure: Cox Regression Curve (adjusted for age<50, sex and aetiology) for time to development of ACR

Conclusion: DSA are more frequent in patients who are female or under 50 years old. DSA expression is associated with an increased risk of developing ACR but is not predictive of overall patient survival. Further work is needed to examine the role of de novo DSA in the development of post-transplant complications.

THU279

Sustained virological response with DAAs decreases glucose level but do not improve renal function, lipid metabolism and blood pressure in liver transplanted patients: a 3-year, long-term follow up

Raffaella Lionetti[1], Manuela Merli[2], Ilaria Lenci[3], Giampiero D'Offizi[4], Mauro Zaccarelli[5], Marco Biolato[6], Martina Milana[3], Chiara Taibi[7], Francesca Di Sario[2], Maria Grazia de Palo[7], Antonio Grieco[6], Ubaldo Visco Comandini[7]. *[1]Lazzaro Spallanzani, POIT, Rome, Italy; [2]University of Rome, La Sapienza, Rome, Italy; [3]Tor Vergata University, Liver Unit, Rome, Italy; [4]Lazzaro Spallanzani, POIT, Rome, Italy; [5]Lazzaro Spallanzani, Rome, Italy; [6]Catholic University, Rome; [7]Lazzaro Spallanzani, POIT*
Email: raffaella.lionetti@inmi.it

Background and Aims: DAAs allowed reduction of HCV-related liver graft failure. Improvement in metabolic profile was reported during a short 48 weeks observation period after SVR. To evaluate, in LT patients (Pts), the impact of SVR on metabolism, renal and liver function and on arterial hypertension during 3 years of follow up (FU).
Method: Assessment of metabolic, kidney and liver function changes, as well as antihypertensive drug modifications, were collected up to 3 years of FU after completion of DAAs therapy. Mean differences were calculated with Anova test and linear regression for continues variables and Fisher' exact test for categorized variable.
Results: 152 LT Pts; all but 6 (n = 152, 96%) showed SVR. Pts : males 84%; age: median 63 yrs (IQR 57–70); baseline MELD 9, (IQR 7–12); cirrhosis 26%; HCC diagnosis 36%; SVR was associated with a decrease in fasting glucose in pts without overt diabetes, with a statistical significance at 3 yr vs. baseline −5.5 mg/dl ±22 ($p < 0.004$). In diabetic pts, mean fasting glucose level showed a trend to decline. Dyslipidemia prevalence increased over time, with a 12.6% incidence (33.3% at 3 yr vs. 20.7% at baseline), as well as BMI (+2.6 at 3 yr ±9; $p = 0.003$). An improvement in liver function was recorded at 1 yr and 3 yr as expressed by bilirubin decrease (mean −0.12 mg/dl ±0.7 [$p < 0.05$] and −0.78 mg/dl ±1.0, respectively [$p < 0.001$]) and albumin increased concentrations (+0.14 g/l at 3 yr. ±0.5; $p = 0.01$). MELD score decreased over time −1.26 at 3 yr; $p < 0.001$). As expected the through serum level of immunosuppressive drugs declined over time ($p < 0.0001$ at 3 yr) showing strong correlation ($p < 0.001$) with creatinine level, and borderline ($p = 0.056$) with glucose level. Moreover, creatinine showed a significant mean increase after SVR (1 yr vs. baseline 0.06 mg/dl ±0.2; 3 yr vs. baseline 0.08 mg/dl ±0.3 ($p < 0.001$). Kidney function deteriorated over time with 34.5% of Pts on CKD ≤3 at 3 yr vs. 24.8% at baseline ($p < 0.001$). Incidence of arterial hypertension was 4.0% at 1 yr and 8.5% at 3 yr compared to baseline ($p < 0.001$), potential expression of the long interval between LT and DAAs therapy (mean 73 months, IQR 22–131) and of preexisting renal and vascular involvement.
Conclusion: elimination of HCV in LT could have a beneficial impact on glucose metabolism but does not improve lipid profile or reno-vascular complications, which are possibly associated to the long-term exposure to immunosuppressive drugs.

THU280
Prospective multicenter study of sofosbuvir-velpatasvir (SOF/VEL) in hepatitis C virus (HCV) negative liver (LT) and kidney transplant (KT) recipients receiving HCV viremic donors

Raymond Rubin[1], David Victor[2], James Burton[3], Elizabeth Verna[4], James F. Trotter[5], Claus Niemann[6], Constance Mobley[2], Norah Terrault[7,8]. *[1]Piedmont Hospital; [2]Houston Methodist Hospital; [3]University of Colorado; [4]Columbia University; [5]Baylor University; [6]UCSF; [7]University of Southern Californai; [8]Keck Medicine at USC*
Email: terrault@usc.edu

Background and Aims: A greater pool of HCV-viremic donors has led to expanded use of these organs in transplant recipients without HCV infection with the goal of reducing wait-list morbidity and mortality. The optimal treatment strategy is unclear, in terms of best DAA option, timing of initiation and duration of therapy. We sought to evaluate the safety and efficacy of SOF/VEL for 12 weeks among HCV-negative LT and KT recipients.
Method: 6 U.S. transplant programs prospectively enrolled adults listed for primary LT or KT with the following exclusions: re-transplant, HBV or HIV infection, multiorgan (except SLK). Donor exclusions were >F1 for LT and kidney donor profile index >85% for KT. SOF/VEL was started once viremia was confirmed post-transplant and patient judged to be clinically stable. The primary endpoints were SVR12 and safety.
Results: Of 115 patients consented, 23 were transplanted (12 liver, 11 kidney) of whom 22 became viremic post-transplant. Recipients had mean age 54 yrs, 57% male; donors' mean was 38 years, 78% male, with 74% with confirmed brain death. HCV genotypes were 57% GT1, 26%GT2, 4%GT3 and remainder not determined. Median log HCV RNA on day 3 was 6.45 (range 1.2–8) in LT and 3.59 (range 1.3–4.7) in KT; the kinetics of HCV RNA decline are shown in Table. All reaching the SVR12 timepoint are HCV negative (13/13), including 2 with detectable HCV RNA at end of treatment. Serious adverse events considered to be possibly related include: 1 antibody-mediated rejection (in A2 to O LT recipient) and 1 progressive biliary sclerosis of indeterminant etiology after LT. Delays in treatment initiation (n = 5 beyond day 21) were related to delayed renal recovery (n = 3), administration of amiodarone (n = 1) and provider preference (n = 1).
Conclusion: SOF/VEL for 12 weeks was highly effective therapy for HCV-negative liver and kidney transplant recipients who received HCV-viremic donors. All transmitted infections (22/23) were detectable by day 3, with different viral kinetics in KT versus LT, supporting early initiation of antiviral therapy. Safety was excellent but vigilance of immune-mediated complications is warranted.

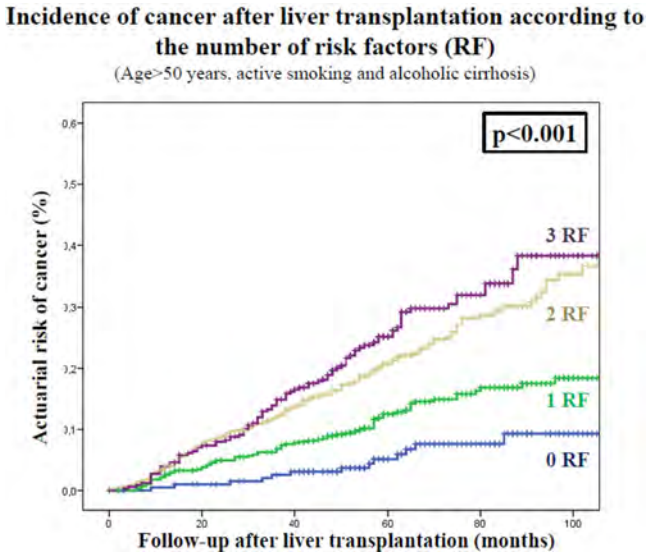
Email: ropeml@hotmail.com

Background and Aims: Cancer screening protocols after liver transplantation (LT) are lacking. We aimed to determine the incidence of cancer after LT and its clinical risk factors.
Method: Observational multicenter study including a consecutive cohort of patients who underwent LT (2010–1015) in 10 Spanish institutions, survived longer than 1 year and received tacrolimus-based immunosuppression. Exclusion criteria: Age<18, combined organ transplantation, retransplantation and HIV+. The incidence of cancer and related mortality were evaluated by using Cox's regression. Standardized incidence rate (SIR) was calculated with general population data obtained from Globocan 2018 (available at https://gco.iarc.fr/).



Results: A total of 1,732 patients were included: mean age 54.4 ± 9.6, 76.3% males, 49% alcoholic cirrhosis, 37.4% with hepatitis C. The indication for LT was hepatocellular carcinoma in 703 patients (40.6%). Median follow-up after LT was 64 months (IQR 48–86). Three hundred and thirty-two patients developed cancer: cumulative incidence = 17% at 5 years; incidence rate = 0.038 cases/person*years; SIR = 3.19 (excluding hepatocellular carcinoma). The incidence of cancer remained unchanged during the inclusion period. The onset of cancer impacted negatively on post-LT survival: 64.1% vs 91.3% at 5 years. Letality of cancer was 46.4%, with a median life expectancy of 6 months (IQR 2–15). After controlling for baseline hepatocellular carcinoma, the independent risk factors of cancer were: Age>50 years old (RR = 2.49; p < 0.001), active smoking (RR = 1.44; p = 0.002) and alcoholic cirrhosis (RR = 1.42; p = 0.003). The number of risk factors was associated with a progressive increase of cancer rates at 5 years: 5.1% in absence of risk factors, 12.5% with 1 risk factor, 20.7% with 2 risk factors and 25.1% with 3 risk factors (figure).
Conclusion: The incidence of cancer after LT is high and carries a dismal prognosis. A consensus is needed to delineate cancer screening strategies after LT, which should be tailored according to the history of smoking and alcoholism.

THU282

Gender disparity in cardiovascular morbidity and mortality post liver transplantation

Caroline Walker[1], Mohammad Bilal Siddiqui[1], Michael Patrone[1], Emily Zhang[2], Emily Lee[2], Jose Hernandez Roman[1], Chandra Bhati[1], Mohammad Siddiqui[1], Samarth Patel[3]. *[1]VCU Medical Center, Richmond, United States; [2]Virginia Commonwealth University, Richmond, United States; [3]McGuire Veterans Hospital, Richmond, United States*
Email: samarth.patel@vcuhealth.org

Background and Aims: Understanding factors associated with long-term survival after liver transplant (LT) is important for predicting, and potentially improving outcomes. Several factors have been implicated in reduced long term survival including older age, frailty, cardiovascular morbidities, and psychosocial factors. Women constitute a unique group of patients defined not only by body mass index (BMI), different etiologies of disease, and psychosocial factors but also by hormonal factors. The interplay of these factors may alter disease course and ultimately transplant outcomes. In this study, we examined the cardiovascular event risk of all liver transplant recipients by gender.
Method: All patients who had LT from January 2007 to January 2017 were evaluated (N = 496). Protocol coronary angiography was performed in all patients ages>50 years, history of coronary artery disease (CAD), abnormal cardiac stress test or risk factors for CAD. A cardiovascular composite outcome including acute coronary syndrome, symptomatic arrhythmia, cardiac arrest, stroke, or cardiac death occurring post LT was the primary outcome. Secondary endpoints included cardiovascular mortality and all-cause mortality.
Results: Our study population was comprised of 137 (27.6%) females. Most common causes of liver disease were alcohol (15.7%), chronic hepatitis C (45.8%), and nonalcoholic steatohepatitis (15.9%). Pre-transplant evaluation for CAD found that there was no statistically significant difference in CAD between males and females (28% vs. 20%, p = 0.1). There was no difference in prevalence of hypertension, hyperlipidemia and diabetes between genders in our study group. In the post-transplant period, men had higher incidence of cardiovascular events (primary outcome), (23.1% vs. 12.4% p = 0.006). The majority of events consisted of symptomatic arrythmia, the incidence of which was higher in men (17.5% vs. 9.5%, p = .02). While the overall incidence of cardiac-related death was 6.7% during the study period, this was significantly higher in men compared to women (8.1% vs 2.9%, p = 0.04). However, there was no difference in all-cause mortality between genders.
Conclusion: In this study of liver transplant recipients, we found that males had a higher risk of cardiovascular events and cardiac death, while the prevalence of cardiovascular risk factors was similar between genders.

THU283

GFR reset point at 3 months after liver transplant is a superior predictor of liver and kidney disease related outcomes: analysis from a large cohort of NASH patients (nail NASH consortium)

Sanjaya Satapathy[1,2], Yu Jiang[3], Masahiko Yazawa[4], Miklos Z. Molnar[5], Tandy Agostini[6], Raiya Sarwar[7], Carlos Figueredo[8], Daniel Maluf[5], Saleh Elwir[9], James F. Trotter[9], Arul Thomas[10], Coleman I. Smith, MD[10], Danielle Brandman[11], Mohammad Siddiqui[12], Kymberly Watt[13], Mary Rinella[14]. *[1]North Shore University Hospital, Manhasset, United States; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Medicine, Hempstead, United States; [3]University of Memphis, Public Health, Memphis, United States; [4]Methodist University Hospital, Surgery, Memphis, United States; [5]Methodist University Hospital, Suregry, Memphis, United States; [6]MedStar Georgetown Transplant Institute in Annapolis, Annapolis, United States; [7]University of Minnesota, Gastroenterology, Minneapolis, United States; [8]Montefiore Medical Center Moses Division, United States; [9]Baylor University Medical Center, Part of Baylor Scott & White Health, Dallas, United States; [10]MedStar Georgetown University Hospital, Washington, United States; [11]UCSF Medical Center, San Francisco, United States; [12]VCU Medical Center, Richmond, United States; [13]Mayo Clinic, Scottsdale, United States; [14]Northwestern Medicine Digestive Health Center Lavin Family Pavilion, Chicago, United States*
Email: sanjaya.satapathy@yahoo.com

Background and Aims: Since the introduction of the MELD score increasing number of patients with renal failure is being transplanted. The evolution of renal function based on the on severity of renal dysfunction at the time of LT is unclear in patients with NASH. We examined, (1) the association of pretransplant renal dysfunction (eGFR closet to LT) with the slope of renal function after LT, (2) incident CKD events after LT, (3) time to progression to CKD after LT and (3) all-cause mortality after LT.

Method: From the NailNASH consortium data set, we identified 696 NASH recipients who received deceased donor LT. Recipients were analyzed in 3 groups: Low GFR (LGFR) (estimated glomerular filtration rate (eGFR) <30 mL/minute/1.73 m^2 at LT; n = 108); High GFR (HGFR) (eGFR ≥ 30 mL/minute/1.73 m^2; n = 483); and those with SLKT (n = 105). The longitudinal data set with eGFR at transplant (0) and 3, 6, 12, 24, 36, 48, and 60 months post-LT. CKD was defined as two eGFR levels <30 mL/min/1.73 m^2 separated by ≥90 days.

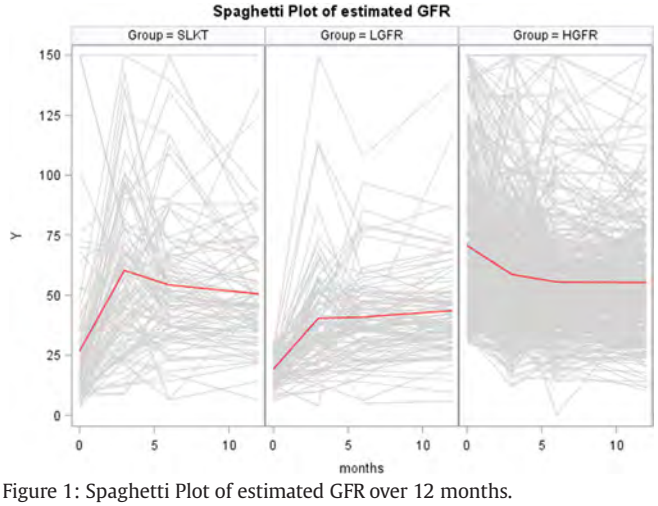


Figure 1: Spaghetti Plot of estimated GFR over 12 months.

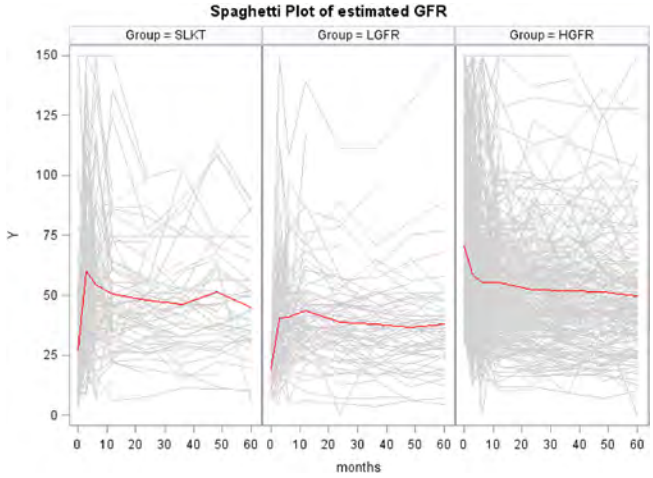

Figure 2: Spaghetti Plot of estimated GFR over 60 months.

Results: Mean age at LT was 60 ± 9 years, 49% male, 74% Caucasian. We censored follow up at 5 years. Figure 1 and 2 represents the eGFR over time by group (over 12 months, and over 60 months respectively) with mean eGFR over time (red line). A statistically significant change in the slope for eGFR at 3 months after LT was noted in all three groups, called as "GFR reset point." The difference between the eGFR slope before 3 months and after 3 months estimated by linear mixed-effects model was significant in all 3 groups (p < 0.0001). Overall unadjusted incident CKD rate was 21.3/1000 patient-years (95%CI: 16.7–25.9). The unadjusted incident CKD rate was significantly higher among patients in the LGFR group (crude incident CKD rate: 48.1/1000 patient-years (95%CI: 32.0–64.3) compared to patients with HGFR (crude incident CKD rate: 15.7/1000 patient-years (95% CI: 10.9–20.5; p < 0.0001) after Bonferroni correction for multiple testing, but not significantly different compared to SLKT group (crude incident CKD rate: 19.1/1000 patient-years (95%CI: 7.–30.3; p = 0.57). Time to CKD event analysis using Kaplan-Meier curves showed a significantly increased risk of progression to CKD in the LGFR group using either preLT GFR (p < 0.0001) or the 3-month post LT reset point (p = 0.05) as the baseline. Additionally, LGFR group had worse overall patient survival using the 3 month "reset point" point as the baseline (P < 0.0001).

Conclusion: In a large multicenter cohort of LT recipients with NASH, grouped by severity of renal dysfunction at the preLT period, a statistically significant change in the slope for eGFR at 3 months after LT (GFR reset point) was noted. Long term liver and kidney disease outcome appears to be modified by this new baseline. LGFR group had increased risk for progression to CKD as well as overall mortality.

THU284

Is hepatitis B immunoglobulin necessary for hepatitis D prophylaxis after liver transplantation? A retrospective multicenter study of a cohort of 174 patients

Sergio Rodríguez-Tajes[1,2], María García Eliz[3], Arantxa Caballero[4], Isabel Campos-Varela[5], Alba Cachero[6], Carmelo Loinaz-Segurola[7], Miguel Angel Gómez-Bravo[8], Manuel Rodríguez-Perálvarez[2,9], Emilio Fabrega[10], Maria Luisa Gonzalez Dieguez[11], Carmen Viaixa[3], Juan Manuel Pascasio[2,8], Inmaculada Fernández Vázquez[7], Carme Baliellas[6], Lluis Castells[2,5], Magdalena Salcedo[4], Martin Prieto[3], Miguel Navasa[1,2], Xavier Forns[1,2]. *[1]Hospital Clínic de Barcelona, IDIBAPS, Liver Unit, Barcelona, Spain; [2]Ciberehd; [3]Hospital Universitario y Politécnico de La Fe, Liver Unit, València, Spain; [4]Gregorio Marañón Hospital, Liver transplant Unit, Madrid, Spain; [5]Vall d'Hebron University Hospital, Liver Unit, Barcelona, Spain; [6]Bellvitge University Hospital, Liver Unit, L'Hospitalet de Llobregat, Spain; [7]University Hospital 12 de Octubre, Liver Transplant Unit, Madrid, Spain; [8]Virgen del Rocio Hospital, Sevilla, Spain; [9]Hospital Universitario Reina Sofia, Córdoba, Spain; [10]Marqués de Valdecilla University Hospital, Liver Unit,*

Email: sergio.tajes@gmail.com

Background and Aims: Chronic hepatitis caused by hepatitis delta virus (HDV) is the most severe form of viral hepatitis, with rapid progression to cirrhosis, which may lead to liver transplantation (LT). It is generally accepted that post-LT prophylaxis includes a nucleos(t)ide analog (NUC) and anti-hepatitis B immunoglobulin (HBIG), which would prevent HDV reactivation in case of surface antigen (HBsAg) reappearance. Our aim was to describe HDV/HBV prophylaxis in real clinical practice in LT recipients and to analyse the incidence and impact of HDV recurrence.
Method: Retrospective study in 10 Spanish Liver Transplant centers. Relevant variables within the pre-LT, LT and post-LT periods were collected from all patients transplanted due to HBV/HDV coinfection between 1988 and 2018.
Results: Of a total of 987 patients undergoing LT due to HBV, 174 (17%) had HDV coinfection. 75% were men, median age at LT 45 years (36–52), 77% were Spanish and 15% from Eastern Europe. The indications for LT were decompensated cirrhosis (68%), decompensated cirrhosis and hepatocellular carcinoma (HCC) (19%), HCC (9%) or fulminant hepatitis (4%). Median MELD score was 18 (15–22) and median Child-Pugh 10 (9–11). At time of LT all patients were HBsAg positive, 17% had detectable HBV-DNA and 55% were on treatment with NUCs. HDV-RNA was available in 76 (44%) and 84% were positive; only 12% had received treatment for HDV. HCV or HIV coinfections were present in 11% and 8% of cases, respectively.
The median post-LT follow-up was 7.8 (2.3–15.1) years. 97% received HBIG in the immediate post-LT, but only 42% were currently on HBIG. The median time that patients were on HBIG was 18 (7–52) months. Reasons for HBIG discontinuation were patient dropout (11%) or center's protocol (66%). At time of analysis 90% were on NUCs and 10% were not receiving any prophylaxis.
During post-LT follow-up, HBsAg was detected in 19 (11%) patients, 48% within the first year and 21% within the second; 6 (32%) were still on HBIG, but only 2 (10%) had anti-HBs >10 U/ml. Regarding NUCs prophylaxis 9 patients were on lamivudine, one on tenofovir and 9 did not receive NUCs. HBV-DNA was detected in 11 (7%) patients, 9 coinciding with reappearance of HBsAg and in 7 (63%) associated with an increase in transaminases. HDV-RNA was detected in only 2 patients; one died due to decompensated cirrhosis. Patients' survival at 1, 5 and 10 years after LT was 95%, 90% and 88%, respectively.
Conclusion: Despite the recommendation of long-term HBIG prophylaxis in HBV/HDV LT recipients, only a minority of patients were on HBIG 2 years after transplantation. Nevertheless, cases of HDV reactivation were rare, even in case of HBsAg reappearance. Despite the limitations of the study, our data do not support the use of long-term HBIG prophylaxis in HBV/HDV LT.

THU285

Pre-transplant diabetes independently predicts atherosclerotic vascular event and death due to cardiovascular disease in liver transplant recipients: a long term multicenter observational study

Email: stefano.gitto@unifi.it

Background and Aims: Liver transplant (LT) recipients often develop metabolic disorders and cardiovascular disease that definitely represent main driver of both morbidity and mortality. Aims of the present study were to detect predictors of atherosclerotic vascular event (AVE), and to assess the impact of AVE on the long-term outcome.
Method: We retrospectively analyzed data from patients transplanted between 2000 and 2005 and followed-up in five Italian *Transplant Outpatient Clinics*. Cox Regression analysis was performed for predictors of AVE, global mortality, and cardiovascular mortality. Survival analysis was completed using the Kaplan-Meier method. $P < 0.05$ was considered significant for all tests.
Results: We analyzed data from 367 subjects registering 37 post-LT AVE during a median follow-up of 14 years. Patients with AVE more frequently showed pre-diabetes mellitus (DM) in respect to the others (48.6 vs 13.9%, $p = 0.000$). In the post-LT period, patients with AVE satisfied criteria of metabolic syndrome in 83.8% of cases while subjects without AVE in 36.7% ($p = 0.000$). At Multivariate analysis pre-LT DM independently correlated with AVE (HR 2.250, CI 10.440–4.848, $p = 0.038$). Moreover, pre-LT DM and AVE were strongly associated with heart-related death (HR 5.418, CI 1.060–29.183, $p = 0.049$ and HR 86.097, CI 9.510–779.480, $p = 0.000$, respectively).
Conclusion: Pre-LT DM is a main risk factor for post-LT AVE and both pre-LT DM and post-LT AVE are strong long-term predictors of heart-related death. Patients with pre-LT DM should obtain a personalized follow-up for prevention or early diagnosis of AVE.

THU286

A novel scoring system for predicting risk of relapse following referral for liver transplantation in patients with alcohol-related liver disease

Stephanie Turner[1], Ellie van der List[1], Kate Forgan-Smith[1], Maree Jarrett[2], Katherine Stuart[1,2]. *[1]Princess Alexandra Hospital, Department of Gastroenterology & Hepatology, Woolloongabba, Australia; [2]Princess Alexandra Hospital, Queensland Liver Transplant Service, Woolloongabba, Australia*
Email: stephanie.turner@uqconnect.edu.au

Background and Aims: Liver transplantation (LT) is an established treatment for the management of decompensated cirrhosis and hepatocellular carcinoma. Approximately 15% of adult LT in Australia and New Zealand are performed for alcohol-related liver disease (ALD). Alcohol relapse, defined as any alcohol after LT, is reported in 20–50% of patients. Risk of relapse to alcohol after referral for LT, including whilst on the waiting list, is not well documented. The aim of this study was to develop a prognostic score from pre-LT variables to predict the relapse risk in patients with ALD referred for LT.
Method: This retrospective observational study conducted at a single LT centre included all patients referred for LT with ALD as a primary or secondary diagnosis between January 2013 and August 2019. Alcohol relapse was defined as positive blood alcohol level (BAL) or any self-reported intake of alcohol. Harmful relapse was defined as alcohol

consumption associated with medical or social harm including positive BAL on the LT waiting list. Binomial logistic regression was used to identify several pre LT patient variables associated with alcohol relapse after LT. These variables were used to construct a prognostic score to predict risk of relapse. The scoring system was analysed using the area under the receiver operating characteristic curve. All statistics were performed using SPSS.

Results: Of 712 adult patients were referred for LT during the study period and 150 (21%) had ALD. Of those, 127 (84.7%) were male with a mean age at time of referral of 54 years and median duration of abstinence pre-referral of 14.5 months (range, 0.67–416). 14 (9.3%) patients were delisted prior to LT due to positive BAL. 13 (8.7%) relapsed post-LT including 5 (3.3%) patients with harmful relapse. On multivariate analysis, four variables were associated with alcohol relapse: LT indication for decompensated ALD [OR 5.48 (95% CI 1.79–16.77), p = 0.022], relapse despite prior specialist advice [OR 3.10 (95% CI 1.22–7.86), p = 0.035], time since diagnosis of ALD [OR 0.859 (95% CI 0.74–1.00), p = 0.044] and documented concern of relapse by transplant hepatologist [OR 4.44 (95% CI 1.85–10.68), p = 0.049]. The Alcohol Risk Assessment Score (ARAS) was developed using these variables (Table 1). Documented concern from transplant hepatologist was excluded from the model due to concerns regarding subjectivity. On modelling, the ARAS produced an AUROC of 0.76 (95% CI 0.66–0.85) for accurately predicting alcohol relapse post-LT. An ARAS score >3 gave NPV 92.5%, PPV 26.5%, sensitivity 81.5% and specificity 50.4% for predicting alcohol relapse after LT referral.

Table 1. Alcohol Risk Assessment Score

Variable	*Points*
Indication for LT	
Decompensated ALD	3
HCC	0
Prior relapse despite specialist advice	2
ALD diagnosed <4 years ago	1

Conclusion: This novel scoring system is a useful predictor of alcohol relapse in patients with ALD referred for LT. It may assist LT committees in identifying patients at high risk of relapse and guiding clinicians in introducing early risk-based interventions before and after LT.

THU287

Improvement of renal function prior to liver transplantation is not associated with better long-term renal outcome or mortality

Thomas Horvatits[1], Marcel Touma[1], Karoline Rutter[1], Lutz Fischer[2], Ansgar Lohse[1], Martina Sterneck[1]. *[1]University Medical Center Hamburg-Eppendorf, 1. Dep. of Medicine, Hamburg, Germany; [2]University Medical Center Hamburg-Eppendorf, Dep. of Transplant Surgery, Hamburg, Germany*
Email: t.horvatits@uke.de

Background and Aims: Since the MELD score (model for end stage liver disease) has been introduced in the liver allograft allocation system renal impairment in liver transplant (LT) recipients has become a topic of increasing importance. This is the first study evaluating the course of renal function prior to LT as a risk factor for long-term renal outcome and overall survival.

Method: All adult patients undergoing LT at the University Medical Centre Hamburg-Eppendorf between 2011 and 2015 were included in this retrospective study. Renal function over a period of 3 months prior to LT as well as long-term renal outcome and survival was assessed in all patients.

Results: Altogether 226 patients with a median age of 60 years (female: 37%) were included in this study. Median follow up post LT was 1491 days. Patients were classified according to the nadir GFR value within a period of 3 months prior to LT (CKD 1: n = 30 (13%), CKD 2: n = 64 (28%), CKD 3: n = 42 (19%), CKD 4: n = 42 (19%) and CKD 5: n = 48 (21%)). With respect to the GFR at the day of LT renal function improved (one CKD stage) in 63 patients (28%) whereas it remained stable or deteriorated in 163 patients (72%). However, course of renal function prior to LT did neither significantly affect 3-moth survival (p = 0.9), 1-year survival (p = 0.6) nor 5-year patients' survival (p = 0.4), as illustrated in figure 1. Furthermore, CKD stage at end of follow-up did not significantly differ between patients with and without improvement of kidney function prior to LT (p = 0.8). Nevertheless, both, need for dialysis pre LT was associated with increased 5-year mortality (56% vs. 29%, p < 0.05) as well as need for dialysis post LT (58% vs. 14%, p < 0.05).

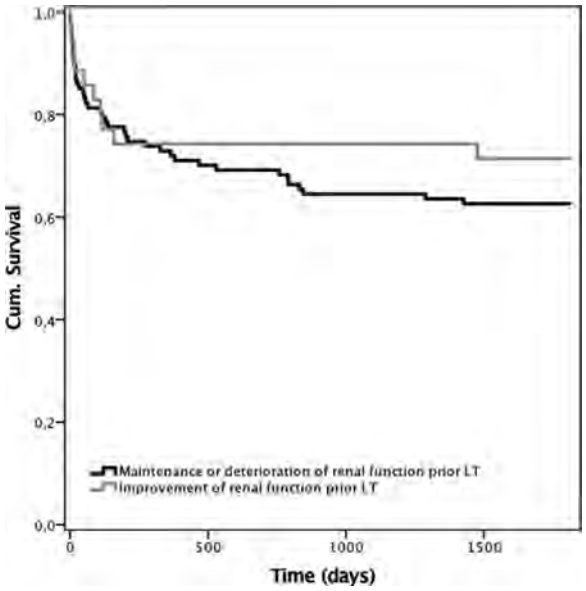

Figure: Kaplan Meier plot of 5-year survival according to alterations (improvement vs. maintenance or deterioration) of renal function (within a time period of 3 months) prior to LT; Log-rank test: p = 0.4

Conclusion: Dialysis pre and postoperatively affected survival in this long-term follow up observational study. However, improvement or worsening of renal function immediately prior to LT had no significant effect on long-term renal or overall outcome. As alterations of renal function and subsequent changes of the MELD score directly affect prioritization of organ allocation, future studies need to clarify the impact of alterations of serum creatinine on waiting time in patients prior to LT.

THU288

An open-label, cohort study of grazoprevir/elbasvir combination therapy for patients with genotype 1b chronic hepatitis C after liver or kidney transplantation

Teng-Yu Lee[1], Ping-Chin Lai[2], Long-Bin Jeng[3], Yu Tung-Min[4], Ming-Ju Wu[4], Cheng-Hsu Chen[4], Shang-Feng Tsai[4], Shao-Bin Cheng[5], Shengshun Yang[6]. *[1]Taichung Veterans General Hospital, Division of Gastroenterology & Hepatology, Taichung, Taiwan; [2]China Medical University Hospital, Division of Nephrology, Department of Medicine, Taichung, Taiwan; [3]China Medical University Hospital, Organ Transplantation Center, Taichung, Taiwan; [4]Taichung Veterans General Hospital, Division of Nephrology, Department of Medicine, Taichung, Taiwan; [5]Taichung Veterans General Hospital, Department of Surgery, Taichung, Taiwan; [6]Taichung Veterans General Hospital, Division of Gastroenterology & Hepatology, Department of Internal Medicine, Taichung, Taiwan*
Email: tylee@vghtc.gov.tw

Background and Aims: Although some new direct-acting antivirals (DAAs) have been used for organ transplantation recipients, individual limitations, such as drug-drug interaction (DDI), may

limit their clinical use. Grazoprevir (GZR)/elbasvir (EBR) is highly effective in the treatment of genotype 1b chronic hepatitis C, but its clinical data on the treatment for patients after liver or kidney transplantation remain lacking. The aim of this study is to assess the efficacy and tolerability of GZR/EBR combination therapy in genotype 1b HCV-infected liver or kidney transplant recipients.

Method: In this phase 4, multi-center, open-label, interventional, single-arm cohort study (ClinicalTrials.gov number NCT03723824), patients receive GZR/EBR for 12 weeks. Inclusion criteria: (1) Chronically infected with genotypes 1b HCV; (2) Underwent liver and/or kidney transplantation; (3) Without clinical or pathologic evidence of moderate or severe rejection. Exclusion criteria: (1) HCV genotype other than 1b; (2) Liver decompensation; (3) Co-infected with HIV or HBV; (4) Prior exposure to an NS5a inhibitor; (5) Any active malignancies; (6) Hemoglobin level less than 10 g/dL; (7) Platelet level of 75,000/mm^3 or less; (8) ALT, AST, or ALKP greater than 10X upper limit of normal (ULN) or more; (9) Total bilirubin greater than 3X ULN or more; (10) Albumin less than 3 g/dL; (11) Using medication that is not considered safe to co-administer with GZR/EBR, such as cyclosporine. The primary endpoints are SVR12 and discontinuations due to adverse events (AEs).

Results: Until the end of October, 2019, 11 patients were enrolled into this study, including 8 (72.7%) kidney and 3 (27.3%) liver transplant recipients. The median age was 66.0 (62.0–69.0) years, and 4 (36.3%) patients were males. The median duration was 10.4 (0.13–15.9) years from the date of organ transplant. The most commonly used immunosuppressants were tacrolimus (100%), everolimus (36.3%), and mycophenolate mofetil (45.5%). The median HCV viral load was 6.30 (5.53–6.93) log^{10} IU/mL at baseline. No patient had liver cirrhosis, and 1 patient (9.1%) was interferon-experienced. In patients whose antiviral responses could be accessed, the rates of RVR, EOT, and SVR12 were 100% (8/8), 100% (7/7), and 100% (4/4), respectively. No patient needed to adjust the dosage of immunosuppressants. No AE was deemed by the investigators to be GZR/EBR-related, and no patient discontinued GZR/EBR during the GZR/EBR therapy period. No transplant organ rejection episodes or deaths occurred during the study period.

Conclusion: In this interim analysis, GZR/EBR is highly effective and well tolerated in genotype 1b HCV-infected liver or kidney transplant recipients, and its DDIs are generally easy to be managed.

THU289

Proximal splenorenal shunt as a secondary prophylaxis for isolated gastric bleeding in patients with non-cirrhotic portal hypertension: a report from a single-center case-series

Utpal Anand[1], Ramesh Kumar[2], Rajeev Priyadarshi[3]. *[1]AIIMS Patna, Surgical Gastroenterology, Patna, India; [2]AIIMS Patna, Gastroenterology, Patna, India; [3]AIIMS Patna, Radiodiagnosis, Patna, India*
Email: utpalanand2@gmail.com

Background and Aims: Gastric variceal bleeding is a frequent problem in patients with non-cirrhotic portal hypertension (NCPH), and endoscopic glue therapy is currently the treatment of choice. However, glue therapy often requires multiple sessions, is associated with risk of thrombo-embolic complications, and not immediately available to patients residing in the rural and remote areas. Because variceal bleeding rather than liver failure is the common cause of death in such patients, we performed splenectomy and proximal splenorenal shunt (PSRS) in NCPH patients with history of gastric variceal bleeding as secondary prophylaxis, and here presents our experience.

Method: This study was conducted at Indira Gandhi Institute of Medical Sciences, Patna, India between January 2012 and June 2017. During this period, 55 patients with NCPH and gastric variceal bleeding presented to us. Patients with suspicion of underlying cirrhosis (n = 04), associated oesophageal varices (n = 18), unsuitable splenic vein for shunt surgery (n = 6) and those unwilling to undergo surgical procedure (n = 02) were excluded from study. PSRS was performed in 25 NCPH patients which included extrahepatic portal vein obstruction (EHPVO, n = 19) and non-cirrhotic portal fibrosis (NCPF, n = 06). Patients were followed up every three months for one year, every 6 months for the second, and yearly thereafter by telephonic conversation and outdoor visits. All patients underwent Upper GI Endoscopy and Doppler Ultrasonography 6 months after surgery to see the status of varices and shunt patency.

Results: The mean age NCPH patients was 18.6 ± 3 years and the majority were male (76%). The median episodes of bleeding prior to surgery was 02 (01–06). An end-to-side PSRS was done in all with a mean shunt diameter of 8.4 mm. The average operative time was 4.5 ± 0.5 hours and the average blood loss during the operation was 865 ± 315 ml. Twenty patients (80%) were followed up for a median period of 3.4 (01–06) years. Gastric Variceal regression was noted in all 20 patients with disappearance of gastric varices in 08 patients. Shunt thrombosis was noted in 20% patients and two of such patients developed rebleeding 6 months and 3 years after shunt surgery, respectively. Features of hypersplenism improved in all patients.

Conclusion: Considering limitations of glue therapy, PSRS is one time, safe and effective therapy in patients with EHPVO and NCPF patients. However, a study using larger sample and control arm is needed.

THU290

Usefulness of the "AFP model" to predict recurrence tumor in patients transplanted with carcinoma hepatocellular within Milan criteria

Victor J Beltrán[1], Maria Luisa Gonzalez Dieguez[1], Valle Cadahía-Rodrigo[1], Carmen Álvarez-Navascués[1], Maria Varela[1], Carmen Garcia-Bernardo[2], Ignacio Gonzalez-Pinto[2], Manuel Rodríguez[1]. *[1]Hospital Universitario Central de Asturias, Liver Unit, Oviedo, Spain; [2]Hospital Universitario Central de Asturias, Hepatobiliary Surgery, Oviedo, Spain*
Email: luisagondi@hotmail.com

Background and Aims: In patients with hepatocellular carcinoma (HCC), elevated AFP levels is a predictor of poor prognosis, both transplanted and non-transplanted. Levels >1000 ng/ml have been associated with high risk of tumor recurrence (TR) post-transplant. In the last years, they have developed prognostic TR models that incorporate AFP, and appear to improve TR prediction post-transplant compared to the Milan criteria. The aims of this study was to evaluate the usefulness of the "AFP Model" to predict TR in patients transplanted with HCC within Milan criteria pre-transplant.

Method: 195 patients transplanted consecutively with HCC within Milan criteria pre-transplant were included. The median follow-up was 4.6 years. The patients with survival less than 3 months postoperatively were excluded. The 87% were men with a median age of 58 years (43–67). The etiology of the hepatic disease was alcohol (45%), HCV (42%), HBV (5%) and others (8%). Variables analyzed: baseline AFP, number and size of tumor nodules pre-transplant and in the explant, tumor differentiation, vascular invasion and scoring of the "AFP Model."

Results: The TR rate was 9.7% (19/195). The 94% of the patients had a score of the "AFP Model" ≤2 (137 patients with score 0; 32 with score 1; 15 with score 2; 10 with score 3 and 1 patient with score 4). The 26% (5/19) of the TR were developed in patients with a score >2 and they represented 5.6% (11/195) of all the cohort. Of those with a score >2, the 45% (5/11) presented TR, compared with 7.6% (14/184) of those with a score ≤2 (p = 0.001). The explant presented criteria >Milan in 63% (7/11) of patients with score >2 and in 16% (31/184) with score ≤2 (p = 0.002). Microvascular invasion was observed in 36% (4/11) of the explants with score >2 and in 10% (19/184) with score ≤2 (p = 0.02). The waitlist time was significantly lower in patients with a score >2 (41.5 ± 36.3 vs 89 ± 82.8 days; p = 0.001). The probability of TR post-transplant at 1,3 and 5 years was higher in patients with a score >2 (10%, 42% and 57% vs 1.7%, 6.7% and 9.6%; p < 0.001). TR-free survival at 1.3 and 5 years was greater in patients with

score ≤2 (96%, 87% and 77% vs 90%, 57% and 43%; p = 0.005) as well as overall survival (98%, 91% and 82% vs 91%, 60% and 60%; p = 0.02).
Conclusion: In patients transplanted by HCC within Milan criteria pre-transplant, the "AFP Model" was able to differentiate 2 groups with a different probability of post-transplant tumor recurrence and with different survival, which confirms its usefulness in the selection of patients for transplant. In our patient series, the application of the "AFP Model" would have avoided a quarter of the tumor recurrences excluding from the transplant only a small number of patients.

THU291

Therapy with DAA increases post-OLT survival but not the risk of recurrence in patients undergoing liver transplantation for HCV-related HCC

Vito Sansone[1], Francesco Tovoli[1], Matteo Ravaioli[2], Giuseppe Mazzella[1], Fabio Piscaglia[1]. [1]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy;* [2]*University of Bologna, Department of General Surgery and Transplantation, Bologna, Italy*
Email: vito.sansone@studio.unibo.it

Background and Aims: The role of direct acting antivirals (DAA) for hepatitis C virus (HCV) in hepatocellular carcinoma (HCC) recurrence is a source of great debate. Current evidence is not able to determine whether DAA therapy either increases or decreases risk of recurrence. However, it has not been thoroughly investigated the role of DAA therapy in patients undergoing orthotopic liver transplantation (OLT) for HCC. As a post-OLT recurrence is an almost invariably deadly event, we aimed to compare the risk of recurrence and the overall survival (OS) of patients treated with DAA and obtaining sustained virological response (SVR) before OLT with an historical cohort of patients transplanted for HCC before the arrival of DAAs.
Method: We enrolled retrospectively 48 patients from the Bologna Liver Transplant Unit who underwent OLT in the DAA era for HCV-related HCC, from 2015 to 2019, comparing to an historic cohort of 128 patients that were transplanted for the same indication from 2003 to 2013. We performed multivariable regression analysis to identify factors associated with time to recurrence and overall survival.
Results: Recurrence rate was 12.5% for the first group (mean time to recurrence 16.8 mo) and 20.3% for the second (mean time to recurrence 24.5 mo). OS was significantly different: 91.7% vs 60.6%. In the Cox analysis, active HCC at transplant, number of nodules and diameter of the largest nodule and alpha-fetoprotein were significantly associated with time-to-progression, whilst OS was associated with DAA treatment, microvascular invasion, diameter of the largest nodule at transplant and LN_{10}AFP at transplant. Analysing the competing causes of death, most of the effects on the increased survival in the DAA cohort derived for the reduction of the risk of liver decompensation.
Conclusion: Post-OLT recurrence did not vary significantly between the two groups. However, overall survival is increased in the DAA group. Therefore probably their efficacy is due to other effects, in particular the prevention of liver decompensation.

THU292

Geographic disparities and socioeconomic determinants in liver transplantation referral at the Scottish Liver Transplant Unit

Wilson Siu[1], Iris Ko[1], Peter Hayes[2]. [1]*College of Medicine & Veterinary Medicine, University of Edinburgh, Edinburgh, United Kingdom;* [2]*Scottish Liver Transplant Unit, Royal Infirmary of Edinburgh and University of Edinburgh, Edinburgh, United Kingdom*
Email: wilson.siu@nhs.net

Background and Aims: Previous studies have shown geographical and socioeconomic disparities in patients' access to liver transplantation. The aim of the study is to assess whether distance from transplant centre and socioeconomic status are associated with worsened outcome.
Method: We performed a retrospective study at Scottish Liver Transplant Unit (SLTU) looking at all transplant assessments for alcohol-related liver disease (ARLD), hepatocellular carcinoma (HCC) and non-alcoholic fatty liver disease (NAFLD) from 1/1/2007 to 31/12/2017. Patients' demographics including gender, age, referring health boards, Scottish Index of Multiple Deprivation (SIMD) decile and distance from SLTU were recorded. Patients' clinical characteristics including UKELD (United Kingdom Model for End-Stage Liver Disease) scores and aetiology of their liver disease were also included. The outcomes of the study included transplant listing outcome and mortality after liver transplantation.
Results: 937 patients (median age 59, IQR 52–64, Male: 75%) with a diagnosis of ARLD (n = 667), NAFLD (n = 157) and/or HCC (n = 432) were admitted for transplant assessments during the 11 years study period. 479/937 (51%) patients were listed for transplant, 403/479 (84%) patients received liver transplantation and of these 68 (17%) died. Multivariable logistic analysis showed the odds of being listed for transplant were 9% higher with each increasing SIMD decile (OR 1.09, CI 1.04–1.14, p value <0.001). Other statistically significant variables associated with transplant listing included the diagnosis of HCC (OR 1.80, CI 1.19–2.73, p value = 0.005) and UKELD score (OR 1.03, CI 1.00–1.06, p value = 0.03). The mortality rate after liver transplant decreased with each increasing SIMD decile but it was not statistically significant (OR 0.92, CI 0.83–1.01, p value = 0.09). Geographic distance from SLTU had no statistically significant association with transplant listing outcome or mortality outcome after transplant.
Conclusion: Our study demonstrated no geographical disparity in referral and assessment at SLTU. However, patients from a more deprived area (SIMD decile 1) were less likely to be listed for transplant. Future prospective studies are required to investigate the causation of these correlations.

THU293

Pre-operative biliary drainage in perihilar cholangiocarcinoma: an overview of systematic reviews

Xinwei Chang[1,2], Hongxia Shen[3], Cornelis Dejong[1,2,4], Ulf Neumann[1,2,4], Jos Kleijnen[5], Frank Schaap[2,4], Steven Olde Damink[1,2,4]. [1]*Department of Surgery, Maastricht University Medical Center, Maastricht, Netherlands;* [2]*Department of Surgery, NUTRIM School of Nutrition and Translational Research in Metabolism, Maastricht University, Maastricht, Netherlands;* [3]*Department of Public Health and Primary Care, Leiden University Medical Centre, Leiden, Netherlands;* [4]*Department of General, Visceral and Transplantation Surgery, RWTH University Hospital Aachen, Aachen, Germany;* [5]*School for Public Health and Primary Care (CAPHRI), Maastricht University, Maastricht, Netherlands*
Email: steven.oldedamink@maastrichtuniversity.nl

Background and Aims: The beneficial effect and route of preoperative biliary drainage (PBD) which can be via percutaneous transhepatic biliary drainage (PTBD) or endoscopic biliary drainage (EBD) in patients with perihilar cholangiocarcinoma (pCCA) are heavily debated. An overview of systematic reviews allows assessment of quality of individual systematic reviews. We performed an overview of systematic reviews to comprehensively collate evidences and clarify the effect of PBD on drainage-related and postoperative outcomes in patients with resectable pCCA to provide the best possible evidence-based recommendations.
Method: An overview of systematic reviews was prospectively registered in PROSPERO (CRD42019141412). A systematic search was performed in PubMed, Embase, Cochrane Library and KSR Evidence from inception to May 31, 2019. We included studies that assessed the use of PBD, and/or compared PTBD and EBD in patients with resectable pCCA. The primary outcomes were postoperative mortality and drainage-related cholangitis.
Results: Eight systematic reviews with meta-analysis involving 4812 participants from 2478 screened reports were identified, including three reviews assessing the use of PBD and five reviews comparing

PTBD with EBD. All original studies included in these reviews were observational retrospective studies. Quality of data abstraction and statistical methods varied across reviews. All systematic reviews had high risk of bias according to ROBIS tool (assessment for risk of bias in systematic reviews). About the use of PBD, three reviews consistently showed that PBD did not decrease postoperative mortality, by contrast, two of these three reviews demonstrated PBD significantly increased overall postoperative morbidity and postoperative infectious morbidity ($p < 0.05$). About the route of PBD, two reviews pointed towards significantly lower drainage-related cholangitis rates (RR, 0.49; 95% CI 0.36–0.67 from the largest review) and overall drainage-related morbidity in PTBD group compared to EBD group ($p < 0.05$), but this superiority of PTBD disappeared in other two reviews. The drainage-related pancreatitis rates were frequently higher in EBD group ($p < 0.05$). EBD groups had longer 1-year, 5-year, and overall survival ($p < 0.05$).

Conclusion: Although the evidence base is still inconclusive, our study suggests that PBD does not decrease postoperative mortality and is therefore not recommended routinely. PTBD results in lower drainage-related morbidity but is associated with lower overall survival compared to EBD in pCCA patients. Large sample sizes and/or international multicentre randomised controlled trials are urgently needed to assess the value of PBD in surgical management of patients with pCCA.

THU294

Imprints of post-liver transplantation: HCV recurrence on immune cell compartment persist despite achieving therapy-induced SVR

Amare Aregay[1], Richard Taubert[1], Kerstin Port[1], Michael P. Manns[1], Elmar Jaeckel[1], Nicolas Richter[1], Markus Cornberg[1], Heiner Wedemeyer[2]. [1]*Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*Essen University Hospital, Gastroenterology and Hepatology, Essen, Germany*
Email: heiner.wedemeyer@uk-essen.de

Background and Aims: Recurrence of hepatitis C virus (HCV) in liver transplanted patients has occurred in almost all patients who were viremic at the time of transplantation. Now that it is possible to achieve sustained virologic response (SVR) in post-liver transplant patients at a comparable frequency to pre-transplanted patients, we aimed to comprehensively characterize immune cell subsets after liver transplantation in patients receiving DAA therapy. Particularly, we aimed to define potential immune correlates which could have impact for the risk to develop rejection episodes associated with HCV clearance.

Method: Peripheral blood mononuclear cells isolated from blood samples of liver transplanted patients during DAA therapy (n = 18) were assessed for phenotypes and distribution of both the myeloid and lymphoid immune cell subsets. Patients received mainly calcineurin inhibitors as the backbone immune suppressant. Results were compared to data from healthy (n = 10) and non-transplanted chronic HCV infected (n = 10) patients. Furthermore, in-vitro functionalities of virus-specific CD8+ T cells were investigated in these groups.

Results: Liver transplanted patients with recurrent HCV infection displayed distinct enrichment of CD16+ classical monocytes, myeloid dendritic Cells (mDC), myeloid derived suppressor cells (MDSC), NKG2C+ NK cells and functional (CD45RO+/IL-17+/TNF+) CD4+CD127-$CD25^{high}$ regulatory T cells (Tregs) as compared to healthy controls and non-transplanted chronic HCV infected patients. In contrast, distribution of MAIT cells, plasmacytoid dendritic cells (pDC) and IFN-y producing NK cells were reduced in liver transplanted patients. Importantly, clearance of HCV post-liver transplantation did not significantly alter the phenotypes and distribution of any of the analysed immune cell subsets. In addition, the in-vitro frequency and functionality of HCV-specific CD8+ T cells were also not significantly altered despite achieving SVR after liver transplantation.

Conclusion: Our data indicate that the HCV specific imprints on immune cell parameters post-liver transplantation are not reversed by therapy-induced HCV elimination. This is in line with the clinical observation that cure of HCV post-transplantation did not trigger rejection episodes in many patients.

THU295

The FOXO1-hedgehog signaling axis regulates NLRP3 inflammasome activation in liver ischemia and reperfusion injury

Changyong Li[1], Mingwei Sheng[1], Yizhu Tian[1], Yuanbang Lin[1], Dongwei Xu[1], Song Wei[1], Yongqiang Zhan[1], Ronald Busuttil[1], Jerzy Kupiec-Weglinski[1], Bibo Ke[1]. [1]*The Dumont-UCLA Transplant Center, Surgery, Los Angeles, United States*
Email: bke@mednet.ucla.edu

Background and Aims: Foxo1 signaling plays important roles in cell metabolism, oxidative stress, inflammation, and apoptosis. Activation of the Hedgehog/Gli pathway regulates cell growth, differentiation, and immune function. However, it remains unknown whether Foxo1 may modulate the Hedgehog/Gli pathway in liver ischemia and reperfusion injury (IRI). This study investigated the functional roles and regulatory mechanisms of myeloid Foxo1 signaling in IR-triggered liver inflammation.

Method: Myeloid specific Foxo1 knockout ($Foxo1^{M\text{-}KO}$), β-catenin knockout ($\beta\text{-catenin}^{M\text{-}KO}$), floxed Foxo1 ($Foxo1^{FL/FL}$) or β-catenin ($\beta\text{-catenin}^{FL/FL}$) mice (n = 6/group) were subjected to 90 min partial liver warm ischemia followed by 6 h of reperfusion. In parallel *in vitro* study, Bone marrow-derived macrophages (BMMs) were isolated from these conditional knockout mice and transfected with CRISPR/Cas9-mediated Gli1 or Snail knockout vector followed by LPS (100 ng/ml) stimulation.

Results: Mice with myeloid-specific Foxo1 knockout ($Foxo1^{M\text{-}KO}$) were resistant to IR-induced hepatocellular damage, with reduced serum ALT levels, cell apoptosis, macrophage/neutrophil infiltration, and pro-inflammatory mediators compared to the Foxo1-proficient ($Foxo1^{FL/FL}$) controls. Unlike in the $Foxo1^{FL/FL}$ controls, $Foxo1^{M\text{-}KO}$ enhanced β-catenin, the hedgehog signaling effector Gli1, and Snail but reduced NLRP3/caspase-1 activation in ischemic livers. Disruption of Gli1 in $Foxo1^{M\text{-}KO}$ livers deteriorated liver function with reduced Snail while enhancing NLRP3/caspase-1 activity. In parallel *in vitro* studies, we found that macrophage Foxo1 and β-catenin co-localized in the nucleus. The Foxo1-β-catenin interaction reduced Gli1 activation while CRISPR/Cas9-mediated Gli1 knockout diminished Snail and augmented NLRP3/cleaved caspase-1 expression, and IL-1β release in LPS-stimulated macrophages.

Conclusion: Myeloid-specific Foxo1 deficiency activates the Hedgehog/Gli signaling and mitigates IR-induced hepatocellular injury through disruption of competitive binding to β-catenin in the nucleus. Myeloid Foxo1 deficiency diminishes the Foxo1-β-catenin interaction, which in turn enhances β-catenin-TCF/LEF binding and activates the Hedgehog/Gli/Snail signaling leading to inhibited NLRP3-driven inflammatory response. Our findings underscore the crucial role of myeloid Foxo1 signaling in liver inflammatory injury and imply the therapeutic potential in organ IRI and transplant recipients.

Mesenchymal stem cells-derived extracellular vesicles carried lncRNA-CEP95 ameliorates acute liver rejection by modulating phenotype of natural killer cells

Liang Chen[1,2], Yingcai Zhang[1,2], Jia Yao[1,2], Jiebin Zhang[1,2], Tongyu Lu[1,2], Jianye Cai[1,2], Yang Yang[1,2], Jun Zheng[1,2]. [1]*The Third Affiliated Hospital of Sun Yat-Sen University, Department of Hepatic Surgery and Liver Transplantation Center, Guangzhou, China;* [2]*The Third Affiliated Hospital of Sun Yat-Sen University, Guangdong Key Laboratory of Liver Disease Research, Guangzhou, China*
Email: zhengj67@mail2.sysu.edu.cn

Background and Aims: Acute rejection remains a major risk factor for graft and recipient survival after liver transplantation. Management of acute rejection mainly rely on immunosuppressive agents, but the therapy is ineffective in about ten percent of the patients. Thus, development of new treatment is required to improve post-transplant survival. Natural killer (NK) cells are important component of lymphocytes resident in liver, yet their role in acute rejection is not completely understood. Mesenchymal stem cells derived extracellular vesicles (MSC-EVS) have been shown to exhibit immunomodulative effect on immune cells including NK cells. This study aimed to examine whether MSC-EVs could ameliorate acute liver rejection by regulating the function of NK cells.
Method: Adult male Brown-Norway (BN) to Lewis rat liver transplantation was performed as a model of acute liver rejection. Extracellular vesicles from human umbilical cord-derived mesenchymal stem cells were isolated. Intravenous MSC-EVs or PBS were administered immediately after transplantation. Liver histology, serum liver function test, pro-inflammatory and anti-inflammatory cytokines were compared. Flow cytometry and immunochemistry staining was performed to study the functional status of CD56-positive NK cells. RNA-seq of MSC-EVs was performed to identify enriched long non coding RNA and its mechanism in MSC-EVs induced protection from acute rejection. *In vitro*, NK cells were incubated with MSC-EVs.
Results: Rats treated with MSC-EVs had a better survival rate and reduced Banff score compared with PBS control group. Serum alanine aminotransferase, aspartate aminotransferase, total bilirubin, and level of pro-inflammatory cytokines (IFN-γ, IL-6) were significantly lower after treated with MSC-EVs, while level of anti-inflammatory cytokines (IL-10, TGF-β) was increased. Flow cytometry and immunochemistry analysis indicated higher percentage of activating NK cell receptors (NKp30, Nkp44) and lower percentage of inhibitory receptor (NKG2A) of intrahepatic NK cells in MSC-EVs treated group. To elucidate possible mechanism, RNA-seq screening was performed and it was revealed that lncRNA CEP95 is enriched in MSC-EVs. RNA pulldown confirmed that LncRNA CEP95 binds with miR-149-5p in NK cells. Upregulated mRNA expression of IL-10 and downregulated expression of IFN-γ in NK cells transfected with lncRNA CEP95 or incubated with MSC-EVs.
Conclusion: This study revealed that extracellular vesicles derived from mesenchymal stem cells ameliorate acute liver rejection by impairing the functional status of NK cells, via upregulating inhibitory receptors of NK cells. This phenotype conversion of NK cells is mediated by MSC-EVs delivered LncRNA CEP95. In sum, our data suggests a new therapeutic strategy for treatment of acute liver rejection by MSC-EVs.

THU297

Hepatic ischemia induces a time-dependent increase in SERPINB3 gene expression

Cristian Turato[1], Laura Giuseppina Di Pasqua[2], Clarissa Berardo[2], Alessandra Biasiolo[3], Andrea Ferrigno[2], Patrizia Pontisso[3], Mariapia Vairetti[2]. *[1]Veneto Istitute of Oncologic, IOV-IRCCS, Padova, Italy; [2]University of Pavia, Dept of Internal Medicine and Therapeutics, Italy; [3]University of Padova, Dept of Medicine, Padova, Italy*
Email: mariapia.vairetti@unipv.it

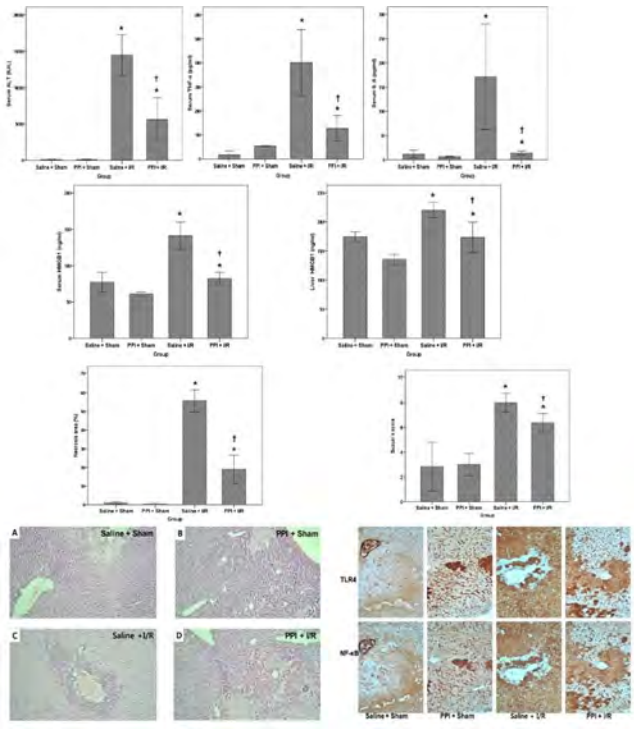
Background and Aims: Understanding the mechanisms of liver ischemia injury and developing strategies to counteract this injury will reduce acute complications in liver transplantation thus expanding the potential pool of usable donor grafts. The inflammatory response to hepatic ischemia is associated with an increase in cytokine production, leading to liver injury. Recently, SerpinB3, that is undetectable in normal liver, has been reported to be induced by oxidative stress in hypoxic conditions and to determine cell death resistance by the inhibition of apoptosis and increase of cell proliferation.
The aim of the present study was to investigate whether acute liver ischemia might affect the molecular expression of SerpinB3 in relation to inflammatory cytokines profile in the liver.
Method: Male Wistar rats (n = 15) were subjected to partial-hepatic ischemia (60, 120, 180 min) by clamping the hepatic artery and the portal vein; sham operated rats (n = 12) were used as control group. At the end of the procedure, liver and blood samples were collected. Hepatic enzymes were analyzed in serum, while gene expression of SerpinB3 and inflammatory cytokines were assessed in the liver.
Results: Liver ischemia injury was confirmed by increased hepatic enzymes (ALP, ALT, γGT) in the ischemia treated group, compared to the sham group.
Hepatic ischemia induced a progressive and significant increase of SerpinB3 expression, reaching a peak (18 fold increase) at 180 min, while the increase of inflammatory cytokines occurred earlier. In detail, for NOX2 and IL1B the peak expression was observed at 60 min, while IL6 and TNFα peaks occurred at 120 min. No significant modifications were observed in the liver of sham-operated rats.
Conclusion: The present data demonstrate that SerpinB3 is increased in ischemic liver, but its late induction, compared to inflammatory cytokines, might explain the inefficient protection in hepatic ischemia. Early administration of SerpinB3-based compounds might be considered as new potential strategies to counteract this injury.

THU298

Esomeprazole attenuates hepatic ischemia/reperfusion injury by modulation of TLR4-mediated signaling in mice

Min Sung Kim[1], Won Mee Lee[2], Dong Hee Kim[1]. *[1]Eulji General Hospital, Eulji University School of Medicine, Department of Surgery, Seoul, Korea, Rep. of South; [2]Eulji General Hospital, Eulji University School of Medicine, Department of Pathology, Seoul, Korea, Rep. of South*
Email: drkms77@eulji.ac.kr

Background and Aims: Recent studies have shown that proton pump inhibitors (PPIs) have a protective effect on various experimental ischemia/reperfusion models, but little is known about its effect on the liver. The aim of this study was to evaluate the beneficial effects of PPI in an experimental model of hepatic I/R injury, focusing on TLR4-mediated signaling, which has been implicated in the development and progression of hepatic I/R injury.
Method: Twenty-four male wild-type (C57BL/6) mice were randomized into four groups: saline + sham, saline + I/R, PPI+ sham, and PPI + I/R. A proton pump inhibitor, esomeprazole, was intraperitoneally injected 30 minutes prior to surgery. The animals were subjected to 60 min of partial warm ischemia (70%), followed by reperfusion for 6 h on the same day. The ischemic lobe of the liver was harvested for hematoxylin and eosin (H&E) stain, western blot and immunohistochemical analyses. Blood was collected and levels of alanine aminotransferase (ALT), proinflammatory mediators and High mobility group box 1 (HMGB1) were measured.
Results: Pretreatment with esomeprazole attenuates hepatocellular injury after hepatic I/R. Pretreatment with esomeprazole decreased production of I/R induced proinflammatory mediators (such as IL-1β and TNF-α) in serum. Pretreatment with esomeprazole suppresses HMGB1 release in serum and ischemic liver after hepatic I/R. Esomeprazole suppresses TLR4-mediated signaling pathway in hepatic I/R. After hepatic I/R, the expression of TLR4, HMGB1, TNF-α, and NF-κB was up-regulated in the Saline + I/R group, but pretreatment with esomeprazole markedly down-regulated the expression of TLR4, HMGB1, TNF-α, and NF-κB in the PPI + I/R group.



Conclusion: Proton pump inhibitor, esomeprazole attenuates hepatic I/R injury by down-regulation of the TLR4-mediated signaling pathway. Esomeprazole can be considered as an agent for use in clinical treatment of hepatic I/R injury.

THU299

MSC-EVs induce liver transplantation tolerance by promoting CD8 +CD28- T cells differentiation and immunomodulatory function via lncRNA MALAT1/IRF4 signaling

Xin Sui[1], Qing Yang[2], Jia Yao[2], Jianye Cai[1], Jun Zheng[2], Tongyu Lu[2], Liang Chen[2], Huimin Yi[1], Yang Yang[2], Yingcai Zhang[2]. [1]*Department of Intensive Care Unit of of the Third Affiliated Hospital, Sun Yat-sen University;* [2]*Organ Transplantation Institution, Department of Hepatic Surgery and Liver Transplantation Center of the Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*
Email: zhangyc3@mail.sysu.edu.cn

Background and Aims: Liver transplantation is the optimal treatment option for end-stage liver disease. Otherwise, it is generally accepted that the side effects of modern immunosuppression drugs remain a significant contributing factor for less satisfactory long term outcomes. It is reported that a high frequency of $CD8^+CD28^-$ T cells, a special subset of regulatory T cells (Treg), contributes to maintaining stable graft function and reducing immunosuppressant dosage after liver transplantation. We previously found that mesenchymal stromal cells (MSCs) could effectively enhance the immunomodulatory function of $CD8^+CD28^-$ T cells. The possible effective components suggest to be MSC-derived extracellular vesicles (MSC-EVs). However, it is unknown whether MSC-EVs could induce transplantation tolerance by affecting the functional status of $CD8^+CD28^-$ T cells.
Method: Livers from DA rats were transplanted into Lewis rats. Allografts either untreated or treat with MSC-EVs. Liver inflammation, apoptosis, cytokine, and the exchange of sub-population of T cell were compared. We applied RNA-seq screening and identified the mRNA enriched in MSC-EVs, and proved the mechanisms of MSC-EVs induced immunosuppression post-transplantation.
Results: MSC-EVs reduced mortality of rats after liver transplantation by increasing the proportion of $CD8^+CD28^-$ T cells. The concentration of IL-10 and TGF-β was significantly increased in MSC-EVs injection group, while inflammatory factor IL-1β was decreased extremely. MSC-EVs inhibited apoptosis and promoted immunosuppressive function by promoting glucose metabolism of $CD8^+CD28^-$ T cells. MSC-EVs could induce the formation of tolerogenic DCs (tolDCs) and promote the phenotypic transformation of $CD8^+CD28^+$ T cells to $CD8^+CD28^-$ T cells, thus promoting the differentiation regulation and functional activity of $CD8^+CD28^-$ T cells. Mechanically, we applied RNA-seq screening of MSC-EVs and identified the enrichment of LncRNA MALAT1. MSC-EVs might have positive effects on, not only improving the statement of glycometabolism in $CD8^+CD28^-$ T cells, also promoting DCs converse to tolDCs, via LncRNA MALAT1 -miR-125b -IRF4 axis. Luciferase assay showed that down-regulated LncRNA MALAT1 in MSC-EVs could not competing antagonise miR-125 binding to IRF4 in T cells and DC cells, suggested that LncRNA MALAT1 served as ceRNA of miR-125 in activation of IRF4 signaling.
Conclusion: MSC-derived EVs induce the formation of immune tolerance by increasing the proportion of $CD8^+CD28^-$ regulatory T cells. MSC-EVs improve the statement of glycometabolism to reduce apoptosis in $CD8^+CD28^-$ T cells, and promote phenotype conversion from DCs to tolDCs via up-regulating IRF4. LncRNA MALAT1 in MSC-EVs performed as ceRNA towards miR-125 so as to activate IRF4 signaling. This work provides a new strategy for inducing liver transplantation tolerance by MSC-EVs.

THU300

Extracellular vesicles derived from human umbilical cord mesenchymal stem cells alleviate hepatic ischemia-reperfusion injury by regulating neutrophils polarization and suppressing neutrophil extracellular traps formation

Tongyu Lu[1], Jia Yao[1], Xiaomei Zhang[1], Liang Chen[1], Jiebin Zhang[1], Jun Zheng[1], Jianye Cai[1], Yingcai Zhang[1], Yang Yang[1]. [1]*the Third Affiliated Hospital, Sun Yat-sen University, Hepatic Surgery and Liver Transplantation Center, Guangzhou, China*
Email: lutongyu@mail2.sysu.edu.cn

Background and Aims: As a result of organ retrieval, cold storage and warm ischemia during surgery, hepatic ischemia reperfusion injury (HIRI) is an important cause of functional failure after liver transplantation, which is one of the most challenging problems in the field of organ transplantation. Evidences demonstrate that neutrophils play a crucial role in the initiating response to sterile inflammation in HIRI. Extracellular vesicles (EVs) derived from mesenchymal stem cells (MSCs) attract widespread attention in liver pathology because they exert therapeutic effects on immunoregulation and tissue repair. However, the efficacy and underlying mechanisms of MSC-EVs based treatment in immunoregulation of neutrophils in HIRI remain unclear.
Method: Extracellular vesicles derived from human umbilical cord mesenchymal stem cell (huc-MSC-EVs) were isolated and characterized. In vivo, a murine model of 70% hepatic ischemia reperfusion injury was used to explore whether huc-MSC-EVs protected hepatic function via modulating neutrophils polarization and neutrophil extracellular traps (NETs) formation. In addition, mouse primary neutrophils were isolated from bone marrow of tibias and femurs by using density gradient centrifugation and co-cultured with huc-MSC-EVs in vitro.
Results: In vivo, we found that NETs form in the sinusoids of mouse ischemic liver lobes. Treatment with huc-MSC-EVs protected against IRI-induced hepatic apoptosis, associated with decreasing serum levels of ALT, AST, ALP and myeloperoxidase (MPO)-DNA complexes, less tissue level of citrullinated-histone H3, converse ratio of N1/N2 neutrophils subtypes, compared to control mice. In vitro, co-culture of mouse bone marrow-derived neutrophils with huc-MSC-EVs showed that neutrophils was induced into N2 phenotype and performed less NETs formation, in which decreasing levels of MPO-DNA complexes was detected. Meanwhile, we found that both the mRNA and protein levels of IRF4 in N2 phenotype neutrophils increased, and siRNA-mediated knockdown of IRF4 in bone marrow-

derived neutrophils increased N1/N2 ratio and promoted NETs formation. These implied huc-MSC-EVs might regulated immunocompetence of the neutrophils via IRF4 signaling pathway.
Conclusion: In summary, huc-MSC-EVs alleviate HIRI by inducing neutrophil N2 subtype differentiation and reduces NETs. These findings provide a new theoretical basis to promote MSC-EVs based treatment in liver transplantation application.

Inhibition of gamma-glutamyl transpeptidase ameliorates hepatic/reperfusion injury in rats with fatty liver
Ryuichi Kubota[1], Nobuhiko Hayashi[1], Mutsumi Tsuchishima[1], Mikihiro Tsutsumi[1], Joseph George[1]. [1]*Kanazawa Medical University, Hepatology, Uchinada, Ishikawa, Japan*
Email: georgej@kanazawa-med.ac.jp.

Background and Aims: Fatty liver or steatosis is a condition of excessive fat deposition in the liver with increased γ-glutamyl transpeptidase (γ-GT) levels. Ischemia/reperfusion (IR) injury is a pathological condition with several deleterious effects. We evaluated the protective effects of a specific inhibitor of γ-GT in experimentally induced IR injury in rats with steatosis.
Methods: The portal vein and hepatic artery of left lateral and median lobes were clamped to induce ischemia. Before clamping, 1 ml of saline (IR group) or 1 ml saline containing 1 mg/kg body weight of GGsTop (γ-GT inhibitor) (IR- GGsTop group) was injected into the liver from inferior vena cava. The blood flow was restored at 30 min after the start of ischemia. Blood was collected before and at 30 min after ischemia, and at 2 h and 6 h after reperfusion. All the animals were euthanized at 6 h and the livers were collected.
Results: Treatment with GGsTop resulted in significant reduction of serum ALT, AST, and γ-GT levels and hepatic γ-GT, malondialdehyde, TNF-α, and 4-hydroxynonenal content at 6 h after reperfusion. Inhibition of γ-GT produced marked elevation of serum and hepatic glutathione levels. There was prominent hepatic necrosis in IR group, which is significantly reduced IR-GGsTop group.
Conclusions: Inhibition of γ-GT with GGsTop significantly increased serum and hepatic glutathione levels, reduced hepatic MDA and 4-HNE levels, and remarkably ameliorated hepatic necrosis after reperfusion. The results indicated that GGsTop might serve as an appropriate therapeutic agent to reduce IR-induced liver injury and related events in obesity.

Influence of PML, RASSF6 and NLRP12 on growth and recurrence of human hepatocellular carcinoma
Natalie Vogel[1], Katja Piras-Straub[1], Maike Busch[2], Nicole Dünker[2], Heiner Wedemeyer[1], Kerstin Herzer[1]. [1]*Essen University Hospital, Gastroenterology and Hepatology, Essen, Germany;* [2]*Essen University Hospital, Anatomy II, Neuroanatomy, Essen, Germany*
Email: natalie.vogel@uk-essen.de.

Background and Aims: Human hepatocellular carcinoma (HCC) is the third leading cause of cancer-related deaths worldwide. Limited therapy options are coupled with bad prognosis and for HCC recurrence post-liver transplantation, there is no cure. PML, RASSF6 and NLRP12 are tumour suppressor proteins involved in cell signalling pathways associated with tumour development and recurrence and for which we could show that they are reduced in expression in tumour tissue in the human HCC. We hypothesize, that their reduced expression impacts tumour growth positively what is investigated using CRISPR/Cas9 knockout in hepatoma cell lines and a chick chorioallantoic membrane (CAM) model. The CAM model is a modern system allowing to investigate tumour growth without a mouse model.
Method: Using CRISPR/Cas9, we generated heterozygote cancer cell lines with a knockout in exon 1 in PML, RASSF6 and NLRP12. Hepatoma cell lines Huh7, Hep3B and HepG2 were transfected and genotyping was performed via PCR and 2% gel electrophoresis. As yet, the Boyden chamber assay was performed in Huh7 by silencing PML to test for the influence on migration potential. These cell lines were further applied in the chick chorioallantoic membrane (CAM) model. Cell lines with and without the knockout generated tumours in the CAM model that were harvested, weighted and measured for tumour growth analysis and comparison of size and weight. The RNA expression was measured via rtPCR.
Results: PML, RASSF6 and NLRP12 expression is reduced in the human tumour tissue as well as *in vivo* in a murine model and *in vitro* in hepatoma cell lines. The generation of heterozygous PML, RASSF6 or NLRP12 knockout cell lines shows reduced expression of the respective genes. So far, functional assays were performed for PML and revealed that reduced PML expression favours cell migration 1.6-fold. PML expression was reduced to 24% in the cell line HepG2, to 27% in the cell line Huh7 and to 43% in the cell line Hep3B. Further in the CAM model, PML shows significant increase in tumour growth ($P \leq 0.02$) after knockout in the cell line HepG2. The relative RNA expression of PML was decreased by up to 73% in the CAM-tumours. Further research is currently being performed on RASSF6 and NLRP12.
Conclusion: Our findings reveal a relevant influence of PML on HCC tumour growth. The effect of the knockout of RASSF6 and NLRP12 on tumour growth, cell proliferation, migration and apoptosis is being further analysed and will be presented.

Email: xavier.verhelst@uzgent.be.

Background and Aims: Graft loss during the first year after liver transplantation (LT) affects up to 15% of liver grafts, mainly in the first 3 months. Prediction of outcome early after LT is limited by the lack of robust clinical predictors. Early allograft dysfunction (EAD) is related to early graft loss but is not a strong predictor in individual patients. The goal of this work was to define a serum glycomic signature early after LT that is associated with graft loss at 3 months after LT.
Method: A prospective study in an experienced liver transplant center was performed between 1/1/2011 and 28 February 2017. Glycomic analysis using DSA-FACE was applied to serum samples on postoperative day 7. Using Lasso regression, an optimal serum glycomic signature was identified, associated with 3 months graft survival.
Results: A total of 117 patients were included. Graft loss at 3 months occurred in 14 patients (11.9%). The cohort was split in a training (82 without, 9 with graft loss) and a validation set (35 without, 5 with graft loss). The glycomic signature contains 13 glycans, using Lasso regression an optimal model was fitted yielding an AUC of respectively 0.95 and 0.94 in these sets for graft loss at 3 months ($p < 0.001$). Based on the Youden index an optimal cutoff of this biomarker was defined at 0.773. In the complete sample, this showed a sensitivity of 94% (95% CI: 0.891–0.981) and a specificity of 93% (95% CI 0.661–0.998). PPV and NPV were respectively 99.1% (95% CI 0.943–0.997) and 68% (95% CI : 0.491–0.989). Graft loss was associated with increased undergalactosylation (a marker of inflammation) and an increased presence of fucosylated and triantennary glycans, both signs of liver regeneration. According to this cut-off, multivariate logistic regression analysis showed a odds ratio of 70.211 (95% CI

10.876–453.231, p < 0.001) for graft loss at 3 months, independently of the development of early allograft dysfunction.

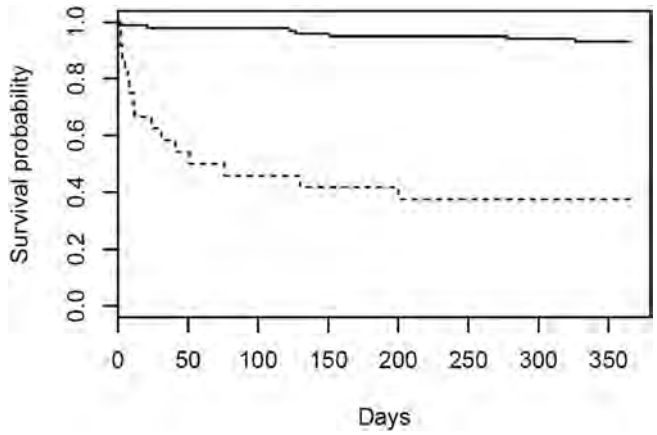

Figure: Full Line: glycomic marker >1.76, Dashed Line: < = 1.76

Conclusion: A serum glycomic signature obtained on postoperative day 7 a after LT is highly associated with graft loss at 3 months after LT. It could guide the clinician in the decision for early retransplantation and thus increase the quality of life and outcome of the patient. It can be applied on routine lab equipment.

THU305

YAP attenuates hepatic ischemia reperfusion injury by inducing autophagy through p38/ERK MAPK pathway

Shuguang Zhu[1], Qing Yang[1], Xuejiao Li[2], Xiaolong Chen[1], Long Xia[2], Hua Li[1]. [1]*The third affiliated Hospital of Sun Yat-sen University, Department of Hepatic Surgery, Liver Transplantation, Guangzhou, China;* [2]*The third affiliated hospital of Sun Yat-sen University, Guangdong Key Laboratory of Liver Disease Research, Guangzhou, China*
Email: lihua100@yeah.net.

Background and Aims: Hepatic ischemia-reperfusion injury (IRI) remains a common complication during liver transplantation (LT), partial hepatectomy and hemorrhagic shock in patients. As a key downstream effector of the Hippo pathway, yes-associated protein (Yap) has been reported to be involved in varieties physiological and pathological processes. However, it remains to elusive whether and how Yap may control autophagy activation during IRI.
Method: Human liver tissues from patients undergone LT and control individuals were obtained to evaluate the correlation between Yap and autophagy specific protein LC3. Liver specific Yap knockout ($Yap^{+/-}$) mice and wild type littermates were used to establish IRI model to determine the exact role of Yap in controlling activation of autophagy. In addition, the underlying mechanism of Yap regulating autophagy were further explored.
Results: Yap positively correlates the autophagic level of hepatocytes in patients and autophagy protect against ischemia-reperfusion injury in mice. Knockdown of Yap inhibits hepatocytes autophagy and aggravates ischemic injury through promoting apoptosis both in vitro and in vivo. In addition, Yap deficiency exacerbates mitochondrial damage by increasing ROS production and promotes inflammatory response with more secretion of pro-inflammatory cytokines. Moreover, the regulation of autophagy by Yap during ischemia-reperfusion injury might mediated by p38/ERK MAPK signalling.
Conclusion: We first showed that Yap protects against hepatic ischemia-reperfusion injury by inducing autophagy that suppress the apoptosis of hepatocytes, which enhance the understanding of the roles of Yap during ischemia-reperfusion injury.

THU306

Extracellular vesicles derived from human umbilical cord mesenchymal stem cell protect liver ischemia/reperfusion injury by reducing CD154 expression on CD4+ T cells via CCT2.

Xiaomei Zhang[1], Yingcai Zhang[2], Jia Yao[2], Jianye Cai[2], Tongyu Lu[2], Jun Zheng[2], Jiebin Zhang[2], Wei Liu[1], Liang Chen[1]. [1]*The Third Affiliated Hospital of Sun Yat-sen University, Guangdong Key Laboratory of Liver Disease Research, Guangzhou, China;* [2]*The Third Affiliated Hospital of Sun Yat-sen University, Department of hepatic surgery, Guangzhou, China*
Email: zhengj67@mail2.sysu.edu.cn.

Background and Aims: Liver ischemia/reperfusion injury (IRI) is widely recognized as a major cause of postoperative complications and early hepatic failure after liver transplantation (LT). Intrahepatic CD4+ T cells activation is known to stimulate inflammatory response and hence could aggravate liver IRI progression. We previously showed the therapeutic potential of both mesenchymal stem cells (MSCs) and their extracellular vesicles (EVs) in inflammation-related diseases. The aim of this study is to investigate whether the umbilical cord derived MSC-EVs (UC-MSC-EVs) could modulate CD154 expression on the intrahepatic CD4+ T cells, which consequently alleviate liver IRI, and explore its potential mechanisms.
Method: UC-MSC-EVs were administrated immediately through peripheral vein after the administration of mouse liver IRI model, and the mice were sacrificed at early period (6 h) after reperfusion. Serological liver enzymes, pro-inflammatory cytokines in serum and liver tissue, histological changes, hepatic apoptosis and the membranous expression of CD154 on the intrahepatic CD4+ T cells were examined. Moreover, the molecular mechanism of UC-MSC-EVs and the target signaling pathway were further explored in vivo and in vitro.
Results: the expression of CD154 on the intrahepatic CD4+ T cells was significantly elevated in the liver IRI model compared with the normal group, accompanied with the increasing levels of serological liver enzymes, pro-inflammatory cytokines and hepatic injury score. Furthermore, we found that UC-MSC-EVs could suppress CD154 synthesis and expression in CD4+ T cells by targeting Ca2+/calcineurin/NFAT1 signaling pathway. Mechanistically, we identified Chaperonin Containing TCP1 subunit 2 (CCT2) as a mediator of UC-MSC-EVs affecting Ca2+ influx and subsequently suppressing CD154 expression in CD4+ T cells. Consistently, the hepatoprotective and immunoregulative effects of UC-MSC-EVs was partially weakened when CCT2 was depleted in UC-MSCs.
Conclusion: This study highlighted the therapeutic potential of UC-MSC-EVs in attenuating liver IRI. Our finding is the first to show that UC-MSC-EVs could deliver CCT2 to the intrahepatic CD4+ T cells and modulate their CD154 expression via Ca2+/calcineurin/NFAT1 signaling pathway.

Decreased level of KEAP1 and activation of NRF2 contribute to sorafenib resistant in hepatocellular carcinoma

Shi Jiang[1], Jiang Chen[2], Di Wu[1], Zhongjie Lin[1], Junjie Xu[3], Yu Pan[1], Lin Ji[1], Zhe Wan[1], Xiujun Cai[2]. [1]*Zhejiang University, Medicine, Hangzhou, China;* [2]*Sir Run Run Shaw Hospital, General Surgury, Hangzhou, China;* [3]*Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Department of General Surgery, Hangzhou, China*
Email: srrsh_cxj@zju.edu.cn.

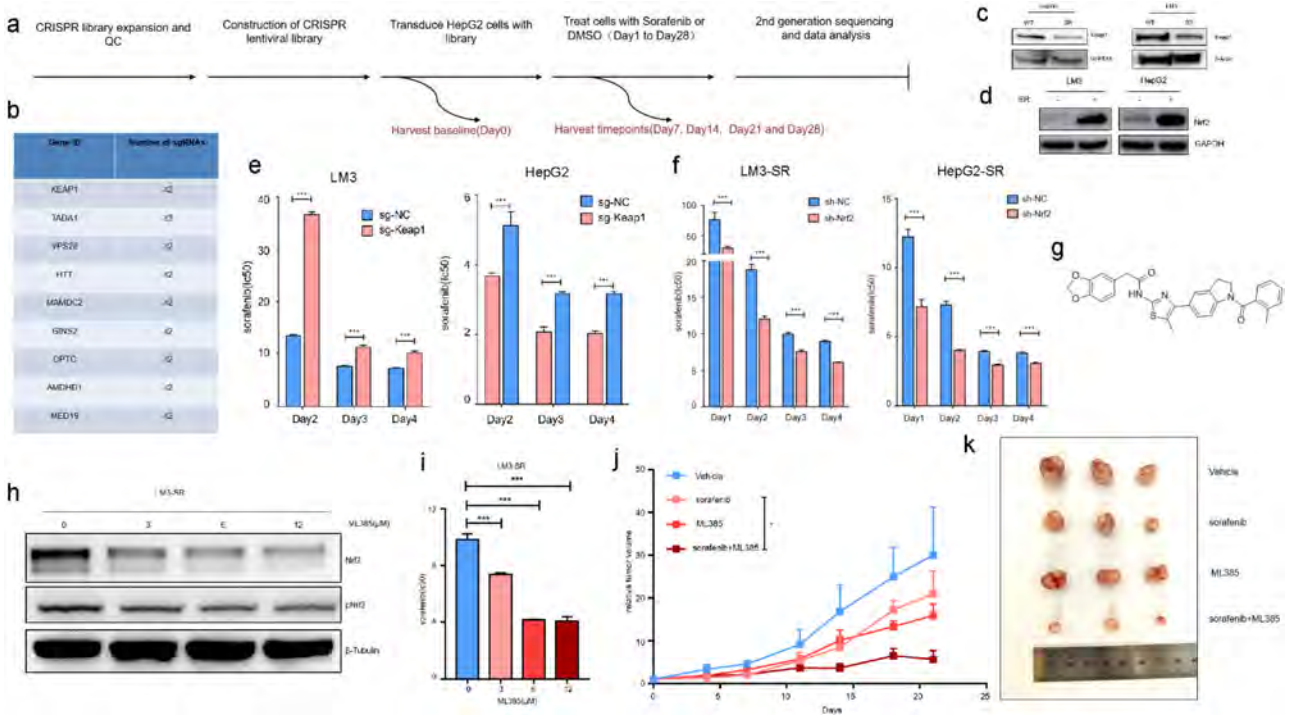

Figure: (abstract: THU307): a. Flowchart of Sorafenib resistance screening; b. Sample list of top ranked genes. c. The protein level of KEAP1 between wild-type HCC cells and sorafenib-resistant HCC cells. WT: Wild Type; SR: Sorafenib Resistant. d. The protein level of Nrf2 between wild-type HCC cells and sorafenib-resistant HCC cells. e. The IC50 of sorafenib in HCC cells after knocking out KEAP1. f. The IC50 of sorafenib in sorafenib-resistant HCC cells after knocking out Nrf2. g. The chemical structure of the Nrf2-specific inhibitor, ML385. h. The protein level of Nrf2 treated by ML385 at different dose in sorafenib-resistant LM3. i. The IC50 of sorafenib in sorafenib-resistant LM3 after treated by ML385 at different dose. j&k. The in vivo combination treatment of ML385 and sorafenib.

Background and Aims: Hepatocellular carcinoma (HCC) in one of the most common malignancies in the world, with multiple resistance and poor prognosis. Sorafenib was the first-time treatment for advanced HCC, but the drug resistance made its efficacy restricted By now, the molecular mechanism of Sorafenib resistance is lack of well understanding.

Method: In this study, by using CRISPR/Cas9 genome library screening, Kelch-like ECH- associated protein-1(KAEP1) was discovered that the decreased Level of KEAP1 contributed to Sorafenib resistance in HCC. And then we exam the function of KEAP1 and its downstream molecule Nrf2 in HCC cell lines.

Results: KEAP1 regulates multiple signaling pathways by ubiquitinating substrate proteins, including nuclear factor erythroid 2-related factor 2 (Nrf2), which are associated with drug resistance of tumor, but the key mechanism of KEAP1 inhibits Sorafenib resistance is unclear. We validate that KEAP1, as an oxidative stress sensor, mediates degradation of Nrf2, thereby conferring sensitivity to Sorafenib; conversely, loss of function of KEAP1, thereby alleviate degradation of Nrf2 and conferring sorafenib resistance. ML385, a Nrf2-specific inhibitor, may increase the sensitivity of Sorafenib in HCC. We examined the combination effect between Sorafenib and ML385 both in vivo and in vitro. We find that ML385 can increase the sensitivity of Sorafenib in sorafenib-resistant cell both in vivo and in vitro.

Conclusion: These studies therefore demonstrate that KEAP1 regulates sensitivity to sorafenib by modulating Nrf2 expression.

THU308

Unravelling the molecular determinants of metabolic syndrome thanks to NMR-metabolomics of urine and serum samples

Chiara Bruzzone[1], Rubén Gil-Redondo[1], Laura delaCruz-Villar[1], Arantza Sanz-Parra[1], Dolores Corella[2,3], Nieves Embade[1], José M. Mato[1], Oscar Millet[1]. *[1]CIC bioGUNE - Centro de Inv. Cooperativa en Biociencias, Derio, Spain; [2]Department of Preventive Medicine, University of Valencia, Valencia, Spain; [3]CIBER Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Instituto de Salud Carlos III, Madrid, Spain*

Email: cbruzzone@cicbiogune.es.

Background and Aims: The metabolic syndrome (MetS) can be described as a cluster of metabolic alterations that leads to an increased risk of developing cardiovascular disease, coronary heart disease, stroke and vascular dysfunction. Taking into consideration the definition of the World Health Organization (WHO), MetS is defined as the presence of insulin resistance and other two of the following conditions: obesity (waist circumference or BMI >30 kg/m^2), hyperlipidaemia, hypertension or microalbuminuria. The role of each of the individual factors in the development of the complex syndrome, the effect of alternative molecular definitions of MetS and of the neglected symptomatology (i.e. non-alcoholic steatohepatitis) are not yet clearly understood. MetS has now gained significant importance due to the increasing number of people affected by this pathology. For this reason, the identification of new diagnostic tools and the determination of new biomarkers for the early diagnosis and prognosis of this disorder is now essential.

Method: Metabolomic phenotypes of matched urine and serum samples from over 10,000 adults recruited from a working population in the Basque Country and from a specific project enriched in MetS patients were measured using nuclear magnetic resonance (NMR).

The combined cohort populates all the intermediate stages of the metabolic syndrome with a significant number of individuals.
Results: According to sample metadata, volunteers were classified into the 16 profiles that define the continuous symptomatic transition from the absence of all the risk factors (asymptomatic patients) up to all the subtypes that canonically define the MetS condition. The analysis of the different metabolomic spectra profiles showed clear differences between the different subtypes emphasizing the significant weight of diabetes in the MetS definition. Considering the results of the untargeted analysis, a group of MetS biomarkers were also identified.
Conclusion: Urine alone is able to discriminate patients undergoing metabolic syndrome from healthy individuals. The responsible metabolites for the discrimination agree well with the metabolic pathways often altered in this syndrome. Remarkably, pairwise analysis and statistical distance determination between two given profiles quantifies the contribution of each symptom to the metabolic syndrome. In this context, our metabolic definition of metabolic syndrome best agrees with the one proposed by the WHO.

THU309
The hedgehog effect: mediating crosstalk between liver and adipose tissue

Fritzi Ott[1], Kim Werner[1], Martin Gericke[2], Rolf Gebhardt[1], Madlen Matz-Soja[1]. *[1]Rudolf-Schönheimer-Institute of Biochemistry, Faculty of Medicine, Leipzig, Germany; [2]Institute of Anatomy and Cell Biology, Medical Faculty of MLU, Halle (Saale), Germany*
Email: fritzi.ott@medizin.uni-leipzig.de.

Background and Aims: As our body and organs form during embryogenesis, different morphogenic pathways influence these processes, one of which is the Hedgehog (Hh) signaling pathway. Despite its crucial role in development, Hh was thought to be inactive in adult organisms for many years, but recently a number of functions in tumorigenesis, organ homeostasis and control of metabolism have been discovered.
In the liver, Hh is highly involved in lipid metabolism and circadian rhythm. Inactivation in hepatocytes causes a severe hepatic phenotype including steatosis, but also influences other organs such as reproductive organs and adipose tissue (AT). Although crosstalk between the liver and AT is known, the role of Hh in this inter-organ communication remains to be elucidated, which is the aim of this study.
Method: Primary hepatocytes and AT – brown (BAT), subcutaneous (SAT), visceral (VAT) – were isolated from mice with hepatocyte-specific inactivation of Hh. The influence of this inactivation was investigated using molecular biological methods such as qPCR. Immunohistochemical markers for BAT were used to conduct immunohistochemistry on AT sections.
Results: Mice with an inactivation of Hh in hepatocytes show a distinct phenotype in liver as well as AT. All types of AT are increased in weight. qPCR analyses show changes in mRNA expression of brown and beige adipocyte markers as well as lipogenesis. An increase of Uncoupled protein-1 (UCP-1)-mRNA in white AT indicates a browning effect. This is supported immunohistochemical stainings revealing stronger innervation as well as clusters of brown hepatocytes emerging in white AT, predominately in VAT.
Conclusion: The morphologic and biochemical changes in mouse AT show the wide influence that hepatic Hh exerts not only in the liver, but also other organs. Browning events occurring in response to inactivation of hepatic Hh could be shown. Although the mechanism that mediates the effects in AT is still under investigation, the results so far show the intriguing role that Hh plays in the liver-AT crosstalk.

THU310
MicroRNA-26b-5p sensitizes hepatocellular carcinoma CD133+ cancer stem cells to cisplatin through downregulation of Jag1-Hes1 and increased BBC3-mediated apoptosis

Hamed Hemati[1,2], Jagdeep Kaur[2], Rc Sobti[2], Nirupma Trehanpati[1]. *[1]Institute of Live and Biliary Sciences, Department of Molecular and Cellular Medicine, New Delhi, India; [2]Panjab University, Department of Biotechnology, Chandigarh, India*
Email: trehanpati@gmail.com.

Background and Aims: CD133$^+$ cancer stem cells in hepatocellular carcinoma (HCC) are the hallmark of poor prognosis and resistance to chemotherapy. It has been shown that miR-26b-5p regulates HCC EpCAM$^+$ cancer stem cells. We aimed to assess the effect of miR-26b-5p-mediated inhibition of NOTCH signalling on the chemosensitivity of CD133$^+$ cells to cisplatin.

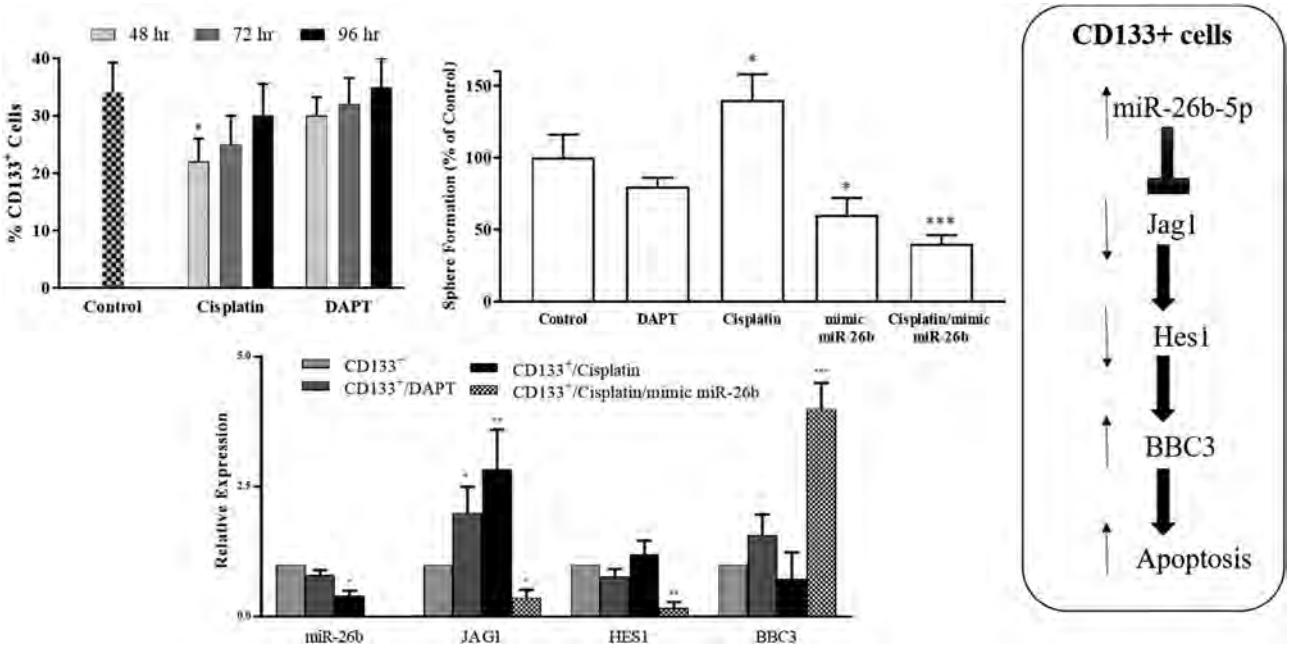

Figure: (abstract: THU310)

Method: Huh7 cells were treated with IC_{50} dose (18 μM) of cisplatin for 48 hr. The $CD133^+$ cells were isolated from untreated and treated cells. Bioinformatics predicted miR-26b-5p targeting JAG1. The expression of miR-26b-5p was assessed using qRT-PCR. $CD133^+$ cells were transfected with mimic and inhibitor of miR-26b-5p, and NOTCH inhibitor γ-secretase DAPT. The cells were analysed for apoptosis by flow cytometry and gene expression of stemness and NOTCH pathway by qRT-PCR. The cell viability and proliferation were analysed by MTT and migration assays. Spheroid formation and self-renewal capacities were assessed in the 3D methylcellulose suspension culture system.
Results: IC_{50} dose of cisplatin decreased $CD133^+$ cells from 35% to 22% ($p < 0.05$). However, cisplatin-resistant $CD133^+$ cells showed upregulation in JAG1, NOTCH1, NOTHC2, NOTCH3, NOTCH4, HES1, and stemness genes SOX2, OC4, and NANOG while significant downregulation in miR-26b-5p compared to untreated and DAPT-treated $CD133^+$ cells. Cisplatin-resistant $CD133^+$ cells formed 30% ($p < 0.05$) more spheroids in 3D culture and had a higher migration capacity than DAPT-treated and untreated $CD133^+$ cells. Mimic miR-26b-5p transfected to cisplatin-treated $CD133^+$ cells led to a significant decrease in cell growth by 45.2% ($p < 0.05$) and enhance apoptosis by 3-fold with 4-fold increased expression of pro-apoptotic BBC3. Cisplatin-treated $CD133^+$ cells transfected with mimic miR-26b-5p formed 39.2% ($p < 0.05$) fewer spheroids and showed decreased expression of JAG1 and HES1 than non-transfected cells.
Conclusion: The upregulation of BBC3 in transfected $CD133^+$ cells was correlated with enhancing the apoptosis rate. MiR-26b-5p-mediated JAG1 downregulation led to a decrease in the expression of HES1. HES1 was reported to negatively regulate BBC3. MiR-26b-5p enhanced sensitivity to cisplatin via enhancing BBC3-mediated apoptosis through downregulation of the JAG1-HES1 axis.

THU311
TMBIM6 regulates ageing and high-fat diet-induced lipid accumulation

Mohammad Fazlul Kabir[1], Hwa Young Lee[1], Hyung-Ryong Kim[2], Han-Jung Chae[3]. *[1]Jeonbuk National University Medical School, Medical Science (Pharmacology), Jeonju-si, Korea, Rep. of South; [2]Dankook University, Institute of Tissue Regeneration Engineering, Cheonan, Korea, Rep. of South; [3]Jeonbuk National University, Medical Science (Pharmacology), Jeonju-si, Korea, Rep. of South*
Email: hjchae@jbnu.ac.kr.

Background and Aims: TMBIM6 is an antiapoptotic protein known to suppress the cell death by regulating ER stress. TMBIM6 contain six transmembrane regions and localize to the ER membranes. TMBIM6 cyto-protective functions conserved in plants and mammals. Our main target to study TMBIM6 effect in high fat diet model and also aging associated fatty liver in normal diet condition. We observed ApoB a lipid transfer protein highly accumulated liver of high fat died (HFD) TMBIM6 KO (knock out) mice after 8 weeks compared to WT (wild type) mice. In addition, we also observed TMBIM6 KO mice aged mice gained body and liver weight and high hepatic triglyceride level when compared with its WT counterparts.
Method: For high fat diet study we categorized TMBIM6 WT and KO mice for HFD model in each group 6 animals. In addition, we also categorized WT and TMBIM6 KO mice into young, middle and old groups, and observed the effect on hepatic lipid accumulation in normal food diet condition. Several Biochemical analysis of the lipid profile, western blotting for the protein expression oxidative stress for the histopathological analysis was performed.
Results: Our result explored that excessive post translational oxidation of protein disulfide isomerase (PDI) intra-ER ROS accumulation and folding capacitance alteration were also observed in HFD-TMBIM6 KO mice, in line the increase in lipid peroxidation level and ROS-induced oxidative stress was observed in TMBIM6 KO aged liver. Loss of TMBIM6 induced excessive ER-mitochondria interactions and high molecular weight complexes of PDI during the aging process. The canonical UPR arms proteins were aberrantly expressed where we observed that the expression of ER chaperone proteins like GRP78 and PDI; ATF6, p-PERK, and p-eIF2 were down regulated and IRE1-mediated JNK signalling was activated in TMBIM6 KO aged liver. In addition to TUNEL positive cells, caspase 7 and 12 were highly activated in TMBIM6 KO mice from the middle to advanced age, suggesting the protective effect of TMBIM6 on aging-induced apoptosis.

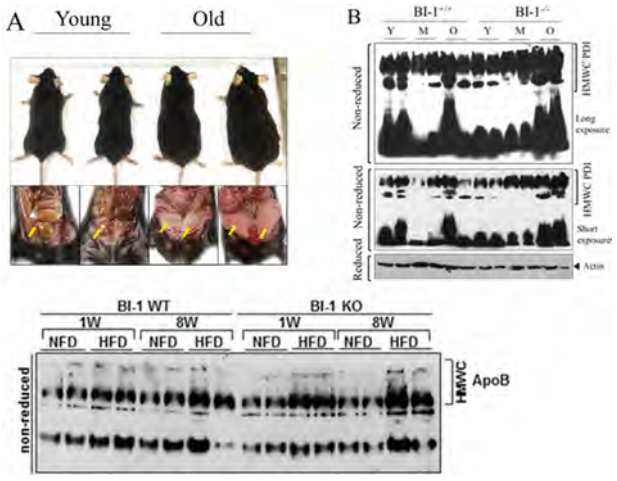

Figure: TMBIM6 regulated hepatic, ApoB secretion and formation of In HFD model. A High fat acculation and Disulfide bonds during oxidative stress aging process.

Conclusion: Our results suggest that TMBIM6 mediated enhancement of ApoB secretion regulates hepatic lipid accumulation in high fat diet condition, likely through regulation of ER stress and ROS accumulation, and also aging-induced fatty liver is regulated by TMBIM6 through the regulation of ER stress and proteostasis.

THU312
Decreased expressions of p70S6 K in NK cells of F4-NAFLD patients inhibited F-actin and was correlated with their impaired function

Johnny Amer[1], Ahmed Salhab[1], Rifaat Safadi[1]. *[1]Hadassah University Hospital - Ein Kerem, Liver Unit, Jerusalem, Israel*
Email: johnnyamer@hotmail.com.

Background and Aims: Co-localization of p70S6 K and stress fibers was suggested to regulate actin polymerization as rapamycin treatment could inhibit the elongation and organization of actin stress fibers via inhibition of p70S6 K. We investigated effects of insulin resistance on mTOR signaling pathway of NK cells as a potential cause for their impairment in Nonalcoholic-Fatty Liver-Disease (NAFLD).
Method: Fresh peripheral blood NK cells isolated from healthy volunteers and 72 NAFLD patients (histology documented adults lacking full criteria of metabolic-syndrome), and characterized by flow-cytometry.
Results: Histologic progression of liver injury significantly correlated with elevated pro-inflammatory serum cytokines and insulin resistance. Western blot analysis of NK cells form NAFLD patients with F4 fibrosis showed to have dramatically reduction in PI3 K pathway. ERK/MAP kinase pathway showed also reductions in these patients. Notably, these results were correlated with inhibitions in mTOR, p70S6 K and F-actin phosphorylation ($p = 0.001$). NK stimulations with insulin (physiologic levels) reversed these effects. Compared to normal HOMA NK-cells by *in-vitro* co-culture with HSCs, high-HOMA $CD56^{dim}$ cells (with F3-F4) exhibited increased apoptosis and fail to block HSCs activation. While insulin incubation stimulated NK cell activation and killing of HSCs. Rapamycin reduced $CD56^{dim}$ expressions of insulin receptors (mimicking NAFLD insulin resistance) and prevented the insulin stimulation effect on NK cells.

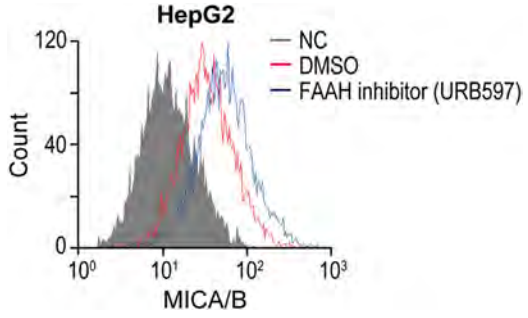
Conclusion: Systemic Insulin-Resistance in NAFLD also includes the NK cells with reduced expressions of p70S6 K and F-actin and therefore impairment in their function, which leads to cirrhosis and probably cancer.

THU313

A fatty acid amide hydrolase inhibitor, URB597, inhibits MICA and MICB shedding

Kazuma Sekiba[1], Motoyuki Otsuka[1], Kazuhiko Koike[1]. [1]*The University of Tokyo, Department of Gastroenterology, Graduate School of Medicine, Tokyo, Japan*
Email: ksekiba-tky@umin.ac.jp.

Background and Aims: MHC class I polypeptide-related sequence A (MICA) and MICB are ligands for natural killer group 2, member D (NKG2D) on natural killer cells and T cells, playing an essential role in immunosurveillance system which prevents the tumor initiation. We previously identified that MICA is an HCC-susceptible gene by genome-wide association study. However, proteolytic cleavage of MICA/B protein releases soluble MICA/B, which works as a decoy for NKG2D, leading to the evasion of tumor cells from immune system. Thus, prevention of MICA/B shedding is crucial for the immune surveillance-mediated prevention of HCC. Here, we report screening results identifying a protease inhibitor, which inhibits MICA/B shedding.
Method: Cell surface MICA/B levels were determined by flow cytometry. Protease inhibitor library was used for identifying the regulators for MICA/B shedding. Nano-luciferase reporter-tagged MICA was used to estimate the soluble MICA levels. *In vitro* cleavage assay and transcriptome analyses were done using recombinant MICA protein and cDNA arrays, respectively. Lentiviral vectors were used to establish cells stably expressing FLAG-tagged fatty acid amide hydrolase (FAAH) and those expressing TIMP3 specific short hairpin RNA.



Results: Out of 53 kinds of proteinase inhibitors, MMP inhibitor increased MICA/B levels on the surfaces of HepG2 and Hep3B cells, consistent with previous reports. Further, it was newly found that cell surface MICA/B proteins levels were significantly increased after the treatment of URB597, an FAAH inhibitor. In contrast, levels of soluble MICA were suppressed by URB597. Because MICA/B mRNA levels were not increased by URB597, it was suggested that URB597 prevented the shedding of MICA/B from the cells and increased its levels on the cell surface. Because URB597 did not have direct effects on MICA/B cleavage in an *in vitro* cleavage assay, the effects seemed indirect. Genome-wide cDNA array suggested that TIMP3 gene expression may be involved in the prevention of MICA/B shedding. Indeed, knockdown of TIMP3 led to promotion of MICA/B shedding without affecting the transcriptional activity of MICA/B. Further, overexpression of FLAG-tagged FAAH resulted in suppression of TIMP3 expression and the promotion of MICA/B shedding.
Conclusion: An FAAH inhibitor, URB597, prevents the shedding of MICA/B proteins through the activation of TIMP3. Because preventing MICA/B shedding from HCC cells theoretically leads to excluding those cells by immune system, treatment of FAAH inhibitor may have preventive effects against HCC. Because FAAH inhibitor is already in clinical trials for the therapeutics of other diseases, further analyses may warrant its use by a drug repositioning for the prevention of HCC.

Email: ksukorea@yuhs.ac.

Background and Aims: Hepatic fibrosis results in cirrhosis, liver failure, and portal hypertension and often requires liver transplantation. Transforming growth factor-beta (TGF-b) signaling plays a pivotal role in liver fibrosis by activating hepatic stellate cells and inducing hepatic cell death. Bone morphogenetic protein (BMP)-7, a member of the TGF-beta superfamily, is an endogenous antagonist of TGF-β. In this study, we examined whether trans-activator of transcription (TAT)-fusion BMP-7 polypeptide, the prodrug of BMP-7, suppresses TGF-beta signaling and its fibrogenic function in a murine model of liver fibrosis.
Method: A model of liver fibrosis was developed by repeated intraperitoneal injection of hepatotoxic carbon tetrachloride (CCl4) twice per week for up to 12 weeks. To investigate the therapeutic effect of BMP7 prodrug on hepatic fibrosis, mice received the drug at a dose of 0 μg/kg (n = 10; control), 50 μg/kg (low-dose group, n = 8), and 500 μg/kg (high-dose group, n = 10). Liver tissues were snap-frozen in liquid nitrogen or fixed in 4% buffered paraformaldehyde for immunostaining.
Results: The aspartate and alanine aminotransferase levels were significantly decreased in the BMP7 prodrug-treated groups compared to those in the control group (all $P < 0.05$). Hepatocyte apoptosis was significantly decreased in the prodrug-treated groups. Fibrous septa surrounding liver parenchyma and marked bridging portal-to-portal with occasional nodules were clearly seen in the control, while the treated groups showed only fibrous expansion of some portal areas with or without short fibrous septa. According to the Batts scoring system, the fibrotic burden in TAT-BMP7-treated mice was significantly reduced compared to that of control mice (all $P < 0.05$). In the treated groups, the mRNA levels of collagen 1A1, smooth muscle α-actin, and connective tissue growth factor (CTGF) were significantly reduced compared to those in the control group (all $P < 0.05$).
Conclusion: Our data demonstrate that TAT-BMP7, a prodrug of BMP7, can reduce hepatic fibrosis by suppressing TGF-beta signaling.

THU315

Dickkopf-1 enhances tumourigenic potential by inducing liver angiogenesis

Seung Up Kim[1,2,3], Kyung Joo Cho[1,4], Sang Hyun Seo[1], Hye Jung Park[1], Jae Seung Lee[1,3], Hye Won Lee[2,3], Beom Kyung Kim[1,2,3], Jun Yong Park[1,2,3,4], Do Young Kim[1,2,3], Sang Hoon Ahn[1,2,3], Kwang-Hyub Han[2,3]. [1]*Severance Hospital, Yonsei Liver Center, Seoul, Korea, Rep. of South;* [2]*Yonsei University College of Medicine, Institute of Gastroenterology, Seoul, Korea, Rep. of South;* [3]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South;* [4]*Yonsei University, Brain Korea 21 PLUS Project for Medical Science College of Medicine, Seoul, Korea, Rep. of South*
Email: ksukorea@yuhs.ac.

Background and Aims: Dickkopf-1 (DKK-1) is an antagonist of Wnt signalling. Several reports have shown that DKK1 is overexpressed in hepatocellular carcinoma (HCC) tissue and that a high serum DKK1 level is an unfavourable prognostic factor in patients with HCC. Here, we explored the role played by DKK-1 in hepatocarcinogenesis using HCC cell lines and xenograft mouse models. We used the clustered regularly interspaced short palindromic repeats (CRISPR)-associated endonuclease Cas9 system to modulate DKK-1 expression.
Method: Cell lines Huh7 and Hep3B, which express DKK-1 at low and high levels, respectively, were used. The CRISPR/Cas9 system was employed to create a Tet-on Huh7 cell line (in which DKK-1 expression was tetracycline-inducible) and a DKK-1 knockout line (KO Hep3B). The angiogenic potential of human umbilical vein endothelial cells (HUVECs) was investigated using the tube formation assay. In addition, the effects of DKK-1 knockdown on tumour growth and angiogenesis were explored in subcutaneous Hep3B- and DKK1-KO Hep3B-tumour xenograft mouse models.
Results: The angiogenic potential of HUVECs significantly increased after treatment with human recombinant DKK-1. The expression level of proteins (as measured by ELISA) secreted from Tet-on Huh7 cells was higher than that secreted from the corresponding control cells, while the expression level of proteins secreted from KO Hep3B cells was lower than that secreted from the corresponding control cells. When HUVECs were treated with Tet-on/off Huh7- and KO Hep3B-conditioned media in an indirect two-dimensional co-culture system, Tet-on Huh7 medium increased the angiogenic potential of HUVECs, whereas Tet-off Huh7 and KO Hep3B media did not. At 6 weeks after xenograft, DKK1-KO Hep3B implantation-induced tumours in mice were smaller than Hep3B implantation-induced tumours in control mice. Although tumour volume did not differ significantly between groups, the tumour weight was lower in the DKK1-KO Hep3B group than in the Hep3B group. Additionally, the level of DKK-1 protein (pDKK-1) secreted in DKK1-KO mice was less than that secreted in control mice, as confirmed by ELISA.
Conclusion: DKK-1 may enhance tumourigenesis by inducing angiogenesis; DKK-1 may serve as a potential therapeutic target.

THU316
The FXR agonist obeticholic acid decreases matrix metalloproteinase activity via RECK and TIMP modulation in hepatic ischemia/reperfusion injury

Laura Giuseppina Di Pasqua[1], Giuseppina Palladini[1,2], Clarissa Berardo[1], Veronica Siciliano[1], Marta Cagna[1], Luciano Adorini[3], Plinio Richelmi[1], Andrea Ferrigno[1], Mariapia Vairetti[1]. [1]*University of Pavia, Dept. of Internal Medicine and Therapeutics, Pavia, Italy;* [2]*Fondazione IRCCS Policlinico San Matteo, Pavia, Italy;* [3]*Intercept Pharmaceuticals, San Diego, United States*
Email: lauragiuseppin.dipasqua01@universitadipavia.it.

Background and Aims: We have recently shown a reduction in the activity of matrix metalloproteinases (MMPs) by the farnesoid X receptor (FXR) agonist obeticholic acid (OCA) in liver submitted to ischemia/reperfusion (I/R). Inducible NOS (iNOS) is known to regulate the MMP activity in I/R injury and we have previously documented the ability of OCA to decrease iNOS content in I/R-treated rats. The reversion-inducing-cysteine-rich protein with kazal motifs (RECK), an MMP modulator, was found to be a novel transcriptional target of FXR. In this study, we evaluated the effects of OCA on RECK and tissue inhibitors of metalloproteinases (TIMPs) content, MMP activity and iNOS expression in liver after I/R.
Method: Male Wistar rats (n = 20) were orally administered 10 mg/kg/day of OCA (Intercept Pharmaceuticals) for 5 days or vehicle and subjected to a 60-min partial hepatic ischemia or sham-operated. After a 60-min reperfusion, tissue samples were collected for RECK,

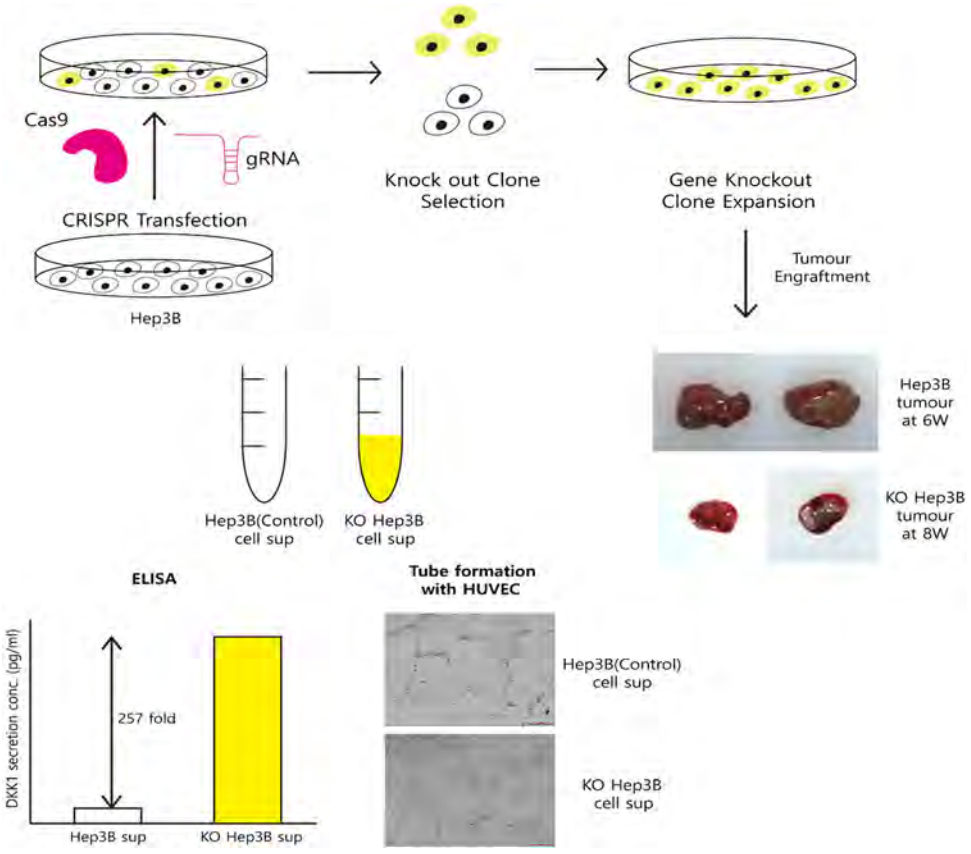

Figure: (abstract: THU315)

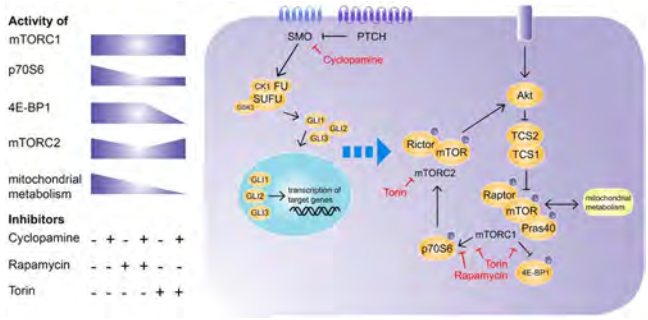
TIMP-1, TIMP-2 and iNOS expression by Western blot analysis and MMP-2 and MMP-9 analysis by zymography. Serum levels of AST and ALT as well as total and direct bilirubin were also quantified.
Results: I/R induced a decrease in liver RECK and TIMPs expression. These changes were concomitant with an increase in MMP-2 and MMP-9 activity. OCA administration increased RECK, TIMP-1 and TIMP-2 and reduced MMP-2 and MMP-9 activity in the liver. An inverse correlation between RECK versus MMP-2 and MMP-9 was found. A positive correlation between MMP-2 and MMP-9 versus iNOS was observed. Furthermore, an inverse correlation between MMP-2 and MMP-9 versus TIMPs was found. Although not significantly, OCA administration reduced hepatic serum enzyme levels in the I/R group, and a significantly lower level of direct bilirubin was detected in the I/R group treated with OCA compared to vehicle-treated I/R rats.
Conclusion: Our results demonstrate the ability of OCA to limit the hepatic activation of MMP-2 and MMP-9 that occurs during liver I/R damage, probably via timely recovery of RECK and TIMPs protein levels. This is supported by an inverse correlation between MMP activity versus RECK and a positive correlation between MMP activity versus iNOS. While further studies will clarify the sequence of alterations and cause-effect patterns, these results suggest that changes in RECK protein may have therapeutic potential in MMP modulation during hepatic I/R damage.

THU317
Cross-linking of liver metabolism - hedgehog as a key regulator of energy metabolism, regulating mechanistic target of rapamycin activity

Luise Spormann[1], Rolf Gebhardt[1], Madlen Matz-Soja[1]. [1]*Rudolf-Schönheimer-Institute for Biochemistry, Faculty of Medicine, Leipzig, Germany*
Email: Luise.Spormann@medizin.uni-leipzig.de.

Background and Aims: The Hedgehog (Hh) pathway plays a crucial part in the maintenance of the homeostasis and the regeneration of hepatic tissue. As a consequence, abnormal Hh signalling contributes to various diseases like steatosis and cancer. Both are closely related to alterations in the energy metabolism of the liver. The direct impact of the Hh pathway on these changes is still unclear. The aim of this study was to examine molecular interactions of Hh signaling and another important morphogenetic pathway called the mechanistic target of rapamycin (mTor), which is a main regulator of energy metabolism.
Method: Primary hepatocytes from a hepatocyte specific knockout mouse model with repressed Hh signaling were used to examine the interactions of the Hh and the mTor pathway in liver metabolism. To analyze the interaction of both pathways in detail, in vitro studies with non-transgenic mice were performed using the Hh inhibitor cyclopamine, the mechanistic target of rapamycin complex 1/2 (mTorC1/C2) inhibitor torin, the mTorC1 inhibitor rapamycin and the combinations thereof. The cells were analyzed using Proteome analyses, immunohistochemistry, Western Blotting, flow cytometry, qPCR and Seahorse technology.
Results: Primary hepatocytes from mice with repressed Hh Signaling exhibit an altered energy metabolism with decreased mTor activity and reduced production of adenosine triphosphate. Moreover, the treatment of cells from non - transgenic mice with diverse mTor and Hh inhibitors revealed a close interaction of both pathways. The inhibition of Hh and mTorC1 showed a synergistic effect on the repression of mTorC1 downstream and mTorC2 activity. In addition, our Seahorse analysis demonstrates the same impact of both inhibitors on the functionality of the electron transport chain. However, the combination of Hh and mTorC1 and C2 inhibitors has no additional effect on mTor signaling or energy metabolism.



Conclusion: Our results propose a possible interaction of the Hh pathway with the mTorC2 complex. We hypothesize that Hh signaling may influence the energy metabolism and other cellular responses through the modulation of mTor signaling, building an interacting network of liver metabolism. This opens up new insights into the use of Hh and mTor inhibitors as part of therapeutic intervention in cancerous diseases like the Hepatocellular carcinoma (HCC).

THU318
Functional consequences of metabolic zonation in murine livers: new insights for an old story

Nikolaus Berndt[1], Erik Kolbe[2], Madlen Matz-Soja[2], Robert Gajowski[3], David Meierhofer[3], Fritzi Ott[2], Hermann-Georg Holzhütter[1]. [1]*Institute of Biochemistry, Berlin, Germany;* [2]*Rudolf-Schönheimer-Institute of Biochemistry, General Biochemistry, Leipzig, Germany;* [3]*Max Planck Institute for Molecular Genetics, Berlin, Germany*
Email: madlen.matz@medizin.uni-leipzig.de.

Background and Aims: Zone-dependent differences in the expression of metabolic enzymes along the porto-central axis of the acinus are a long-known feature of liver metabolism. A prominent example is the preferential localization of the enzyme glutamine synthetase in pericentral hepatocytes, where it converts potentially toxic ammonia to the valuable amino acid glutamine. However, with the exception of some key regulatory enzymes, there is still no comprehensive and quantitative assessment of zonal differences based on the abundance of metabolic enzymes and, above all, an assessment of the associated functional differences between portal and central hepatocytes.
Method: We addressed this knowledge gap by establishing an alternative method for the separation of periportal and pericentral hepatocytes based on flow cytometry that yields sufficiently pure cell fractions. Specific marker proteins with no overlap in zonal expression were chosen for intracellular staining and subsequent sorting of isolated primary hepatocytes into pure populations of periportal and pericentral hepatocytes. An antibody against glutamine synthetase (*GLUL*) was used to obtain cells from the pericentral region, whereas cadherin-1 (*CDH1*) was selected to isolate periportal hepatocytes. Quantitative shotgun proteomics identified hundreds of differentially expressed proteins? between the two cell populations. These proteomics datasets were used to extend the kinetic model of central hepatic metabolism, Hepatokin1, to generate portal and central instantiations of the model.
Results: Our analysis indicated that there are significant differences in the abundance of two-thirds of metabolic enzymes between periportal and pericentral hepatocytes. Modeling of the proteome profiling data suggested that the functional differences implied by unequal enzyme abundances along the porto-central axis depended essentially on the actual plasma concentrations of metabolites and hormones. For example, despite large zonal differences in the capacity of the urea cycle and glutamine synthesis, significant porto-central differences in the total ammonia-detoxifying capacity are only expected for external ammonia concentrations that are far above the physiological value.

Conclusion: The model simulations revealed significant portal-to-central differences in almost all metabolic pathways, including carbohydrates, fatty acids, amino acids, and detoxification.

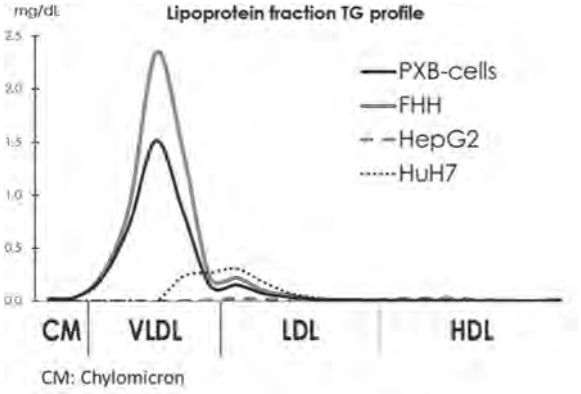
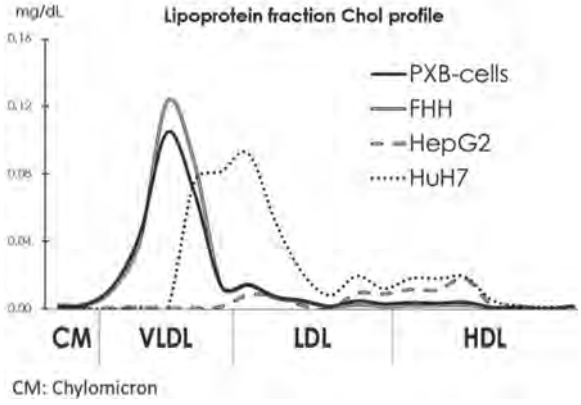
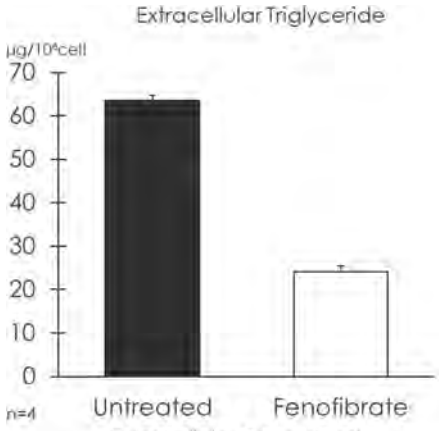
PXB-cells for the study of lipid metabolism: robust and human-specific lipid profile in human hepatocytes freshly isolated from chimeric mice with humanized liver

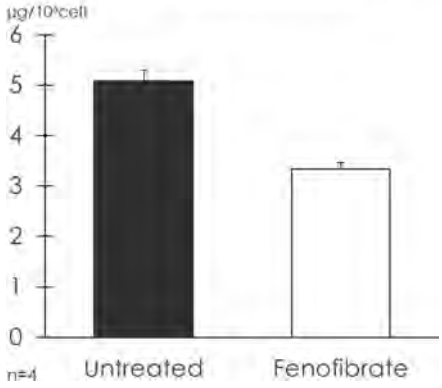
Masaki Takahashi[1], Masakazu Kakuni[1], Sayaka Tomatsu[2], Keishi Hata[2]. [1]*Phoenix Bio Co., Ltd., Study Service Department Unit, Higashi-Hiroshima, Japan;* [2]*Akita Research Institute of Food and Brewing, Akita, Japan*
Email: masaki.takahashi@phoenixbio.co.jp.

Background and Aims: Dysregulation of lipid metabolism is one of the most common factors in pathogenesis of lifestyle diseases. Restoring lipid metabolism, therefore, represents an attractive therapeutic approach; however, development of therapeutics targeting lipid metabolism pathways is often hampered by species differences. Thus, having research tools that provide human-specific lipid profiles and that are available in a consistent manner is key to R&D success. We have previously demonstrated successful mass production of human hepatocytes freshly isolated from chimeric mice with humanized liver (PXB-cells). Since PXB-cells maintain high levels of human albumin (hAlb) secretion and cytochrome P450 activity in culture, we hypothesized that PXB-cells also maintain human-like lipid profiles. In this study, we investigated the utility of PXB-cells for lipid metabolism-related research in comparison with HepG2, HuH7, and fresh human hepatocytes (FHH).
Method: PXB-cells were cultured in maintenance medium for 8 ~ 13 days and then in analysis medium, which does not contain lipid components, for additional 2 days. To characterize the lipid profile of PXB-cells, extracellular lipoprotein fraction, intra/extracellular lipid content, and lipid metabolism-related gene and protein expression levels were analyzed. HepG2, HuH7 and FHH were evaluated in the same manner. In addition, PXB-cells were treated with antihyperlipidemic agents for 2 days and extra/intracellular lipid components were analyzed.
Results: PXB-cells secreted larger amounts of cholesterol (Chol), triglyceride (TG), hAlb than HepG2 and HuH7. Strikingly, most Chol and TG secreted by PXB-cells were attributed to very low density lipoprotein (VLDL) fraction, which was similar to FHH but in contract to HepG2 and HuH7. In addition, high levels of expression were confirmed for several lipid metabolism-related genes and proteins in PXB-cells. Furthermore, the antihyperlipidemic agents reduced the lipid parameters in PXB-cells.
Conclusion: PXB-cells possess unique characteristics that resemble FHH with the steady supply and the human-like lipid profiles, including high levels of VLDL secretion. In addition, PXB-cells exhibited human-like responses to antidyslipidemic agents. Since PXB-cells maintain high hepatocyte functionality such as drug metabolism, they are a promising *in vitro* research model for the development of drugs targeting the lipid metabolism in the liver.









THU320

Ductular reaction and its microenvironment is aetiology driven

Matthias Van Haele[1], Tim Dierckx[2], Mohammed Benkheil[3], Olivier Govaere[4], Frederik Nevens[5], Tania Roskams[1]. [1]*KU Leuven and University Hospitals Leuven, Department of Imaging and Pathology, Leuven, Belgium;* [2]*Rega Institute for Medical Research, Department of Microbiology and Immunology, Leuven, Belgium;* [3]*VIB-Centre for Cancer Biology, Laboratory of Tumour Inflammation and Angiogenesis, Leuven, Belgium;* [4]*Newcastle University, Institute of Cellular Medicine, Newcastle, United Kingdom;* [5]*KU Leuven and University Hospitals Leuven, Department of Hepatology, Leuven, Belgium*
Email: matthias.vanh@gmail.com.

Background and Aims: Ductular reaction (DR) is observed in the vast majority of chronic liver injuries. This reaction represents the activation of the liver progenitor cells (LPCs) in humans. However, the ductular reaction and its microenvironment are poorly characterised in human liver diseases. In this study, we aim to define an aetiology driven microenvironment of the ductular reaction in acute and chronic liver diseases.
Method: Laser capture microdissection and RNA sequencing of the ductular reaction is performed on snap-frozen tissue (n = 34) from primary sclerosing cholangitis (PSC), primary biliary cholangitis (PBC), non-alcoholic steatohepatitis (NASH), alcoholic steatohepatitis (ASH), autoimmune hepatitis (AIH), hepatitis C virus (HCV), drug-induced liver injury (TOX) and normal (CTRL) livers. Multiplex staining is performed on an expanded disease cohort (n = 174).
Results: Reduction analysis of the transcriptomic expression levels shows that the DR and its adjacent microenvironment are clustered by disease aetiology. We established a distinctive gene expression signature between the separate diseases regarding the immune microenvironment (e.g. CD9, CD22), the extracellular matrix (e.g. MMP14, collagen type IV) and angiogenesis (e.g. VEGF). Furthermore, a multiplex analysis approach reveals the interacting cells (e.g. T cells, B cells, macrophages) of the ductular reaction by neighbourhood analysis in an aetiology dependent manner.
Conclusion: Our study characterizes an aetiology specific ductular reaction and accompanying microenvironment.

THU321

Increased autophagy is linked to exosomes secretion in ductular cells of cirrhosis

Tzu-Min Hung[1,2], Yu-Chun Lin[1], Po-Huang Lee[2,3]. [1]*E-DA Hospital, Department of Medical Research;* [2]*National Taiwan University Hospital, Department of Surgery;* [3]*E-DA Hospital, Department of Surgery*
Email: pohuang1115@ntu.edu.tw.

Background and Aims: Exosomes are vesicles released from cells by fusion of multivesicular bodies (MVB) with plasma membrane. Autophagy has been reported to intersect with biogenesis and secretion of exosomes. This study aimed to investigate whether autophagy regulates exosomes secretion in the context of ductular cells of cirrhosis.
Method: We purified ductular cells from a rat model of AAF/CCL4-induced liver cirrhosis using EpCAM-positive selection. Autophagic flux and MVB pathway were evaluated by Western blot and immunofluorescence staining in ductular cells. Rat bile, a local fluid can represent the secretion of biliary epithelial cells, and the culture supernatants from isolated ductular cells were collected for precipitation of exosomes using ExoQuick™. Exosomes concentration was analysed by nanoparticle tracking system.
Results: Western blot of bile samples confirmed the successful extraction of exosomes by revealing the presence of TSG101, flotillin-1 and CD9 markers. Bile exosomes concentration was found to be higher in normal rat than in AAF/CCL4 rat. *In vitro* experiment also demonstrated that exosomes derived from normal cells have higher abundance compared to exosomes released by ductular cells from AAF/CCL4 livers. To address whether cirrhotic induction of autophagy would promote the interaction of MVB with autophagic structure, ductular cells were incubated with monodansylcadaverine (MDC), an autofluorescent compound that accumulates in autophagic vacuoles, and the fluorescent sphingolipid N-Rh-PE, which efficiently labels MVB. There was increased colocalization of MDC-labeled vacuoles with the N-Rh-PE–labeled MVB in ductular cells from AAF/CCL4 livers, compared to those from normal livers. Interaction between MVB and autophagosome was also confirmed by immunostained for the recycling endosomal marker Rab11 and the autophagosome marker LC3B. A relocation of Rab11-positive vesicles from plasma membrane to the LC3B-positive punctae was observed in ductular cells from AAF/CCL4 livers. Importantly, the decreased exosomes secretion and the increased colocalization of autophagosome with MVB were rescued on silencing of the autophagy regulator ATG7, suggesting autophagy may re-route MVB toward autophagic pathway, hampering exosomes release.
Conclusion: Our findings discovered mechanisms controlling exosome release and identify a process where autophagy crosstalk with the exosomal pathway in liver cirrhosis.

THU322

Screening of components involved in activation of innate immune responses and inflammation in NEMO KO mice

Mick Frissen[1], Veerle Bieghs[1], Vera Jankowski[2], Joachim Jankowski[2], Eicke Latz[3], Christian Trautwein[1]. [1]*University Hospital RWTH Aachen, Clinic for Gastroenterology, Metabolic Disorders and Internal Intensive Medicine, Aachen, Germany;* [2]*University Hospital RWTH Aachen, Institute for Molecular Cardiovascular Research, Aachen, Germany;* [3]*UKB Universitätsklinikum Bonn, Institute for Innate Immunity, Bonn, Germany*
Email: mfrissen@ukaachen.de.

Background and Aims: Inflammation is a hallmark of chronic liver disease of which the cellular and molecular mechanisms are at present not fully understood. Nonetheless, the inflammasome seems to contribute to the progression and fibrogenic response in several liver diseases. The inflammasome leads to activation of caspase-1 and subsequent maturation of pro-inflammatory cytokines, resulting in pyroptosis and the regulation of cell survival and cell death. While many different signals can activate the NLRP3 inflammasome, hepatocyte mediated activation of the inflammasome is not not well investigated. In our present study, we aim to identify endogenous danger signals responsible for inflammasome activation from dying hepatocytes of $NEMO^{\Delta hepa}$ mice.
Method: To evaluate hepatocyte mediated activation of the inflammasome we used an immortalized macrophage reporter cell line with a constitutively active NLRP3 and ASC-mCerulean tag. These cells were subjected to HPLC fractionated supernatant from isolated $NEMO^{\Delta hepa}$ hepatocytes. Positive fractions were selected and subjected to multiple fractionation steps after which positive fractions were identified by MS and peptides were synthesised. Activity was measured *in vitro* by fluorescence imaging and FACS analysis. RNAseq analysis was used for confirmation of inflammasome activation and pathway analysis.
Results: Stimulation of reporter cells with supernatant from WT or $NEMO^{\Delta hepa}$ hepatocytes resulted in activation of the NLRP3 inflammasome after 3 hour stimulation by the $NEMO^{\Delta hepa}$ but not the WT supernatant. After HPLC fractionation activation of the NLRP3 inflammasome occurred in several fractions after 3 hours of stimulation. After three subsequent fractionation steps 14 peptides were identified by MS from the NLRP3 inflammasome activating fractions. Subsequent synthetisation and stimulation showed that 2 peptides activated the NLRP3 inflammasome, which was in turn confirmed by FACS and RNAseq.
Conclusion: Supernatant from hepatocytes isolated from $NEMO^{\Delta hepa}$ mice activates the NLRP3 inflammasome *in vitro* and this activation can be measured by using a specific reporter cell line. After repeated fractionation, several fractions were still able to activate the NLRP3 inflammasome and as such, positive MS identified fractions were

synthesized. These synthesized peptides could still activate the NLRP3 inflammasome, suggesting possible new endogenous danger signals, derived from dying hepatocytes of NEMO$^{\Delta hepa}$ mice.

Establishment of murine model of acute-on-chronic liver failure

Nidhi Nautiyal[1,2], Deepanshu Maheshwari[1], Dhananjay Kumar[1], Rekha Kumari[1], Anupama Parasar[1], Chhagan Bihari[3], Subhrajit Biswas[2], Archana Rastogi[3], Rakhi Maiwall[4], Anupam Kumar[1], Shiv Kumar Sarin[4]. *[1]Institute of Liver and Biliary Sciences, Molecular and Cellular Medicine, New Delhi, India; [2]Amity Institute of Molecular Medicine and Stem Cell Research, Amity University, Noida, Uttar Pradesh, India; [3]Institute of Liver and Biliary Sciences, Pathology, New Delhi, India; [4]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: shivsarin@gmail.com.

Background and Aims: Acute-on-chronic liver failure (ACLF) is characterized by liver failure due to acute hepatic injury on an underlying chronic liver disease, accompanied by acute decompensation, organ failure, and high mortality. Pathophysiology of disease remains unclear, necessitating the need for animal model. In this study, we aim to develop murine model of **ACLF** mimicking characteristics of human ACLF.

Method: Chronic liver injury were induced by i.p. administration of CCl4 (0.1–0.5 ml/kg) in C57BL6 mice (n = 25), acute injury was induced by i.p. administration of LPS (50 µg/kg) and Acetaminophen (350 mg/kg) (fig 1A). Animals were sacrificed at week 10 (n = 5); and at 24hrs, day 7 and day 11 after acute injury, blood was collected, and organs were harvested for histological and IHC analysis.

Results: Liver histology confirmed fibrosis and cirrhosis after 10 weeks of CCl4 injury. No secondary organ damage or ascites were

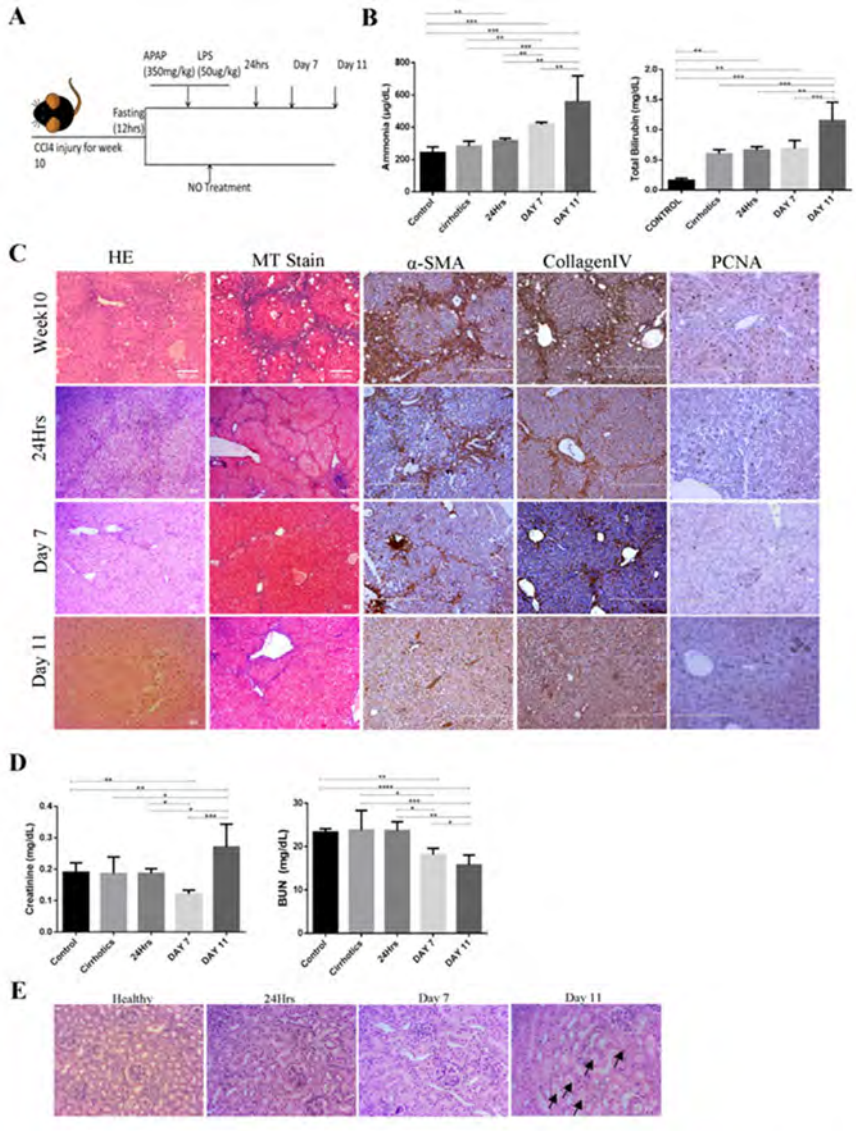

Figure 1 (A) The diagrammatic illustration of model development. (B) Liver Function test, ammonia and total bilirubin levels. (C) Liver histology at different time interval (24Hrs, Day 7 and Day 11) and immunohistochemistry w.r.t Week 10 of chronic liver injury. (D) Kidney parameters (Creatinine and BUN). (E) Histology of kidney (arrow marking ATN at week 11)

Figure: (abstract: THU323)

observed however liver showed enhanced portal inflammation with fibrosis and cirrhosis. Hepatocytes showed eosinophilic cytoplasm with enlarged reactive nucleus with marked hepatocytes proliferation (Fig 1-C). 24 h after LPS and APAP treatment hepatocytes showed ballooning and prominent peripheral condensation of organelles that gave rigid appearance to cell membrane (Fig 1). From 24 h to day 11, hepatocyte ballooning decreased with increased hepatocyte necrosis and cholestasis (figure 1-C). All animals developed ascites at day-9–11 post LPS and APAP treatment. Animals sacrificed on day 11 showed AF with SAAG 1.2 ± 0.1 g/DL. There was progressive decrease in fibrosis after APAP+LPS treatment (Figure1-C) hepatocyte proliferation markedly decrease and there was progressive increase in plasma T.bilirubin and ammonia (Fig 1B). Analysis of lungs, kidney and spleen tissue showed the presence of progressing acute tubular necrosis (ATN) from day 7 to day 11 post-acute insult with increase in serum creatinine and decrease in blood urea nitrogen (BUN) (Fig 1-E) suggesting renal injury. Interstitial pneumonia and exudate pneumonia were observed in 3 mice at day 11. Altogether these data suggested the secondary organ failure following the liver failure post APAP+LPS treatment.

Conclusion: Our model showed progressive increase in bilirubin and ammonia, ascites and secondary organ failure a characteristic feature of ACLF as per APASL/EASL and can be used to understand the pathomechanism of ACLF as well as for preclinical studies and development of new therapies.

THU324

The method of spheroid formation for 3D cultures of primary hepatocytes influences hepatocellular functions and hepatotoxicity

Jana Moer[1], Dieter Runge[1], Natalia Sanchez-Romero[2], Anett Ullrich[1]. *[1]Primacyt Cell Culture Technology GmbH, Schwerin, Germany; [2]Cytes Biotechnologies, S.L., R&D, Barcelona, Spain*
Email: anett.ullrich@primacyt.de.

Background and Aims: Primary hepatocytes of human and animal origin are the gold standard for all pharmacological-toxicological studies in drug development. They play a major role in eco-toxicological evaluation as well. Three-dimensional (3D) cultures became more popular in recent years since they might mimic the *in-vivo* cell morphology, polarity and cell-cell interactions better than traditional two-dimensional (2D) cultures. Here, two types of cell culture plates were used to generate 3D cultures with primary hepatocytes: the GravityPLUS Hanging Drop System with subsequent culture in Gravity TRAP plates in comparison to U-bottom ULA (ultra-low attachment) plates with cell repellent surfaces. Standard 2D cultures were performed as well.

Method: Hepatocellular detoxification functions like urea release and CYP450 activity as well as the response to the hepatotoxin Diclofenac were analysed in these culture systems. The results were normalized to the corresponding volume of culture medium or to protein content.

Results: The secretion of urea was improved and maintained at higher levels in U-bottom ULA plates compared to the Hanging Drop System. CYP1A activity was better inducible by beta-Naphthoflavone in U-bottom plates than in the Hanging Drop System at all 3 tested cell numbers. Basal Cytochrome P450 activities were higher in U-bottom plates and showed a better inducibility in these plates compared to the Gravity TRAP plates.

Diclofenac, a known and well-described hepatotoxic compound, did show similar effects on hepatocytes with regard to the ATP content in both 3D culture systems. Beside this, the decrease of ATP content due to Diclofenac treatment was higher in 2D culture than in the 3D culture systems.

Conclusion: In summary, our results indicate that major differences may exist between different 3D culture systems and in comparison, to standard 2D culture methods. These differences may lead to different and conflicting results in the assessment of drug toxicity and drug-drug interaction.

THU325

Bioengineering of 3D bile ducts from 2D micropatterns by self-organogenesis

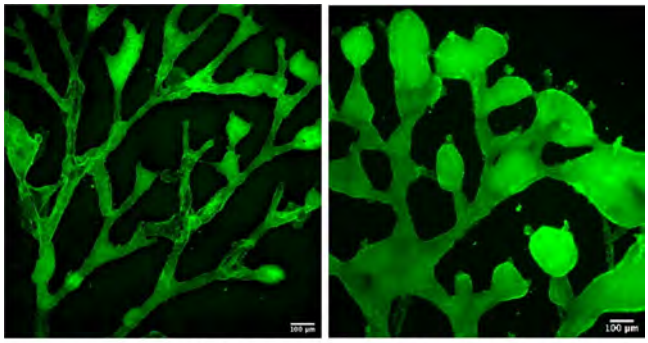
Pascale Dupuis-Williams[1], Emilie Gontran[2], Lorena Loarca[2], Bouzhir Latifa[2], Fuchs Alexandra[3]. *[1]Interactions Cellulaires et Physiopathologie Hépatique, Orsay, France; [2]Interactions Cellulaires et Physiopathologie Hépatique, Orsay, France; [3]IRIG/DRF/CEA Unité de Thérapie Cellulaire, Paris, France*
Email: pascale.dupuis-williams@u-psud.fr.

Background and Aims: Despite its central role in detoxification, a functional bile duct system has been precluded from most bioengineered liver projects. In this work, we explored the conditions allowing the development of tubular networks based on cholangiocyte self-organogenesis.

Method: Cholangiocytes were first grown as an epithelial sheet on 2D micropatterned surfaces from which tubular structures were formed by addition of hydrogels that induce self-organogenesis. Various geometries of lines and tree patterns were explored to characterize the conditions that allow the development of hollow tubes, and that favor the coalescence of lumen in the network. Polarity and secretion properties of the tubes were assessed by fluorescein secretion assays and immunolocalization of epithelial markers.

Results: By varying the geometries, sizes of the micropatterns and the source of cells, we identified conditions that allow the development of a network of bile ducts with diameters ranging from 15 to 150 µm, mimicking the organization of an intrahepatic biliary network. In particular, the co-culture with endothelial cells suggests a scaffolding effect on cholangiocyte self-organogenesis while enhancing their lumenogenesis potential to form tubes, Figure 1.

Conclusion: To our knowledge, this is the first study to present biliary duct networks built *in vitro* from 2D micropatterns inspired from the shapes of distal biliary trees. This work opens interesting opportunities for gaining insights in bile duct organogenesis and paves the way for performing functional analyses in cholangiocyte-related diseases.



Biliary duct network made from culture of biliary cells alone

Biliary duct network made from a coculture of biliary cells and endothelial cells

Histidine triad nucleotide-binding protein-2 is present at the cross-road of ER-mitochondria interactions and modulates adaptive stress response in hepatocytes

Pavitra Kumar[1], Raviprasadh Rajasekaran[1], Maria Guarino[1,2], Jean-François Dufour[1,3], Marie V. St-Pierre[1]. *[1]University of Bern, Department of Biomedical Research, Bern, Switzerland; [2]University of Naples, Department of Clinical Medicine and Surgery, Napoli, Italy; [3]University Hospital Bern, University Clinic of Visceral Surgery and Medicine, Bern, Switzerland*
Email: jean-francois.dufour@dbmr.unibe.ch.

Background and Aims: Histidine triad nucleotide-binding protein 2 (Hint-2) is a mitochondrial adenosine phosphoramidase expressed in hepatocytes. Hint2 knockout (*Hint2*$^{-/-}$) mice show hepatic steatosis, lysine hyperacetylation and reduced mitochondrial respiration, but the mechanism is unclear. Dysfunction in mitochondria affects communication with the endoplasmic reticulum (ER) via mitochondria-associated membranes (MAMs), which is mediated by associations between IP3R, GRP75 and VDAC1. Since Hint-2 itself binds to GRP75, we postulated that Hint2 modulates proteomic composition of MAMs and participates in the adaptive response of hepatocytes to ER stress.
Method: MAMs were isolated from *Hint2*$^{+/+}$ and *Hint2*$^{-/-}$ livers and subjected to LCMS/MS proteomics. Response to the ER stressor tunicamycin was tested in *Hint2*$^{+/+}$ and *Hint2*$^{-/-}$ hepatocytes and in control and Hint-2 overexpressing SNU-449 cells. Response to ethanol was examined in *Hint2*$^{+/+}$ and *Hint2*$^{-/-}$ hepatocytes and *in vivo*. Oxygen consumption rates (OCR) was assessed by XF-Seahorse analyzer.
Results: Proteomic heterogeneity was reduced in Hint2$^{-/-}$ MAMs: 113 unique proteins and 15 unique proteins were detected in *Hint2*$^{+/+}$ and *Hint2*$^{-/-}$ livers, respectively. Hint-2 itself was detected in MAMs. With tunicamycin treatment, the ER stress proteins, CHOP, XBP-1s and ATF6 increased by 53-, 22- and 11-fold, respectively, in Hint-2 overexpressing cells but only 16-, 9- and 4-fold, respectively, in control SNU-449. Similarly, CHOP increased 40-fold in *Hint2*$^{+/+}$ hepatocytes but only 13-fold in *Hint2*$^{-/-}$.
Ethanol triggered a 3.4 fold higher increase in lysine acetylation in *Hint2*$^{-/-}$ hepatocytes than in *Hint2*$^{+/+}$ ($p < 0.05$). However, the ethanol triggered ROS production was lower in *Hint2*$^{-/-}$ than in *Hint2*$^{+/+}$ hepatocytes ($p < 0.001$). As expected, basal and maximal OCRs were lower in *Hint2*$^{-/-}$ hepatocytes and further reduced after ethanol treatment ($p < 0.05$). Autophagy was triggered in ethanol treated *Hint2*$^{+/+}$ hepatocytes but not in *Hint2*$^{-/-}$. The phosphorylation (S-228) of PTEN-induced kinase 1, a marker for stress-induced mitochondrial dysfunction, was increased 2-fold only in *Hint2*$^{+/+}$ mitochondria.
Conclusion: Hint2, a mitochondrial protein, partly resides in MAMs and its absence changes the proteomic landscape of MAMs. Lack of Hint2 diminishes cellular sensitivity to tunicamycin and ethanol-mediated ER stress. Therefore, we conclude that Hint2 participates in the adaptive response of hepatocytes to ER stress.

Email: peter.revill@vidrl.org.au.

Background and Aims: The absence of proof-reading in the reverse transcriptase during Hepatitis B virus (HBV) replication generates haplotypes, which may emerge depending on selection pressure and viral fitness in chronic hepatitis B (CHB) disease.
Method: We investigated haplotype frequency and diversity at both the nucleotide and amino acid level across the complete HBV genome in 4110 haplotypes from 368 patients with history of CHB during three phases of natural history of disease, immune tolerant, immune clearance, and immune reactivation, for genotypes A to D. Haplotype frequencies were compared to serum HBsAg, HBeAg, HBV DNA viral load, and liver alanine aminotransferase.
Results: Number of haplotypes per samples (frequency) was higher in samples from patients of Asian ethnicity (genotype B and C) compared to Caucasians (genotype A and D), and in the immune clearance and immune reactivation phase compared to immune tolerant phase. Haplotype frequencies and genetic diversity increased over the course of CHB history, from the immune tolerant, to the immune clearance and immune reactivation phases for most genotypes, except for genotype C. Haplotype genetic diversity varied across CHB natural history, most notably in the precore/core gene. Analysis of sequence conservation across all five functional genes and all six regulatory regions in all 4110 haplotypes showed that between 18.2% and 41.8% of nucleotides and between 5.9% and 34.3% of amino acids in the HBV genome were 100% conserved, depending on the genes and regions analysed. Haplotype frequencies were generally negatively correlated with HBsAg titre, HBeAg titre and viral load, although this varied by HBV genotype and CHB. The highest negative correlation was observed between genotype A immune clearance samples and HBsAg titre (Spearman R –0.7292, P < 0.0001) and HBeAg titre (Spearman R – 0.7383, P < 0.0001) and between genotype D immune clearance samples and HBsAg titre (Spearman R – 0.5513, P 0.0002) and HBeAg titre (Spearman R – 0.5801, P = <0.0001).
Conclusion: These findings reveal a previously unrecognised degree of HBV haplotype heterogeneity across the complete HBV genome, which spans multiple phases of CHB natural history. Highly conserved sequences were identified at both the nucleotide and amino acid level in key genes and regulatory regions, which may be suitable targets for antiviral therapies.

THU328

Tolerogenic dendritic cells modulate pathogenic CD4+ T cells in an ex vivo co-culture system in a concanavalin A -mice model of type-I autoimmune hepatitis

Ranjana W. Minz[1], Prabhsimran Singh[1], Lekha Rani[1], Mohan Ramachandra Wani[2], Yashwant Kumar[1], Shashi Anand[1]. [1]*Post-Graduate Institute of Medical Education and Research (PGIMER), Immunopathology, Chandigarh, India;* [2]*National Center for Cell Science, Pune, India*
Email: rwmin.minz88@gmail.com.

Background and Aims: Tolerogenic dendritic cells (tolDCs) have the potential to prevent autoimmune hepatitis via sustained release of immunoregulatory cytokines, increased induction of regulatory T cells and suppression of autoreactive/effector T cells. In the present study, we investigated the modulation of pathogenic CD4$^+$ and CD8$^+$ T cells by syngenic tolerogenic DCs.
Method: Tolerogenic dendritic cells were generated from mouse bone marrow using immunoregulatory IL-10. Phenotypic and functional characterization of induced DCs was done by flowcytometry. Gene expression for inflammatory and maturation markers was estimated via RT-PCR. Syngenic tolerogenic DCs were co-cultured with liver pathogenic CD4$^+$ and CD8$^+$ T cells, derived from mice mode of autoimmune hepatitis, *ex* vivo to observe modulation of CD24, TIM-1 and TIM-3 molecules.
Results: Ex vivo generated tolDC had an adherent phenotype with low surface expression of CD80, CD86, CD40, MHC-II and relatively high surface expression of PD-L1 and PD-L2. The tolDCs had poor CD4$^+$ T cell stimulatory capacity and also showed greater Treg induction potential. Tolerogenic DCs had high mRNA expression of TGFβ1, PD-L1 and low expression of CCR7, IL-12. In the co-culture study, tolerogenic DCs were found to downregulate CD24 and upregulate TIM-3 on T cells.
Conclusion: This study is first of its kind to demonstrate immunomodulation of pathogenic T cells by tolerogenic dendritic cells. Based on our results, we found that tolerogenic DCs could not only suppress

proliferation of IFNγ secreting effector cells but also promote additional immunological regulation via increasing expression of inhibitory TIM-3 molecule. We strongly suggest that a therapy involving tolDCs can effectively inhibit acute or chronic inflammation leading to autoimmunity.

THU329

Hepatic inflammation upregulates netrin-1 in mice and in vitro through translational activation and transcript topology alteration in a LA-related protein-1 (LARP1)-dependent manner

Romain Barnault[1], Maud Michelet[1], Anna Rita Redavid[2], Federica G Centonze[3], Hesso Farhan[3], Benjamin Gibert[2], Patrick Mehlen[2], Fabien Zoulim[1], Romain Parent[1]. *[1]Cancer Research Center of Lyon, Immunology & Virology, Lyon, France; [2]Cancer Research Center of Lyon, Signaling of Tumoral Escape, Lyon, France; [3]University of Oslo, Molecular Medicine, Oslo, Norway*
Email: romain.parent@inserm.fr.

Background and Aims: Links between hepatic inflammation and HCC are likely incompletely defined. Netrin-1 is a developmental neurogenic factor reactivated upon general carcinogenesis and bearing pro-tumorigenic properties (Mehlen, Nat. Rev. Cancer 2011). Converging data indirectly suggest its detrimental implication in end stage liver pathology, including HCC (Plissonnier et al. Plos Biol 2016 & Oncogene 2017; Lahlali et al. CMGH 2016).
Method: In the present study, patient samples, mouse samples as well as in vitro cell biology and mechanistic approaches were used.
Results: We show that netrin-1 mRNA (*NTN1*) levels positively correlated with activity scores of human livers biopsies (up to +6-fold in A2 vs A0 samples, p = 0.02, n = 162, Panel A). Using poly(I:C) as a TLR3 agonist, experimentally-induced inflammation in mice upregulated netrin-1, through the implication of parenchymal cells (Panel B). Netrin-1 was found in vitro-inducible by a panel of TLR2 to 6 agonists, a dataset strengthening the pathophysiological relevance of this in vitro phenotype (Panel C). Surprisingly, neither total mRNA levels (RT-qPCR), nor transcriptional levels (plasmid reporter assays, pre-mRNA RT-qPCR) nor splicing (mRNA over pre-mRNA ratios calculations), nor mRNA stability were found implicated (not shown). In contrast, robust transfer of *NTN1* to the ER (+7-fold, p < 0.05, as observed by sequential fractionation) and its translational activation could be evidenced (+40%, p < 0.05, by polysomal fractionation as well as polysomal run-off on HepaRG cells and PHH, respectively, Panel D). This phenotype was reversed by RNAi depletion of the La Related Protein-1 (LARP1) RNA binding protein (Panel E). This dataset suggests phenotypical convergence for netrin-1 induction through distinct regulatory scenarios depending on the cellular context (HepaRG or PHH). Secretory levels of the hepatocyte-like cells were left unchanged (AAT-GFP RUSH assay), suggesting the non-implication of netrin-1 secretion alteration in this phenotype.
Conclusion: Such data identify the less frequently addressed polysomal activation and mRNA topological regulation processes as sufficient events allowing netrin-1 induction. They also further document the pathogenic consequences of inflammation in the liver, in the present case through the implication of netrin-1, a documented carcinogenic factor.

Cirrhotic extracellular matrix affects Hic-5 expression in primary human hepatic stellate cells

Simona Onali[1], Elisabetta Caon[1], Kessarin Thanapirom[1], Martina Marrali[2], Maria Giovanna Vilia[1], Luca Frenguelli[1], Walid Al-Akkad[1], Giuseppe Mazza[1], Massimo Pinzani[1], Krista Rombouts[1]. *[1]University College London, Institute for Liver and Digestive Health, London, United Kingdom; [2]Engitix Ltd, London, United Kingdom*
Email: simona.onali@yahoo.it.

Background and Aims: Activation of hepatic stellate cells (HSC) by transforming growth factor beta (TGFb) is a well-established driver of liver fibrogenesis. Previously we demonstrated that primary human HSC (hHSC) cultured in a 3D model based on human liver extracellular matrix (ECM) scaffolds, showed a different cell behaviour compared to the traditional 2D plastic cultures. In this study we aim to assess the impact of the liver ECM environment (healthy versus fibrotic) on the expression of a TGFb1-modulated protein, namely Hydrogen peroxide Inducible Clone-5 (HIC-5), in primary hHSC cultured in decellularized healthy and cirrhotic human liver ECM scaffolds.

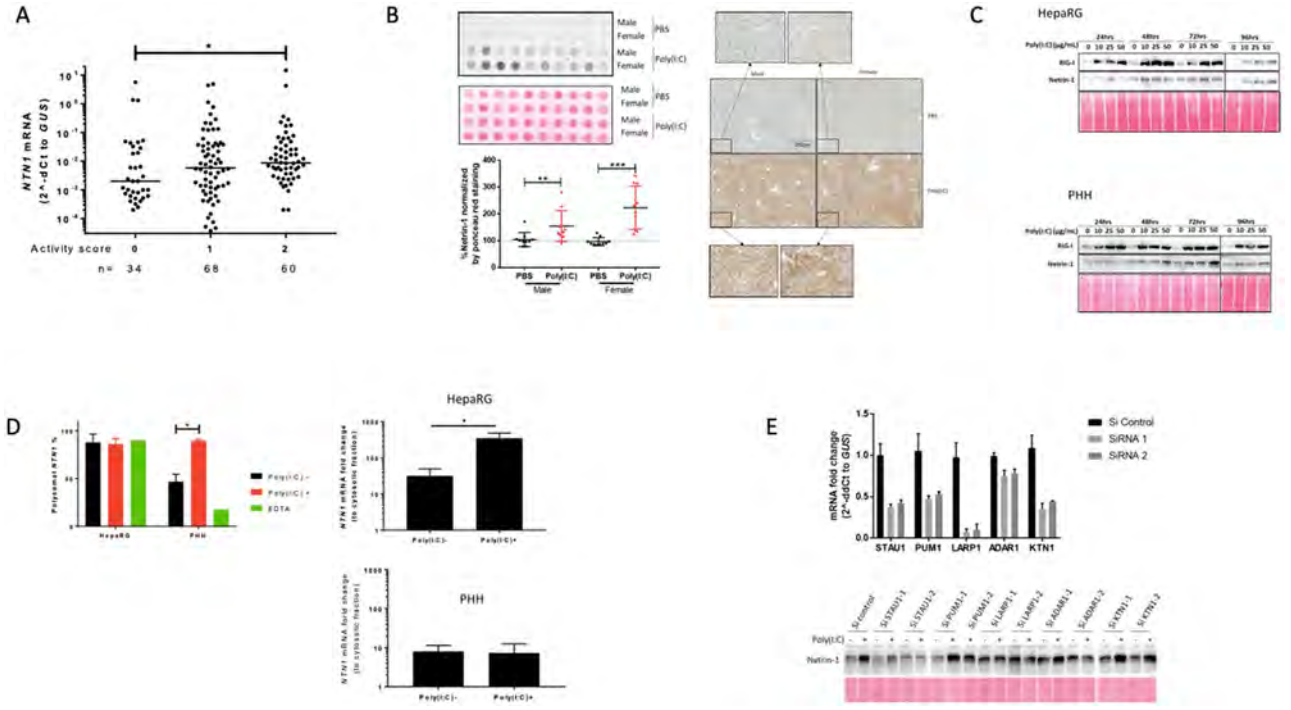

Figure: (abstract: THU329)

Method: Decellularized human liver 3D scaffolds were repopulated with primary hHSC ($0.25*10^6$) for 10 days. HSC were exposed to H_2O_2 (100 uM) and TGFb1 (5 ng/mL) for 24 h, w/wo pre-treatment of H_2O_2/TGFb1. HSC engraftment was assessed histologically and by immunohistochemistry, while viability was quantified by PrestoBlue assay. Pro-fibrogenic protein expression was assessed by Western Blot.
Results: Engraftment in healthy and cirrhotic scaffolds was demonstrated histologically, while Prestoblue assay showed that hHSC remain viable in both types of scaffolds.
Simultaneous exposure to H_2O_2 and TGFb, pretreatment with H_2O_2 followed by TGFb, or TGFb pretreatment followed by H_2O_2 exposure upregulated HIC-5 protein expression in HSC engrafted in cirrhotic scaffolds compared to healthy scaffolds. This finding indicates that TGFb and H_2O_2 affect HIC-5 regulation and hHSC activation when cultured in diseased ECM scaffolds. A similar tendency was observed in Acta2 protein expression which showed to be highly upregulated in all conditions tested in cirrhotic scaffolds compared to healthy scaffolds, further demonstrating the strong impact of fibrotic ECM on hHSC behaviour.
Conclusion: Primary hHSC express differently HIC-5, when cultured in healthy versus cirrhotic 3D ECM scaffolds suggesting that their activation status and response to fibrogenic stimuli is strongly affected by the hepatic ECM features. These findings support the use of human tissue-specific 3D scaffolds as a more realistic pathophysiological model to further investigate the role of HIC-5 in primary hHSC and to define the specific role and modulation of the TGFb1 signalling pathway in hepatic fibrogenesis.

Phenotypic characterization of ABCG5/G8 deficiency: selective knockout in liver or intestine leads to genocopies

Susanne N Weber[1], Friederike Poppenborg[1], Caroline Bopp[1], Frank Lammert[1]. [1]*Saarland University, Department of Medicine II, Homburg, Germany*
Email: susanne.weber@uks.eu.

Background and Aims: Gallstone disease is one of the most common disorders worldwide. Gallstones result from cholesterol supersaturation of bile, which causes the formation of cholesterol crystals in hypomotile gallbladders. Cholesterol is transported across the hepatocanalicular membrane by the heterodimeric ATP-dependent transporter ABCG5/G8. Besides its function in the liver, *Abcg5/g8* is also expressed in the intestine. The specific aim of this study was to compare the physical-chemistry of bile secretion and gene regulation when the transporter is selectively disrupted in liver or intestine, respectively.
Methods: Using BAC-based recombineering, we have generated conditional *Abcg5/g8* knock-out mice allowing tissue-specific deletion of the first two exons of *Abcg5* and the first exon of *Abcg8*, respectively, by Cre-mediated recombination. *Abcg5/g8* flox mice were crossed to *Villin*-Cre mice, expressing Cre in the intestine under the control of the *Villin* promoter (Int-KO), and *Albumin*-Cre mice, allowing hepatocyte-specific deletion of the transporter (Hep-KO). Hepatic bile was obtained after cannulation of the common bile duct, and bile flow and biliary lipid secretion rates were measured during the first three hours of the acute bile fistula. In addition, lipid and expression analyses of cholesterol regulatory genes in liver and intestine were performed.
Results: Conditional knockout mice developed normal, were fertile, and showed no gross abnormalities. Int-KO mice presented with higher liver to body weight ratios as compared to Hep-KO mice, whereas body and liver weights did not differ. Bile acid concentrations were elevated in bile of Int-KO mice, and phospholipids were decreased. Cholesterol and cholesterol saturation indices (CSI) were higher in conditional knockout mice (CSI = 2.1–2.3), but did not differ between Hep-KO and Int-KO. Hepatic cholesterol concentration were similar, but phytosterols accumulated massively in the livers from both conditional knockout strains (wild-type: 17.4 ± 4.6, Hep-KO: 199.4 ± 86.1, Int-KO: 494.9 ± 611.3 mg/g cholesterol; p = 0.002). The expression of the alternative cholesterol transporter *Abcg1* as well as the bile acid transporter *Abcb11* were decreased in livers of Int-KO mice, while *Fxr* expression was increased. The expression pattern of *Hmgcr, Cyp7a1, Acat1, Srebf1/2, Ldlr* and *Npc1l1* was comparable between genotypes.
Conclusions: Our results illustrate that the tissue-specific deletion of *Abcg5/g8* in either liver or intestine leads to comparable phenotypes (genocopies) regarding biliary lipid output and expression of cholesterol metabolism-related genes. Expression of the transporter at both sites appears critical and exerts synergistic effects to maintain sterol balance in liver and bile.

THU332

Synthesis and comparative assessment of bile acid C3-hydroxyl stereoisomers as farnesoid X receptor modulators

Tarek Moustafa[1], Alex Zaufel[1], Sandra van de Wiel[2], Günter Fauler[3], Peter Fickert[1], Stan van de Graaf[2], John Gilmer[4]. [1]*Division of Gastroenterology and Hepatology, Dept. of Internal Medicine, Medical University of Graz, Austria, Graz, Austria;* [2]*Tytgat Institute for Liver and Intestinal Research, Dept. of Gastroenterology and Hepatology, Amsterdam University Medical Centers, University of Amsterdam, Amsterdam, Netherlands;* [3]*Clinical Institute of Medical & Chemical Laboratory Diagnostics, Medical University of Graz, Austria, Graz, Austria;* [4]*The School of Pharmacy and Pharmaceutical Sciences, Trinity College Dublin, Dublin, Ireland*
Email: tarek.moustafa@medunigraz.at.

Background and Aims: Primary bile acids (BAs) are synthesized from cholesterol in the liver and usually occur with a C-3 hydroxyl group in alpha configuration (3a-OH). The binding of BAs by the farnesoid X receptor (FXR) is crucial in the regulation of hepatic and intestinal steroid- and lipid homeostasis. Microbial metabolism produces secondary BAs and stereoisomers with C-3 hydroxylation in beta configuration (3b-OH, isoBAs), the latter being re-epimerized to their 3a-OH forms in rat and human livers. To gain further insights into the physiologic and regulatory functions of 3b-OH BAs, we investigated a series of different BA-stereoisomers on FXR activation using cultured cells and C57/BL6 mice.
Method: Individual isoBAs, in comparison to their 3-alpha stereoisomers were tested for FXR transactivation using a) RNA expression profiling of cultured cells, b) luciferase-based assays, c) fluorescence-based coactivator association assay (BA-Sensor) that measure FXR activation in real time, and d) in vivo, by administering C57/BL6 mice with various isoBAs at (50 mg/kg).
Results: We first show that isoBAs are less toxic to cultured cells than their 3a-OH isomers (100 µM vs. vehicle). HepG2 cells were treated for 16 h with chenodeoxycholic (CDCA), deoxycholic (DCA), or ursodeoxycholic (UDCA), and their 3b-stereoisomers and FXR target genes were quantified by Q-PCR. CDCA and isoCDCA strongly activated FXR; DCA and isoDCA weakly increased, whereas UDCA and isoUDCA were virtually inactive on mRNA levels of FXR target genes. However, all BAs increased the precursor-mRNA (pre-mRNA) of FXR target genes (CDCA>DCA>UDCA). The regulation of target genes (ratio pre-mRNA/mRNA) seems to depend on the localization of mRNA and its half-life (e.g. *Kng*1, nuclear; long half-life; *Ost*-b cytosolic, short half-life). Importantly, we further realized that already after 4–5 h 50% of isoBAs were metabolized to 3-oxo BAs (inactive for FXR) making it difficult to study the full impact on FXR activity or to compare to 3a-isomers in cell based assays with long treatment duration. Real time monitoring of FXR activity using the BA-senor revealed that i) isoCDCA > CDCA activated FXR, and iso-DCA/UDCA were ineffective; ii) iso-DCA/UDCA suppressed FXR activation by CDCA; iii) fully activated FXR (saturated), cannot be further stimulated even by highly potent FXR agonists (e.g. GW4064). Importantly, iso-DCA/UDCA allowed saturated FXR to be re-activated by GW4064. In mice, co-administration of a single dose of iso-DCA/

UDCA slightly potentiated the effect of GW4064 on repression of *Cyp*7a1 or induction of FXR targets in liver and intestine.
Conclusion: A burst induction and a short half-life of target gene mRNA are needed to observe proper FXR activation. Secondary (iso)-BAs allow reactivation of saturated FXR that would assure cycling dynamics and accurate control of gene transcription within the enterohepatic circulation.

THU333
Upregulation of CCNB1, CDC20 and CENPF genes is associated with poor prognosis in hepatocellular carcinoma (HCC)
Tengfei Si[1], Yuanhang Jiang[1], Abigail Walker Jacobs[1], Shaqira Gill[1], Robert Hegarty[2], Mohammad Hamza[1], Shirin Elizabeth Khorsandi[1,3], Wayel Jassem[1,3], Nigel Heaton[1,3], Yun Ma[1]. Email: yun.ma@kcl.ac.uk.

Background and Aims: Hepatocellular carcinoma (HCC) is the most common primary liver cancer with a low 5-year survival rate. The early stage of HCC is usually asymptomatic and many patients were diagnosed at the late stage and missed best chance to be treated effectively. Screening or surveillance with ultrasound in conjunction with alpha fetoprotein (AFP) is inefficient in detecting early tumour; therefore, new and sensitive biological markers for disease are required. The aim of this study was to search for potential gene markers for the early identification of HCC.
Method: Four GSE profiles (GSE6764, GSE6222, GSE101685 and GSE102083) were screened out after searching the GEO database. Candidate genes with at least a 2-fold change (|log FC|>2) in expression were filtered using Venn diagram software. Core genes from the protein-protein interaction (PPI) network were identified through online dataset STRING and Cytoscape software (MCODE module analysis). The correlation between the core genes and prognosis of HCC was sought. The biologically functional contributions of poor-prognosis related genes were recognised via GO and KEGG enrichment analysis. The diagnostic and predictive values of the identified genes were also verified by the GEPIA and HPA database.
Results: A total of 202 common differentially expressed genes (52 up-regulated and 150 down-regulated) were filtered from the GSE profiles (Figure 1A). 32 genes were potentially associated with poor prognosis of HCC (Figure 1B), of which 12 were found to be significantly up-regulated in HCC tumour tissue (Figure 1C). Analysis of the 12 core genes by GO and KEGG enrichment analysis revealed that CCNB1, CDC20 and CENPF were involved in the development of HCC. Positive correlations among these three genes were identified and all signatures of three genes were associated with worse prognosis of HCC (Figure 1D & E). The PCA analysis indicated that these three genes could clearly distinguish HCC tumour tissue from normal liver tissue (Figure 1F & G). Moreover, among digestive tract tumours, CCNB1, CDC20 and CENPF were uniquely associated with significant survival difference in HCC (Figure 1F).
Conclusion: CCNB1, CDC20 and CENPF genes were identified to associate with HCC poor prognosis. The expression of these genes might serve as sensitive biomarkers for the early diagnosis of HCC.

THU334
Bax inhibitor-1 inhibits acetaminophen induced hepatotoxicity by reducing the drug induced ER stress through regulating the RIDD activity of IRE1 alpha
Han-Jung Chae[1], Thoufiqul Alam Riaz[1], Hyun-Kyoung Kim[1], Hyung-Ryong Kim[2]. [1]*Jeonbuk National University Medical School, Department of Medical Science (Pharmacology), JeonJu, Korea, Rep. of South;* [2]*Daegu Gyeonbuk Institute of Science & Technology (DGIST) Graduate School, Daegu, Korea, Rep. of South*
Email: hjchae@jbnu.ac.kr.

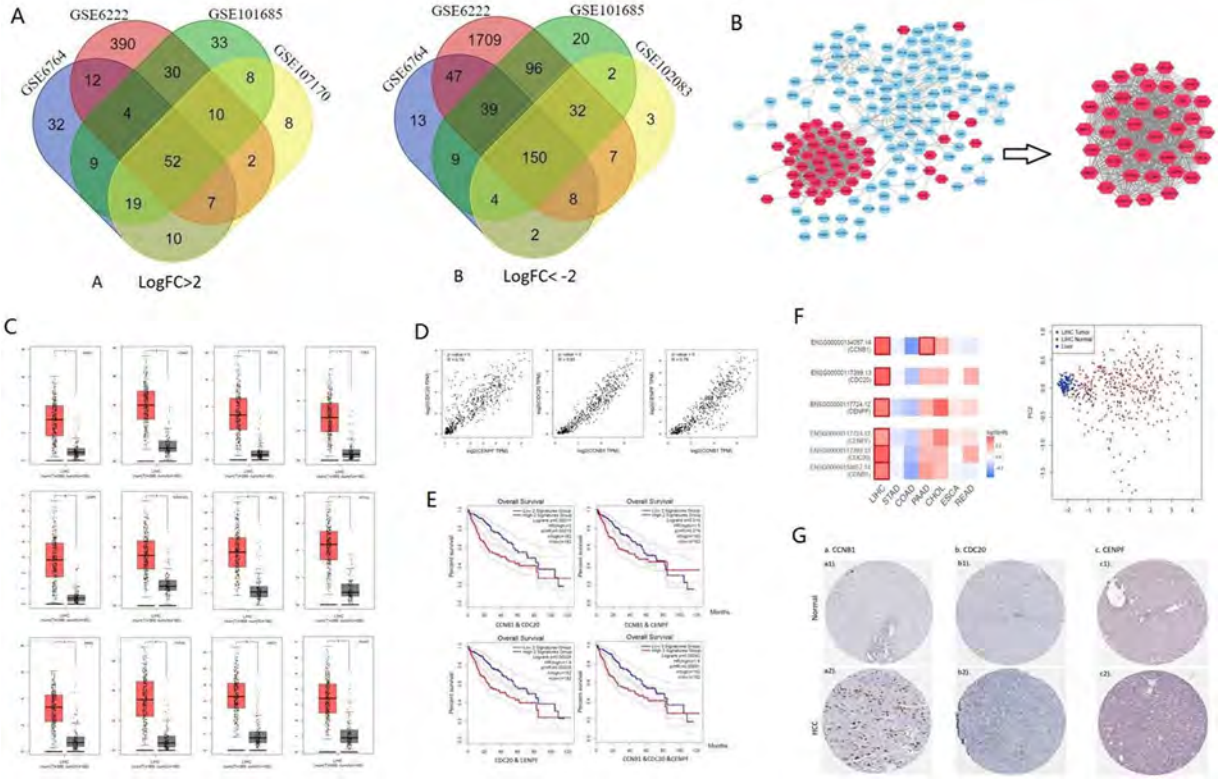

Figure: (abstract: THU333)

POSTER PRESENTATIONS

Background: Acetaminophen (APAP) overdose is the most frequent cause of acute liver failure and is primarily caused by CYP2E1 driven conversion of APAP into NAPQI, a hepatotoxic metabolite. APAP induced oxidative stress creates intraluminal redox imbalance of the ER and consequential activation of UPR and proapoptotic signaling. Bax inhibitor1 (BI-1),an antiapoptotic protein known to suppress the cell death by regulating ER stress response.

Aims: To study, whether BI-1 gives the protective effect against APAP induced ER stress. If so, to find out the possible mechanism of BI-1 which give the protective effect.

Method: Hep3B cell line overexpressing BI-1 and Neo were cultured in DMEM medium supplemented with 10% FBS and 100 μg/ml streptomycin, and 100 units/ml penicillin. Acetaminophen treated at 10 mM concentration and cells were harvested at 0, 3, 6, 12, and 24 hours after treatment. BI-1 wild type and BI-1 knockout mice of 9 weeks old were treated with APAP, 500 mg/Kg body weight for 24 hrs. Samples were examined for the immunoblot and histology.

Results: Our results showed that APAP induced ER stress was reduced in the presence of BI-1 and BI-1 over expressing cells compare knockout and neo control system respectively. BI-1 knockout mice showed massive hepatotoxicity and large number of cytoplasmic vacuoles as revealed by H&E staining. Further it increased ALT and AST levels, protein oxidation and lipid peroxidation. We observed reduction of CYP2E1, a RIDD substrate, expression in BI-1 over-expressing cells. To examine the possible relation of BI-1 in CYP2E1 lower expression in the ER stress, we hypothesized that BI-1 may regulate the IRE1 response. As, it is known that XBP1s requires oligomer sate of activated IRE1α and this XBP1s is reduced in BI-1 expressing cells but at the same time phosphorylation of IRE1 was also observed. So, It indicates that in BI-1 overexpressing cells IRE1α is activated but held in dimer state for extended time compare to PC cells. In consequence, the dimer state of activated IRE1α has the RIDD activity and helps in initial adaptive stress response by reducing the further load of protein synthesis during ER stress. As a consequence CYP2E1 mRNA degraded and resultantly lesser conversion of APAP to toxic metabolite. So, our results suggest a role for BI-1 in the regulation of RIDD activity in early adaptive responses against APAP induced ER stress.

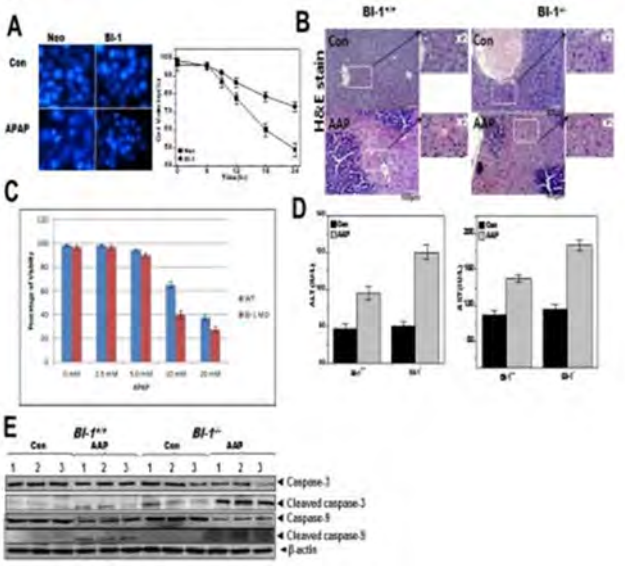

Fig. 1. BI-1 reduced the acetaminophen induced cell apoptosis and liver injury in mice.

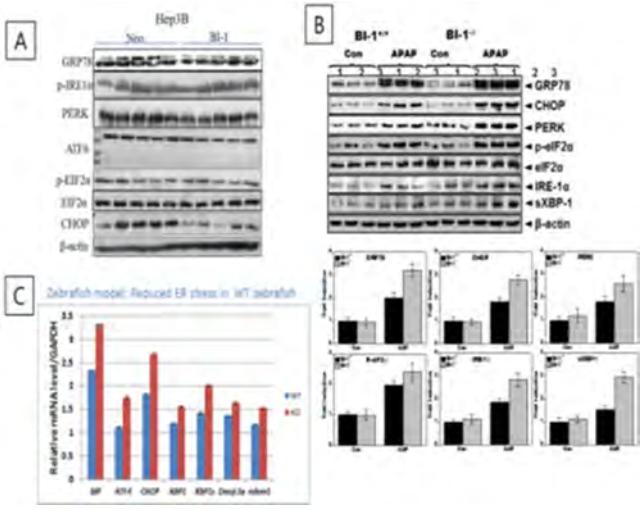

Fig. 2. BI-1 reduced the acetaminophen induced ER stress.

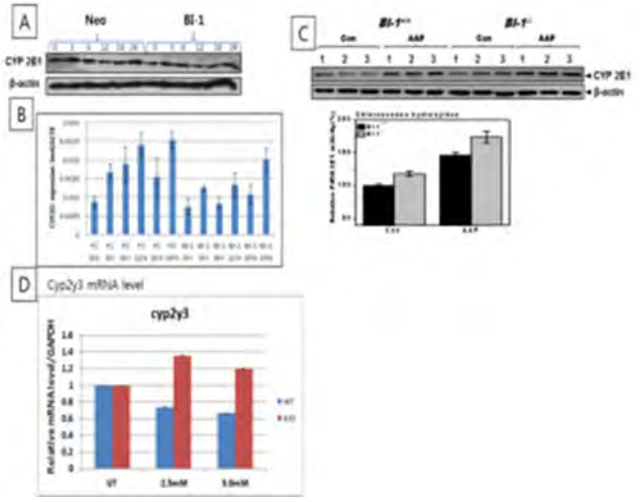

Fig. 3. CYP2E1 expression is reduced in presence of BI-1.

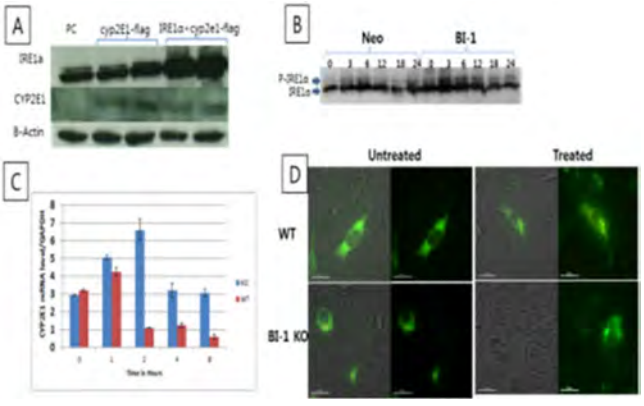

Fig. 4. BI-1 reduces oligomerization of IRE1α.

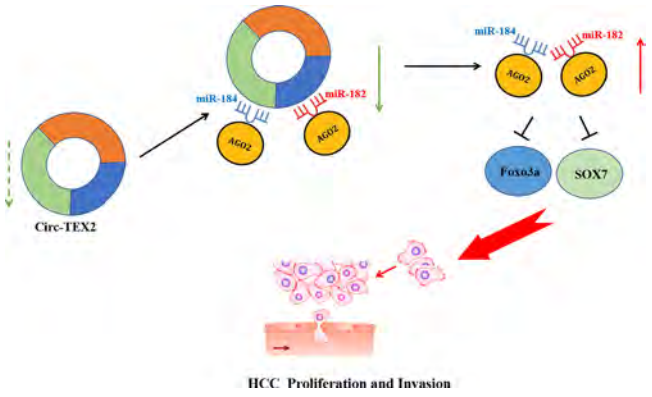
Conclusion: Phosphorylation of IRE1α was observed but not oligomerization in the presence of BI-1,CYP2E1 mRNA levels were reduced in the presence of BI-1 and resulted in less toxic effect of APAP. Further, experiments need to be carried out to fully confirm the BI-1regulation of IRE1α.

THU335

Circular RNA circ-TEX2 acts as the sponge of miR-182 and miR-184 to suppress hepatocellular carcinoma proliferation and invasion

Rong Li[1], Jinliang Liang[2], Zhongying Hu[3], Xuejiao Li[1], Wei Liu[1]. *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangdong Provincial Key Laboratory of Liver Disease Research, Guang Zhou, China; [2]The Third Affiliated Hospital of Sun Yat-sen University, Guangdong Provincial Key Laboratory of Liver Disease Research, Guang Zhou, China; 3The Third Affiliated Hospital of Sun Yat-sen University, Guangdong Provincial Key Laboratory of Liver Disease Research, Guang Zhou, China*
Email: lwei6@mail.sysu.edu.cn

Background and Aims: Multiple circular RNAs are dysregulated in Hepatocellular carcinoma (HCC). However, the function and molecular mechanism of them are largely unclear. Previous studies suggested that circular RNAs can play important roles in the development of cancer. Therefore, identify the key circular RNAs in HCC and reveal their potential function and molecular mechanism have important significance for improving the diagnosis and treatment of HCC.
Method: The dysregulated circular RNAs were identified through integrating the analysis of three human circular RNA microarrays (GSE94508, GSE97332 and GSE 78520) and were further validated using qRT-PCR in HCC tissues and HCC cell lines. The characteristics of circular RNA were verified through Sanger sequencing, divergent primer PCR, RNase R treatment, RNA intracellular localization analysis and the structure was predicted in Mfold. The functions of circular RNA in HCC were assessed through CCK8 assays, clone formation assays, EDU assays and Transwell assays in vitro and tumor xenografts in vivo. The mechanism of circular RNA in HCC was demonstrated using dual-luciferase reporter, RNA immunoprecipitation assays and western blot.
Results: Circ-TEX2 was down-regulated in HCC and associated with the pathological staging of HCC. The vitro experiments showed that overexpressing circ-TEX2 can significantly inhibit the proliferation and invasion of HCC cells. Tumor xenografts in vivo also confirmed that circ-TEX2 can effectively suppress the growth of HCC. Furthermore, we demonstrated that circ-TEX2 can bind with miR-182 and miR-184 to up-regulate the expression of their downstream target genes (Foxo3a and SOX7).



Conclusion: Our study reveal that the down-regulation of circ-TEX2 in HCC attenuates the binding of circ-TEX2 and miR-182 or miR-184 to release their functions which decrease the expression of Foxo3a, and SOX7, ultimately enhance the proliferation and invasion of HCC.

THU336

CircRNA_104797 mediates acquired sorafenib resistance in hepatocellular carcinoma through regulating ROS

Junjie Xu[1], Yelin Ruan[1], Lin Ji[1], Haoqi Pan[1], Zhongjie Lin[1], Xiujun Cai[1]. *[1]Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Department of General Surgery, Hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: Hepatocellular carcinoma (HCC) is a fatal cancer with limited treatment methods. Sorafenib is one offering great clinic benefit. However, sorafenib resistance often occurs within one year. The mechanism behind sorafenib resistance is still unclear. Circular RNAs (circRNAs) are widely expressed noncoding RNAs with complicated biological functions. Recently, some studies found that circRNAs may play important roles in regulating reactive oxygen species (ROS) and mediate drug response. In this study, we aimed to study circRNA_104797 in regulating sorafenib response through ROS regulation.
Method: Sorafenib resistant (SR) cell lines were established by sustained treatment of small dose of sorafenib in the media. A CircRNA Array analysis and mass spectrum were carried out to detect possible targets. Flow cytometry was performed to analyze ROS and apoptosis level. Protein level was measured by western blotting. RNA pulldown and immunoprecipitation were carried out to detect possible binding between circRNA and protein. Confocal fluorescence microscope was used to reveal colocalization between circRNA and protein.
Results: In this study, we found a circRNA named circRNA_104797 was upregulated in HepG2 SR cell line compared with parental cell. Depletion of circRNA_104797 by siRNA transfection could increase cellular ROS and induce mitophagy; while overexpression of circRNA_104797 could reduce ROS level under sorafenib treatment. Besides, we found the ROS scavenger N-acetyl-cysteine could reduce apoptosis level induced by circRNA depletion. Mass spectrum analysis was performed to explore distinctive proteins after circRNA depletion. Another mass-spectrometry was conducted to analyze protein binding with this circRNA. Results suggested protein Ubiquilin 1 was stabilized by circRNA_104797. RNA immunoprecipitation, RNA pulldown and confocal fluorescence microscopy results confirmed our suggestion. What's more, Ubiquilin 1 degradation was accelerated after circRNA_104797 depletion. Overexpression of Ubiquilin 1 could partly reduce apoptosis caused by circRNA depletion.
Conclusion: Our results uncovered one function mechanism of circRNA_104797. Under sorafenib treatment, circRNA_104797 mediated ROS regulation through stabilizing Ubiquilin 1. Therefore, circRNA_104797 and Ubiquilin 1 may offer to be potential targets in treating HCC.

THU337

Ubiquilin 1 mediates sorafenib resistance in hepatocellular carcinoma through targeting mitochondrial biogenesis via regulating PGC1?

Junjie Xu[1], Lin Ji[1], Zhe Wan[1], Zhongjie Lin[1], Shi Jiang[1], Dong Cen[1], Yu Pan[1], Xiujun Cai[1]. *[1]Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Department of General Surgery, Hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: Hepatocellular carcinoma (HCC) is a fatal cancer with limited treatment options. Systemic treatment using sorafenib offers great clinical curativeness; however, resistance often occurs. The mechanisms of resistance include dysregulation of PI3K/Akt and JAK/STAT pathways, epithelial–mesenchymal transition, and the hypoxia-inducible response. Meanwhile, recent studies have revealed sorafenib targets electron transport chain complexes, resulting in reactive oxygen species (ROS) generation. This study aimed to study the role of ROS in sorafenib resistance.
Method: Flow cytometry was used to measure intracellular ROS levels. Oxygen consumption rate (OCR) detection and transmission

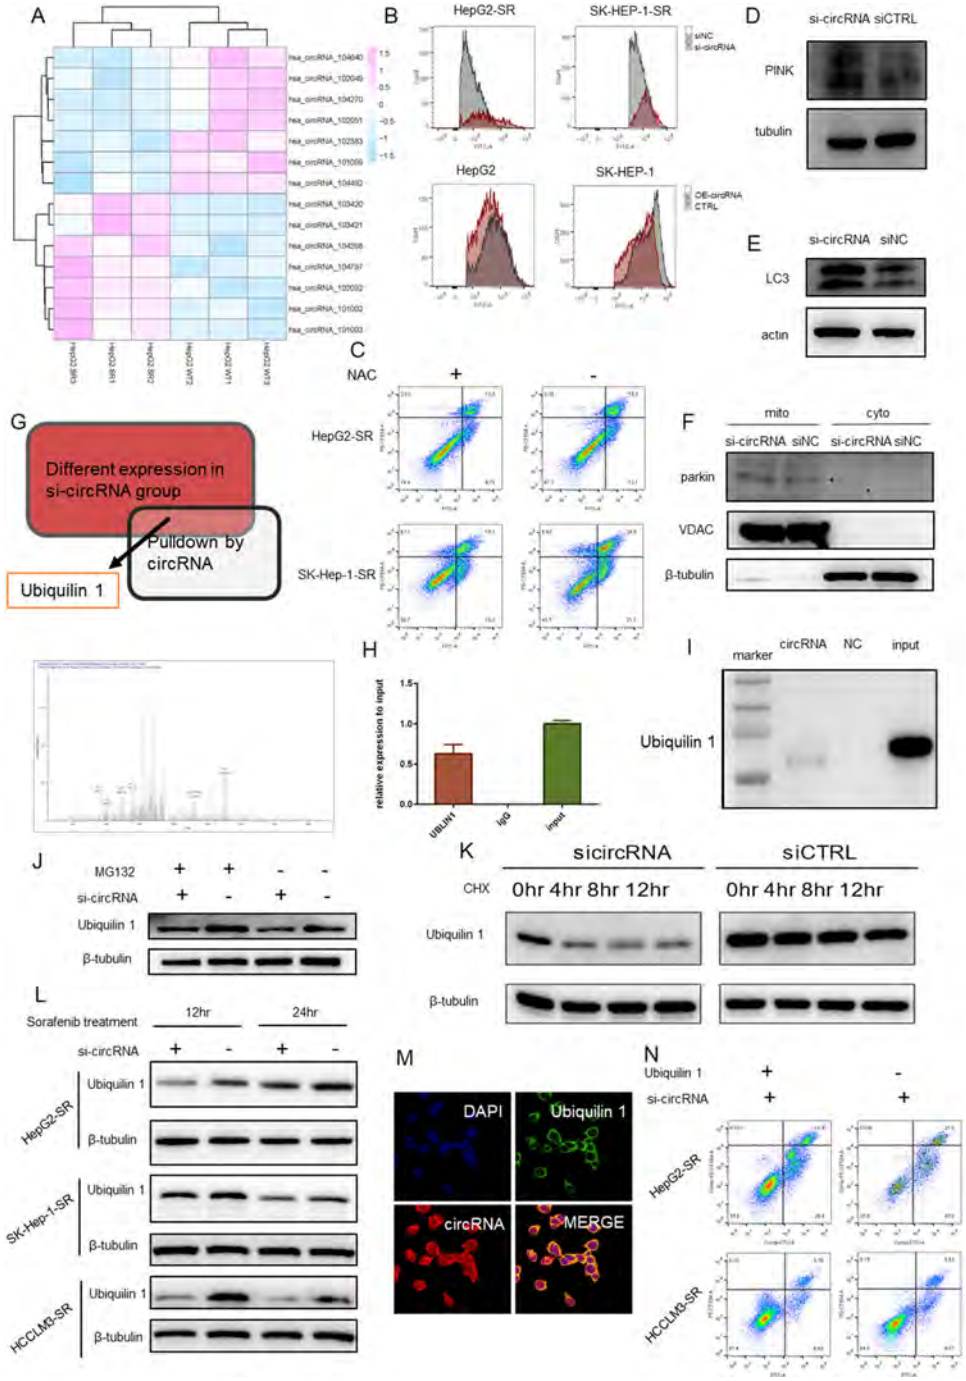


Figure: (abstract: THU336)

electron microscopy were adopted to investigate the function and morphological changes of mitochondria. Western blotting and qRT-PCR were used to measure protein and mRNA levels. A mass spectrum was performed to identify distinctive proteins. Expression level of ubiquilin 1 in patient tissue was valued by immunohistochemistry.

Results: Sorafenib induced ROS responses were repressed in sorafenib-resistant cells than parental cells. Mitochondria maintained greater integrity both functionally and morphologically in resistant cells under sorafenib treatment. However, the number of mitochondria decreased in sorafenib-resistant cells, as detected via transmission electron microscopy, mitochondria DNA content and cellular OCR measurements. Further investigation found mitochondrial biogenesis was inhibited by downregulated expression of peroxisome proliferator-activated receptor γ coactivator 1β (PGC1β). In addition, we found that ubiquilin 1 was upregulated in sorafenib-resistant cells, and thus accelerates the protein degradation of PGC1β to attenuate ROS generation under sorafenib treatment in sorafenib-resistant cells. Importantly, genome wide proteome analysis with mass-spectrometry between the parental and sorafenib-resistant HCC tumors from mouse models showed that proteins altered in sorafenib-resistant cells were enriched in ubiquitin-mediated proteolysis pathway and mitochondrial organization function. Clinical data further demonstrated that patients with high ubiquilin 1 levels had worse recurrence-free survival.

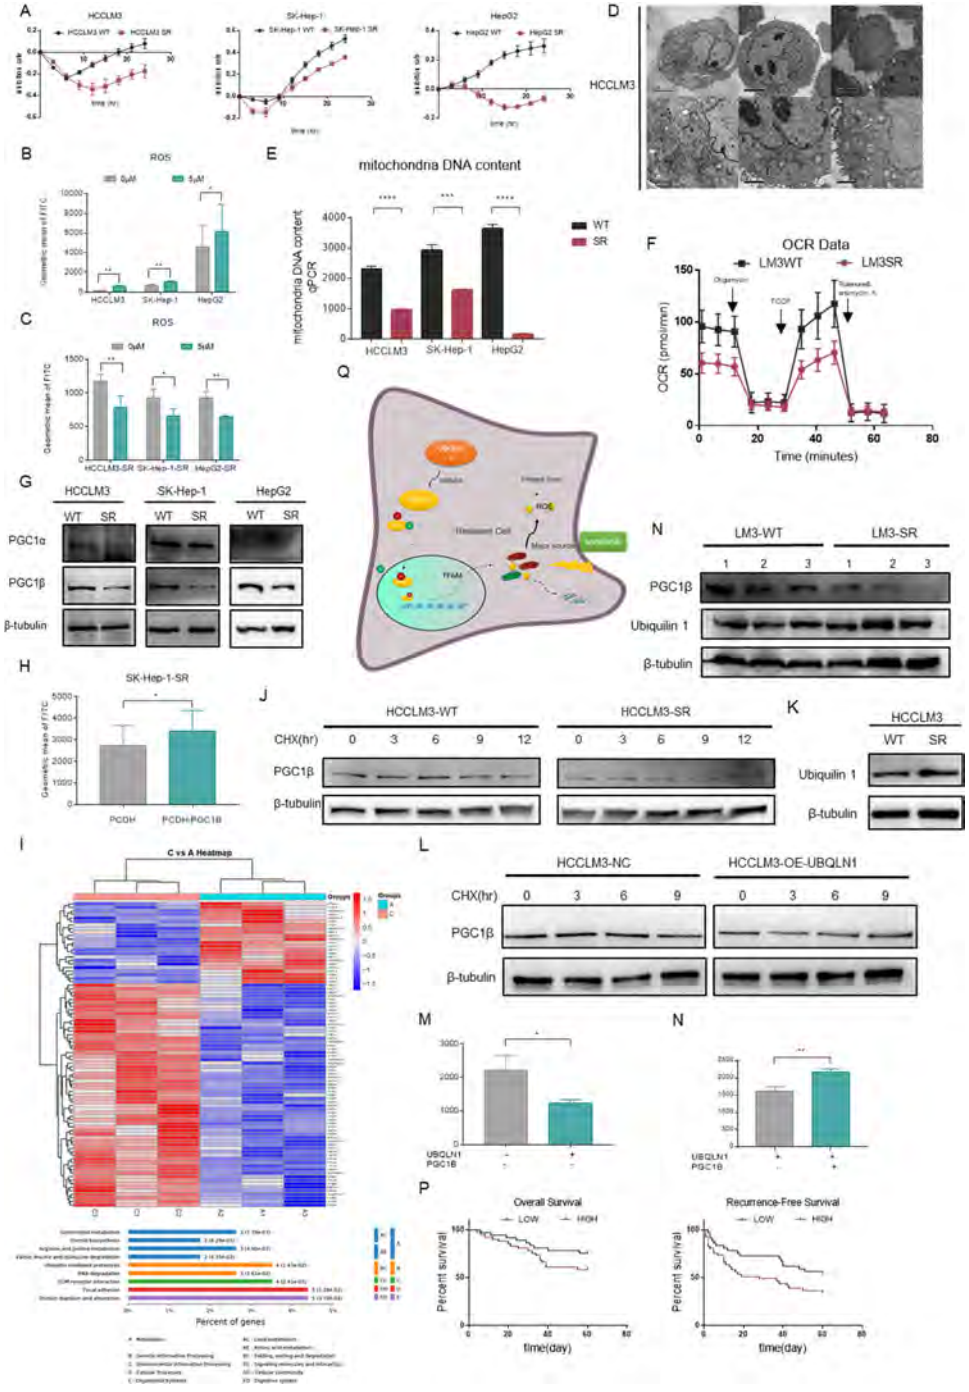

Figure: (abstract: THU337)

Conclusion: We proposed a new mechanism of sorafenib resistance in relation to mitochondrial biogenesis and ROS generation. We found that upregulation of Ubiquilin 1 in sorafenib-resistant HCC cells enhanced the degradation of PGC1β, which resulted in down-regulated mitochondria number and suppressed ROS level, thus contributing to the sorafenib resistance. These findings provide novel mechanistic insights and therapeutic strategies for HCC patients.

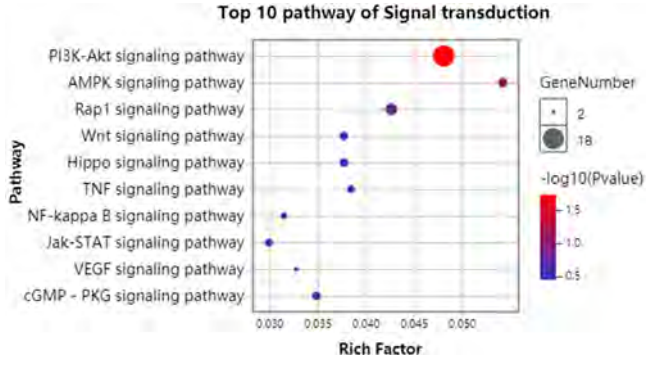
THU338

Investigating the mechanism of treating acute-on-chronic liver failure with human bone marrow-derived mesenchymal stem cells via hepatocytes exosomal miRNAs

Jing Zhang[1], Juan Gao[1], Bingliang Lin[1]. [1]*The Third Affilirated Hospital, Sun Yat-sen University, Department of Infectious Diseases, Guangzhou, China*

Email: lamikin@126.com

Background and Aims: Acute-on-Chronic liver failure (ACLF) is a severe syndrome of liver disease; The mortality rate is up to 30–50% in non-transplanted patients in worldwide. It is reported that human bone marrow mesenchymal stem cells (BMSCs) can improve the prognosis of ACLF, but the underlying mechanism remains unclear. To explore the roles of BMSCs on hepatocyte-to-hepatocyte communication, we used next-generation sequencing (NGS) and bioinformatics techniques to detect exosomal miRNAs in the hepatocyte microenvironment and to try to find the key genes and signaling pathways that could be affected hepatocytes survival.
Method: Primary hepatocytes from normal or ACLF mice were isolated and cultured in vitro. Human BMSCs were co-cultured with ACLF primary hepatocytes. Isolated exosomes from cell supernatant and build the miRNAs sequencing database.
The study include the normal group, the ACLF group and the BMSCs treatment group. The final target genes were analyzed by Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analysis.
Results: Human BMSCs could reverse the change of exosomal miRNA abundance in the hepatocyte microenvironment of ACLF mice. In the ACLF group, 44 miRNAs were down-regulated, such as miR-122-5p and miR-148a-3p. 88 miRNAs were up-regulated, such as miR-24-3p and miR-99a-5p. Accordingly, 151 genes were up-regulated and 246 genes were down-regulated in the ACLF group. GO enriched 62 differentially expressed genes related to cell proliferation. CXCL5, SOX4, IGF1, Wnt and some other genes could be the targets for promoting hepatocyte growth. KEGG enrichment annotates the pathways associated with cell growth, death, and signal transduction. The PI3K-AKT signaling pathway could be up-regulated by BMSCs in ACLF hepatocytes.



Conclusion: Human BMSCs can regulate the exosomal miRNAs of hepatocytes in ACLF, which may affect the prognosis of patients. The further study need done to confirm these results and developing new therapeutics methods for ACLF.

Viral hepatitis C: Clinical aspects except therapy

THU339

A novel hepatitis C intervention in Denmark to test and treat people who inject drugs

Jeffrey Lazarus[1], Anne Øvrehus[2,3], Jonas Demant[4], Louise Krohn-Hehli[5], Nina Weis[5,6]. [1]*University of Barcelona, Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain;* [2]*Odense University Hospital, Department of Infectious Diseases, Odense C, Denmark;* [3]*University of Southern Denmark, Faculty of Health Sciences, Department of Clinical Research, Odense C, Denmark;* [4]*Brugernes Akademi, Copenhagen, Denmark;* [5]*Copenhagen University Hospital, Hvidovre, Department of Infectious Diseases, Hvidovre, Denmark;* [6]*University of Copenhage, Faculty of Health and Medical Sciences, Department of Clinical Medicine, Copenhagen N, Denmark*
Email: anne.oevrehus@rsyd.dk

Background and Aims: Providing testing and treatment for hepatitis C (HCV) for people who inject drugs (PWID) is a key component in eliminating HCV. Reaching this population with health care services can be challenging. Combining point-of-care testing with peer support and counselling has been shown to be effective. However, treatment also needs to be more accessible. The aim of this study was to investigate if a mobile van equipped with rapid detection tests for HCV antibodies and RNA could test and link PWID to care and treatment in a hospital.
Method: In Copenhagen, Denmark, a peer-led mobile service providing counselling, anti-HCV testing (In-Tech™), and linkage to standard of care was equipped with a point-of-care HCV-RNA finger-prick test (Xpert HCV Viral Load *Finger-Stick* Point-of-Care Assay, Cepheid). All clients were eligible for testing but only those with a legal residence in Denmark could be referred for treatment. Eligible HCV-RNA+ individuals were offered assisted referral to a fast-track hospital clinic for treatment, and peers provided assistance as needed.
Results: From 1 May to 31 October 2019, a total of 304 anti-HCV tests were performed, and 42 individuals were found to be HCV-RNA+. In addition, 6 individuals with known HCV infection contacted the service to be linked to care. Of the 48 individuals with possible chronic HCV infection, 24 (50%) were evaluated at the hospital clinic and by 15 November 2019, all had initiated treatment with direct-acting antiviral therapy. The main reasons for not being evaluated were being in the country illegally (n = 10, 42%) and being lost to follow up (n = 8, 33%). Two died before being linked to care and two ended up in prison. Among those initiating treatment, 14 were connected to drug treatment services and could be treated while receiving opioid substitution therapy. The peer-led service assisted all treated with inter alia communication with the hospital nurse, collecting medicine, and accompaniment to follow-up visits.
Conclusion: A peer-led mobile service can engage PWID in HCV testing and treatment. We identified being an illegal migrant as a major cause for not accessing care. This poses a challenge for HCV elimination in Denmark, in part due to the risk of onward transmission, and is a health threat to the individual.

THU341

Kidney transplant from hepatitis C positive donors to hepatitis C negative recipients: report on the first experience in the UK

Brendan Healy[1], Rhys Oakley[2], Matthijs Backx[1], Robert Bradley[2], Michael Stephens[3], Nicola Price[4], Sian Griffin[3], Catherine Moore[4], Jonathan Evans[4], Sarah Browne[3]. [1]*Public Health Wales, Microbiology Dept, Cardiff, United Kingdom;* [2]*University Hospital of Wales, Pharmacy, Cardiff, United Kingdom;* [3]*University Hospital of Wales, Nephrology, Cardiff, United Kingdom;* [4]*Public Health Wales, National Virology Centre, Cardiff, United Kingdom*
Email: brendan.healy@wales.nhs.uk

Background and Aims: Recent papers have reported the safety of transplanting kidneys from Hepatitis C (HCV) positive donors to HCV negative recipients with initiation of pan-genotypic therapy immediately after detecting transmission post-transplantation. Sustained SVR near 100% have been achieved.
Method: Cardiff Transplant Unit is the first unit in the United Kingdom to transplant kidneys from HCV positive donors into suitably consented HCV negative recipients. Details of the service development will be presented. Strong established links with virology and infectious diseases team and work in partnership with patients enabled the programme to be established. We present data from 9 kidney transplant recipients who received a transplant from 6 HCV positive donors.

No.	Age	Sex	Transplant Date	Transplant type	Date PCR positive	VL	Genotype	Treatment start date	Treatment
1	64	M	26/05/2019	DCD	05/06/2019	121176	3a	07/06/2019	Maviret

9	37	M	14/10/2019	DBD	17/10/2019	22	1a	18/10/2019	Maviret

Figure: (abstract: THU341)

Results: Between May and September 2019, nine Caucasian patients (8 male, 1 female) in Cardiff have received kidney transplants from HCV positive donors. The mean (+/– SD) age of recipients was 55 +/– 12 years. All developed viraemia within 3 to 7 days after transplant and have been treated with pan-genotypic therapy. Four have been treated with Glecaprevir/Pibrentasvir and five with Sofosbuvir/Velpatasvir.

To date 6 patients have completed antiviral (DAA) treatment. All patients have become undetectable on treatment. Treatment choice has been principally influenced by renal function at the time of initiation. None of the patients had a clinically significant increase in aminotransferase levels.

All patients in Cardiff are treated with tacrolimus and mycophenolate mofetil (with or without steroids) as maintenance immunosuppression with regular monitoring of tacrolimus levels. Post transplantation kidney function has been good; mean eGFR 51 ml/min (IQR 38 ml/min–65 ml/min). One patient underwent graft nephrectomy 10 days post transplant due to renal vein thrombosis (not related to HCV or DAA therapy). SVR 12 data will be presented at the conference.

Conclusion: The first cases of transplant of HCV positive donors to HCV negative recipients in the UK are presented. The success of these first cases warrants consideration for wider adoption of this practice in line with UK Position Statement on the use of organs from Hepatitis C viraemic Donors and increased infectious risk donors in Hepatitis C negative recipients.

THU342

Pharmacy-based molecular point-of-care testing for hepatitis C (HCV) in high-risk patients: feasibility and linkage to care

Benedict Rogers[1,2], James Spear[3], Vinay Mistry[4], Martin Wiselka[1,2], Manish Pareek[1,2]. [1]*University Hospitals of Leicester NHS Trust, Infectious Diseases and HIV Medicine;* [2]*University of Leicester, Respiratory Sciences;* [3]*University Hospitals of Leicester, Hepatitis C Operational Delivery Network;* [4]*Leicestershire Local Pharmaceutical Committee*
Email: brsr2@le.ac.uk

Background and Aims: Achieving HCV elimination will require novel approaches to testing and treatment, particularly in high-risk patient groups, such as people who inject drugs, who may not readily access or engage with healthcare. Testing methods that are both easy to deliver and are acceptable to patients are essential. This study aimed to assess the feasibility of delivering rapid molecular HCV testing using the Cepheid® GeneXpert IV:II within community pharmacies and subsequent linkage to care.

Method: Eight community pharmacies within Leicestershire, England, were invited to take part. All had established needle exchange and/or opiate substitution therapy programmes and had facility for a private consultation room. Individual pharmacists received training on use of the GeneXpert platform, as well as the consent and testing process. Patients returned after 1-hour to receive their result or at an agreed alternative time.

Results: Over a nine-week period a total of 203 tests were performed at 6/8 pharmacies, with the majority (92%) undertaken by three pharmacies. 30 (15%) patients were found to have detectable HCV RNA, with a median HCV RNA of 715500 IU/ml. Of these, 20 (66%) were not previously known to the Leicester treatment network. All positive patients were offered a clinic appointment and to date 20 (66%) have attended. 12 (40%) of the 30 positive patients have now completed treatment and one is due to commence imminently. 2 patients (7%) were ineligible for treatment on clinical grounds (pregnancy and spontaneous clearance), 2 (7%) defaulted from further follow-up, 2 (7%) are under ongoing review and one patient declined treatment.

Conclusion: Our study has shown that hepatitis C testing of high-risk patients using Cepheid® GeneXpert within a pharmacy setting was feasible and that subsequent linkage to care was achieved in two thirds of all positive cases. Rapid HCV RNA results offers a same-day result, which may be advantageous over antibody testing methods such dried blood spot, and implementation on a wider scale could play an important role in achieving HCV eradication.

THU343

Improving female street sex worker (FSSW) access to hepatitis C testing and treatment

Catherine Wigglesworth[1], Diane Williams[1], Mark Aldersley[1]. [1]*Leeds Teaching Hospitals NHS Trust, Hepatology, Leeds, United Kingdom*
Email: markaldersley@hotmail.co.uk

Background and Aims: Female Street Sex Workers (FSSWs) have high rates of substance misuse and sexually transmitted infections, which are a key contributors to the increased incidence of HCV infection seen in this population. If the WHO target to eliminate HCV is to be met, this group will require specific test and treat strategies. Two local charities (The Joanna Project and Basis Yorkshire) who work closely with FSSWs were identified to work with during the project. A previous survey had identified that venepuncture and travelling to healthcare facilities were significant barriers to accessing testing and treatment for HCV. The aim of the study was to improve access to treatment for FSSWs without the need for direct engagement with health services.

Method: Over a 12 weeks period in 2018 FSSWs working in Leeds were approached in support facilities/charity premises and offered counselling and dry blood spot HCV antibody testing with subsequent capillary blood PCR testing in the local laboratory. Any patient testing PCR positive was offered pan genotypic HCV treatment with

Epclusa® or Maviret® within the charity premises after checking for drug drug interactions with their prescribed and non-prescribed medication.

Results: 46 FSSWs were tested during the 12 week period. 22/46 (47.8%) of those FSSWs tested were HCV antibody positive and 18/46 (39.1%) were HCV PCR positive indicating very high prevalence rates in line with their known high risk behaviour. Of those 18 PCR positive patients 13 commenced HCV treatment, three patients declined treatment and two are continuing to consider whether to be treated or not.

Outcomes - RNA Positive	No of FSSW	Outcomes - RNA Positive	No of FSSW
Started Treatment	13	Declined Assessment	0
Declined Treatment	3	Considering Treatment	2

Figure: Treatment Commencement for FSSW testing HCV PCR positive.

Conclusion: FSSWs have a very high prevalence of HCV PCR positivity but are willing to be treated for HCV if this service is provided outside of a healthcare centre and does not involve venepuncture. Following up this group post treatment to ensure cure and reduce risks of reinfection is also likely to be a challenging despite ongoing support and education in the charity sector.

THU344

Screening and treatment difficulties of hepatitis C virus infected patients with substance use disorders or dual pathology, despite centralized management in an addiction and dual diagnosis center

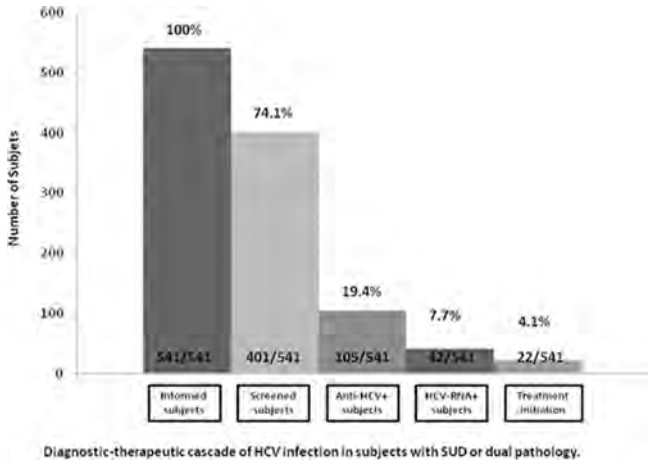
Cristina Marcos Fosch[1], Felipe Palma-Alvarez[2], Ariadna Rando[3], Constanza Daigre[2], Mar Riveiro Barciela[1], Jordi Llaneras[1], Marta Perea[2], Francisco Rodriguez Frias[3], Rafael Esteban[1], Lara Grau-López[2], Maria Buti[1]. *[1]Vall Hebrón Hospital, Liver Unit, Barcelona, Spain; [2]Vall Hebrón Hospital, Psychiatry Department, Barcelona, Spain; [3]Vall Hebrón Hospital, Microbiology Department, Barcelona, Spain*
Email: cmarcos@vhebron.net

Background and Aims: WHO goal is to eliminate hepatitis C virus (HCV) infection as a public health threat by 2030. In order to achieve this target, screening and treatment strategies for risk populations with poor access to the health system are necessary. The objective of the study was to establish an HCV screening and treatment program for subjects with substance use disorders (SUD) or dual pathology (psychiatric plus SUD) treated in an Addiction and Dual Diagnosis Center (ADDC).

Method: Prospective study for screening and treatment of HCV in subjects with SUD or dual pathology followed in an ADDC from November 2018 to June 2019. Anti-HCV antibodies were determined with reflected HCV-RNA determination. In those HCV-RNA positive cases the liver lesion was evaluated and the treatment started at the ADDC.

Results: The study was proposed to 541 subjects and 401 (74%) accepted. 75% were male, the average age was 45 years and 61% had dual pathology. 105 (26.2%) were anti-HCV positive and 42 (10.5%) HCV-RNA positive. Treatment was only initiated to 22 subjects due to the high loss of follow-up. Those anti-HCV positive had higher frequency of poly-drug abuse ($p < 0.001$), need for internalization in therapeutic communities ($p < 0.001$), SUD to illegal substances ($p < 0.001$), use of injected drugs ($p < 0.001$), number of overdose episodes ($p < 0.001$), use of opioid substitution therapy ($p < 0.001$), personality disorders ($p = 0.02$) and psychotic symptoms due to substance abuse ($p < 0.001$).

Those HCV-RNA positive subjects were in larger proportion women ($p = 0.02$), younger ($p = 0.003$), with more cocaine consumption in the last 6 months ($p = 0.02$) and greater deterioration in mental quality of life ($p = 0.04$) than HCV-RNA negative.



Diagnostic-therapeutic cascade of HCV infection in subjects with SUD or dual pathology.

Conclusion: There is a significant difficulty in the screening and treatment of HCV in subjects with SUD or dual pathology probably related to their underlying pathology. The HCV-RNA positive are often young women with greater cocaine consumption and more deterioration of the mental quality of life.

THU345

Integrating hepatitis C virus screening by dry blood spot test into colorectal cancer screening: a randomized controlled trial

María Cristina Reygosa Castro[1], Felicitas Diaz-Flores[2], María Mercedes Dorta Espiñeira[3], María Luisa Galván Luis[3], Raquel Llada Marrero[3], Myriam Sánchez Pérez[3], Alejandro Jiménez Sosa[4], Enrique Quintero[1], José Ramón Vázquez Días[3], Manuel Hernandez-Guerra[1]. *[1]Hospital Universitario de Canarias, Aparato Digestivo, Cuesta (La, Spain; [2]Hospital Universitario de Canarias, Laboratorio Central, Cuesta (La, Spain; [3]Hospital Universitario de Canarias, Unidad de Atención Familiar y Comunitaria La Laguna-Tenerife Norte, Cuesta (La, Spain; [4]Hospital Universitario de Canarias, Unidad de Investigación, Cuesta (La, Spain*
Email: mhernandezguerra@gmail.com

Background and Aims: To achieve WHO goals for the elimination of hepatitis C virus (HCV) infection by 2030 screening is mandatory, and targeting high prevalence groups such as birth cohorts adults is a good option. Currently, in our health care setting this population is being invited for colorectal cancer (CRC) screening with biennial fecal immunochemical testing (FIT). Integrating a simplified diagnostic tool such as the dry blood spot test (DBS) to FIT screening could be of great help for HCV microelimination. However, it is unknown if both screening strategies interfere regarding participation. This study was aimed to study whether adding DBS to FIT CRC screening may improve HCV screening adherence.

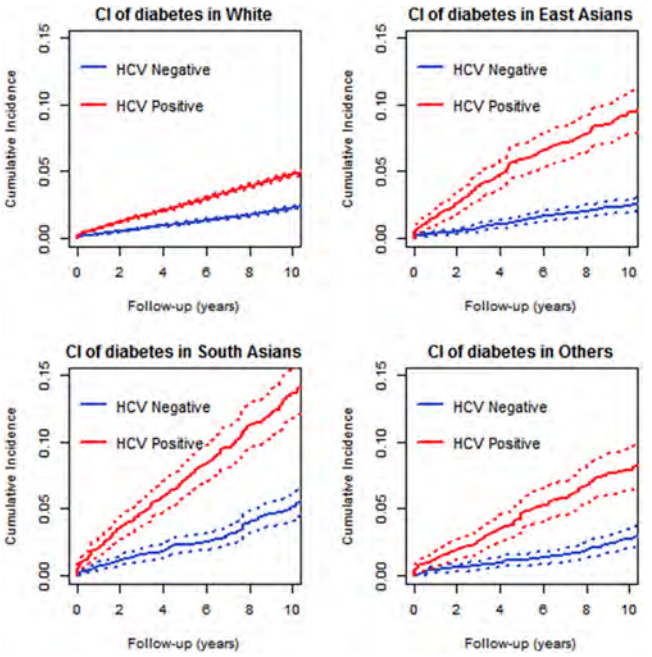
Method: A randomized controlled trial (NCT04037046) was conducted in asymptomatic individuals aged 50–70 years, attended by four general practitioners (GPs) in our area. Participants (n = 609) were stratified by age, sex and address and randomized to one of three groups: 1) HCV (DBS kit) screening at the healthcare center, following invitation letter and appointment with their GP; 2) Combined screening for HCV and CRC (FIT kit); and 3) Self-testing screening for HVC and CRC with pre-sealed envelope for sending kit samples to the central laboratory. DBS were positive if >15UI (Cobas 6800®) and FIT ≥ 20ug/g feces (OC-Sensor kit®).

Results: Among randomized patients (mean 59.4 ± 5.4 years, 51.2% male), and excluding 7.3% after not receiving postal mail, 132 (23.3%) subjects participated with test delivery in a median of 30.5 days (IQR 13.8–46.2); 30% in DBS, 28.4% in DBS+FIT and 13.5% in the self-testing strategy ($p < 0.01$). In the first two strategies, 38.7% and 25.2% had previous opportunistic screening with FIT or colonoscopy respectively, and 9% had performed a serology for HCV. No differences

between groups were observed. Patients in the DBS strategy compared to DBS+FIT were higher alcohol consumers (p = 0.028). All DBS and FIT sent to the center for analysis were considered valid (including self-testing samples), with 0.81% of viremia and 12.3% of positives, respectively.
Conclusion: HCV screening by invitation letter from GPs to perform DBS in the healthcare center is equally accepted when it is associated with CRC screening by FIT, and independently of the previous testing for CRC or HCV. This integrating screening strategy can be particularly useful in healthcare areas where CCR screening program are widely implemented with a high participation rate.

THU346
Ethnic disparities in the risk of hepatitis C virus-related diabetes in a large population-based cohort in Canada
Dahn Jeong[1,2], Stanley Wong[2], Mohammad Ehsanul Karim[1,3], Mawuena Binka[2], Zahid Butt[2,4], Younathan Abdia[1,2], Prince Adu[1,2], James Wilton[2], Amanda Yu[2], Maria Alvarez[2], Dr. Margo Pearce[1,2], Sofia Bartlett[1,2], Mel Krajden[2,5], Naveed Janjua[1,2]. *[1]The University of British Columbia, School of Population and Public Health, Vancouver, Canada; [2]BC Centre for Disease Control, Vancouver, Canada; [3]St. Paul's Hospital, Centre for Health Evaluation and Outcome Sciences, Vancouver, Canada; [4]University of Waterloo, School of Public Health and Health Systems, Waterloo, Canada; [5]The University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada*
Email: dahn.jeong@bccdc.ca

Background and Aims: There is increasing evidence that persons living with hepatitis C virus (HCV) infection are at a higher risk of type 2 diabetes (T2D). Studies based in multi-ethnic settings have shown an ethnic disparity in diabetes, with an increased risk in non-White populations. Thus, the impact of HCV infection on diabetes incidence may differ across ethnic groups. This study assessed the impact of HCV on diabetes incidence within a large ethnically diverse population-based cohort. We conducted stratified analyses to examine the ethnic disparity.
Method: The incidence of T2D by HCV status was assessed in the British Columbia (BC) Hepatitis Testers Cohort, which includes ~1.7 million individuals tested or reported as a case of HCV in BC, linked with various health administrative data. Diabetes was defined using a validated algorithm modified with data on prescription drug dispensation. Individuals tested for HCV since 1990 were followed from the date of their first positive or last negative HCV RNA test to the earliest of 1) incident type 2 diabetes, 2) death or 3) end of study (12/31/2015). Propensity scores (PS) were estimated based on age at HCV diagnosis, duration of follow up and other key covariates and HCV-positive and negative individuals were matched at a 1:1 ratio without replacement. We used Fine and Gray competing risk models adjusted with potential confounders to estimate hazard ratios and 95% confidence intervals for incident diabetes, overall, and stratified by ethnicity.
Results: After PS matching, the study sample included 117,192 individuals. When adjusted for potential confounders and competing risk of mortality, HCV infection was significantly associated with incident T2D, with an adjusted hazard ratio of 2.32 (95% CI 2.20–2.46). Other characteristics significantly associated with an increased risk of T2D included older age at diagnosis, non-White ethnicities, material deprivation, obesity, having a mood and anxiety disorder, problematic alcohol use and injection drug use. When stratified by ethnicity, cumulative incidence of T2D was higher for HCV positive individuals in non-White populations (figure).



Conclusion: This analysis supports other studies that HCV infection is associated with a higher risk of developing diabetes. Furthermore, this risk was amplified among non-White populations. The findings of this study highlight the need for continued care and screening for HCV-related chronic diseases such as diabetes in individuals living with HCV infection especially among Asian populations.

THU347
The electronegative low-density lipoprotein in patients with chronic hepatitis C infection
Chia-Yen Dai[1,2,3], Yi-Shan Tsai[1], Chung-Feng Huang[1,2], Ching-I Huang[1,2], Ming-Lun Yeh[1,2], Pei-Chien Tsai[3], Jee-Fu Huang[1,2], Wan-Long Chuang[1,2], Ming-Lung Yu[1,2]. *[1]Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung Medical University, Internal Medicine, Kaohisung, Taiwan; [2]Kaohsiung Medical University, Faculty of Internal Medicine, College of Medicine, Kaohsiung, Taiwan; [3]Kaohsiung Medical University Chung-Ho Memorial Hospital, Community Medicine, Kaohsiung, Taiwan*
Email: daichiayen@gmail.com

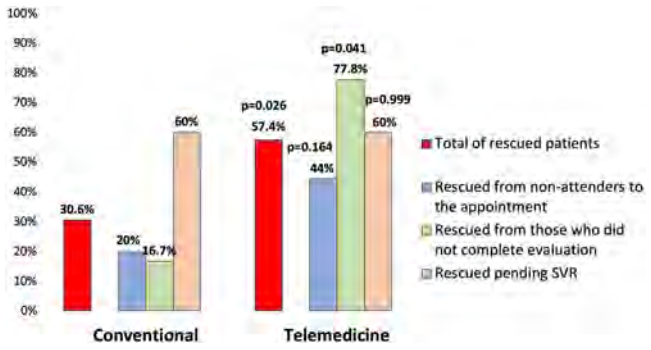
Background and Aims: Patients with chronic hepatitis C virus (HCV) infections have shown to have significantly higher mortality such as increased incidence of cancer and cancer-related mortality and extrahepatic diseases such as cardiovascular diseases and cerebral vascular diseases (CVD) than the general population. Nevertheless, patients with HCV infection display significantly decreased triglyceride, total cholesterol, high density lipoprotein-cholesterol (LDL-C) and low density lipoprotein-cholesterol (LDL-C) level in plasma. Plasma LDL has been classified into five charge-defined sub-fractions LDL L1, L2, L3, L4 and L5 using anion-exchange chromatography and L5, the most negatively charged LDL, is more abundant in patients with increased cardiac risks than in the healthy population. The present study aimed to investigate the relationship between the HCV infection and serum LDL L5 level and the impact of the antiviral therapy on the serum LDL L5 level.
Method: Patients with CHC and controls were enrolled in the present study. Patients treated with direct antiviral agents (DAAs) were enrolled for testing the serial change of the L5 at baseline, end-of-treatment (EOT) and end-of-follow up (EOF) which is the 12 weeks after cessation of therapy with definition of the sustained virological response (SVR12). Laboratory data were collected and plasma were tested for the LDL 5 sub-fractions (L1, L2, L3, L4, and L5) using the increasing negative charge on anion-exchange columns. L5% means

percent of L5 in total LDL. L5 concentration ([L5]) estimated by L5%* LDL-C.
Results: Total 477 subjects enrolled into the study. There were 167 (35.0%) with negative anti-HCV and 310 (65.0%) with positive anti-HCV and 73 subjects with the baseline, EOT and EOF samples after DAA treatment for testing the L5% and [L5]. The L5% was an independent risk factor associated with for HCV infection (the risk of L5% >1.8 was approximately ten-fold (OR = 10.28) and the risk of L5% >5 (OR = 8.1) was approximately eight-fold after adjusting the other risk factors. The anti-HCV positivity was the only factor significantly associated with the risk of L5%>1.8 in multivariate analyses. Among patients with HCV infection, L5% was significantly associated with ALT and platelet levels. For patients with DAA therapy, plasma L5 (%) and [L5] significantly decreased by successful anti-viral treatment ($p < 0.0001$ for L5% and $p = 0.0018$ for [L5]).
Conclusion: LDL L5, showing an increased level compared to controls, indicates that it can be used as a new biomaker for liver-related disease caused by HCV infection. Although the elevated serum lipid profile has been noted after successful DAA therapy, the decreased level of L5 after cure of the HCV RNA implicate a role in the decreased risk of CVD.

THU348
Telemedicine and decentralized treatment dispensation to rescue patients in a hepatitis C micro-elimination program based on on-site dried blood spot testing in drug addiction centers

Dalia Morales Arraez[1], Maria Jesus Medina Alonso[2], Felicitas Diaz-Flores[3], Fernando Gutierrez[4], Victor Perez Perez[2], Luz Goretti Santiago Gutiérrez[5], Julia Nazco Casariego[4], Enrique Quintero[1,6], Manuel Hernandez-Guerra[1,6]. *[1]Hospital Universitario de Canarias. Universidad de La Laguna, Servicio de Digestivo, Spain; [2]Unidad de Atención a las Drogodependencias ANTAD, Spain; [3]Hospital Universitario de Canarias, Laboratorio Central, Spain; [4]Hospital Universitario de Canarias, Servicio de Farmacia, Spain; [5]Unidad de Atención a las Drogodependencias San Miguel, Spain; [6]Instituto Universitario de Tecnologías Biomédicas CIBICAN, Departamento de Medicina Interna, Psiquiatría y Dermatología, Universidad de La Laguna, Spain*
Email: mhernandezguerra@gmail.com

Background and Aims: Despite incorporating decentralized tests such as on-site dried blood spot testing (DBS) in Drug Addiction Centers (DAC) to facilitate HCV care cascade, a high percentage of patients drop-out, mainly due to socioeconomic reasons. This fact is a further barrier to reach WHO elimination goals by 2030. Our aim was to evaluate if telemedicine linked to a decentralized dispensation of HCV treatment is a feasible and effective strategy to rescue dropouts in this model of care.
Method: Between January 2017 to July 2018, patients lost to follow-up from a micro-elimination plan in DAC based on anti-HCV DBS testing were registered. These patients were proposed to RNA DBS testing (Cobas 6800©) and according to the center: a) telemedicine (Webex-Cisco©), and DAC staff-led model of treatment dispensation, or b) schedule an appointment with the specialist as the conventional model. A questionnarie for the assessment of patient satisfaction with realtime telemedicine was performed to participants.
Results: Among 512 prospective participants, 178 patients were positive for anti-HCV and were scheduled with the specialist. 55.6% (n = 99 of these patients did not complete the program (85.5% male, 46 ± 9.5 years): 44 patients were non-attenders to the appointment with the specialist, 25 patients did not complete the evaluation and 30 patients (among 68 treated) were pending assessment for sustained virological response. The number of rescued patients that completed the program was significantly higher in the telemedicine group than in the conventional model (57.4% vs. 30.6%, $p = 0.026$), especially in those patients with a previous incomplete evaluation (77.8% vs. 16.7%, $p = 0.041$) (see figure). Patients satisfaction with telemedicine care was excellent among participants.



Conclusion: Telemedicine linked to a decentralized model for HCV treatment dispensation, as an interventional strategy in a program based on on-site diagnosis, is well accepted and effective to rescue patients previously lost to follow-up in DAC, facilitating micro-elimination in this priority population.

THU349
The success of outreach hepatitis C screening among a Belgian population of drug users in a rural and urban setting

Dana Busschots[1,2], Rob Bielen[1,2], Özgür Koc[1,2,3], Eefje Dercon[4], Tessa Windelinckx[5,6], Griet Maertens[5], Stefan Bourgeois[7], Rita Verrando[4], Catharina Matheï[8], Geert Robaeys[1,2,9]. *[1]Hasselt University, Health and Life Sciences, Diepenbeek, Belgium; [2]Ziekenhuis Oost-Limburg, Department of Gastroenterology, Genk, Belgium; [3]Maastricht University, Medical Microbiology, School of NUTRIM, Maastricht, Netherlands; [4]zorGGroep Zin vzw (fusie van CGG VGGZ en CAD Limburg), Hasselt, Belgium; [5]Free Clinic ngo Antwerp, Antwerpen, Belgium; [6]Coordinator GIG (Health promotion in Injecting Drug use), Harm Reduction, Belgium; [7]ZNA Stuivenberg, Department of Gastroenterology, Antwerpen, Belgium; [8]Katholieke Universiteit Leuven, Department of Public Health and Primary Care, Leuven, Belgium; [9]UZ Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium*
Email: dana.busschots@uhasselt.be

Background and Aims: Hepatitis C viral (HCV) infection is most prevalent in people who use drugs (PWUD). In Belgium, all PWUD have access to needle-syringe programs (NSP) and low threshold opioid agonist therapy (OAT). Various local initiatives to screen for HCV in addiction care centers providing OAT have already been successful. However, groups such as ex-PWUD or people who inject stimulants are mostly unreached. There are also no good estimates of the size and characteristics of these subgroups in Belgium. We want to outreach to PWUD who are not connected to OAT centers, using screening for HCV as a bridge to re-integration in medical care.
Method: This study was carried out simultaneously in Antwerp (urban) and Limburg (rural), Belgium. The participants were recruited by outreaching at organised screening events on different locations. The location of these events were communicated in advance, using posters and flyers and planned in accordance with local authorities, health care workers and peers. The eligible candidates (>18 years and PWUD) were tested by finger prick for HCV antibodies (Ab) using OraQuick®. While waiting for the results, an encoded questionnaire was filled out. An incentive of €10 was provided to participants after receiving their results.
Results: A total of 425 PWUD were reached and tested for HCV Ab. Out of all PWUD 148 (34.8%) had ever injected drugs (PWID). In relation to intravenous (IV) use of stimulants, people in an urban setting were more likely to inject amphetamines though there was no difference in IV use of cocaine (Table 1). Although every PWID in Belgium has access to NSP and low-threshold OAT still not everyone was connected (Table 1). HCV Ab was present in 14.8% and was more prevalent in the urban setting (Table 1).

	Antwerp (n=207)	Limburg (n=218)	p-value
PWID	68 (32.9%)	80 (36.7%)	0.233
IV amphetamine	47/68 (69.1%)	40/80 (50.0%)	**0.014**
IV cocaine	49/68 (72.1%)	47/80 (58.8%)	0.064
Recently (<6m) injected **not** connected to NSP (n=73)	5/42 (11.9%)	8/31(25.8%)	0.095
Recently (<6m) used opioid **not** connected to OAT (n=97)	27/54 (50.0%)	22/43 (51.2%)	0.536
HCV Ab +	38 (18.4%)	25 (11.5%)	**0.031**

Figure: (abstract: THU349)

Conclusion: The outreach method worked to contact and screen a group of PWUD not connected to care. Of these, more than half were (former) amphetamine injectors. An important part of the study group was positive for HCV Ab and the prevalence was higher in an urban setting. Although Belgium is a country with low-threshold access to addiction care not everyone was connected neither in an urban or rural setting.

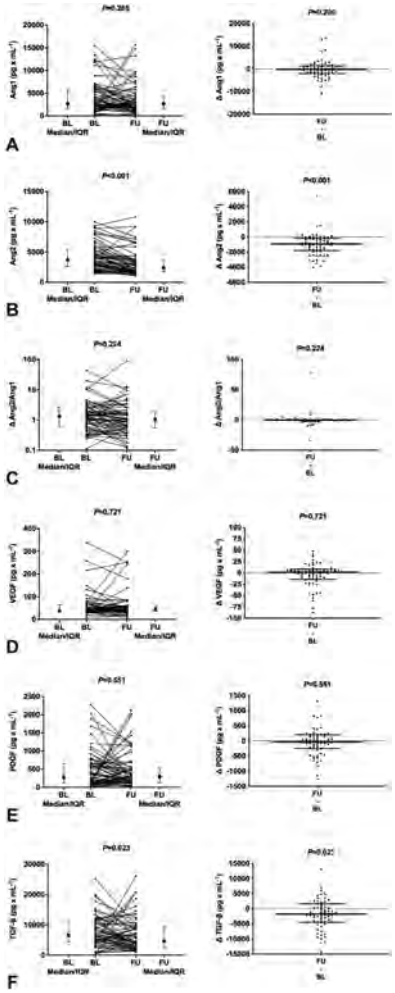
Angiopoietin 2 levels decrease with SVR and correlate with dynamics of portal hypertension in patients with HCV-induced advanced chronic liver disease

David JM Bauer[1,2], Karin Kozbial[1], Philipp Schwabl[1,2], David Chromy[2], Benedikt Simbrunner[1,2], Albert Stättermayer[1,2], Matthias Pinter[1,2], Petra Munda[1], Michael Trauner[1], Peter Ferenci[1], Thomas Reiberger[1,2], Mattias Mandorfer[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Wien, Austria; [2]Vienna Hepatic Hemodynamic Lab*
Email: david.bauer@meduniwien.ac.at

Background and Aims: Sustained virologic response (SVR) decrease hepatic venous pressure gradient (HVPG) in patients with HCV-induced advanced chronic liver disease (ACLD), which translates into a clinically meaningful benefit. We recently identified a panel of cytokines reflecting hepatic angiogenesis, fibrogenesis, and hepatocarcinogenesis that were increased in patients with persistent necroinflammatory activity despite HCV cure, which in turn resulted in lower rates of hemodynamic response. In the present study, we aimed to investigate (I) the impact of HCV cure on plasma levels of biomarkers of hepatic angiogenesis (angiopoietin 1 [Ang1], 2 [Ang2], and vascular endothelial growth factor [VEGF]) as well as fibrogenesis and hepatocarcinogenesis (platelet derived growth factor [PDGF] and transforming growth factor β [TGF-β]). Moreover, we assessed (II) the relationship between changes in these cytokines and HVPG.
Method: Pre- (baseline [BL]) and post-treatment follow-up [FU] plasma levels of cytokines and von Willebrand factor (VWF) as well as HVPG were assessed in 66 patients with ACLD and pre-treatment portal hypertension (HVPG ≥6 mmHg) who achieved SVR to interferon (IFN)-free therapy.
Results: At BL, the majority of patients were Child-Turcotte-Pugh (CTP) A, while 26% percent of patients were CTP B. Median MELD was 9 (interquartile range [IQR]: 3) points, median HVPG was 12.5 (IQR: 8) mmHg, and 68% of patients had clinically significant portal hypertension (CSPH; HVPG ≥ 10mmHg).
HCV cure induced profound decreases in Ang2 (Figure; panel B) and also decreased plasma levels of TGF-β (F), while Ang1 (A), the ratio between Ang2/Ang1 (C), VEGF (D), and PDGF (E) remained unaffected. Patients with CSPH at BL achieving an HVPG-decrease ≥ 10% had a more pronounced relative decreases in Ang2 (−34.5 [IQR: 30.3]%), as compared to patients without an HVPG-response (−13.5 [IQR: 31.2]%); P = 0.041). Moreover, relative changes in Ang2 showed direct correlations with relative changes in HVPG (Spearman's ρ = 0.276; P = 0.029), as well as with relative changes in VWF levels (Spearman's ρ = 0.324; P = 0.009).



Conclusion: Plasma levels of Ang2 - which have been previously linked to liver fibrosis and de-novo hepatocellular carcinoma after antiviral therapy - substantially decreased after SVR. Interestingly, decreases in Ang2 were more pronounced in patients achieving an HVPG-decrease ≥ 10%. Moreover, changes in Ang2 correlated with the dynamics of portal hypertension as well as VWF, a marker of endothelial dysfunction that confers additional HVPG-independent prognostic information. Finally, HCV-cure also decreased plasma levels of the key profibrotic and oncogenic cytokine TGF-β.

A program of hepatitis C surveillance with linkage to care for inpatients from non-infectious departments in two tertiary hospitals from Jiangsu, China

Yuxin Chen[1], Rui Huang[2], Jian Wang[1], Xiaomin Yan[1], Xiujun Zhang[2], Longgen Liu[2], Chao Wu[1]. *1Nanjing Drum Tower Hospital, Infectious Disease, Nanjing, China; [2]The third people's hospital of Changzhou, Infectious Disease, Changzhou, China*
Email: yuxin_chen2015@163.com

Background and Aims: An estimated 20 million Chinese are chronically infected with hepatitis C virus (HCV). However, the majority are unware of their HCV diagnosis and few are treated. A retrospective study from our tertiary hospital in China indicated a lack of knowledge of non-infectious departments (non-ID) physicians regarding the criteria of HCV antibody screening and an insufficient follow-up of patients with positive HCV antibody (Ab) from non-IDs. Therefore, we designed and evaluated a compressive hospital-led program for enhanced HCV surveillance with linkage to care in non-IDs of hospitals, with the goal to expand HCV surveillance and enhance follow-up of potential HCV patients with access to treatment at hospital level.
Method: This program was launched in two tertiary hospitals in Jiangsu province of China. The program consisted of an educational campaign to raise awareness of physicians from non-IDs to expand HCV surveillance; a new HCV clinical algorithm responsible for efficient follow-up of patients with positive HCV Ab; and comprehensive testing, diagnosis, and treatment. In our new HCV clinical algorithm, firstly HCV Ab testing is expanded among the inpatients who meet the criteria of HCV surveillance. Further, for those patients with positive Ab, the physician-in-charge invited ID physicians for the joint consultation regarding RNA PCR testing and the possible referral in near future. Once HCV infection is diagnosed, the ID nurse follow up with the patients and schedule appointments of HCV clinics.
Results: With our new launched program of hepatitis C Surveillance with linkage to care for the last 8 months (from Mar 2019 to Oct 2019), a total of 68.7% (64,111/93,291) of inpatients had HCV Ab screen test. Among them, 0.54% (343/64,111) of non-ID inpatients were found with positive HCV Ab. While 81.9% patients were enrolled in our study, 100% (281/281) of patients with positive HCV Ab was followed up for HCV RNA PCR testing, and 42.5% (119/281) of patients were HCV RNA positive. Currently, 71.4% (85/119) of HCV patients were linked to care, 57.6% (49/85) started DAA treatment.
Conclusion: This hospital-led educate, test and treat demonstration project achieved enhanced HCV Surveillance with linkage to care. This approach could be an important strategy in hospital setting to improve the hepatitis C care continuum by identifying individuals unaware of their HCV status and facilitating their access to HCV treatment.

Feasibility and acceptability of self-testing for hepatitis C infection among the general population in Egypt

Elena Ivanova[1], Ahmed Farahat[2], Amira Elbeeh[3], Reham Soliman[3], Philippa Easterbrook[4], Gamal Shiha[3]. [1]*Foundation for Innovative New Diagnostics, Geneva, Switzerland;* [2]*Association of Liver Patient Care, Mansoura, Egypt;* [3]*Association of Liver Patient Care, Mansoura, Egypt;* [4]*World Health Organization, Geneva, Switzerland*
Email: elena.ivanova@finddx.org

Background and Aims: Insufficient testing coverage is a major barrier to hepatitis C virus (HCV) elimination. Self-testing, a process in which people can collect their own specimen, perform a test and interpret the result, often in private or with someone they trust, has been very successful in promoting uptake of HIV testing. As for HIV, it is considered that introduction self-testing for HCV infection has a high potential to expand the coverage of HCV testing services. In order to evaluate feasibility and acceptability of HCV self-testing in HCV-prevalent settings, FIND has conducted a pilot observational study in Mansoura region, Egypt.
Method: Prospective cross-sectional study conducted in two hospitals located in Mansoura region. Prototype OraQuick® HCV Self-Test developed by OraSure Technologies (US) was used to perform self-testing from oral fluids. Hospital staff screened and recruited eligible participants, sought informed consent and demonstrated the use of the OraQuick® HCV Self-Test. The participant then used the OraQuick® HCV Self-Test while observed by a study staff who documented errors made and difficulties faced during the testing procedure. Upon the completion of the testing, all participants were administered a multiple-choice questionnaire asking about acceptability and usability of the self-test. All participants were tested by a hospital staff on professional use OraQuick® HCV Rapid Diagnostic Test and results of professional use test and self-testing were compared.
Results: A total of 116 participants were recruited in the study, out of which 17 (15%) could not read. The majority (87%) of participants completed self-testing without any assistance. More than 95% completed each step of the testing correctly and found the procedure to be easy (52%) or very easy (44%). Almost all participants (99%) indicated that they would recommend HCV self-test to friends and family and over 96% would use the self-test again if it was available. Majority (97%) also said that they would contact a healthcare facility if results of self-testing were positive, and 67% knew that HCV can be cured. While 65% of the participants preferred oral fluid-based test, 24% indicated that they would rather use blood-based test for self-testing. Concordance between the results of self-testing and professional use OraQuick® HCV Rapid Diagnostic Test was 89% (Kappa 0.66).
Conclusion: This study demonstrates high acceptability and usability of oral fluid-based self-testing for HCV. This additional approach has a potential to increase uptake of HCV testing services in settings with high awareness of HCV infection. Further research of acceptability and feasibility in high-risk populations as well as evaluation of performance of HCV self-tests is underway.

The HSD17B13 rs6834314 variant is associated with liver stiffness measurement in untreated HCV-3 patients with cirrhosis

Enrico Galmozzi[1], Floriana Facchetti[1], Riccardo Perbellini[1], Roberta D'Ambrosio[1], Elisabetta Degasperi[1], Roberta Soffredini[1], Marta Borghi[1], Pietro Lampertico[1]. [1]*Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, CRC "A. M. and A. Migliavacca" Certer for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy*
Email: enrico.galmozzi@gmail.com

Background and Aims: Recently, the single-nucleotide polymorphism (SNP) rs6834314 near to the 17-beta hydroxysteroid dehydrogenase 13 (HSD17B13) gene has been associated with NAFLD histology. Particularly, the minor G allele of the rs6834314 variant correlated with increased steatosis but decreased inflammation. This study aimed to analyzed the correlation between the rs6834314 genotypes and liver stiffness measurement (LSM) in chronic hepatitis C (CHC) patients.
Method: 410 Caucasian CHC cirrhotic patients were retrospectively enrolled in a single Hepatology centre: median age 64 (28–87) years, 57% males, BMI 25 (16–40) Kg/m^2, ALT 75 (10–770) U/L, LSM 17.5 (12–75) kPa, and 19% with diabetes. HSD17B13 rs6834314 was genotyped by TaqMan allelic discrimination assay (Applied Biosystems).
Results: HSD17B13 rs6834314 genotype was AA in 251 (61%), AG in 143 (35%) and GG in 16 (4%). Overall, the rs6834314 variant showed no association with median baseline LSM values: 17.8 (95%CI 17,2–19,1) kPa in AA vs 17.0 (95%CI 15,4–18,3) kPa in AG/GG, ($p = 0.24$). Stratifying patients according to hepatitis C virus (HCV)-genotypes, we found that in HCV-3 patients ($n = 41$) median LSM values significantly differed according to rs684314 genotypes: 25.8 (95%CI 18.5–28.3) kPa in AA vs 15.4 (95%CI 13.1–20.3) kPa in AG/GG ($p = 0.014$), unlike to HCV-1: 18.2 (95%CI 16,9–21) kPa in AA vs 17.3 (95% CI 15,0–19,6) kPa in AG/GG ($p = 0.13$), HCV-2: 18.5 (95%CI 17,1–22,3) kPa in AA vs 16.9 (95%CI 13,1–20,9) kPa in AG/GG ($p = 0.30$), and HCV-4: 19.8 (95%CI 17,3–21,6) kPa in AA vs 21.2 (95%CI 17,1–31,0) kPa in AG/GG ($p = 0.22$). Moreover, in the HCV-3 subgroup the prevalence of patients with increased risk of significant portal hypertension (i.e. those with LSM ≥ 25 kPa) was higher in AA than in AG/GG carriers (56% vs. 17%, $p = 0.01$). Multivariate binary logistic regression analysis

confirmed that in HCV-3 cirrhotics, the minor G allele of rs6834314 reduces the risk of exceed the LSM 25 kPa cut-off more than nine fold (OR 0.11, 95%CI 0.02–0.62, p = 0.013) together with age (OR 0.9, 95%CI 0.76–0.99, p = 0.03) and independently of gender, BMI, ALT, diabetes and PNPLA3 rs738409 polymorphism.
Conclusion: In untreated HCV-3 cirrhotics, the rs6834314 variant was associated with lower LSM values suggesting that the correlation between HSD17B13 SNP and liver disease severity might be triggered mainly by virus-mediated steatosis.

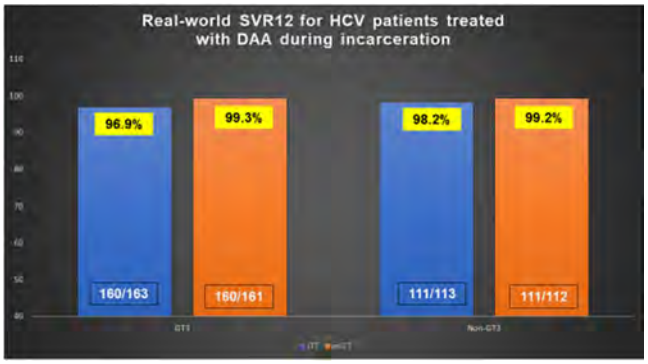
Email: eugene.wong.y.j@singhealth.com.sg

Background: Despite the disproportionally high prevalence of hepatitis C virus (HCV) amongst prisoners, eradication remains challenging due to logistic and financial barriers. Genotype-3 (GT3) was considered difficult to treat even with the introduction of direct-acting antiviral (DAA). To date, the real-world treatment outcomes of GT3 HCV prisoners with DAA remains limited.
Objective: To compare the real-world efficacy of DAA and the impact of universal access of DAA among GT3 and non-GT3 HCV prisoners.
Method: 307 HCV prisoners treated with DAA in our specialized liver clinic from 2013–2019 were prospectively included in a treatment database and sustained virological responses at 12 weeks (SVR12) were compared. Universal access to pan-genotypic DAA was commenced in 2019. GT3 HCV patients received either 12 weeks of sofosbuvir/daclatasvir and ribavirin (SOF/DAC/Riba) or 12-weeks of sofosbuvir/velpastavir (SOF/VEL). Genotype 1 (GT1) patients receive HARVONI, VIEKIRA PAK or SOF/VEL for 12 weeks. Ribavirin was added for patients with clinically significant portal hypertension, prior treatment or hepatocellular carcinoma.



Results: GT3 (57.7%) was the commonest genotype followed by GT1 (39.7%) amongst prisoners. Patients were mostly male (93.2%) and cirrhotic (52.1%), with a mean age of 52.5 years. The majority received SOF/VEL +/– ribavirin (58.9%) followed by VIEKIRA PAK +/– ribavirin (23.2%) and SOF/DAC/Riba (14.7%). The overall SVR12 based on intention-to-treat (ITT) and modified ITT analysis for GT3 and GT1 were 96.9%, 99.3% and 98.2%, 99.2%, respectively (Figure 1). While virological failure occurred in SOF/DAC/Riba (n = 1) and VIEKIRA PAK (n = 1), there was no virological failure using SOF/VEL regimen. The SVR12 was similar between GT3 and non-GT3 prisoners after adjusted to platelet count, PT and baseline viral load (99.4% vs 99.2%,95%CI: 0.03–76.7). Compared to the year 2018, universal access to pan-genotypic DAA alone significantly improved treatment access among HCV prisoners by 130% and allowed more non-cirrhotic HCV prisoners to be treated in 2019 (62.1% vs 42.6%, p < 0.001).
Conclusion: We demonstrated that GT3 HCV prisoner is no longer a difficult-to-treat cohort in the pan-genotypic DAA era, and high SVR12 can be achieved in the real-world setting. Our result shows that universal access to DAA among HCV prisoners is an impactful strategy for HCV micro-elimination in this cohort.

Email: fegarcia@ugr.es

Background and Aims: For exploring the diagnosis situation of hepatitis C virus (HCV) infection in Spain, in 2017 we conducted a survey across hospital diagnostic laboratories, finding that only 31% of them were providing reflex testing (HCV antibodies and HCV RNA on the same sample). As a consequence, the Spanish Societies of Infectious Disease & Clinical Microbiology (GEHEP-SEIMC), Hepatology (AEEH, SEPD) and the Viral Hepatitis Elimination Alliance (AEHVE) signed a position document with recommendations on reflex testing. In addition, training and dissemination activities were developed by the mentioned organizations to promote reflex testing implementation in the Spanish hospitals. Our aim was to evaluate how reflex testing has been implemented in Spain, and to gain knowledge on access to new diagnostic strategies across hospital Spanish laboratories.
Method: Cross-sectional study with data collection through a survey addressed to hospitals of the Hospitals National Catalogue with the following inclusion criteria: 1) general hospital (monographic, e.g., psychiatric hospitals are excluded); 2) with at least 200 beds; and 3) public, or teaching hospital if private. A questionnaire with the variables of interest, designed by a scientific committee composed of hepatologists and microbiologists, was sent to the selected hospitals. The fieldwork was carried out in September and October 2019.
