Background and Aims: The long-term outcome of hepatitis B virus (HBV) infection among patients dually infected with HBV and hepatitis C virus (HCV) receiving direct-acting antivirals (DAA) therapy remains unclear. We aimed to investigate thedynamicchange of hepatitis B surface antigen (HBsAg) and reactivation of HBV in the clinical setting.
Method: A total of 79 HBV/HCV dually-infected patients who completed DAA therapy with at least 3-month posttreatment follow-up were enrolled. HBsAg titer and HBV DNAwere measured before, during and post-DAA therapy. The primary endpoint was HBsAg seroclearance; secondary endpoints included changes of HBsAg titer, HBVreactivation (>1 log increase or >100 IU/ml in HBV DNA if baseline undetectable), and hepatitis flare.
Results: The HBsAg declined from a median of 73.3 IU/ml at baseline to 16.2 IU/ml at end-of-DAA and gradually increased to 94.1 IU/ml at 12 months post-DAA. During a mean follow-up period of 11.1 months (range, 3–36 months), eight (10.1%) of the 79 patients developed HBsAg seroclearance, including four during the DAA therapy. The cumulative probability was 10.3% at 12 months post-DAA. Pre-treatment HBsAg ≤10 IU/ml was the only factor associated with HBsAg loss (HR: 8.52, 95% CI: 1.048–69.312, p = 0.045). Thirty (38.0%) patients experienced an HBV reactivation with a 12-month cumulative probabilityof 40.4%. Pre-treatment HBsAg >10 IU/ml was the only factor associated with HBV reactivation (HR: 2.88, 95% CI: 1.057–7.844, p = 0.039). Six patients (2 non-cirrhotic, 4 cirrhotic) happened HBV related clinical reactivation; Three of the four cirrhotic patients developed liver failure with two mortality despite of immediate anti-HBV nucleos(t)ide therapy.
Conclusion: HBsAg loss could develop among HBV/HCV dually infected patients receiving DAA therapy, especially those with low pre-treatment HBsAg titer. Prophylactic anti-HBV therapy is mandatory for patients with baseline cirrhosis, irrespective of HBV DNA levels.

Hepatitis C reinfection by treatment pathway among people who inject drugs in Tayside, Scotland

Madeleine Caven[1], Emma Robinson[1,2], Iain Macpherson[1], John Dillon[1,2]. *[1]University of Dundee, Gut Group, Division of Molecular & Clinical Medicine, Dundee, United Kingdom; [2]NHS Tayside, Department of Gastroenterology, Dundee, United Kingdom*
Email: mzcaven@dundee.ac.uk

Background and Aims: The efficacy of pan-genotypic direct acting antivirals (DAA) provide an excellent opportunity to scale up Hepatitis C (HCV) diagnosis and treatment, ultimately achieving the WHO target of HCV elimination by 2030. However, HCV reinfection among people who inject drugs (PWID) remains a concern and may impede elimination efforts. We assessed reinfection rates among people with a risk factor for HCV of intravenous drug use, including

PWID, and those on opiate substitution therapy (OST), across six specialised treatment pathways in Tayside, Scotland.
Method: Data was collected retrospectively for every treatment episode that resulted in a sustained viral response (SVR) after undergoing treatment. Reinfection rates were calculated for each treatment pathway: hospital outpatient clinic; community pharmacy; drug treatment outreach; prison clinic; nurse led outreach clinic; and injection equipment provision site. Reinfection is defined as a positive RNA test result after SVR. Incidences of reinfection are expressed in 100 person-years (PYs).
Results: In total, 1175 treatment episodes were identified that resulted in a SVR after treatment. Of these, 100 reinfections were identified, generating an overall reinfection rate of 5.3 per 100 PYs (95%CI: 4.4–6.4). Reinfection rates per treatment pathway are displayed in Table 1. The hospital outpatient clinic had the lowest reinfection incidence of the six treatment pathways (1.8 per 100 PYs, 95%CI: 1.1–2.9), with the injection equipment provision site treatment pathway having the highest reinfection incidence (19.9 per 100 PYs, 95%CI: 14.9–26.5).

Treatment Pathway	Reinfection rate per 100 PYs (95%CI)
Hospital outpatient clinic	1.8 (1.1–2.9)
Drug treatment outreach	3.1 (1.6–6.2)
Nurse led outreach	6.4 (4.0–10.1)
Prison clinic	8.1 (4.9–13.5)
Community pharmacy	12.1 (6.3–23.2)
Injection equipment provision site	19.9 (14.9–26.5)

Conclusion: Specialised treatment pathways in Tayside yield varying reinfection incidence rates. Our results suggest that resources should be targeted at the injection equipment provision site treatment pathway in order to reduce the incidence of reinfection and achieve elimination targets. It is imperative that harm reduction services are available and regular post treatment HCV testing is carried out in order to reduce reinfection risk among PWID.

FRI450

Influence of DAA treatment in patients with HCV-cirrhosis and esophageal varices on liver transplant free survival and risk of developing hepatocellular carcinoma

Noelia Rodríguez Ferreiro[1], Pablo Florez Díez[1], Alejandro Nieto Jara[1], Victor J Beltrán[1], Miguel Fraile[1], Carmen Álvarez-Navascués[1], Maria Luisa Gonzalez Dieguez[1], Maria Varela[1], Valle Cadahía-Rodrigo[1], Manuel Rodríguez[1]. [1]*Hospital Universitario Central de Asturias, Gastroenterology and Hepatology, Oviedo, Spain*
Email: noelia_xyz@hotmail.com

Background and Aims: Most evidence on the benefit of DAA treatment is based on series with SVR. The presence of esophageal varices (EV) is associated with a higher probability of presenting complications of cirrhosis and hepatocellular carcinoma (HCC). To know the influence of DAA treatment in HCV-cirrhosis (CC) with EV on transplant-free survival (TFS) and risk of HCC.
Method: All patients with CC, viremic, Child A/B, with EV prospectively followed bianually in a HCC surveillance programme (n = 383) were analyzed. 146 (38%) received DAA (DAAp); the start of treatment was the time of inclusion. Follow-up was censored at month 54. 16 variables collected at inclusion were analyzed.
Results: Male 70%, age 55 years, 33% with previous decompensation (PD), 81% Child A. DAAp were older (55 vs 53; p = 0.012) and obtained SVR more frequently (95% vs 4%; p < 0.001), without differences in the rest of the variables. During 42 months of follow-up (27–54), 104 (27%) received a liver transplant (LT)(n = 33) or died (n = 71) (TFS at 54 months: 68%). In the univariate analysis, PD (p < 0.001), alcohol consumption (p = 0.001), ALT>ULN (p = 0.024), platelets $<100 \times 10^3/mm^3$, Child B (p < 0.001), no1-GT (p = 0.006), BMI 25–30 (p = 0.019), inclusion prior to 2005 (p < 0.001) and not having received DAA (no-DAAp)(p = 0.001) were associated with lower TFS. TFS at 54 months was 61.5% in no-DAAp and 80% in DAAp. In the multivariate analysis, no1-GT (HR:1,724; 95% CI:1,082–2,749), PD (HR:2,812; 95% CI:1,737–4,551) and CHILD B (HR:2,156; 95% CI:1,307–2,749) were associated with a higher risk of death/LT, while DAAp had lower risk (HR:0.463; 95% CI:0.283–0.760). During a follow-up of 39 months (21–54), 56 (15%) developed HCC. Age>53 years (p = 0.007), HBsAg (p = 0.014), PD (p = 0.007), platelets $<100 \times 10^3/mm^3$ (p = 0.016) and Child B (p = 0.003) were associated with an increased risk of HCC at the univariate analysis. The probability of developing HCC at 54 months was 21% in no-DAAp and 13.4% in DAAp (p = 0.16). In multivariate analysis, age>53 (HR:2,407; 95% CI:1,334–4,340), HBsAg (HR 4,970; 95% CI:1,540–16,042), platelets $<100 \times 10^3/mm^3$ (HR: 1,858; 95% CI: 1,009–3,422; p = 0.047) and Child B (HR:2,539; 95% CI: 1,397–4,616) were associated with increased risk of HCC, while no association was observed with DAA (HR:0.614; 95% CI: 0.312–1.210).
Conclusion: DAA treatment, regardless of SVR, increases transplant-free survival in Child A/B HCV-cirrhotic patients with EV, without increasing the risk of developing HCC.

FRI451

Dynamic changes of serum M2BPGi as a fibrosis marker of patients with HCV mono-infection and HCV/HIV co-infection receiving direct-acting anti-viral therapy

Natthaya Chuaypen[1], Salyavit Chittmittrapap[1], Anchalee Avihingsanon[2], Pisit Tangkijvanich[1]. [1]*Center of Excellence in Hepatitis and Liver Cancer, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, Bangkok;* [2]*The HIV Netherlands Australia Thailand Research Collaboration (HIV NAT), Bangkok, Thailand, Bangkok*
Email: pisittkvn@yahoo.com

Background and Aims: Significant fibrosis regression has been observed in patients with chronic hepatitis C virus (HCV) infection after direct-acting anti-viral (DAA) therapy, particularly individuals with sustained virological response (SVR). The aim of this study was to evaluate dynamic changes of serum Mac-2 binding protein glycosylation isomer (M2BPGi) levels in patients with HCV genotype 1, who received elbasvir/grazoprevir (EBR/GZR) therapy.
Method: A total of 85 patients, who received EBR/GZR with or without ribavirin for 12 or 16 weeks in a clinical trial were included. Serum M2BPGi were serially measured by an automated lectin-antibody sandwich immunoassay at baseline, during and after therapy. Using magnetic resonance elastography (MRE) as a reference, the diagnostic performance of serum M2BPGi at baseline and SVR24 were compared to those of transient elastography (TE) and AST/platelet ratio index (APRI).
Results: Overall 59 HCV mono-infected and 26 HCV/HIV co-infected patients were analyzed. SVR24 rates in the mono- and co-infected groups were 93.2% and 96.2%, respectively. The correlations with MRE at baseline for TE, M2BPGi and APRI were r = 0.788, r = 0.703 and r = 0.564, respectively (all P < 0.001). Based on MRE, the area under the ROC curves for TE, M2BPGi and APRI in differentiating significant fibrosis (≥F2) were 0.89 (95%CI; 0.82–0.96, P < 0.001), 0.84 (0.76–0.93, P < 0.001) and 0.76 (0.66–0.87, P < 0.001), respectively. The corresponding figures for distinguishing severe fibrosis (≥F3) were 0.93 (0.88–0.99, P < 0.001), 0.92 (0.86–0.98, P < 0.001) and 0.81 (0.71–0.92, P < 0.001), respectively. Overall, all fibrosis markers were significantly changed at the time of SVR24 compared with their baseline levels. The correlations with MRE at SVR24 for TE, M2BPGi and APRI were r = 0.63(P < 0.001), r = 0.503(P < 0.001) and r = 0.359(P = 0.001), respectively. Of note, serum M2BPGi levels gradually declined during and after therapy in only patients achieving SVR24 (responders) but not in patients without SVR (non-responders). In responders, M2BPGi reduction from baseline were 0.8 ± 1.0 COI at week 4, 1.0 ± 1.3 COI at end-of-therapy, 1.4 ± 1.5 COI at SVR12 and 1.4 ± 1.5 COI at SVR24 (all P < 0.001). The corresponding figures for non-responders were 0.3 ± 0.5, 0.4 ± 0.6, 0.4 ± 0.3 and 0.1 ± 0.3 COI,

respectively (all P > 0.05). In multivariate analysis, age, the presence of significant fibrosis at baseline and achieving SVR24 were independent factors associated with M2BPGi reduction.
Conclusion: Compared to APRI, serum M2BPGi represented a better non-invasive marker for the assessment of liver fibrosis at baseline and after DAA therapy in patients with chronic HCV infection. Serum M2BPGi significantly declined during the administration of DAA, particularly in patients achieving SVR24. Moreover, the dynamic changes of serum M2BPGi were not influenced by the status of HIV co-infection.

Non-invasive tests of fibrosis and risk of liver-related complications: observations following successful sofosbuvir-based treatment in patients with HCV cirrhosis

Rajender Reddy[1], Andrew Muir[2], Susanna Naggie[2], Eric Lawitz[3], Edward Gane[4], Brian CONWAY[5], Peter Ruane[6], Ziad H. Younes[7], Frances Chen[8], Marianne Camargo[8], Anuj Gaggar[8], Robert Myers[8], Anand Chokkalingam[8], Barbara Leggett[9], José Luis Calleja Panero[10], Kosh Agarwal[11], Ira Jacobson[12], Alessandra Mangia[13]. *[1]University of Pennsylvania, Philadelphia, United States; [2]Duke University, Durham, United States; [3]Texas Liver Institute, San Antonio, United States; [4]Auckland City Hospital, Auckland, New Zealand; [5]Vancouver Infectious Diseases Centre, Vancouver, Canada; [6]Ruane Medical & Liver Health Institute, Los Angeles, United States; [7]Gastro One, Germantown, United States; [8]Gilead Sciences, Inc., Foster City, United States; [9]University of Queensland, Australia; [10]Hospital Puerta de Hierro, Spain; [11]King's College Hospital, London, United Kingdom; [12]NYU Langone Health, New York, United States; [13]Casa Sollievo della Sofferenza, Italy*
Email: marianne.camargo2@gilead.com

Background and Aims: Noninvasive tests of fibrosis (NITs) are an alternative to liver biopsy for fibrosis staging and monitoring; however, associations between NITs and disease progression are poorly understood. Our aim was to evaluate the risk of liver-related complications according to baseline at enrolment (BL) and changes in the Enhanced Liver Fibrosis (ELF) test and liver stiffness by transient elastography (LS by TE) following sustained virologic response (SVR) in patients with HCV cirrhosis.
Method: Patients with pre-treatment HCV cirrhosis who achieved SVR with sofosbuvir (SOF)-based regimens were enrolled in an ongoing, prospective registry (NCT02292706). Patients underwent routine clinical and laboratory assessments, including semi-annual ELF testing and annual LS by TE. At BL, fibrosis stage was defined based on ELF (F0-F2, <9.8; F3, 9.8–11.3; F4, >11.3) and LS by TE (F0-F2, <9.6 kPa; F3, 9.6–12.5 kPa; F4, >12.5 kPa). Changes at 48 weeks (improved, no change, worse) were defined based on ELF response (≥0.5 unit change from BL) and LS by TE response (≥25% change from BL). Associations between NITs and all-cause mortality, hepatocellular carcinoma (HCC), and total liver-related events (hepatic decompensation, transplantation, HCC, and liver-related death) were evaluated using Cox regression.
Results: We included 1,370 subjects with HCV Child-Pugh A cirrhosis (median 60 years of age, 32% female). At BL, median ELF was 9.8 (IQR 9.1, 10.7); 530 (39%) and 158 (12%) patients had ELF scores consistent with F3 and F4 fibrosis, respectively. Median LS by TE was 13.9 kPa (IQR 9.1, 21.3); 210 (15%) and 640 (47%) patients had LS by TE consistent with F3 and F4 fibrosis, respectively. After a median follow-up from BL of 144 weeks (IQR 119, 172), BL ELF and LS by TE class were associated with risks of all-cause mortality, HCC, and liver-related events (Table). Relative to BL F0-F2, significantly increased risks for all outcomes were observed for both F3 and F4 fibrosis defined by ELF, and F4 fibrosis defined by LS by TE. Worsening of ELF at 48 weeks was significantly associated with increased risk of all-cause mortality, while risks of HCC and total liver-related events were numerically, but non-significantly, higher for this group. In contrast, worsening of LS by TE at 48 weeks was not significantly associated with increased risks of the studied outcomes. Improvements in either measure were not associated with the risk of complications.
Conclusion: Following successful HCV therapy in patients with HCV-related cirrhosis, BL NITs are prognostic. Changes in NITs over 48 weeks may also be predictive of disease progression; however, further study is necessary following the accrual of additional follow-up time and events. This study is among the first to show an association between changes in liver fibrosis and changes in liver-associated morbidity and mortality in patients with compensated cirrhosis.

Figure: (abstract: FRI452)

infected patients, however the changes in HCC incidence over time following HCV eradication and impact of these therapies on tumor behavior is less clear. Here, we identified incident HCC after HCV eradication and compared the characteristics of HCC diagnosed before starting of DAA therapy with those of de novo HCC which developed following DAAs treatment in large population based cohort.

Method: In an outreached program in 73 villages across Egypt, 204,749 individuals were screened for HCV antibody and HBsAg, 15,892 (7.8%) were viremic of those 14,495 (91.2%) were treated with DAAs. Liver fibrosis was assessed by FibroScan and 1671 patients and 616 were showed to have cirrhosis (F4) and advanced fibrosis (F3), respectively. Of those, 166 patients had active HCC before initiation of DAA therapy (group I). Patients were followed after treatment for median of two years (12–45 months), during which 109 incident HCCs were identified (group II).

Results: 11 out of the 109 de novo HCC cases (10.1%) occurred during the first year of follow up, 53 (48.6%) during the second year, 35 (32.1%) during the third years, while 10 (9.2%) occurred after the third year of follow up. Notably, according to BCLC classification; advanced stages (BCLC-C and D) were significantly lower group II than group I (26.6% & 3.7% vs 36.1% &8.4% respectively, $p < 0.001$). BCLC stage B is significantly higher in Group II (30.3% vs 16.3%, $p < 0.001$). Portal vein invasion was also significantly lower in group II than group I (7.3% vs 44%, $p < 0.001$).

Conclusion: Patients with baseline cirrhosis or significant fibrosis maintain an increased risk for HCC up to 4 years after HCV eradication. However, HCC developed in those patients tend to display less aggressive pattern when compared to HCC diagnosed before DAAs therapy. Further studies are required to clarify the mechanisms of these effects and duration of ongoing HCC surveillance after HCV eradication.

FRI454

Long-term evaluation of liver stiffness in HCV patients after sustained virological response to DAAs: predictive factors for disease improvement and hepatocellular carcinoma development

Riccardo Nevola[1,2], Valerio Rosato[2], Ernesto Claar[2], Carmine Coppola[3], luca fontanella[4], Anna Ludovica Fracanzani[5], Guido Piai[6], Giovanna Valente[6], Antonio Ascione[4], Rosa Lombardi[5], Mariarosaria Saturnino[3], Laura Staiano[3], Pasquale Perillo[1], Pia Clara Pafundi[1], Aldo Marrone[1], Ferdinando Carlo Sasso[1], Luigi Elio Adinolfi[1], Luca Rinaldi[1]. *[1]University of Campania "Luigi Vanvitelli", Department of Advanced Medical and Surgical Sciences, Napoli, Italy; [2]Betania Evangelical Hospital, Hepatology Unit, Napoli, Italy; [3]Gragnano Hospital, Internal Medicine and Hepatology Unit, Gragnano, Italy; [4]Fatebenefratelli Hospital, Department of Internal Medicine, Liver Disease Unit, Napoli, Italy; [5]Cà Granda IRCCS Foundation, Policlinico Hospital, Department of Pathophysiology and Transplantation, Milano, Italy; [6]AORN Sant'Anna e San Sebastiano, Liver Unit of Transplant Management (SATTE), Caserta, Italy*
Email: riccardo.nevola@unicampania.it

Background and Aims: The viral clearance by direct-acting antiviral agents (DAAs) in HCV setting is associated with an early liver stiffness (LS) reduction. However, in patients who obtain a sustained virological response (SVR), the long-term progression of LS remains still unclear. Aim of the study is thus the assessment of long-term changes in LS and any factors negatively affecting its decline.

Method: This is an observational multicenter study. All patients with chronic HCV infection treated by DAAs who achieved a SVR were enrolled from 6 italian Center. Clinical, laboratory and instrumental (ultrasound and transient elastography) evaluations were performed pre-treatment (T0), at 6 (T6) and 24 months (T24) since the end of therapy.

Results: 466 HCV patients, of which 276 with cirrhosis, were enrolled and evaluated for a mean follow-up time of 23 months. LS significantly decreased from T0 to T6 (median 14.3 kPa vs. 11.1 kPa, $p = 0.002$), with a progressive reduction till T24 (8.7 kPa, $p < 0.001$). Only patients with liver steatosis and HCC onset not showed a significant late LS improvement. Moreover, a ROC curve analysis on LS for the risk of HCC development showed that a LS pre-treatment cut-off of 21.4 kPa (sensitivity 70%, specificity 83%) (AUC:0.756, 95% C.I.

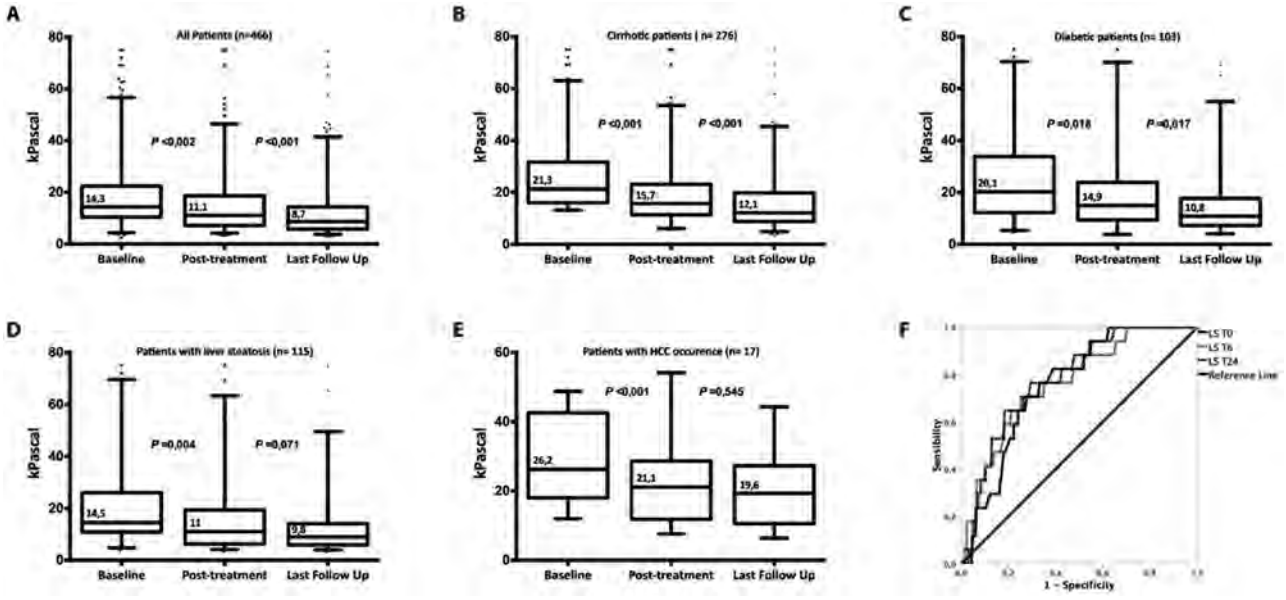

Figure 1: (abstract: FRI454): Box-plots: (a) LS changes over time in all patients; (b) in cirrhotic subgroup; (c) in diabetic patients; (d) in patients with liver steatosis and (e) in HCC patients. (f) ROC curve for HCC occurrence at the three LS time-points.

0.665–0.846; p < 0.001) and a LS post-treatment (T6) of 14.0 kPa (sensitivity 70%, specificity 86%, AUC:0.765, 95% C.I. 0.658–0.873; p < 0.001) were predictive for HCC onset. At univariate analysis, BMI, LS-pre-treatment >21.4 kPa and LS post-treatment >14.0 kPa were associated with a higher HCC development risk. However, at the multivariate only LS post-treatment (T6) >14.0 kPa was independently associated with an increased risk of HCC onset (O.R: 9.316, 95% C.I. 1.158–74.939; p = 0.036).

Conclusion: Our findings show that SVR achievement allows a progressive LS decline, even in the long-term. Hepatic steatosis and HCC development seem to negatively affect late LS changes. Moreover, a failure in long-term LS reduction could represent a potential risk factor for HCC onset. Patients showing a post-treatment LS >14 kPa seem to have a higher risk of HCC development. Therefore, this subset should undergo intensive surveillance protocols.

Hepatitis C virus infection, endogenous retrotransposons activation and cancer risk

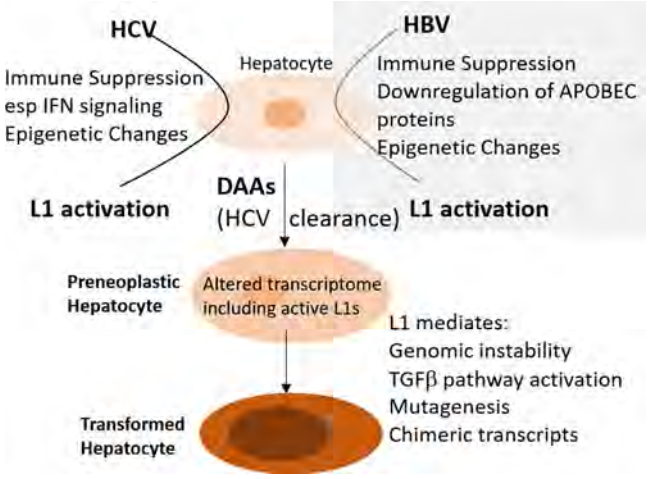
Ruchi Shukla[1], Helen L. Reeves[2], Stuart McPherson[3], Misti McCain[2], Praveen Sudhindar[1], Yvonne Bury[3], Geoffery Faulkner[4], John Lunec[1]. *[1]Newcastle University, Biosciences Institute, United Kingdom; [2]Newcastle University, Translation and Clinical Research, United Kingdom; [3]Newcastle-upon-Tyne Hospitals NHS foundation, Freeman Hospital, United Kingdom; [4]University of Queensland, Mater Institute, Australia*

Email: ruchi.shukla@ncl.ac.uk

Background and Aims: Mortality from hepatocellular carcinoma (HCC) continues to rise, due to a combination of late detection and lack of curative treatments. Chronic Hepatitis C (CHC) virus infection is a major risk factor for HCC and the use of direct acting antivirals (DAAs), potentially curing HCV infection, heralded a major breakthrough. However, the risk of HCC persists even after HCV clearance. The key drivers of HCC in chronic liver disease remain elusive, as do the mechanisms post-DAAs. Recently, we demonstrated the activation and mutagenic consequences of long-interspersed repeat elements (L1 s) in human HCC, when the epigenetic silencing of these elements is compromised. Since HCV infection contributes to global epigenetic changes, we hypothesise that L1 s become activated during the process, mediating genomic instability, with chimeric transcripts and consequent upregulation of TGFβ signaling leading to cancer development post viral clearance. We aimed to evaluate activation of L1 s in chronic hepatitis C patients, in association with viral hepatitis-associated HCC development and prognosis.

Method: L1 transcript expression was evaluated in RNAseq datasets of CHC (GSE84346) and The Cancer Genome Atlas-Liver Hepatocellular Carcinoma (TCGA-LIHC) with an in-house pipeline. Immunohistochemical (IHC) examination of L1orf1 protein (L1orf1p) in the biopsy and/or resection tissue of CHC and CHC-HCC patients was using an automated Ventana system. An *in vitro* engineered-L1 retrotransposition assay in Huh7 cells in the presence or absence of an HCV replicon evaluated the influence of HCV on retrotransposition rate.

Results: Liver L1 transcripts were upregulated in GSE84346 CHC patients compared to controls (p = 0.001), as well as in TCGA-LIHC non-tumour tissue in patients with a history of viral hepatitis or alcohol abuse (p < 0.05). In our own IHC pilot study, the L1 status of HCC expression in diagnostic biopsies matched that of L1orf1p expression in the non-tumour biopsy tissues predating HCC development by a number of years. *In vitro*, there was a 4-fold increase in retrotransposition rate in Huh7-HCV compared to control Huh7 cells, confirming an influence of HCV on retrotransposons activation.



Model depicting activation of L1 upon HCV infection, contributing to HCC development.

Conclusion: L1 can be activated before oncogenic transformation in patients with chronic HCV infection, with HCV promoting retrotransposition and potentially its mutagenic consequences. Persistence of L1 activation may contribute to HCC development even beyond viral clearance.

Post-treatment wisteria floribunda agglutinin-positive mac-2-binding protein is a useful predictor of hepatocellular carcinoma development after hepatitis C virus eradication

Shunsuke Sato[1], Hironori Tsuzura[1], Takuya Genda[1]. *[1]Juntendo University Shizuoka Hospital, Gastroenterology and Hepatology, Shizuoka, Japan*

Email: syusato@juntendo.ac.jp

Background and Aims: Interferon (IFN)-free therapy of hepatitis virus C (HCV) has higher efficacy than previous IFN-based therapy, and a large number of patients currently achieve a sustained virological response (SVR). Although the eradication of HCV reduces the incidence of hepatocellular carcinoma (HCC), HCC development is not rarely observed even in patients achieved SVR. Wisteria floribunda agglutinin-positive Mac-2-binding protein (WFA+-M2BP) was recently developed as a noninvasive glycolbiomaker of liver fibrosis. Previously, we reported that pre-treatment serum WFA+-M2BP level is a useful predictor for HCC development after SVR by IFN-based therapy. However, it remains unclear the change of WFA+-M2BP level after viral eradication and its association with HCC development.

Method: A total of 522 patients achieved SVR (IFN-based therapy, 228; IFN-free therapy, 294) were included. Patients with follow-up period of<0.5 year after the end of treatment (EOT) were excluded. Serum WFA+-M2BP levels were measured before treatment and at 24 weeks after EOT. Univariate and multivariate Cox proportional hazard analysis were used to estimate the hazard ratios (HRs) for HCC development and, Kaplan-Meier method and log-rank test were used to determine the cumulative incidence of HCC development.

Results: During the median follow-up time of 2.9 years, 14 patients developed HCC. The estimated cumulative incidences of HCC development in the entire cohort were 1.7% and 3.3% at three and five years, respectively. WFA+-M2BP levels were significantly reduced after SVR (P < 0.001). Multivariate analysis revealed that high WFA +-M2BP level at SVR24 (HR = 1.215, p = 0.020), low platelet counts at pre-treatment (HR = 0.876, p = 0.036) and elderly patients (HR = 1.073, p = 0.011) were independent risk factors for HCC development. From the receiver operator characteristics curve analysis, WFA +-M2BP level >1.37 COI was identified as a cut-off value with an adjusted HR 12.2 (95%CI 3.41–43.91, p < 0.001). The three- and five-year cumulative incidence of HCC in patients with low WFA+-M2BP at

SVR24 were 0.7% and 0.7%, respectively, whereas those of patients with high WFA+-M2BP were 4.8% and 12.4%, respectively (p < 0.001). In addition, WFA+-M2BP was significantly associated with HCC development stratified by IFN-based and IFN-free therapy.
Conclusion: Post-treatment WFA+-M2BP is a useful predictor for HCC development after achievement of SVR, possibly even in IFN-free therapy era.

FRI457
Erradication of HCV with direct-acting antivirals increased small LDL particle number in SVR48

Vanesa Bernal Monterde[1,2], Diego Casas Deza[1,2], Eva Fernandez Bonilla[1], Silvia Espina[3], Marta Fernández Esgueva[4], Ana Martinez-Sapiña[4], Javier Fuentes[1,2], Jose M Arbones Mainar[5,6]. *[1]Hospital Universitario Miguel Servet, Gastroenterology and Hepatology, Zaragoza, Spain; [2]IIS Aragon. Unidad de Investigación Clínica HUMS, Zaragoza, Spain; [3]Hospital Santa Barbara, Soria, Spain; [4]Hospital Universitario Miguel Servet, Microbiology, Zaragoza, Spain; [5]Hospital Universitario Miguel Servet, Translational investigation unity. CIBEROBN, Zaragoza, Spain; [6]Instituto Aragonés de Ciencias de la Salud - IACS, Zaragoza, Spain*
Email: 630552@unizar.es

Background and Aims: HCV interferes with the lipid metabolism of the host, producing low levels of VLDL and LDL-cholesterol. Its eradication with direct-acting antivirals (DAA) causes an increase in LDL-cholesterol. It is still not clear whether those changes might alter the atherogenic risk of individuals treated with DAA. To analyze the lipid profile associated with HCV infection and its variation after DAA eradication and at the SVR48, using the 2D DOSY NMR technique.
Method: Longitudinal prospective study including all treatment naive patients with DAA therapy for HCV eradication during 2018 in the Gastroenterology Department at the Hospital Miguel Servet (Zaragoza. Spain). Lipid and lipoprotein profiles were characterized before and after DAA treatment, as well as at the SVR48 using the routine method and by 2D-DOSY NMR (Liposcale test, Biosfer Teslab). This technique determines the size and number of particles for all subclasses of VDLD, LDL and HDL allowing better characterization of their atherogenic risk.
Results: By November/2019 we have completed the follow-up of 77 DAA-treated patients: 39 (51%) F1, 13 (17%) F2, 14 (18%) F3, 9 (12%) F4. 54.5% women. The median age was 55 years (range 33–83). The eradication of HCV increased the concentration of total and LDL-cholesterol (p = 0.021 and p = 0.003 respectively), as well as the LDL/HDL ratio (p = 0.022) after treatment and then until the SVR48. Total triglycerides and HDL-cholesterol levels did not changed. The number of VLDL and LDL particles also increased significantly at the end of the treatment and at the SVR48, especially the small LDL, the ones with the highest atherogenic risk (p < 0.0001; table 1).
Conclusion: Eradication of HCV with DAA causes lipid changes at the end of the treatment that persists after one year. The characterization of lipoproteins by NMR detects an increase in small LDL particles that might increase the atherogenic risk of DAA-treated patients.

FRI458
Development or worsening of esophageal varices in patients with cirrhosis after DAA-induced HCV clearance

Vincenza Calvaruso[1], Massimo Licata[1], Fabio Simone[1], Lorenza Di Marco[1], Luigi Cusimano[1], Graziano Troina[1], Luciano Crapanzano[1], Gerlando Gibilaro[1], Salvatore Petta[1], Antonio Craxi[1], Vito Di Marco[1]. *[1]University of Palermo, Gastroenterology and Hepatology Unit, PROMISE, Palermo, Italy*
Email: vincenza.calvaruso@unipa.it

Background and Aims: Use of direct acting antivirals (DAAs) has allowed to clear HCV in almost all patients even in the presence of advanced cirrhosis. Although it has been suggested that cirrhotic portal hypertension may regress after SVR, the ultimate effect of HCV clearance on the development and progression of esophageal varices (EV) is still unexplored. We assessed in a prospective cohort of patients with cirrhosis the evolution of endoscopic features of portal hypertension after SVR obtained by DAA.
Method: We analysed 207 consecutive patients (mean age 67.8 ± 9.5, males 53%) with HCV Child-Pugh A5-A6 cirrhosis treated with DAAs between January 2015 and May 2016. All patients underwent esophagogastroscopy (EGS), liver ultrasound (US), liver stiffness measurement (LSM) by Transient Elastography and laboratory tests before the starting DAAs and after achieving SVR. LS * spleen diameter/platelet ratio (LSPS) and RESIST-HCV criteria (Albumin >3.6 g/dl and PLT > 120000 mmc) were evaluated as previously described (1,2).
Results: Thirty-eight patients were excluded from the analysis, 28 (13.5%) since they had F2/F3 EV at baseline and were treated with beta-blockers (BB), 5 (2.4%) died during follow up and 5 developed HCC (2.4%). Overall, 169 SVR patients were analysed. At baseline, 42 patients (24.9%) did not have EV and 127 (75.1%) had small EV. None received beta-blockers. After a median of 37 months EGS showed *de novo* development of EV (dimension/occupation ≥ 10%) in 4/42 (9.5%) patients and progression from F1 to F2/F3 EV in 14/127 patients (11%), p = 0.69 by Kaplan Meier. By Cox univariate regression analysis, age, PLT count, spleen diameter, LSPS and RESIST-HCV criteria were associated with EV progression (p < 0.05 for all). At multivariate model, RESIST-HCV criteria (HR: 0.21, CI95%:0.05–0.95, p = 0.04) and younger age (HR: 0.95, CI95%: 0.92–0.99, p = 0.035) were associated with a lower risk of EV progression. Gender (p = 0.93), BMI (p = 0.84) and diabetes (p = 0.24) did not correlate with progression of EV.
Conclusion: Progression of clinically significant portal hypertension, as assessed by the evolution of esophageal varices, is not uncommon among patients with HCV cirrhosis after HCV clearance. Non-invasive, simply algorithm including only albumin and PLT count can assist in identifying patients in whom portal hypertension is likely to progress notwithstanding SVR.

Table 1: (abstract: FRI457): Lipid profile characterization

Variable	Basal	Post-tto	SVR	SVR 48	P*
Lipid concentrations (median [interquartilic range])					
Total cholesterol mg/dl)	187 [162;222]	206 [177;242]	216 [170;244]	216 [178;248]	**0.021**
LDL	112 [91.8;136]	130 [106;164]	135 [107;169]	141 [108;156]	**0.003**
HDL (mg/dl)	53.0 [47.0;66.0]	54.0 [45.0;63.0]	52.0 [45.0;62.0]	55.0 [48.0;67.0]	0.498
Non-HDL cholesterol (mg/dl)	129 [108;156]	152 [125;183]	156 [125;190]	160 [119;178]	**0.003**
LDL/HDL Ratio	3.20 [2.70;4.30]	3.70 [3.20;4.40]	3.80 [3.10;4.80]	3.70 [3.20;4.60]	**0.022**
Number of particles (media [confidence interval 95%])					
LDL (nmol/l)	1238 [1179;1297]	1379 [1310;1448]		1396 [1323;1469]	**<0.0001**
VLDL (nmol/l)	39.6 [33.9;45.3]	41.4 [35.9;46.9]		48.5 [39.5;57.5]	**0.007**
Small LDL (nmol/l)	680 [652;708]	748 [711;784]		777 [733;822]	**<0.0001**
HDL (μmol/l)	27.9 [26.4;29.5]	27.2 [25.8;28.6]		28.2 [26.8;29.6]	0.2776

*P value for the longitudinal variation with a mixed lineal model.

Partial restoration of brain structural and connectivity changes after HCV cure with direct acting antivirals (DAA)

Zoe Mariño[1], José Carlos Pariente[2], Emma Muñoz-Moreno[2], Concepció Bartres[1], Loreto Nacar[1,3], Myriam Cavero[3], Sabela Lens[1], Sergio Rodriguez-Tajes[1], Ricard Navinés[3], Silvia Cañizares[3], Xavier Forns[1], Nuria Bargalló[2,4], Rocío Martin-Santos[3]. *[1]Liver Unit, Hospital Clinic Barcelona, CIBERehd, IDIBAPS, Universitat de Barcelona, Spain; [2]Magnetic Resonance Image Core Facility, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Psychiatry and Psycology Unit, Hospital Clinic, CIBERsam, IDIBAPS, Universitat de Barcelona, Spain; [4]Neuroradiology Section, Radiology Unit, Hospital Clinic Barcelona, Spain*
Email: rmsantos@clinic.cat

Background and Aims: HCV infection is associated with neuropsychiatric manifestations. Previous neuroimaging studies showed brain connectivity dysfunction among HCV patients. The aim of this study was to assess, by magnetic functional resonance in resting state (fMR), the potential structural and connectivity changes before and after HCV eradication with DAA, along with clinical parameters.
Method: Inclusion of HCV-infected patients(≤55 years) with no baseline psychiatric disease, eligible for DAA therapy. Clinical and brain MR evaluation (T1 and fMR) were done at baseline(BL) and after viral cure(FU12). Comparisons were made between HCV patients at BL/FU12 and compared with a non-HCV control group by means of paired/independent T-test analysis. Variables were expressed as n(%); median/$IQR_{(25-75)}$. Brain volume and local gyrification index(LGI) were assessed in T1; functional connectivity was assessed by seed-based analysis (region of interest: left insula). Depression and neurotoxicity were assessed by means of MADRS/PHQ9 and neurotoxicity rating scales, respectively.
Results: Twenty-one HCV patients and 25 controls were included. Among HCV patients: 52% female, age 46 years, RNA-VHC 6.03 $\log_{10}$ (IU/L), elastography 5.2 Kpa (4.3–6), ALT 61UI/L (25–87). DAA were used for 8–12 weeks with 100% cure rate. HCV patients presented significant improvements after HCV cure (FU12) in depression/neurotoxicity parameters compared to BL ($p < 0.01$). HCV (BL and FU12) patients showed a reduced volume in a right lateroccipital area compared to controls (CWP<0.005) (Fig.1A); this volumetric difference was smaller between FU12-HCV and controls. Moreover, LGI was significantly higher in FU12-HCV patients compared to BL-HCV (CWP<0.0005). The connectivity analysis showed a high association of the insula with occipital/parietal territories among HCV patients, compared to controls; this difference in connectivity was higher among BL-HCV and controls, whereas differences were limited to the occipital areas among FU12-HCV and controls (Fig.1B)
Conclusion: Left insula is disturbed among HCV infected patients in structure(gyrification) and connectivity(mainly concerning the occipital area, where a volume reduction was also observed). After HCV cure, differences with controls were reduced, suggesting a partial restoration of brain connectivity. Clinical parameters assessing depression and neurotoxicity improved consistently after HCV cure

Glycogen synthase 2 (GYS2) restricts tumor metastatic ability via attenuating autophagy and breaking glycogenic homeostasis in hepatocelluar carcinoma

Di Wu[1], Zhongjie Lin[2], Xiujun Cai[3]. *[1]Zhejiang University, School of Medicine, HangZhou, China; [2]Zhejiang University, School of Medicine, Hangzhou, China; [3]Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, General surgery, Hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: Aberrant metabolic reprogramming tightly linked to carcinogenesis or tumor progression. However, rare attention has been paid to glycogen metabolism. The regulation of glycogen in liver, as the main organ of glycogen metabolism, might be different to other organs with unknown mechanisms. Here we are willing to demonstrate that Glycogen synthase 2 (GYS2) restrict tumor metastatic ability via attenuating autophagy and breaking glycogenic homeostasis in hepatocellular carcinoma.
Method: GYS2 expression pattern was investigated by both **weighted gene co-expression network analysis** and **Robust Rank Aggregation method** and verified by RT-qPCR, westernblot and immunochemistry in HCC tissue. MTS, metastasis mouse model, transwell assay and tandem mCherry-GFP-LC3 fusion protein assay

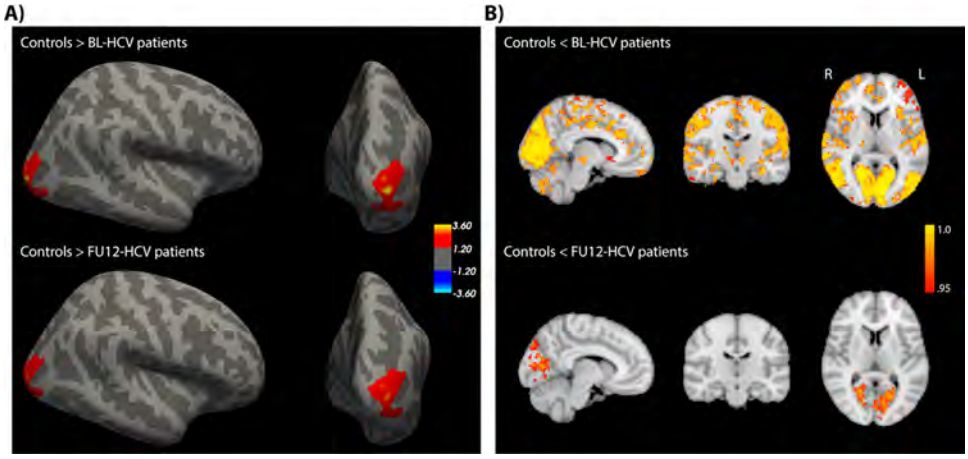

Figure: (abstract: FRI459)

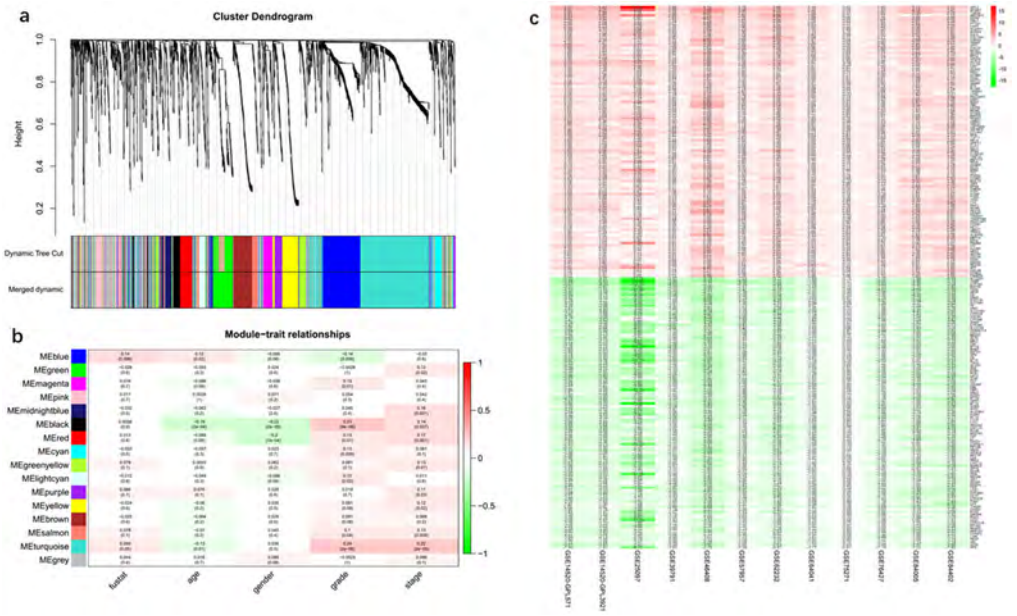

Figure: (abstract: FRI460)

were utilized to assess the function of GYS2 on proliferation, metastasis and autophagy of HCC cells in vitro and in vivo.
Results: GYS2 downregulation was quite prevalent in HCC tissues and closely correlated with worse overall survival. Furthermore, GYS2 overexpression significantly suppressed cell growth, migration and autophagy, the expression of ZEB1, Snail, βcatenin, and increased E-cadherin level. Overexpression of GYS2 induced a decline of PYGL even in starvation condition, consequent glycogen accumulation led to increased reactive oxygen species (ROS) levels and celluar senescence.
Conclusion: In summary, our findings suggested that GYS2 serves as a prognostic factor and functions as a tumor suppressor by inhibiting autophagy and interpreting glycogenic homeostasis in HCC. GYS2 might be a promising target for prevention, treatment and prognostic prediction of HCC.

EIF4EBP3, methylated in gastric cancer, acts as a tumor suppressor restraining tumor proliferation and liver metastasis via targeting EIF4E/B-catentin axis

Zhongjie Lin[1], Shuting Zhai[1], Haoqi Pan[1], Yelin Ruan[1], Shi Jiang[1], Zhe Wan[1], Lin Ji[1], Xiujun Cai[1]. [1]*Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Department of General Surgery, Hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: Epigenetic aberrations of tumor suppressor genes (TSGs), particularly DNA methylation, are frequently involved in the pathogenesis of gastric cancer (GC). Through a methylome study, we identified eIF4EBP3 as a methylated gene in GC. However, the role of eIF4EBP3 in GC progression has not been explored.
Method: The expression and promoter region methylation of eIF4EBP3 in GC and healthy tissues were analyzed in public datasets. eIF4EBP3 expression in GC was detected by semi-quantitative RT-PCR, western blot and immunohistochemistry. The clinical significance of eIF4EBP3 was analyzed. We also studied epigenetic alterations and functions in GC. The effects of eIF4EBP3 on cell proliferation, migration and invasion were conducted by functional experiments in vitro and in vivo, and epithelial-mesenchymal transition markers were analyzed. Label-free proteomic analysis was applied to identify targets of eIF4EBP3 using Vector/ eIF4EBP3 SGC7901 cells, and functional experiments were performed to confirm a selected target.
Results: The mRNA levels of eIFEBP3 were downregulated in gastric cancer due to promoter region CpG methylation, which was associated with poor survival and tumor progression in GC patients. Ectopic expression of eIFEBP3 significantly inhibited tumor cell growth, migration and invasion both in vitro and in vivo. Label-free proteomic analysis indicated eIFEBP3 downregulated the protein level of β-catenin, which was confirmed by western blot. Overexpression of β-catenin reversed the inhibitory effects of eIFEBP3 on cell growth and migration, indicating that eIFEBP3 acts on GC cells by targeting the eIF4E/β-catenin axis. These observations demonstrate that eIFEBP3 downregulation is a common event in GC specimens and is closely correlated with cancer proliferation and liver metastasis and that EIFEBP3 restrains EMT by a β-catenin-mediated signaling pathway.
Conclusion: These results suggest that eIFEBP3 is a novel TSG methylated in gastric cancer that may play important roles in GC development and liver metastasis and indicate eIFEBP3 as a potential metastasis and survival biomarker for GC.

Email: jmllovet@clinic.cat

Background and Aims: Mongolia has the world's highest incidence of hepatocellular carcinoma (HCC), (~100 cases/100,000 inhabitants/year). We aim to perform a molecular characterization of HCC in this country.

Method: 192 paired fresh-frozen HCC/non-tumoral samples from patients undergoing resection in Mongolia were analyzed. Whole exome sequencing (WES) and RNAseq were performed in 151 and 106 samples, respectively. WES was used for mutation calling, mutational signatures (MutSig) analysis, and tumor mutational burden (TMB, mut/Mb) evaluation. The Mongolia cohort was compared to a Western cohort (n = 187) and to an Eastern cohort (n = 231) [*Ahn et al, Hepatology 2014*] to evaluate differences in the genomic profile.

Results: Mongolian patients, compared to Western, were younger (61 vs 66 years old), with lower male predominance (54% vs 80%), and less advanced hepatic fibrosis (F3-4, 38% vs 79% (all $p < 0.001$). Etiologies in Mongolia were: 30% hepatitis C virus (HCV), 9% hepatitis B virus (HBV), 40% HBV coinfection with hepatitis delta virus (HBV/HDV), 6% triple infected (HBV/HCV/HDV), and 15% non-infected. HDV was detected in 84% of HBV-infected samples in Mongolia and 7% in the Western cohort ($p < 0.001$). All HBV+ and HDV+ patients in Mongolia were infected by genotype D and 1, respectively. Unique molecular features were identified in Mongolian HCC: a) Distinct molecular classes: 3 Mongolian classes were identified. MGL1 class (44%) was associated to HCV infection (32% vs. 7%/3%) in older patients (62 vs. 56 years old) ($p < 0.05$), and recapitulate the S3 Western subclass ($p = 0.001$). MGL2 (26%) and MGL3 classes (30%) were enriched with HBV/HDV infection (93%/97% vs. 60%, $p < 0.001$). MGL2 class showed a female/male ratio of 2:1, and clinical (e.g. higher AFP > 400) and molecular features of aggressiveness (i.e. Proliferation classes). MGL3 was enriched with immune features, both from adaptive and innate immune response. b) Mongolian compared to Western and Eastern cohorts showed higher TMB (4 mut/Mb vs. 2.1 vs. 2.3, respectively, $p < 0.001$), without differences among etiologies, and more mutations in *TP53* (46% vs. 32% vs. 27%), *ARID1A* (17% vs. 10% vs. 3%), and *TSC2* (9% vs. 1% vs. 3%), ($p < 0.05$). c) MutSig 3, associated with DNA double-strand break-repair, and MutSig22, associated with aristolochic acid exposure, were detected in 34% and 11% of samples in Mongolia and 5% and 3% in the Western cohort ($p < 0.001$).

Conclusion: HCC in Mongolia shows unique molecular traits, including a) distinct molecular classes, two of which relate to HBV/HDV infection and younger age, b) higher number of mutations per tumor and c) high prevalence of a mutational signature related to DNA repair, suggesting the presence of a distinct genotoxic agent in this country.

NK-cell dysfunction in hepatocellular carcinoma: modulatory approches for functional restoration

Alessandra Zecca[1], Valeria Barili[2], Raffaelle Dalla Valle[2], Danila Rizzo[2], Andrea Olivani[1], Elisabetta Biasini[1], Carlo Ferrari[2], Elisabetta Cariani[3], Gabriele Missale[2]. *[1]Azienda Ospedaliero-Universitaria of Parma, Laboratory of Viral Immunopathology, Unit of Infectious Diseases and Hepatology, Parma, Italy; [2]University of Parma, Department of Medicine and Surgery, Parma, Italy; [3]Ospedale Civile S. Agostino-Estense, Laboratory of Toxicology, Modena, Italy*
Email: gabriele.missale@unipr.it

Background and Aims: Several immune mechanisms contribute to an immunosuppressive tumour immune milieu: regulatory immune cells, checkpoint receptors, low nutrients and hypoxia that can affect immune cells metabolism and function. Metabolic profiles rather than phenotypic characteristics seem to define the functional role of NK cells and their influence in a correct anti-tumour effect. NK-cell response is functionally impaired in Hepatocellular Carcinoma (HCC), however little is still known about NK-cell metabolism in this tumour.
Method: Liver and tumour infiltrating lymphomononuclear cells from 10 patients were derived from surgical specimens and NK-cells were purified by flow activated cell sorting in order to perform gene expression profiling. NK-cell phenotype, glucose uptake and mitochondrial polarization were defined by multi-parametric flow cytometry. Modulatory compounds were identified on the basis of gene expression profiling and employed to restore tumour infiltrating NK-cells metabolism and cytotoxic functions.
Results: Genome-wide expression profiling showed enrichment of upregulated genes belonging to metabolic pathways in HCC-infiltrating NK cells: glycolysis and oxidative phosphorylation, cell cycle, DNA damage and p38-related pathway. Higher level of phosphorylated-p38 protein was confirmed in tumour infiltrating NK cells while phenotypic characterization showed enrichment of CD49a positive and CD27CD11b double negative NK-cells that has been associated with regulatory and dysfunctional NK-cells. Functional and metabolic assessment showed defective degranulation capacity, reduced autophagy and glucose consumption. Targeting MAPK pathway by two different p38-inhibitors could restore NK-cell functions.
Conclusion: We identified an impairment of energy metabolism of HCC-infiltrating NK-cells associated with functional defects that can be rescued modulating MAPK pathway. These results provide the basis to develop new strategies to potentiate NK-cell response in HCC.

FRI464

Global characterisation of tumour infiltrate of intrahepatic cholangiocarcinoma by single cell sequencing

Cristiana Soldani[1], Barbara Franceschini[1], Michela Anna Polidoro[1], Clelia Peano[2], Alberto Termanini[3], Paolo Kunderfranco[3], Enrico Lugli[4], Simone Puccio[4], Giorgi Alvisi[4], Federico Colombo[5], Alessio Aghemo[6], Matteo Donadon[6], Guido Torzilli[6], Ana Lleo[6]. *[1]Humanitas Clinical and Research Center IRCCS, Hepatobiliary Immunopathology Lab, Rozzano (MI), Italy; [2]Humanitas Clinical and Research Center IRCCS, Genomic Unit and Sequencing facility, Rozzano (MI), Italy; [3]Humanitas Clinical and Research Center IRCCS, Bioinformatic Unit, Rozzano (MI), Italy; [4]Humanitas Clinical and Research Center IRCCS, Laboratory of Translational Immunology, Rozzano (MI), Italy; [5]Humanitas Clinical and Research Center IRCCS, Flow Cytometry Facility, Rozzano (MI), Italy; [6]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele (MI), Italy*
Email: ana.lleo@humanitas.it

Background and Aims: Intrahepatic cholangiocarcinoma (iCCA) is the second most common primary liver cancer, characterized by high resistance to chemotherapy and poor prognosis. We have previously demonstrated that the tumor immune microenvironment (TME) has a prognostic impact on iCCA patients; however, little insight exists on immune subsets involved in iCCA and precise criteria to assess tumor biology are still lacking.
Method: we examined immune infiltrate with single cell-RNA sequencing (scRNAseq) of iCCA tumor and peritumor liver sample. scRNAseq was performed on CD45+ sorted cells isolated from tumoral and peritumoral sample of iCCA patients (n = 6) surgically resected at the Division of Hepatobiliary and General Surgery in Humanitas. Cell suspensions were converted to barcoded scRNAseq libraries with 10× Genomics Chromium Single-cell system and were sequenced on Illumina NextSeq 500. CellRanger (v3.0.1, 10× Genomics) pipeline were applied to obtain gene espression data. For each cluster, gene average expression and marker genes were obtained. A principal component analysis (PCA) was performed both for the whole dataset and for each cluster of cells. Clusters classification by cell types was performed by comparing each single cell gene expression with public transcriptomic datasets of pure cell types by using the SingleR (v0.9) Bioconductor R package.
Results: We obtained an integrated dataset of 12 samples for a total of more than 30,000 good quality single cells with a median of 800 detected genes each. This analysis revealed that tumor samples clearly separate from peritumoral ones according to the main principal immune cells population for each patient. Key actor of these differences, identified by clustering and classification analysis, were T cells, NK cells and myeloid cells. Moreover, each of them is characterized by cell subpopulations with transcriptional differences between tumoral and peritumoral samples.
Conclusion: These results highlighted that TME strongly differs from the immune system infiltrating the peritumoral area. Further, our study provides a new approach for patient stratification and will help further understand the functional states and dynamics of TME in iCCA.

New prognostic score utilizing glypican-3 serum levels for the prediction of 6-month outcome after transarterial therapies for patients with intermediate stage hepatocellular carcinoma

Anne Olbrich[1], Olga Groß[1], Karen Rother[2], Tim-Ole Petersen[3], Bettina Maiwald[3], Timm Denecke[3], Thomas Kahn[3], Florian Lordick[4], Dirk Forstmeyer[4], Thomas Lincke[5], Sandra Purz[5], Osama Sabri[5], Robert Sucher[6], Daniel Seehofer[6], Thomas Berg[2], Florian van Bömmel[2]. *[1]University Clinic Leipzig, Division of Hepatology, Clinic and Policlinic for Gastroenterology, Hepatology, Infectiology, and Pneumology, Leipzig, Germany; [2]University Clinic Leipzig, Division of Hepatology, Clinic and Policlinic for Gastroenterology, Hepatology, Infectiology, and Pneumology, Leipzig, Germany; [3]University Clinic Leipzig, Department of Diagnostic and Interventional Radiology, Leipzig; [4]University Clinic Leipzig, University Cancer Center Leipzig (UCCL), Leipzig, Germany; [5]University Clinic Leipzig, Department of Nuclear Medicine, Leipzig, Germany; [6]University Clinic Leipzig, Department of Visceral, Vascular, Thoracic and Transplant Surgery, Leipzig, Germany*
Email: anne.olbrich@medizin.uni-leipzig.de

Background and Aims: The selection of patients with intermediate stage hepatocellular carcinoma (HCC) for transarterial therapies currently relies on liver function and tumor properties. Outcome prediction by circulating biomarker is desirable, but not established. The aim of this study was to assess experimental HCC biomarkers for their association with survival after transarterial therapies.
Method: Data were retrospectively collected from 125 consecutive HCC patients with intermediate stage HCC (BCLC-B) undergoing either transarterial chemoembolization (TACE, n = 98) and/ or selective internal radiation therapy (SIRT, n = 28) at one German University Hospital between 2010 and 2017. Patients and tumor

characteristics including total diameter and number of tumor lesions, C-reactive protein (CRP), platelets, leucocyte counts, albumin, bilirubin and alanine transaminase (ALT) levels as well as circulating HCC biomarkers including AFP, AFP-L3, des-gamma-carboxy prothrombin (DCP), alone and summarized in the GALAD score, glypican-3 (GPC-3), and Dickkopf-related protein 1 (Dkk-1) were quantified on cryopreserved serum samples taken prior to therapy. Univariate and multivariate analyses were performed to identify the predictive value of the different biomarkers for 6-month survival. The parameters with the strongest independent association with survival were included into a new scoring system.

Results: Univariate analyses showed that lower GPC-3 as well as DCP serum levels were significantly associated with 6-month survival (median GPC-3: 8 pg/ml vs. 32 pg/ml, p = 0.002; DCP: 4 ng/ml vs. 16 ng/ml, p = 0.004). Moreover, higher GALAD-scores were associated with a poorer prognosis (4.85 vs. 1.32, p = 0.008). In contrast, all other patient and tumor related parameters showed no significant difference regarding 6-month survival.

By multivariate analysis, the biomarkers with the highest association with treatment response were GPC-3, the number of lesions and CRP. A combination of the three markers in a new prognostic score GLC (GLC = 2.873–2.161/100 * **G**PC-3 (pg/ml) - 0.185 * number of **l**esions - 0.052 * **C**RP (mg/l))was developed resulting in a specificity of 72.7% and sensitivity of 77.9% for prediction of 6 months survival (Fig. 1).

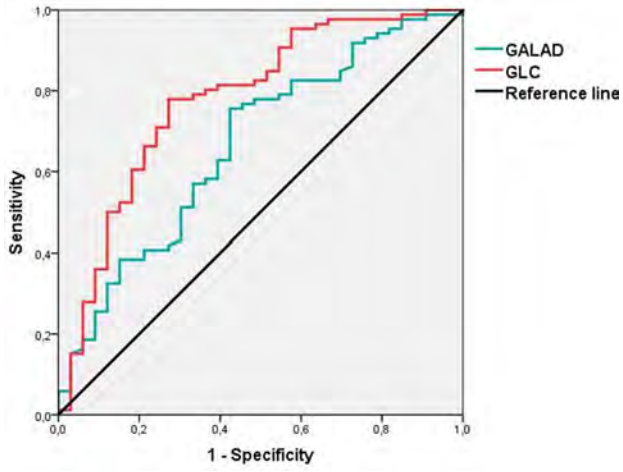

Fig 1 Receiver operating characteristic (ROC) analysis of sensitivity and specificity by the GALAD and the GLC score in predicting 6-month-survival.

Conclusion: The combination of novel HCC biomarkers might be a potent tool for tailoring individualized treatment strategies for patients with intermediate stage HCC. The GLC-Score can help to estimate the 6-month-survival rate of these patients with high sensitivity and specificity. A GLC-Score above 1.4 is associated with a 6-month survival rate of 80%.

Ganglioside patterns in the human cholangiocarcinoma stem cell subset

Antonella Mannini[1], Chiara Raggi[1], Margherita Correnti[2], Elisabetta Rovida[1], Benedetta Piombanti[1], Mirella Pastore[1], Massimo Aureli[3], Emma Carsana[3], Jesper Andersen[4], Cedric Coulouarn[5], Fabio Marra[1]. *[1]University of Florence; [2]Humanitas Research Center; [3]University of Milan; [4]University of Copenhagen; [5]University of Rennes*
Email: antonella.mannini@unifi.it

Background and Aims: Cancer stem cell (CSC) represents a critical therapeutic target in neoplastic diseases. Gangliosides (GS) are a family of sialic acid–containing glycosphingolipids, which have been associated with the malignant phenotype of several cancers (i.e. breast, melanoma, glioblastoma, ovary). Recent evidence indicates the possible involvement GS in tumor stem cell biology, but no data regarding GS composition in human cholangiocarcinoma (CCA) are available. The aim of this study was to provide a GS profiling of the stem-like subset and of their parental cells in human CCA.

Method: Stem-like subset was enriched by sphere culture (SPH) using well-established human intrahepatic CCA cells (HUCCT1, CCLP1). CCA GS patterns were analyzed by chromatographic procedures. Assessment of GS turnover and identification of GS molecular species were evaluated using 3Hsphingosine. The role of GS in the modulation of stem features was investigated using D-threo-1phenyl-2-palmitoylamino-3-N-morpholine-1-propanol (PPMP), a GM3 synthase inhibitor. FACS-sorted GD2+ SPH cells were examined for stem-like gene expression compared to GD2- SPH.

Results: In both CCA lines, the amount of total GS was markedly different comparing parental cells grown in monolayer conditions (MON) and their stem-like subsets (SPH). CCA-SPH showed enrichment in the major GS class (GM3), reduction of GM2 and the presence of GD2. This was corroborated by high expression levels of GM3 synthase as well as of GD3 and GM2/GD2 synthases in CCA-SPH. Enzymes involved in GS biosynthesis were strongly expressed in CCA-SPH compared to MON. Notably, sphere-forming ability and expression of CSC-related genes were reduced in cells treated with by PPMP. Likewise, GD2+ SPH cells were enriched with CSC-markers (CD133, EpCAM, CD44) and expressed at higher levels several genes involved in pluripotency, self-renewal and epithelial mesenchymal transition compare to GD2- SPH. Notably, expression of GM2/GD2 synthases was significantly increased in tumor samples compared to paired non-tumoral tissue of CCA patients (n = 104) and significantly correlated with the presence of satellite nodules, lymph node invasion and recurrence.

Conclusion: We show for the first time that the CCA stem-like properties may be associated with modification in the GS synthetic pathway.

FRI467

T cell exhaustion dynamics are linked to clinical outcomes in hepatocellular carcinoma

Zhen Zhang[1], Catrin Tauber[1], Moritz Hess[2], Sasikanth Manne[3], Annette Schmitt-Gräff[1], Frances Winkler[1], Takuya Ohtani[3], Tobias Flecken[1], Patricia Otto-Morra[1], Michael Schultheiss[1], Bettinger Dominik[1], Andrew Rech[3], David J. Pinato[4], Marcus Buggert[5], Thomas Berg[6], Stefan Fichtner-Feigl[1], Harald Binder[2], E. John Wherry[3], Maike Hofmann[1], Robert Thimme[1], Bertram Bengsch[1]. *[1]University Medical Center Freiburg, Freiburg im Breisgau, Germany; [2]University of Freiburg - Institute for Biometry and Statistics; [3]University of Pennsylania; [4]Imperial College London, Surgery & Cancer; [5]Karolinska Institutet; [6]University Medical Center Leipzig*
Email: bertram.bengsch@uniklinik-freiburg.de

Background and Aims: Hepatocellular Carcinoma (HCC) is the major cause of liver cancer, a major global health problem with limited treatment options and poor prognosis. The immunobiology of hepatocellular carcinoma is poorly understood. Exhausted and liver-resident T cells have been identified in HCC patients but their role and clinical relevance remained unclear. We therefore aimed to assess the clinical impact of exhausted T cells in HCC patients by using a system immune profiling approach based on newly developed transcriptomic and cytometric signatures.

Method: Comprehensive phenotypic and functional exhaustion profiling of the peripheral and intrahepatic immune compartment (tumor-surrounding and tumor microenvironment) was performed ex vivo on samples from 20 HCC patients using flow and mass cytometry. Single-cell- and population based transcriptome profiles from published datasets of HCC resections were *in silico* assessed for signatures of T cell exhaustion and residency and their link to patient survival. Exhaustion and residency of exhausted T cells were further analyzed by immunohistochemistry.

Results: We found that exhausted T cells can be identified in the peripheral blood and enriched in the liver of HCC patients. High-parametric phenotypic and functional analysis identified significantly exhausted CD8+ T cells in the tumor microenvironment. Importantly, a strong enrichment of more exhausted subtypes of CD8+ T cells with differential expression of multiple immune checkpoint targets in the tumor microenvironment at the expense of liver resident memory T cells and cytotoxic T cell signatures was negatively linked to patient survival. These findings were confirmed by *in silico* analysis of exhaustion and residency signatures in TCGA HCC samples.
Conclusion: These data underline the clinical relevance of the exhausted T cell response in HCC patients. The dynamics between exhausted and resident liver T cells have implications for immune-based diagnostics, rational patient selection and monitoring during HCC immunotherapies.

Lactate promotes invasion and metastasis of hepatocellular carcinoma via changes in mitochondrial and histone acetylation
Jiebin Zhang[1], Jia Yao[1], Jianye Cai[1], Jun Zheng[1], Liang Chen[1], Tongyu Lu[1], Yingcai Zhang[1], Yang Yang[1], Wei Liu[1]. [1]*Organ transplantation institution, Department of Hepatic Surgery and Liver Transplantation Center of the Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*
Email: lwei6@mail.sysu.edu.cn

Background and Aims: Acidosis is nowadays considered as a hallmark of human cancers. We previously found that lactate secreted by cancer associated hepatic stellate cells (HSCs) was a major source to form acidosis microenvironment in hepatocellular carcinoma (HCC). However, the mechanism underlying lactate promotes HCC malignant progression was not fully demonstrated.
Method: Glucose metabolism reprogramming (glucose uptake ability, oxygen consumption rate, lactate accumulation) of HSCs, invasive ability and acetyl-CoA content of HCC cells were detected in the HCC-HSCs co-culture model. ^{14}C labeled lactate was introduced to trace the contribution to downstream carbon metabolic intermediates. The expression and acetylation levels of mitochondrial pyruvate carrier 1 (MPC1) were measured to determine the degradation of MPC1 in HCC cells. In addition, the acetylation levels of H3K27 and key transcription factor TWIST2 of HCC cells were detected. The therapeutic effect of combination of acetyltransferase p300 inhibitor C646 and monocarboxylate transporter 1 (MCT1) inhibitor CHC were determined by invasive ability *in vitro* and lung metastasis *in vivo*.
Results: Glucose metabolism reprogramming of HSCs was occurred from oxidative phosphorylation to glycolysis, especially characterized by large amount of lactate secretion, after co-cultured with HCC. Furthermore, ^{14}C labeled lactate tracer was used and found that mitochondrial proteins and histone were hyperacetylated. In detail, MPC1 was acetylation modified and subsequently degraded, leading to decreased mitochondrial pyruvate uptake and increased glycolysis in HCCs. Meanwhile, lactate activated *TWIST2* expression indirectly by promoting H3K27 acetylation on the *TWIST2* promoter, mediated by histone acetyltransferase p300. Moreover, combination of acetyltransferase p300 inhibitor C646 and MCT1 inhibitor CHC could remarkably inhibit invasion and metastasis of HCC.
Conclusion: In this study, our work revealed that acidosis microenvironment shaped by lactate promoted invasion and metastasis of HCC by regulating acetylation of MPC1 and H3K27. Thus, lactate blockade might be a potential metabolism-based target to enhance the therapeutic efficacy.

Dysregulation of aquaporin-1 in human CCA cells triggers epithelial-mesenchymal transition
César Gaspari[1,2,3], Seth Richard[1], Javier Vaquero[4], Ander Arbelaiz[2], Marie Vallette[2], Aalekhya Biswas[1], Julieta Marrone[3], Raúl Marinelli[3], Laura Fouassier[2], Sergio Gradilone[1]. [1]*The Hormel Institute, University of Minnesota, Austin, Minnesota, United States;* [2]*Sorbonne Université, Inserm, Centre de Recherche Saint Antoine, CRSA, Paris, France;* [3]*Instituto de Fisiología Experimental-CONICET, Universidad Nacional de Rosario, Rosario, Argentina;* [4]*TGF-β and Cancer Group, Oncobell Program, Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain*
Email: sgradilo@umn.edu

Background and Aims: Cholangiocarcinoma (CCA) is a tumor arising from biliary epithelial cells. The overall prognosis is very poor due to the ability of the tumor to develop chemoresistance and metastasis. Epithelial-mesenchymal transition (EMT) is a multistep process during which epithelial cells gradually adopt structural and functional characteristics of mesenchymal cells. EMT is required for tumor cell migration, invasion and has been considered an early event of metastasis. EMT occurs in CCA where is associated with progression and chemoresistance. The function of aquaporin (AQP) water channels in tumors has been the focus of substantial research efforts. However, the role of AQPs in liver cancers and specifically in CCA remains unknown. Our aim was to study the role of aquaporin-1 (AQP1) in the regulation of EMT in CCA.
Method: Two established human CCA cell lines, HuCCT1 and KMCH, were used as experimental models. We generated KMCH AQP1 shRNA knock-down and HuCCT1 AQP1 KO by CRISPR/Cas9 system. Cell proliferation and migration were assessed by the Incucyte live-cell imaging system. We performed an unbiased discovering experiment using RNAseq comparing wild-type and AQP1 KO CCA cells. EMT and stemness markers expression were evaluated by RT-qPCR, western-blot and confocal microscopy.
Results: Both CCA cell lines express AQP1 largely located in intracellular compartments. Dysregulation of AQP1 in tumor cells significantly induces proliferation and migration, suggesting a tumor suppressor role of AQP1 in CCA. RNAseq of AQP1 KO cells showed a total of 2702 differentially expressed genes. The Ingenuity Pathway Analysis showed Cancer (p-value range 3.36E-04-9.16E-34), Cellular movement (p-value range 2.54E-04-1.71E-20), and Cellular Growth and Proliferation (p-value range 2.23E-04-3.34E-11) as the top affected Diseases and Biological functions. In addition, the epithelial markers genes were significantly downregulated upon AQP1 silencing (E-cadherin gene *CDH1* by −133 fold change; $p < 0.001$, cytokeratin19 gene *KRT19* by -8 fold change; $p < 0.001$), while mesenchymal markers genes were significantly upregulated (vimentin gene *VIM* by 4 fold change; $p < 0.001$, fibronectin gene *FN1* by 3.51 fold change; $p < 0.001$), suggesting that the loss of AQP1 induced EMT. Furthermore, these changes were corroborated at mRNA and protein levels, with a major E-cadherin downregulation along with an upregulation of mesenchymal markers vimentin, fibronectin and EMT-inducing transcription factors ZEB1 and ZEB2.
Conclusion: Our data suggest that AQP1 acts as a tumour suppressor in CCA cells by acting both on proliferation and migration through an EMT process. Therefore, AQP1 might have an important role by restraining CCA progression.

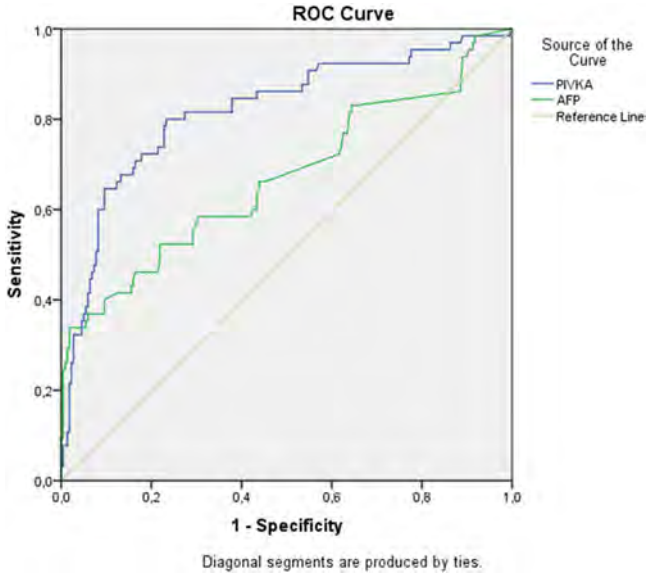
Email: claudio.galli@abbott.com

Background and Aims: Hepatocellular carcinoma (HCC) represents the second leading cause of cancer deaths worldwide. HCC has a silent course making clinical diagnosis often delayed, with a significant impact on prognosis. Protein induced by vitamin K absence (PIVKA-II) has been proposed as a potential biomarker for HCC. This study has been designed to evaluate the role of PIVKA-II in the diagnosis of HCC through the comparison between PIVKA-II and alpha-fetoprotein (AFP) serum levels on HCC patients and the two control groups of patients with liver disease and without HCC.
Method: In an Italian prospective cohort, PIVKA-II levels were assessed on serum samples by an automated chemiluminescent immunoassay (Abbott ARCHITECT). The study population included 65 patients with HCC (both "de novo" and recurrent), 111 with liver cirrhosis (LC) and 111 with chronic hepatitis C (CHC). The diagnostic accuracy of PIVKA-II for HCC diagnosis was assessed by the receiver-operating characteristic (ROC) analysis.
Results: PIVKA-II levels were increased in patients with HCC (median 63.75, range: 12–2675 mAU/mL) compared to LC (median value: 30.95, range: 11.70–1251 mAU/mL, Mann Whitney test $p < 0.0001$) and CHC (median value: 24.89, range: 12.98–67.68 mAU/mL, $p < 0.0001$). The area under curve (AUC) for PIVKA-II was 0.817 (95% Confidence Interval (CI), 0.752–0.881). At the optimal threshold of 37 mAU/mL, identified by the Youden Index, the sensitivity and specificity were 79% and 76%, respectively. PIVKA-II was a better biomarker than AFP for the diagnosis of HCC, since the AUC for AFP was 0.670 (95% CI 0.585–0.754, $p < 0.0001$) and at the best cutoff of 16.4 ng/mL AFP yielded 98% specificity but only 34% sensitivity. PIVKA-II and AFP presented a low degree of correlation (Spearman $r = 0.15$, $p = 0.013$) and no correlation at all in the HCC group ($r = 0.016$). The combination of PIVKA-II and AFP reached positive and negative predictive values of 100% and 85%, respectively. The sub-analysis of HCC population showed that PIVKA-II values were significantly higher in Barcelona Clinic Liver Cancer (BCLC) stage B than in BCLC A (median 211.48 vs. 59.28, $p = 0.0013$) and in BCLC 0 (median 55.13, $p = 0.02$)

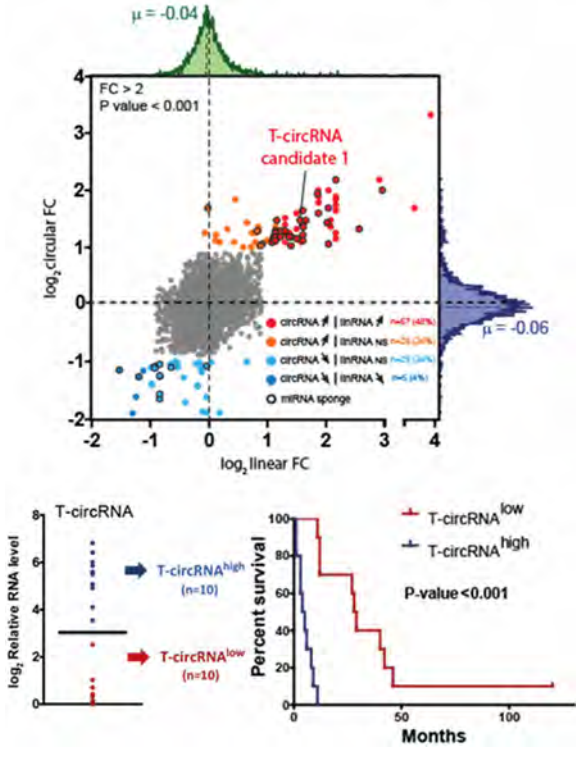


Conclusion: These initial data suggest the potential utility of this tool in the diagnosis of HCC. PIVKA-II alone or in combination may help to an early diagnosis of HCC and a significant optimization of patient management.

FRI471
TGF-beta-associated circular RNAs in cholangiocarcinoma: mechanisms and biomarkers

Corentin Louis[1], Matthis Desoteux[1], Angenard Gaelle[1], Julien Edeline[2], Cedric Coulouarn[1]. [1]*Inserm, Rennes, France;* [2]*Centre de Lutte contre le Cancer Eugène Marquis, Rennes, France*
Email: cedric.coulouarn@inserm.fr

Background and Aims: Cholangiocarcinoma (CCA) is a deadly cancer worldwide, as a result of increased incidence and limited therapeutic options. Transforming growth factor beta (TGFb) plays a key role in hepatobiliary cancer and interfering with this pathway represents a clinically relevant therapeutic strategy. However, targeting TGFb is complex due to its functional duality (pro-cytostatic at an early stage vs. pro-metastatic at an advanced stage). So far, the molecular mechanisms involved in this functional duality are not fully understood. We hypothesize that non-coding RNA (ncRNAs), including circular RNA (circRNA) and microRNA (miRNA), take part of the TGFb network to switch the actions of TGFb toward metastasis in CCA progression. Thus, we aim at characterizing pro-metastatic TGFb-regulated circRNA acting as miRNA sponges and serving as relevant biomarkers in human CCA.
Method: Unsupervised gene expression profiling (RNA sequencing) was used to identify known and novel TGFb-regulated coding and ncRNA (mRNA, lncRNA, miRNA and circRNA) in human CCA cell lines. A bioinformatics pipeline was developed to identify a TGFb-associated gene regulatory network of coding and ncRNA and to identify circRNA acting as miRNA sponges. Candidates were validated in several CCA cell lines, and their clinical relevance (e.g. survival analyses) was evaluated in a collection of 50 clinically well annotated intrahepatic CCA from the French Liver Network. Exosomes were isolated by ultracentrifugation and validated by electron microscopy and q-Nano.



Results: Genome-scale profiling identified 119 TGFb-regulated circRNA, including T-circRNA1, a novel TGFb-induced circRNA, which displayed 5 binding sites for miR-338, a well-known tumor suppressor miRNA. Hence, T-circRNA1 acts as a competitive RNA keeping away miR-338 from its natural linear targets, including CXCR4, SKIL and SOX4, which results in the overexpression of these pro-metastatic effectors. Analysis of T-circRNA1 expression in resected iCCA tumors demonstrated its prognostic value. Patients with a low T-circRNA1 expression showed a better survival than patients with high T-circRNA1 expression. T-circRNA1 expression was also identified in exosomes upon TGFb stimulation and in the serum of patients.
Conclusion: Our data highlight circRNA as novel regulators of the TGFβ network in CCA. T-circRNA1 induction results in switching the action of TGFβ toward tumor progression. T-circRNA1 constitutes a relevant biomarker in human CCA.

Tracking neutrophils within the hepatocellular carcinoma microenvironment - development of relevant orthotopic and ex-vivo 3D liver-HCC culture models

Daniel Geh[1,2], Amy Collins[1], Caroline Wilson[1], Helen L. Reeves[2,3], Derek A Mann[1], Jack Leslie[1]. *[1]Fibrosis Research Group, Biosciences Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom; [3]Hepatopancreatobiliary Multidisciplinary Team, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*
Email: daniel.geh@newcastle.ac.uk

Background and Aims: Immunotherapies have exciting potential in hepatocellular carcinoma (HCC), given that up to 50% of tumours have an immune component. Despite this, clinical studies indicate that only 15% of HCC patients respond to T cell immune checkpoint inhibitors. Targeting more than one component of the immune microenvironment may improve response rates and our previous work supports neutrophils as drivers of HCC and candidate immunotherapy targets. To better understand the complex role of neutrophils in HCC our aims were to develop models with an immune-rich tumour microenvironment, in which to explore the importance of neutrophils for tumour growth.
Method: Murine liver hepatoma Hep 53.4 cells were implanted via surgical intrahepatic injection into the left lateral lobe of wild type mice. A group of mice also underwent Ly6G antibody mediated neutrophil depletion prior to tumour implantation. Mice were harvested at 10 and 25 days and precision cut liver slice (PCLS) from cores of tumour, peri-tumour and non-tumour tissues created. Slices were kept in a bespoke PCLS bioreactor and rocked under incubation to ensure viability and retention of functionality. Isolated neutrophils were labelled for imaging and added to PCLS prior to multiphoton microscopy to visualise neutrophil uptake within the slices.
Results: Tumours were engrafted in all mice injected with Hep 53.4 cells and progressed up to 2 cm in size at 4 weeks (Figure A). On microscopic examination we noted substantive collagen deposition and stromal formation (Figure B, white lines). FACS sorting of dissociated ex-vivo tumours revealed infiltration by multiple immune cell types including neutrophils. Neutrophil depletion significantly reduced tumour growth. PCLS from diseased livers survived for at least 5 days and added neutrophils migrated through the full thickness of the liver tissue, but preferentially accumulated in peri-tumour regions (Figure B, neutrophils in red).

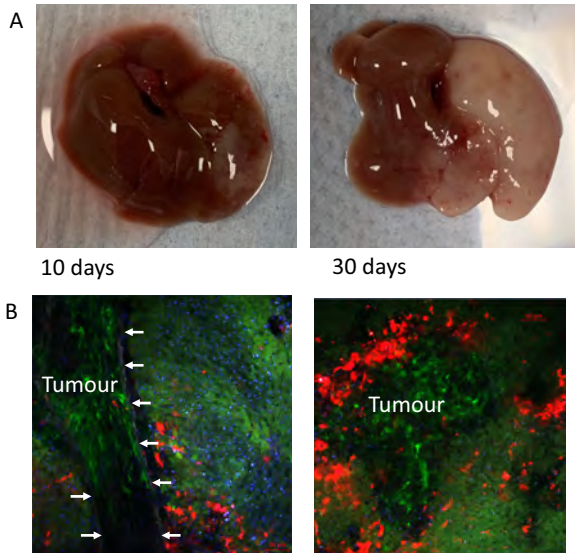

Figure: (abstract: FRI472)

Conclusion: We have developed a new orthotopic model of HCC in mice that becomes populated by a variety of host immune cells. Tumours can also be incorporated ex-vivo in a PCLS-HCC model, designed for drug discovery and mechanistic investigations. The Hep 53.4 model has the advantage of its speed of set up and the opportunity to interrogate effects of manipulation of specific immune cell types including neutrophils, which were confirmed as important drivers of HCC.

FRI473

Identification of PD-L1- expressing exosome-derived microRNAs in human hepatocellular carcinoma

Yu Rim Lee[1], Jae Kyoung Seo[2], Gyeonghwa Kim[2], Se Young Jang[1], Soo Young Park[1], Won Young Tak[1], Young Oh Kweon[1], Jung Gil Park[3], Min Kyu Kang[3], Hye Won Lee[4], Keun Hur[2]. *[1]School of Medicine, Kyungpook National University, Kyungpook National University Hospital, Department of Internal Medicine, Daegu, Korea, Rep. of South; [2]School of Medicine, Kyungpook National University, Department of Biochemistry and Cell Biology, Daegu, Korea, Rep. of South; [3]College of Medicine, Yeungnam University, Department of Internal Medicine, Daegu, Korea, Rep. of South; [4]Keimyung University School of Medicine, Department of Pathology, Daegu, Korea, Rep. of South*
Email: deblue00@naver.com

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most aggressive cancer and the third leading cause of cancer-related death worldwide. Recently, PD-1 and PD-L1 inhibitors, monoclonal antibodies that target either PD-1 or PD-L1, have been widely used in patients with advanced stage HCC. However, response rate of the PD-1/PD-L1 inhibitors is not certain in overall patients, which limits the application in clinical practice. Cancer cell derived exosomes have been evaluated as biomarkers for diagnosis and prognosis in cancers. The aim of this study was to investigate exosomes from high PD-L1-expressing cancer cells and their containing microRNAs (miRNAs) in HCC.
Method: Five HCC cell lines (HepG2, Hep3B, Huh7, SK-Hep-1, and SNU-398) and serum samples from HCC patients were analyzed. Exosomes were isolated from cell culture medium and serum samples using ExoQuick, and it was confirmed by expression of exosome markers (CD9, CD63, and ALIX) based on immunoblotting. PD-L1 protein expression was determined by western blot analysis using anti-PD-L1 antibody. Expression of PD-L1 mRNA and miRNAs were determined by quantitative real-time PCR (qRT-PCR).
Results: We found strong PD-L1 expressing cell lines group (Hep3B, SK-Hep-1, and SNU-398) and weak PD-L1 expressing cell lines group (HepG2 and Huh7). The two cell lines (SK-Hep-1 and HepG2)

displayed consistent PD-L1 expression status in mRNA as well as protein. In further analysis of PD-L1 related miRNAs, 3 exosomal-miRNAs (miR-15a, -16, and -203) were positively correlated and 2 exosomal-miRNAs (miR-21 and -34a) were negatively correlated with PD-L1 expression. We also found significant correlations between PD-L1 expressing exosome numbers and clinicopathological features in serum samples of HCC patients.
Conclusion: We provided the evidence for the potential of exosomal-miRNAs as novel non-invasive circulating markers for prediction of treatment efficacy of anti-PD-1/anti-PD-L1 therapy in HCC patients.

FRI474
Long interspersed nuclear element-1 (line-1) hypomethylation is associated with poor outcomes via the activation of ST18 in human hepatocellular carcinoma
Yu Rim Lee[1], Gyeonghwa Kim[2], Hye Won Lee[3], Se Young Jang[1], Soo Young Park[1], Won Young Tak[1], Young Oh Kweon[1], Jung Gil Park[4], Min Kyu Kang[4], Keun Hur[2]. *[1]School of Medicine, Kyungpook National University, Kyungpook National University Hospital, Department of Internal Medicine, Daegu, Korea, Rep. of South; [2]Cell and Matrix Research Institute, School of Medicine, Kyungpook National University, Department of Biochemistry and Cell Biology, Daegu, Korea, Rep. of South; [3]Keimyung University School of Medicine, Department of Pathology, Daegu, Korea, Rep. of South; [4]College of Medicine, Yeungnam Universit, Department of Internal Medicine, Daegu, Korea, Rep. of South*
Email: deblue00@naver.com

Background and Aims: The level of long interspersed nuclear element-1 (LINE-1) methylation, representing the global DNA methylation level, could contribute to the prognosis of cancer via the activation of oncogenes. This study was performed to evaluate the prognostic implications of LINE-1 hypomethylation in patients with hepatocellular carcinoma (HCC) and the possible mechanisms related to oncogene activation.
Method: Seventy-seven HCC patients between October 2014 and September 2015 were enrolled in this prospective study. Quantitative pyrosequencing was performed to assess the LINE-1 methylation level of HCC and matched non-HCC tissue samples. The expression of suppression of tumorigenicity 18 (ST18) was measured by immunohistochemistry and its correlation with LINE-1 methylation levels was examined.
Results: LINE-1 was significantly hypomethylated in the HCC tissue compared with the matched non-tumor tissue (64.0 ± 11.6% vs. 75.6 ± 4.0%, $P < 0.001$). LINE-1 hypomethylation was an independent risk factor for overall survival (HR = 27.291, $P = 0.032$) and disease progression (HR = 5.298, $P = 0.005$). The expression of ST18 was higher in the hypomethylated LINE-1 HCC tissue than the hypermethylated LINE-1 tumor tissue ($P = 0.030$).
Conclusion: LINE-1 hypomethylation is associated with poor prognosis in HCC patients, possibly due to the activation of ST18. LINE-1 hypomethylation may serve as a potential prognostic marker for patients with HCC.

FRI475
Tristetraprolin is a key driver of hepatic inflammation, fibrosis and cancer development in vivo
Dobrochna Dolicka[1], Cyril Sobolewski[1], Monika Gjorgjieva[1], Marta Sousa[1], Berthou Flavien[1], Claudio Devito[2], Didier Colin[3], Olivia Bejuy[3], Margot Fournier[1], Christine Maeder[1], Perry Blackshear[4], Laura Rubbia-Brandt[2], Michelangelo Foti[1]. *[1]University of Geneva, Faculty of Medicine, Department of Cell Physiology and Metabolism, Geneva, Switzerland; [2]Geneva University Hospitals, Division of Clinical Pathology, Geneva, Switzerland; [3]University Hospitals and University of Geneva, Small Animal Preclinical Imaging Platform, Geneva, Switzerland; [4]National Institute of Environmental Health Sciences, Research Triangle Park, Laboratory of Signal Transduction, Durham, NC, United States*
Email: dobrochna.dolicka@unige.ch

Background and Aims: Tristetraprolin (TTP) is a key post-transcriptional regulator of inflammatory and oncogenic transcripts. Accordingly, TTP was reported to act as a tumor suppressor in specific cancers. Herein, we investigated how TTP contributes to the development of liver inflammation and fibrosis, which are key drivers of hepatocarcinogenesis, as well as to the onset of hepatocellular carcinoma (HCC).
Method: TTP expression was investigated in mouse/human models of hepatic metabolic diseases and cancer. The role of TTP in non-alcoholic steatohepatitis (NASH) and HCC development was further examined through *in vivo* approaches using liver-specific TTP knock-out mice (LTTPKO mice) and *in vitro* using a panel of HCC hepatic cancer cells.
Results: TTP is downregulated in high-grade human HCC and its loss correlates with poor prognosis. Consistently, we uncover HNF4α as a key regulator of TTP expression and that TTP downregulation is associated with an induction of key oncogenes driving hepatocarcinogenesis. Finally, although TTP overexpression in cultured HCC cancer cells triggers apoptosis and decreases cell migration, TTP loss *in vivo* strongly restrains development of hepatic steatosis and inflammation/fibrosis in mice fed a methionine/choline-deficient diet, as well as HCC development induced by diethylnitrosamine (DEN).
Conclusion: Loss of TTP is a biomarker of high-grade HCC associated with poor prognosis. While TTP displays tumor-suppressive activity *in vitro*, it promotes NASH and hepatic carcinogenesis in mouse *in vivo* models.

FRI476
Identification of neoantigens as potential vaccines in hepatocellular carcinoma
David Reparaz[1], Maria Ruiz[1], Diana Llopiz[1], Leyre Silva[1], Enric Vercher[1], Ibon Tamayo[1], Sandra Hervás-Stubbs[1], Juan J. Lasarte[1], Mercedes Iñarrairaegui[2], Luigi Buonaguro[3], Maria Tagliamonte[3], Angela Mauriello[3], Beatrice Cavalluzzo[3], Bruno Sangro[2], Pablo Sarobe[1]. *[1]Centro de Investigación Médica Aplicada (CIMA), Universidad de Navarra, Pamplona, Spain; 2 IdiSNA, Instituto de Investigación Sanitaria de Navarra, Pamplona, Spain 3 CIBEREHD, Pamplona, Spain, Immunology and Immunotherapy, Pamplona, Spain; [2]IdiSNA, Instituto de Investigación Sanitaria de Navarra, Pamplona, Spain 3 CIBEREHD, Pamplona, Spain 4 Clínica Universidad de Navarra, Pamplona, Spain, Liver Unit, Pamplona, Spain; [3]Istituto Nazionale Tumori "Pascale", Cancer Immunoregulation Unit, Naples, Italy*
Email: dreparaz@alumni.unav.es

Background and Aims: Neoantigens, new immunogenic sequences arising because of tumor mutations, have been associated with response to immunotherapy and are considered potential targets for vaccination. Hepatocellular carcinoma (HCC) is a moderately mutated tumor, where the neoantigen repertoire has not been characterized. Our aim was to identify neoantigens in HCC patients, testing their immunogenicity for future use in therapeutic vaccination.
Method: Whole exome sequencing and RNAseq were performed in a cohort of twelve HCC patients submitted to surgery or liver transplant. To identify mutations, single nucleotide variants (SNV) originating non-synonymous changes that were confirmed at the RNA level were analyzed. In silico HLA binding algorithms, in vitro biochemical HLA binding assays and in vivo immunization procedures in HLA class I and class II transgenic mice were used to confirm the generation of neoAgs from mutated sequences.
Results: In an initial group of nine patients, a median per patient of 312 SNV originating missense changes were found, which were narrowed to 21 when considering only those non-annotated in databases and expressed at the mRNA level. HLA binding algorithms predicted a median of 10 and 4 peptides per patient as potential binders to class I and class II molecules, respectively. For HLA-A2.01-predicted binders, binding was experimentally confirmed in 72% of them. While none of the non-confirmed binders resulted immunogenic, immunogenicity was demonstrated in 70% of confirmed binders, generating polyfuctional T cell responses that specifically

recognized the mutated but not the wild-type sequence. Vaccination with longer peptides encompassing these sequences confirmed their immunogenicity and demonstrated their processing in vivo and in vitro. Equivalent results were obtained when analyzing a second group of three patients. In the case of class II HLA-DRB1*01-predicted peptides, 66% of them were confirmed as binders and 45% were immunogenic. Finally, co-immunization experiments combining CD8 and CD4 neoantigen epitopes resulted in stronger CD8 T cell responses.

Conclusion: These results show that mutations arising in HCC tumors may generate neoantigens recognized by CD8 and CD4 T cells, with potential applicability for therapeutic vaccination.

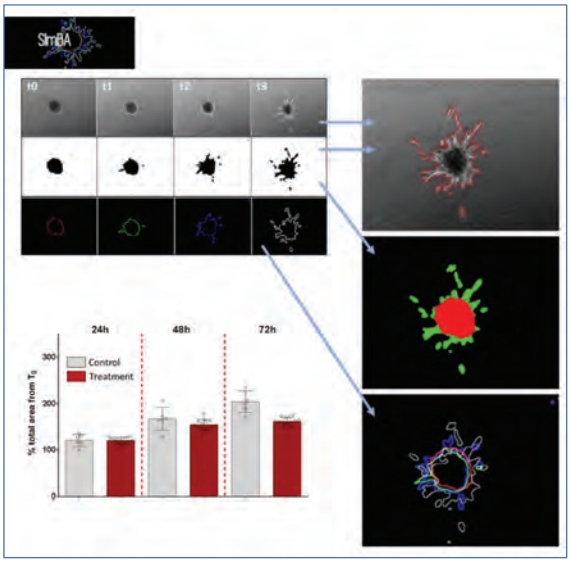
SIMBA: a user-friendly high-throughput tool for spheroid invasion analysis of hepatocellular carcinoma cell lines

Elias Van De Vijver[1,2], Astrid Vandierendonck[2], Christophe Ampe[1], Marleen Van Troys[1], Hans Van Vlierberghe[2]. [1]*Ghent University, Department of Biomolecular Medicine, Ghent, Belgium;* [2]*Ghent University, Department of Internal Medicine & Pediatrics, Ghent, Belgium*
Email: eliasvdv@gmail.com

Background and Aims: Due to the complex pathology of hepatocellular carcinoma (HCC) and its asymptomatic early stages, intrahepatic invasion and extrahepatic metastasis to a.o. the lung and abdominal lymph nodes are often already present at diagnosis. The evaluation of treatment effects on HCC invasion in *in vivo* models is currently far from evident[A] and not feasible for high-throughput drug screening. 3D *in vitro* assays such as the spheroid invasion assay (SIA) have already proven their physiological relevance in different cancer types[B] and have been applied in experimental HCC[C]. In order to use SIA in high-throughput screening of HCC drugs, methods for fast and in depth data analysis are required. Accordingly, we developed SImBA (Spheroid Image Batch Analysis), a FIJI-based software tool which allows to perform high-throughput image segmentation, visualization and quantification of invasive spheroids.



Method: Spheroids of two HCC cell lines (HEP3B and SNU423) were embedded in a 3D collagen Type I matrix. Phase contrast microscopy images were recorded at different time points to evaluate the invasive process of control and treated spheroids. Since FIJI is commonly used free software[D], SImBA has been written as an open-source FIJI macro which ensures high user-friendliness and easy customization by the user. SImBA allows batch image processing independent of data set size and is applicable on images of variable and low contrast.

Results: Since SImBA is able to visualize and quantify the invasion data in multiple ways (using total spheroid area, spheroid outlines, area overlaps, montages and a derived invasion index), it allows to robustly demonstrate the effects of various drugs compared to control treatment. Importantly, effects on invasion and cytotoxicity can be linked using SImBA when fluorescent images of cytotoxicity from e.g. Sytox green staining are recorded.

Conclusion: We created a highly functional, easy to use free software tool for the quantitative analysis of high-throughput spheroid invasion and visualization of the invasive capacity of hepatic cancer cell lines. This will contribute to future drug screening in HCC using either 3D SIA or related assays using organoids.

Email: s.chokshi@researchinliver.org.uk

Background and Aims: Experimental models of liver cancers lack the complex interactions between the immune system and tumour, they also fail to capture inter-individual variability, 3D tissue architecture, cellular heterogeneity and tumour specific immune landscape. This has hindered the understanding of the pathogenesis of disease and development of personalised treatment approaches. We aimed to develop ex-vivo human immunocompetent models of primary (hepatocellular carcinoma; HCC) and secondary (neuroendocrine liver metastasis; LM-NEN) liver cancers using precision cut tissue slice (PCTS) technology from surgical waste for discard or explanted tissue.

Method: To date, 6 HCC and 5 LM-NEN tissue samples have successfully been collected and sliced using previously established protocols. PCTS were cultured ex-vivo for 8–15 days in i) 95% O2, ii) atmospheric O2, iii) atmospheric O2 + microfluidic organ-on-a-chip system (CNBio). Each day the viability of slices was assessed by measuring apoptotic vs non-apoptotic cell death (cytokeratin 18), lactate dehydrogenase release, ATP content and histological analysis. Immunofluorescence was used to quantify proliferative capacity (Ki67) and neuroendocrine differentiation (chromogranin A (LM-NEN)). Metabolic capacity was examined by measuring adenylate energy charge using HPLC. Innate and adaptive immune components of the slices were interrogated using PCR microarray analysis.

Results: Histologically, the characteristic tissue architecture including tumour morphology, stroma and immune infiltration is maintained over the culture period and tissue viability markers remained stable. HCC slices remained viable for up to 8 days and preferred a normoxic environment whereas LM-NEN could be maintained for 15 days when cultured in high oxygen conditions. This was confirmed by consistently low levels of apoptotic cell death (<5%) over duration of culture. Proliferative capacity remained constant and distinctive immunological features associated with an immune infiltrated ('hot')

or immune deserted ('cold') tumour micro-environment were preserved in the slices.
Conclusion: We have successfully developed a human personalised ex-vivo model of primary and secondary liver cancers that retain the structural, metabolic and immunological signatures observed *in vivo*. This model is ideal to understand the immunopathogenesis of liver cancers and could potentially be used to develop a personalised medicine approach for patients to determine best treatments for residual disease post-surgery.

FRI479

Macrophage autophagy protects against hepatocellular carcinoma by modulation of the hepatic immune microenvironment

Anthony Deust[1,2], Marie-Noële Chobert[1,2], Isaac Ruiz[1,2], Jean-Michel Pawlotsky[1,2], Fatima Teixeira-Clerc[1,2]. [1]*INSERM, U955, Créteil, France;* [2]*Université Paris-Est, UMR-S955, Créteil, France*
Email: fatima.clerc@inserm.fr

Background and Aims: Autophagy is a lysosomal degradation pathway of cellular components that regulates macrophage properties. Macrophages are a major component of leukocyte infiltrate of HCC microenvironment and play a major role in malignant progression by stimulating tumor growth, metastasis, angiogenesis and immune suppression. Here, we investigated the role of macrophage autophagy in hepatocellular development and progression.
Method: Experiments were performed in mice invalidated for the autophagy gene ATG5 in the myeloid lineage ($ATG5^{Mye-/-}$ mice), and their respective littermate wild-type (WT) mice. Hepatocellular carcinoma was induced via a single i.p. injection of N-Diethylnitrosamin (DEN) at day 14. The HCC-related immune response was analyzed by flow cytometry. In vitro, the HCC cell line Hepa1–6 was used in conditioned medium experiments with peritoneal macrophages.
Results: As compared to WT littermates, ATG5Mye−/− mice showed enhanced tumor burden, hepatocyte proliferation and expression of tumoral markers as compared to WT mice. As macrophage autophagy is implicated in the control of immune responses, we evaluated the impact of macrophage autophagy invalidation on the immune microenvironment during hepatocarcinogenesis. By flow cytometry analysis, we showed a significant difference in intrahepatic immune cell populations with a reduction in the number of recruited macrophages, CD4+ T helper cell as well as CD8+ cytotoxic T cell subsets in DEN-treated ATG5Mye−/− mice as compared to treated WT mice. Moreover, recruited macrophages, CD8+ T cells and NK cells exhibited a decrease in activation marker expression suggesting that macrophage autophagy invalidation compromised the antitumor immune response. Finally, *in vitro* studies demonstrated that the conditioned medium of the HCC cell line, Hepa1-6, impaired the autophagy flux of macrophages.
Conclusion: These results demonstrated that macrophage autophagy displays beneficial effects on HCC development and progression by regulating the hepatic immune response. Moreover, our results highlight the existence of a vicious circle in which tumor cells inhibit macrophage autophagy, which in turn suppresses antitumor immune responses leading to tumor progression.

FRI481

Blocking IRE1a-endoribonuclease activity in hepatic stellate cells decreases tumor cell proliferation and metastasis in hepatocellular carcinoma

Natasa Pavlovic[1], Kessarin Thanapirom[2], Giuseppe Mazza[2], Krista Rombouts[2], Pär Gerwins[1,3], Femke Heindryckx[1]. [1]*Department Medical Cell Biology, Uppsala University, Uppsala, Sweden;* [2]*UCL Institute for Liver and Digestive Health, Division of Medicine, London, United Kingdom;* [3]*Uppsala University Hospital, Radiology, Uppsala, Sweden*
Email: natasa.pavlovic@mcb.uu.se

Background and Aims: Hepatocellular carcinoma (HCC) is a primary liver tumor that usually occurs in the background of liver cirrhosis. Activated stellate cells play a key role in the pathogenesis of HCC. They are the main source of pro-fibrotic signaling and produce growth factors that actively fuel tumor cell proliferation and migration. In this study, we aimed to identify the role of ER-stress in the cross-talk between stellate cells and cancer cells in HCC.
Method: Mice were injected once per week with diethylnitrosamine to induce HCC with underlying liver cirrhosis. Mice were treated with an IRE1a inhibitor 4u8C or control, samples were taken after 25 weeks. Tumor burden and collagen deposition was quantified on H&E and Sirius red staining, respectively. To study the interactions between stellate cells and tumor cells in vitro, HCC-cell lines (HepG2 and Huh7) and stellate cell line (LX2) were co-cultured using transwell assays, 2D co-cultures, 3D spheroids and cell-engrafted human liver 3D-scaffolds. Chemotaxis was assessed on fluorescently labelled cells using scratch wound assays and 2D CellDirectors, respectively. Images from biopsies from patients with HCC stained with antibodies against WIPI1, SHC1, PPP2R5B and BiP were obtained through the Human Protein Atlas. Gene expression profiles of HCC with and without a fibrous stroma was accessed through PubMed's Gene Expression Omnibus, and a gene-set enrichment assay was performed.
Results: Treatment with 4u8C lead to a significant decrease in size and number of HCC in vivo. Sirius red staining showed a significant decrease in collagen deposition after treatment with 4u8C, compared to controls. In vitro experiments showed that tumor cells secrete factors that cause hepatic stellate cells to undergo endoplasmic reticulum (ER)-stress, which contributes to their activation. These activated stellate cells induce the progression of HCC by promoting tumor cell proliferation and migration. Inhibiting IRE1a-ribonuclease activity with 4u8C or siRNA-transfection decreased stellate cell activation, which inhibited tumor cell proliferation and migration in vitro. A gene-set enrichment assay revealed an increase of genes involved in ER stress in fibrotic samples of HCC patients. Immunohistochemistry on HCC patient-liver biopsies confirmed the presence of ER stress markers in the fibrotic scar tissue and near hepatic blood vessels.
Conclusion: These results suggest that IRE1a could play an important role in mediating the cross-talk between stellate cells and cancer cells. Components of the ER-stress pathway may be therapeutically relevant for treating patients with HCC.

Comprehensive analysis of cancer-related genes and AAV/hepatitis B virus integration into genome on development of hepatocellular carcinoma in patients with prior hepatitis B virus infection

Fukiko Kawai-Kitahata[1,2], Yasuhiro Asahina[2,3], Sei Kakinuma[2,3], Miyako Murakawa[2,3], Sayuri Nitta[2,3], Masato Miyoshi[2,3], Ayako Sato[2,3], Jun Tsuchiya[2,3], Taro Shimizu[2,3], Eiko Takeichi[2,3], Mina Nakagawa[2,3], Yasuhiro Itsui[2,3], Seishin Azuma[2,3], Shinji Tanaka[2,3], Minoru Tanabe[2,3], Shinya Maekawa[3,4], Nobuyuki Enomoto[3,4], Mamoru Watanabe[2,3]. [1]*Tokyo, Japan;* [2]*Tokyo Medical and Dental University;* [3]*Japan;* [4]*University of Yamanashi*
Email: fkawai.gast@tmd.ac.jp

Background and Aims: Hepatitis B viral (HBV) DNA is often integrated into the genomes of hepatocellular carcinoma (HCC) in patients with chronic persistent HBV infection. However, it is controversial whether prior infection of HBV is responsible for hepatocarcinogenesis. This study aimed to elucidate genetic characteristics and viral integration associated with HCC developed from prior infection of HBV.
Method: Two hundred and one HCC patients consisting of 79 non-B non-C (NBNC)-, 79 HCV Ab positive- and 43 HBsAg positive- HCC were investigated. Of these, 21 were prior HBV infection (patients with HBsAg-negative and anti-HBc and/or anti-HBs positive) with

HCV infection, and 30 were prior HBV infection without HCV infection. Genomic DNA obtained from HCC and corresponding background liver were deep-sequenced targeting 54 cancer-related genes. TERT promoter mutation at 2 hot spots, HBV- and AAV-human genomic junction breakpoints were also deep-sequenced on a MiSeq instrument.

Results: In 21 prior HBV with HCV-HCC, recurrent mutations were frequently found in TP53 (9.5%), TERT (85.7%) and CTNNB1 (28.6%), and these gene mutational profile were similar to those in HCV without prior HBV-HCC (TP53 29.3%, TERT 81.0%, CTNNB1 34.5%). However, 30 prior HBV infection without HCV-HCC had substantially different gene mutational profile compared to those in prior HBV with HCV- and HBsAg positive-HCC (prior HBV infection; TP53 46.7%, TERT 70.0%, CTNNB1 33.3%: HBsAg positive; TP53 67.9%, TERT 30.0%, CTNNB1 10.7%: $p < 0.05$). Although 52% background liver of prior HBV with HCV-HCC were diagnosed as cirrhosis, all prior HBV without HCV-HCC were arising from normal liver or chronic hepatitis. In prior HBV without HCV tumor tissue, a total of 21 HBV integration breakpoints were detected in 23.3% (7/30) in 13 cancer-related genes including TERT, MTRNR2L1, NTM which were also targeted by chronic HBV. AAV integration were detected in tumor tissue. Moreover, 7 HBV and AAV2 breakpoints were detected 20% (6/30) in background liver tissue and the virus genome were integrated into cancer-related genes including TERT, PAK5. In contrast to prior HBV without HCV infection, neither HBV nor AAV integration were detected in prior HBV with HCV-HCC.

Conclusion: Half of prior HBV with HCV-HCC were developed from cirrhotic liver and were not related to integration of HBV into human HCC genome. However, prior HBV without HCV-HCC were arising from non-cirrhotic liver and almost 20% had HBV integration into cancer-related genes. These results suggest that prior HBV infection is one of the mechanisms for the development of non HCV-HCC.

FRI484

TIGIT and PD1 dual checkpoint blockade restores functionality of tumor-infiltrating T cells in hepatocellular carcinoma

Zhouhong Ge[1], Guoying Zhou[1], Lucia Campos Carrascosa[1], Erik Gausvik[1], Patrick Boor[1], Lisanne Noordam[1], Qiuwei Pan[1], Joanne Verheij[2], Joris Erdmann[3], Michael Doukas[4], Jan IJzermans[5], Jaco Kraan[6], Maikel Peppelenbosch[1], Jaap Kwekkeboom[1], Dave Sprengers[1]. *[1]Erasmus Medical Center, Gastroenterology and Hepatology, Rotterdam, Netherlands; [2]Academic Medical Center, Pathology, Amsterdam, Netherlands; [3]Academic Medical Center, Surgery, Amsterdam, Netherlands; [4]Erasmus Medical Center, Pathology, Netherlands; [5]Erasmus Medical Center, Surgery, Netherlands; [6]Erasmus Medical Center, Medical Oncology, Netherlands*
Email: d.sprengers@erasmusmc.nl

Background and Aims: T cell immune receptor with Ig and ITIM domains (TIGIT) has been described as a co-inhibitory receptor on tumor-infiltrating immune cells, and its suitability as a target for cancer immunotherapy is currently being investigated in early-phase clinical trials. For hepatocellular carcinoma (HCC), however, both TIGIT expression and functionality are not yet understood. Here we aim to determine expression of TIGIT, its co-stimulatory counterpart CD226, and their ligand CD155, as well as the effects of TIGIT/PD1 co-blockade in HCC.

Method: Human mononuclear leucocytes were isolated from tumors (TILs), paired tumor free liver tissues (TFL) and peripheral blood of HCC patients, and used for flowcytometric phenotyping and functional assays. Polyclonal and tumor antigen-specific T-cell stimulation assays were used to study the *ex vivo* effects of TIGIT/PD1 single or dual blockade on T cell proliferation.

Results: TIGIT was expressed on cytotoxic T cells, helper T cells and regulatory T cells in tumors as well as in TFL and blood, but tumor-infiltrating T cells showed reduced CD226 expression. Additionally, we found TIGIT was enriched and CD226 expression was reduced in $PD1^{high}$ CD8+ TILs. $PD1^{high}$ TIGIT+ CD8 TILs were found in 53% of HCC patients. They were devoid of perforin and granzyme B, produced lowest IFN-gamma and TNF-alpha in response to PMA/Ionomycin restimulation and had significantly higher TOX expression. Prominent expression of CD155 was found on conventional dendritic cells and monocytes/macrophages, while tumor cells showed significantly higher expression compared to hepatocytes in TFL. Co-blockade of TIGIT and PD1 with specific antibodies improved the *ex vivo* proliferation of CD4+ and CD8+ TILs, especially in low PD1 expressers, but single TIGIT or PD-1 blockade did not. CD226 blockade reversed the effect of TIGIT blockade.

Conclusion: Tumor-infiltrating T cells in HCC show reduced CD226 expression, which may contribute to their suppression via TIGIT within the tumor micro-environment with prominent CD155 expression. TIGIT is enriched in $PD1^{high}$ CD8+ TILs which display a dysfunctional phenotype and express the exhaustion-specific transcription factor TOX. Dual blockade of TIGIT/PD1 increased the *ex vivo* proliferation of CD4+ and CD8+ TILs cells, especially in Low PD1 expressers, suggesting that combined targeting of these two immune checkpoints may have therapeutic promise in about half of HCC patients.

FRI485

Regulation of the biology of cholangiocarcinoma (CCA) cells by the extracellular-signal regulated kinase 5 (ERK5)

Alessandra Gentilini[1], Giulia Lori[1], Alessandra Caligiuri[1], Elisabetta Rovida[1], Chiara Raggi[1], Giovanni Di Maira[1], Jesus M. Banales[2], Sabina Di Matteo[3], Domenico Alvaro[3], Fabio Marra[1]. *[1]University o Florence; [2]Biodonostia; [3]University Rome La Sapienza*
Email: alessandra.gentilini@unifi.it

Background and Aims: Cholangiocarcinoma (CCA) is characterized by high resistance to chemotherapy and poor prognosis. Epidermal growth factor (EGF) is involved in CCA development, and over-expression of the EGF receptor (EGFR) has been linked to tumor progression. The EGF signaling pathway may be associated with activation of extracellular signal-regulated kinase 5 (ERK5), a protein belonging to the MAPK family involved in the pathogenesis of different types of cancer. Additionally, ERK5 is implicated in cytoskeletal remodeling and cell motility. The purpose of this study was to investigate the role of ERK5 in the biology of CCA cells.

Method: Two intrahepatic human cholangiocarcinoma cell lines (HuCCT-1 and CCLP-1) and two primary human iCCA cells were used in this study. Cell growth was determined by cell counting and BrdU incorporation assay. Cell motility and invasion were assessed using modified Boyden chambers. ERK5, p-ERK5, EGFR, VEGF and Angiopoietin 1 were investigated by Western blotting. Silencing of cells was performed by gene silencing with shRNA. XMD8-92 and AX15836 were used to inhibit ERK5 activity.

Results: ERK5 was upregulated in all CCA cells examined and phosphorylation of ERK5 was increased in cells exposed to EGF. Growth of CCA cells in serum-containing medium was decreased after exposure to 10μM XMD8-92. In addition, migration and invasion induced by EGF were significantly reduced by both XMD8-92 and AX15836 (2μM). Similar results were obtained in ERK5-silenced cells exposed to EGF, when compared to treated with non-targeting (NT) shRNAs. In addition, in ERK5 silenced cells, expression of VEGF and angiopoietin 1 was reduced compared to NT cells. Of note, conditioned medium (CM) obtained from HuCCT-1 cells induced an increase in migration of both human hepatic stellate cells (HSC) and THP-1 monocytes, an effect reduced when conditioned medium from ERK5-silenced cells was used. Furthermore, the inhibitory effects of metformin on cell growth were more evident in ERK5-silenced cells.

Conclusion: In cholangiocarcinoma cells, ERK5 activity regulates cell growth and motility, release of angiogenic factors and drug resistance.

FRI486

Fatty acids regulate the biology of cholangiocarcinoma cells

Giulia Lori[1], Richell Booijink[1,2], Benedetta Piombanti[1], Mirella Pastore[1], Elisabetta Rovida[1], Fabio Marra[1]. [1]*University of Florence;* [2]*University of Twente*
Email: giulia.lori@unifi.it

Background and Aims: The incidence of cholangiocarcinoma (CCA) is increasing worldwide and is associated with poor patient outcomes. Identification molecular features of CCA could be helpful in designing new therapeutic approaches. Cancer cells are often exposed to a metabolically challenging environment with scarce availability of nutrients. This metabolic stress leads to changes in the balance between endogenous synthesis and exogenous uptake of fatty acids (FAs), which are needed by cells to support their own growth. Moreover, alterations in lipid metabolism may affect the response of tumor cells to different drugs. Yet, little is known about the lipid profile of CCA.
Method: CCA cells lines (CCLP1, HUCCT) were treated with increasing concentration of different fatty acids for 48 h, and cell viability was evaluated. Proliferation and survival were evaluated with Western Blot analysis. Responsiveness of CCA cells to Oxalyplatin, Cisplatin and 5-FU was tested with crystal violet staining. The epithelial-mesenchymal transition program and stem-like markers were tested with real-time PCR.
Results: Exposure of both CCA lines to fatty acids led to a marked increase in cell proliferation, especially with oleic and palmitoleic acid. Western blot analysis demonstrated a robust activation of growth and survival pathways, including AKT and ERK1/2. In addition, exposure to fatty acids before treatment with and chemotherapeutic agents made CCA cells less sensitive to the toxic action of these drugs. Finally. Fatty acid treatment resulted in a marked upregulation of genes controlling epithelial-mesenchymal transition and key gene controlling stemness.
Conclusion: Our results indicate that CCA cells exploit lipid metabolism to gain growth, invasiveness and survival advantages. When exposed to fatty acids, cancer cells are more resistant to the toxic effects of antineoplastic drugs, show a modulation of stem-like features, indicating that lipid metabolism could be a new potential target to affect CCA progression.

FRI487

Circulating exosomal microRNA-125b inhibits metastasis of hepatocellular carcinoma

Hye Seon Kim[1], Jin Seoub Kim[1], Wonhee Hur[1], Heechul Nam[1], Pil Soo Sung[1], Si Hyun Bae[1], Jong Young Choi[1], Seung Kew Yoon[1], Jeong Won Jang[1]. [1]*The Catholic University of Korea, Internal Medicine, Seoul, Korea, Rep. of South*
Email: garden@catholic.ac.kr

Background and Aims: Exosomes are 30–150 nm-sized vesicles that are released from many cell types into the body fluids. Exosomal miRNAs have recently emerged as potentially promising biomarkers in cancers and play an important role in cell to cell communication. The aim of this study is to investigate exosomal miRNAs regulating extrahepatic metastasis from hepatocellular carcinoma (HCC).
Method: Microarray-based miRNA profiling was performed to explore potential markers on the whole blood samples from patients with various liver diseases. Exosomes were extracted using Exoquick and Total exosome isolation kit (TEI), respectively. The selected miRNAs were tested in sera of 45 healthy controls and 239 patients with and without metastasis. Then, target gene prediction was performed using TargetScan. Targets by miRNAs and epithelial-mesenchymal transition (EMT)-related protein expressions were assessed by Western blot. Transfer of miRNA through exosome into recipient cells was confirmed by confocal microscopy. Biological functions of selected exosomal miRNAs in metastasis were investigated with a series of in vitro experiments including cell migration and invasion assay.
Results: Microarray-based miRNA profiling revealed several miRNAs with differential expressions, of which four exosomal miRNAs were further evaluated regarding metastasis. Transmission electron microscopy and western blot assay for exosomal markers confirmed the isolation of circulating exosomes from serum and cell conditioned media. Among the selected miRNAs, exosomal miR-125b correlated with patient outcome, with increasing expression trends with tumor stage progression but followed by a significant drop with extrahepatic metastasis. Low exosomal miR-125b expression was associated with poor survival in patients as well as early metastases. For patients with serial serum samples before and after metastasis, exosomal miR-125b levels decreased upon metastasis. The miRNA was taken up into recipient cells through exosome transfer. Transfection of exosome with miR-125b mimic downregulated SMAD2 expression level of recipient cells to regulate cancer metastasis. Moreover, miR-125b mimic inhibited migration and invasion ability of recipient cells.
Conclusion: Exosomal miR-125b has an anti-metastatic role by inhibiting metastatic ability and regulating EMT in HCC. Our findings suggest that exosomal miR-125b could be a potential biomarker and novel therapeutic target for metastasis from HCC.

Modelling liver tumor organoids and cancer-associated fibroblasts interaction reveals the robust effects of stromal niche in cancer nurturing and treatment resistance

Jiaye Liu[1], Pengfei Li[1], Ling Wang[1], Meng Li[1], Zhouhong Ge[1], Lisanne Noordam[1], Ruby Lieshout[2], Monique M.A. Verstegen[2], Buyun Ma[1], Junhong Su[1], Dave Sprengers[1], Ruyi Zhang[1], Guoying Zhou[1], Ron Smits[1], Jaap Kwekkeboom[1], Luc J.W. van der Laan[2], Maikel Peppelenbosch[1], Qiuwei Pan[1], Wanlu Cao[1]. [1]*Erasmus mc, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands;* [2]*Erasmus mc, Department of Surgery, Rotterdam, Netherlands*
Email: j.liu.2@erasmusmc.nl

Background and Aims: Cancer associated fibroblasts (CAFs) are known to play a key role in a variety of cancer types. However, there is a lack of robust models for studying the interactions between liver cancer cells and CAFs. We aim to establish a 3D organotypic co-culture model of primary liver tumor derived organoids with CAFs, and to understand their interactions and the response to treatment.
Method: Mouse liver tumor organoids and CAFs were cultured from N-nitrosodiethylamine induced mouse tumors. Human tumor organoids were from primary cholangiocarcinoma (CCA) and CAFs derived from hepatocellular carcinoma (HCC) or CCA. Liver tumor organoids and CAFs were sorted out by using flow cytometry and then co-cultured to establish a 3D co-culture model in vitro. This co-culture model and a trans-well culture system were used to study the direct contact or paracrine effect in cell proliferation and relative gene expression. Xenograft model was used to interrogate the cell-cell interactions *in vivo*. The effects of CAFs or its conditioned medium on the response of tumor organoids to anti-HCC drugs were tested.
Results: We observed that the expression of several CAFs markers, including FAP, CD29 and Periostin was significantly elevated in tumor compared to adjacent tissues in our HCC cohort ($n = 75$, $p < 0.001$). This was further confirmed in the publically available TCGA database, and importantly high level expression of FAP, CD29 or Periostin was correlated with poor overall survival of liver cancer patients ($p < 0.05$, $n = 36$ CCA and 364 HCC). To functionally investigate the interactions of liver tumor cells with CAFs, we have successfully established 3D co-culture models of liver tumor organoids with CAFs of mouse or human origin. We found that CAFs promote tumor organoid growth ($n = 18$, $p < 0.01$) but not initiation in co-culture with direct cell-cell contacts. However, this effect is also partially through paracrine signaling as demonstrated in the trans-well system ($n = 6$, $p < 0.01$). Reversely, the conditioned medium from organoids also enhances the proliferation of CAFs and regulates CAF markers expression ($n = 6$, $p < 0.01$). Consistently, co-transplantation of CAFs with liver tumor

organoids of mouse (n = 9, p < 0.05) or human (n = 5, p < 0.01) origin promotes tumor growth in xenograft models *in vivo*. Moreover, organoids conferred resistance to clinically used anti-HCC drugs Sorafenib and Regorafenib in the presence of CAFs (n = 6, p < 0.001), or the conditioned medium of pre-treated CAFs (n = 6, p < 0.05).

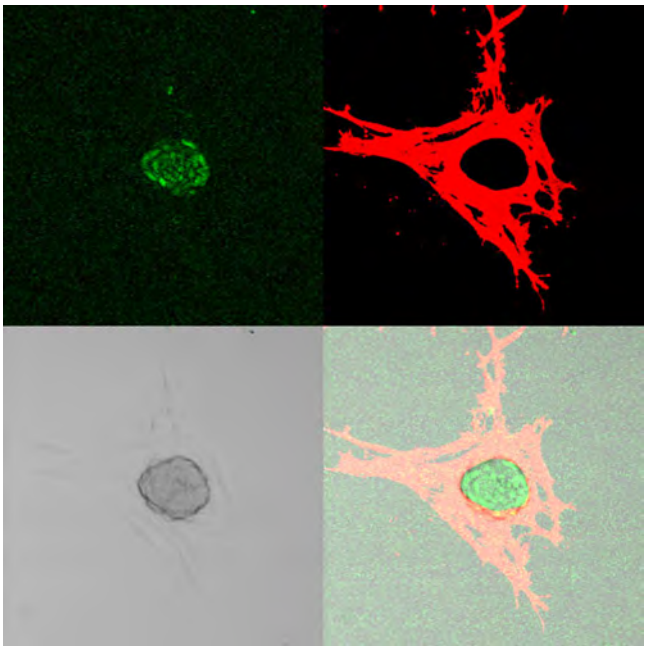

Figure: (abstract: FRI488)

Conclusion: We have successfully established 3D co-culture models of primary liver tumor derived organoids with CAFs of mouse or human origin. We have revealed the robust effects of CAFs in liver cancer nurturing and treatment resistance. These model systems will be helpful for future research on the interactions of liver cancer cells with the stromal compartment and facilitate therapeutic development.

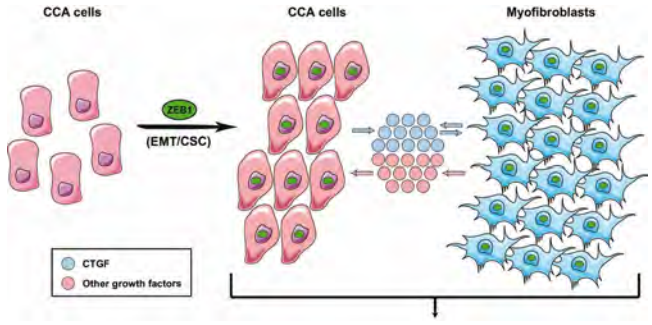
Background and Aims: Cholangiocarcinoma (CCA) arises from biliary epithelial cells and has poor prognosis due to its late clinical presentation and the lack of effective non-surgical treatment. CCA is characterized by a prominent fibrous stroma mainly composed of cancer-associated fibroblasts (CAF). ZEB1 is a transcription factor expressed by tumor and stromal cells including CAF that contributes to the acquisition of metastatic and stem cell properties. Recently, ZEB1 has been associated with poor prognosis in CCA. Yet, the regulatory functions that ZEB1 exerts in CCA are poorly defined.
Method: Correlations of ZEB1 expression with selected markers in human CCA, were investigated by transcriptomic analyses of whole tumor or laser microdissected stroma and by immunohistochemistry. Viral infection was used to generate gain/loss of function models in human CCA cell lines and liver myofibroblasts (LMF), i.e. immortalized activated hepatic stellate cells, as a model of CAF. Conditioned media (CM) was used to examine tumor-stroma communication. In vivo experiments were performed using a xenograft tumor model in immunodeficient mice.



Results: ZEB1 was expressed in tumor cells in 20% of human CCA and its expression was associated with poor differentiated tumors (p < 0.05). In vitro, ZEB1 promoted the acquisition of EMT/CSC traits in tumor cells along with increased migration and spheroid formation. In vivo, CCA cells that expressed ZEB1 formed larger tumors with higher stromal content. Interestingly, we found an increased expression of the fibrotic marker CTGF in tumor cells and in human and mouse CCA that correlated with ZEB1 expression, suggesting a role of CTGF in the development of desmoplastic microenvironment. In vitro, CM from CCA tumor cells overexpressing ZEB1 or CTGF induced LMF proliferation. Moreover, ZEB1 was found to be expressed by alpha-SMA positive CAF in human CCA. At mRNA level, ZEB1 correlated with alpha-SMA, COL4A1, TGF-beta and CTGF in LMF and in human and mouse CCA stroma. Co-injection of tumor cells plus ZEB1-expressing LMF generated larger tumors than tumor cells plus ZEB1-invalidated LMF. Crosstalk experiments showed that CM from ZEB1-expressing LMF increased tumor cell viability as compared to CM from ZEB1-invalidated LMF.
Conclusion: ZEB1 plays a key role in CCA progression by regulating tumor cell-LMF cross-communication, leading to tumor dedifferentiation and CAF activation.

FRI492

DNA damage response protein checkpoint kinase 2 (CHK2) links chromosomal instability to cellular metabolism in hepatocellular carcinoma (HCC)

Matteo Lulli[1], Veronica Ghini[2], Tommaso Mello[3], Caecilia Sukowati[4], Antonio Mazzocca[5], Paola Turano[2], Krista Rombouts[6], Andrea Galli[3], Vinicio Carloni[7]. Email: vinicio.carloni@unifi.it

Background and Aims: Chromosome mis-segregation can cause DNA damage and induce DNA damage response (DDR). Although known as an energy-dependent process, mechanisms linking DDR to HCC cellular metabolism are unknown. Here, the involvement of CHK2, a central effector of DDR, in energy expenditure, mitochondrial functions and glycolysis was investigated.
Method: Extracellular vesicles-associated total mRNA was extracted from blood of patients with HCC (n = 22), cirrhosis(n = 14)and 20 healthy subjects. Steady-state metabolomic profile was performed by 1H-NMR spectroscopy in patients and cell cultures. Expression of pyruvate kinase M2 (PKM2), succinate dehydrogenase (SDH), CHK2 and γ-H2AX was evaluated by IHC in a HCC transgenic model. HuS, a human hepatocyte cell line immortalized with TERT, Huh7 and colon carcinoma cell line HCT116 were used and Illumina RNAseq was performed. Glycolysis and O2 consumption was quantified by Seahorse XF-96 analyser. Intracellular ATP was quantified by FRET-based biosensor and quantification of glycolytic/TCA cycle intermediates by trace experiments. Mitochondrial functions were assessed by TMRM.
Results: HCC patients have increased CHK2 mRNA content in extracellular vesicles which was associated with increased glycolytic metabolites. This was confirmed in a transgenic HCC model with elevated expression of PKM2 and SDH in neoplastic lesions associated with a nuclear upregulation of γ-H2AX/CHK2. During mitosis, PKM2 and phosphoglycerate kinase 1 co-localize with CHK2 and CHK2 controlled PKM2 and SDHA expression, whilst intervening with mitochondrial functions confirmed by SDH-dependent ROS production RNAseq data provided significant changes in metabolic pathways. Cells with high levels of γ-H2AX and CHK2 exhibited increased extracellular acidification-and O2 consumption rate. Unstable cells significantly rely on glycolysis for ATP production due to a defective function in mitochondrial ATP production; abolished by CHK2 knockdown. CHK2 and γ-H2AX expression promote glycolysis and succinate oxidation in unstable cells marked by increased glucose oxidation through the TCA cycle. Mitochondrial TMRM fluorescence confirmed that CHK2-controlled SDH expression is key in sustaining $\Delta\psi$m hyperpolarization and ROS production.
Conclusion: These data demonstrate that DNA damage and CHK2 exert an unprecedented recognized control of mitochondrial function and indicate that CHK2 is a pivotal mediator in linking DDR to cellular metabolism and mitochondrial functions.

FRI493

Interplay of PNPLA and HSD17B13 variants in modulating the risk of hepatocellular carcinoma among hepatitis C virus infected patients

Carla De Benedittis[1], Martina Crevola[1], Venkata Ramana Mallela[1], Matteo Nazzareno Barbaglia[1], Stefano Fangazio[2], Ceriani Elisa[2], Mattia Bellan[1], Cristina Rigamonti[1], Rosalba Minisini[1], Mario Pirisi[1].
[1]Università del Piemonte Orientale, Translational Medicine, Novara, Italy; [2]AOU Maggiore della Carità, Internal Medicine, Novara, Italy
Email: rosalba.minisini@med.uniupo.it

Background and Aims: A single nucleotide polymorphism causing a C to G change in the PNPLA3 gene (rs738409) is associated with disease severity and development of hepatocellular carcinoma (HCC) in non-alcoholic fatty liver disease; the insertion variant rs72613567: TA of the 17β-Hydroxysteroid-dehydrogenase type 13 (HSD17B13) mitigates this detrimental effect. Our aim was to evaluate if the same holds true in chronic hepatitis C virus infection (HCV).
Method: With a case control retrospective study design, we selected 110 patients who developed HCC on a background of HCV infection, matching each HCC patient for sex and age (±30 months) to three HCV infected, non-HCC patients. All participants underwent genotyping for *PNPLA3* and *HSD17B13*) gene variants. Both univariate and multivariate (conditional logistic regression) analysis of risk factors for advanced disease and HCC were performed.
Results: Carriage of *PNPLA3* G* allele was associated with a trend of progressively more severe liver disease, from mild fibrosis to significant fibrosis, cirrhosis and HCC (p = 0.007). When the *HSD17B13:TA* status of these patients was taken into account, the abovementioned trend was strengthened among *HSD17B13* wild-type homozygotes, and completely blunted among carriers of the variant allele (p = 0.0003 and 0.953, respectively) (Figure, panels A and B).
In a conditional logistic regression model including diabetes and AST-to-platelets ratio index in the set of predictor variables, the unfavourable genetic profile characterized by the co-existence of mutated *PNPLA3* and *HSD17B13* wildtype was an independent risk factor for HCC (OR = 2.00, CI95%: 1.23–3.26) together with history of alcohol abuse.
Conclusion: The combination of being *PNPLA3* mutated and *HSD17B13* wild-type significantly increases the risk of developing HCC among HCV-infected patients. The interplay between the two genes may explain some of the controversy on this topic, and may be exploited to stratify HCC risk in hepatitis C.

Alisporivir, a cyclophilin inhibitor, reduces fibrosis and tumor burden derived from non-alcoholic steatohepatitis in a mouse model

Joseph Kuo[1], Philippe Gallay[1]. [1]*The Scripps Research Institute, Immunology & Microbiology, La Jolla, CA, United States*
Email: gallay@scripps.edu

Background and Aims: With the rise of obesity and diabetes, non-alcoholic fatty liver disease has become the most prevalent liver disorder in the Western world. Accumulation of fat droplets in hepatocytes creates stress in the liver and can progress to non-alcoholic steatohepatitis (NASH) and fibrosis. Patients with NASH are at increased risk to advance to hepatocellular carcinoma (HCC), one of the major causes of cancer mortality. With limited approved efficient treatment for HCC and none for NASH, we aimed to examine whether alisporivir (ALV), a non-immunosuppressive cyclophilin inhibitor, would decrease the development of fibrosis and HCC from NASH in a mouse model.
Method: Male C57BL/6J mice were administered 0.2 mg streptozotocin at 2-day-old to disrupt pancreatic cells and nourished with high-fat diet (60%kcal fat) since 3-week-old. Mice were then randomly assigned to be orally treated with 50 mg/kg ALV (n = 10) or vehicle control (n = 6) daily for 10 weeks before the 30-week-old endpoint for the establishment of HCC. Body weight and liver weight were recorded. Moreover, livers were histologically examined for inflammation, steatosis, and ballooned cells. Collagen was measured by Sirius Red staining of hepatic tissues. Nodules of livers were measured and scored according to a developed system with number and size of nodules as criteria. Two-tailed Mann-Whitney statistical analyses, with alpha value set at 0.05, were conducted with GraphPad Prism.
Results: Decreased body weight (p = 0.0596) and liver weight (p = 0.0397) were observed in ALV-treated mice compared to vehicle control. However, steatosis and ballooning were evident in both murine groups (p > 0.9999). In contrast, ALV reduced collagen deposition (p = 0.0420) and inflammation score (p = 0.0396). Moreover, ALV statistically reduced the number of tumorous nodules (p = 0.0075) and tumor burden (p = 0.0246). No evidence of toxicity was observed.
Conclusion: Our study suggests ALV as a safe and potent candidate for clinical trials on both NASH-derived fibrosis and HCC. Future studies include determining the mechanisms of action of ALV on decreasing tumorous nodule formation and comparing the efficacy of ALV to other cyclophilin inhibitors.

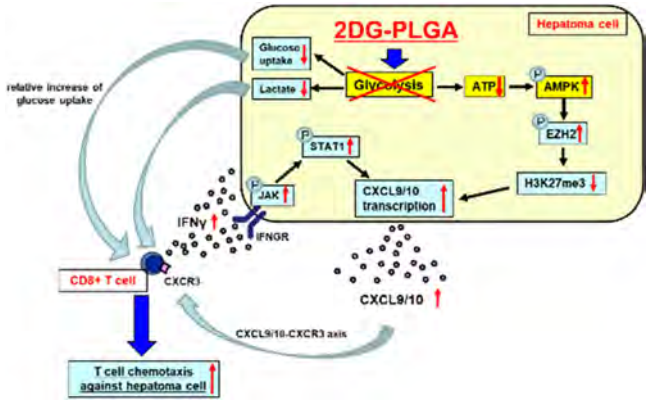
2-deoxy-D-glucose encapsulated PLGA nanoparticles suppress hepatocellular carcinoma through cytotoxic effect and activation of antitumor immunity

Kyo Sasaki[1], Sohji Nishina[1], Akira Yamauchi[2], Kotaro Fukuda[3], Yuichi Hara[1], Keisuke Hino[1]. [1]*Kawasaki Medical School, Department of Hepatology and Pancreatology, Kurashiki, Japan;* [2]*Kawasaki Medical School, Department of Biochemistry, Kurashiki, Japan;* [3]*SENTAN Pharma Inc., Fukuoka, Japan*
Email: kyo1979825@yahoo.co.jp

Background and Aims: The glucose derivative, 2-deoxy-D-glucose (2DG) has been shown to exert antitumor effect through inhibition of anaerobic glycolysis. We have developed 2-deoxy-D-glucose (2DG)-encapsulated poly (lactic-co-glycolic acid) (PLGA) nanoparticles as a cancer cell-specific inhibitor of glycolysis.
Method: We investigated whether 2DG-PLGA exerts antitumor effect on HCC, using hepatoma cell lines, nude mice with xenograft tumors, and hepatocarcinogenic mouse model.
Results: In vitro 2DG inhibited cell proliferation and induced apoptosis through the suppression of anaerobic glycolysis, ROS production and activation of ER stress. The in vivo imaging system combined with PLGA encapsulating the fluorescent dye ICG demonstrated specific accumulation of PLGA in HCC xenograft tumor. Of note 2DG-PLGA exhibited more vigorous antitumor effect along with CD3 and IFN-γ-positive lymphocyte infiltration into HCC in immunocompetent mice (STAMTM mouse and DEN-induced HCC mouse models) without any adverse effects. The following results were obtained as the underlying mechanisms behind activation of tumor immunity by 2DG-PLGA. 2DG-PLGA increased the production of chemokines (CXCL9 and 10) through the activation of IFN-γ/Jak-Stat1 signal and the inhibition of histone methylation via AMPK activation. Glucose uptake decreased in Huh7 cells but increased in T-cells after co-culture of both cells following 2DG treatment, which promoted chemotaxis of T-cells ex vivo. The infiltration of regulatory T-cells was not increased by 2DG-PLGA in immunocompetent mice. We also found that 2DG-PLGA exhibited antitumor effect in C57BL/6 mice transplanted with PD1-resistant melanoma cell line (B16F10). Furthermore, combined administration of 2DG-PLGA and PD-1 antibody therapy markedly exhibited antitumor effect in STAMTM mice. Finally, metabolome analysis revealed that 2DG did not compensate activation of fatty acid synthesis under circumstances of glycolysis suppression.



Conclusion: The 2DG-PLGA specifically inhibited cancer cell glycolysis, and suppressed HCC development through cytotoxic effect and activation of antitumor immunity. These results show the promising potential of 2DG-PLGA as a new therapeutic agent against HCC.

FRI496

SPARC negatively correlates with prognosis after transarterial chemoembolization and facilitates growth and metastasis of hepatocellular carcinoma via ERK/MMP signaling pathways

Yao Liu[1], Ying Feng[1], Xianbo Wang[1]. [1]*Beijing Ditan Hospital, Capital Medical University, Center of Integrative Medicine, Beijing, China*
Email: wangxb@ccmu.edu.cn

Background and Aims: Transarterial chemoembolization (TACE) represents a widely accepted treatment procedure for intermediate stage or unresectable hepatocellular carcinoma (HCC). Nevertheless, the prognosis associated with TACE remains poor. Extrahepatic progression following TACE is an important factor in this context. However, very few studies have evaluated serologic prognostic factors in HCC patients before TACE. Secreted protein acidic and rich in cysteine (SPARC) is a matricellular glycoprotein that can remarkably affect tumorigenesis and metastasis, leading to the poor prognosis in HCC. Therefore, for further exploration of the potential value of SPARC in preoperative prognosis of HCC patients undergoing TACE, the expression of SPARC in patient sera was quantified. Furthermore, the molecular mechanisms underlying the regulation of HCC by SPARC were investigated.
Method: The study population included 43 HCC patients who underwent TACE. We collected and analyzed information on their clinical characteristics and survival. To evaluate SPARC expression in

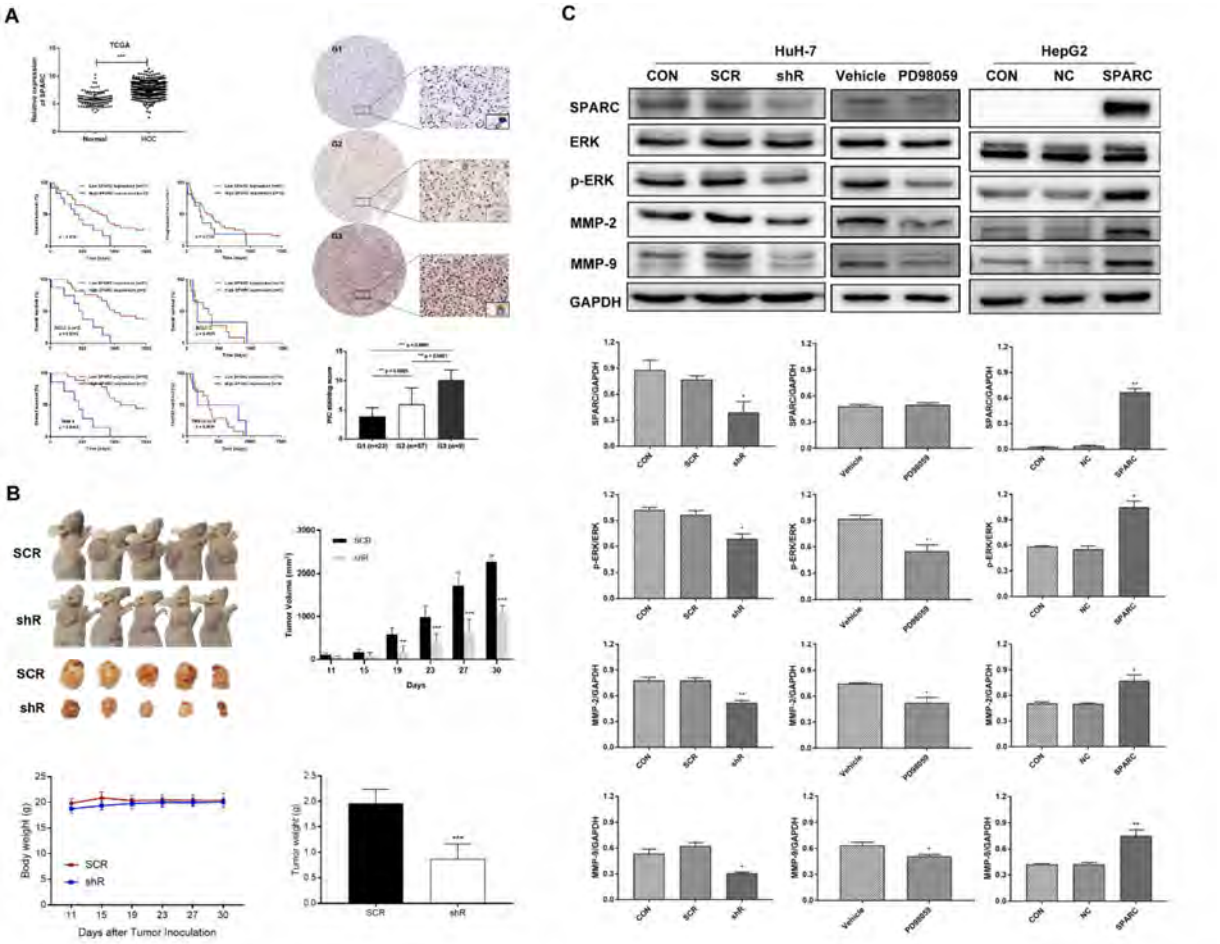


Figure. Serum expression of SPARC in HCC patients treated with TACE was related to the overall survival time. SPARC was significantly upregulated in high pathological grade human HCC tissues (A). SPARC downregulation inhibits tumor growth in vivo (B). Knockdown of SPARC inhibits the ERK1/2-MMP2/9 pathway, leading to suppression of HCC cell proliferation and metastasis (C). *p < 0.05, **p < 0.01, and ***p < 0.001.

different pathological tissue grades, we studied tissues collected from 89 HCC patients by immunohistochemical assays. We designed lentiviral vector plasmids that carried interference sequences as well as plasmids that harbored the complete open reading frame of SPARC for the knockdown or overexpression of SPARC in HuH-7 or HepG2 cells, respectively. This allowed us to determine the biological functions of SPARC in vitro and in vivo. In addition, the expression levels of extracellular signal-regulated kinases 1/2 (ERK1/2) and matrix metalloproteinases 2/9 (MMP2/9) were evaluated.

Results: We evaluated the association of serum SPARC levels with survival at different TNM and Barcelona-Clinic Liver Cancer (BCLC) stages in HCC patients treated with TACE. We observed a significant upregulation of SPARC in high pathological grade human HCC tissues, which predicts unfavorable prognosis and suggests an important tumor-promoting effect of SPARC. Functional studies indicate that downregulation of SPARC expression contributed immensely to the inhibition of HuH-7 cell proliferation and metastasis in vitro, whereas the overexpression of SPARC leads to opposite phenotypes. Mechanistically, decreased SPARC expression results in dephosphorylation of ERK1/2 and deactivation of MMP2/9, thereby inhibiting HCC growth and metastasis. Importantly, low expression levels of SPARC inhibited the formation of subcutaneous tumors in nude mice.

Conclusion: SPARC was found to facilitate HCC proliferation and metastasis via modulation of the ERK1/2-MMP2/9 signaling pathways. Our research elucidates the biological mechanism of action of SPARC and may contribute to the treatment of liver cancer.

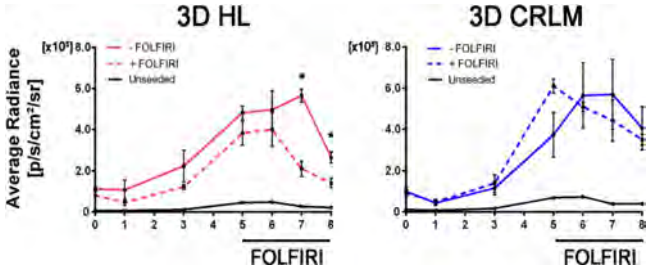
Email: luca.urbani@researchinliver.org.uk

Background and Aims: Colorectal cancer (CRC) is the second leading cause of cancer-related deaths, and liver is the most common site of CRC metastasis. None of the current tissue culture models for studying hepatic metastasis mimics the biological, biochemical and structural characteristics of the metastatic microenvironment such as the extracellular matrix (ECM). The aim of this study was to develop a 3D model of colorectal cancer liver metastasis (CRLM) and matched CRC using patient-derived decellularized matrices to recapitulate and study the role of the tissue-specific microenvironment.
Methods: Decellularization of patient-derived samples of matched healthy colon (HC), CRC, healthy liver (HL) and CRLM was performed with a detergent-enzymatic process. A 3D culture model was generated seeding decellularized scaffolds with CRC cell line HT-29.



Results: Decellularization preserved tissue-specific biological and ultrastructural properties of CRC and CRLM ECM. Seeded CRLM and CRC scaffolds supported cancer cell adhesion and, when compared to the respective normal counterpart, they showed increased proliferation and migration. 3D models generated with CRC and CRLM scaffolds also demonstrated induction of epithelial-mesenchymal transition (EMT), supported by protein expression (E-cadherin, Vimentin and SNAI1/2) and gene set enrichment analysis. Cells cultured in the CRLM environment displayed significant differences in their gene expression profile in respect to conventional 2D cultures, with the most represented biological processes involving cellular response to stress metabolic processes, to oxygen level and to starvation, and demethylation and deacethylation. When HT-29 cells grown in CRLM or HL scaffolds were exposed to IC_{50} of 5-FU and FOLFIRI determined in 2D conditions, the cellular response to the chemotherapy agents was affected by the tissue-specific decellularized scaffolds. HT-29 cells grown in CRLM scaffolds, but not in HL scaffolds, were more resistant to treatment with 5-FU and FOLFIRI (Figure), which would be the normal situation in man.
Conclusion: We have established a physiologically relevant 3D tissue culture model which is able to mimic in vivo features of CRLM such as proliferation, migration, and chemotherapeutic drug response of CRC cells in liver metastatic tissue and, as such, represents a new powerful tool to investigate formation and progression of liver metastases.

Interplay between O-GlcNAc transferase and enhancer of zeste homolog 2 in hepatocellular carcinoma

Margot Thirion[1], Marie-Laure Plissonnier[1], Oceane Floriot[1], Francesca Guerrieri[1], Claude Caron de Fromentel[1], Massimo Levrero[1,2], Mirjam Zeisel[1]. *[1]Cancer Research Center of Lyon, UMR Inserm 1052 CNRS 5286, Mixte CLB, UCBL1, Lyon, France; [2]Hospices Civils de Lyon, Service d'Hépato-Gastroentérologie / Hôpital de la Croix Rousse, Lyon, France*
Email: massimo.levrero@inserm.fr

Background and Aims: Hepatocellular carcinoma (HCC) is the second leading and fastest rising cause of cancer death worldwide. Despite recent improvements, treatment options for HCC remain largely unsatisfactory. Increased expression of histone methyltransferase enhancer of zeste homolog 2 (Ezh2), responsible for H3K27 di- and trimethylation (H3K27me2 and H3K27me3), is frequently detected in HCC tissues and correlates with the aggressiveness and/or poor prognosis of HCCs. Ezh2 knockdown in HCC cells reverses tumorigenicity in a nude mouse model, suggesting a potential therapeutic value of Ezh2 inhibition in HCC. Ezh2 activity is regulated by post-translational modifications, including phosphorylation and glycosylation by O-linked N-acetylglucosamine (O-GlcNAc) transferase (OGT). We have previously shown that OGT expression is increased in tumor tissue from HCC patients (Herzog et al. Gut 2019). In breast cancer MCF-7 cells, OGT and Ezh2 have been reported to co-repress a subset of potential tumor suppressor genes. The aim of our project is to uncover the interplay between OGT and Ezh2 in HCC.
Method: Liver tissues samples from HCC patients were analyzed by RT-PCR. O-GlcNAcylated proteins were purified using a click chemistry-based protocol. Multiplex transcriptomic analysis of human hepatoma HepG2 cells was performed using NanoString nCounter® technology. Chromatin immunoprecipitation (ChIP) PCR experiments were done using antibodies directed against OGT, Ezh2 or H3K27m3.
Results: We showed that in a cohort of 183 HCC patients, OGT and Ezh2 are upregulated in tumor tissue as compared to peri-tumor tissue. Analysis of purified O-GlcNAcylated proteins showed that Ezh2 is post-translationally modified by OGT in HepG2 cells. Transcriptomic analysis of HepG2 cells showed that OGT- and Ezh2-silencing modulate the expression of more than 100 genes belonging to major different cancer-associated canonical pathways. ChIP experiments demonstrated that OGT and Ezh2 are recruited to the promoter region of several genes whose expression increased following silencing of either OGT or Ezh2 and marked by H3K27m3, suggesting that these genes are targeted for repression by OGT and Ezh2 in transformed liver cells.
Conclusion: Taken together, our data uncovered an interplay between OGT and Ezh2 associated with the modulation of cancer pathways in transformed liver cells and provides perspectives for epigenetic strategies as potential future anti-HCC therapies.

FRI499

The metabolic plasticity of neoplastic cholangiocytes: perspective for target therapy in intrahepatic cholangiocarcinoma.

Michela Anna Polidoro[1], Laura Brunelli[2], Cristiana Soldani[1], Barbara Franceschini[1], Giovann Sestito[2], Alessio Aghemo[3], Matteo Donadon[3], Roberta Pastorelli[2], Guido Torzilli[3], Ana Lleo[3]. *[1]Humanitas Clinical and Research Center IRCCS, Hepatobiliary Immunopathology Lab, Rozzano (MI), Italy; [2]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Protein and Metabolite Biomarkers Unit, Mass Spectrometry Laboratory, Milano, Italy; [3]Humanitas University, Department of Biomedical Sciences, Italy*
Email: ana.lleo@humanitas.it

Background and Aims: Intrahepatic cholangiocarcinoma (iCCA) is a deadly cancer arising from biliary epithelial cells (BECs) lining the biliary tree. iCCA is a highly chemoresistant tumor and pharmacological therapies are generally unsuccessful. Furthermore, due to the

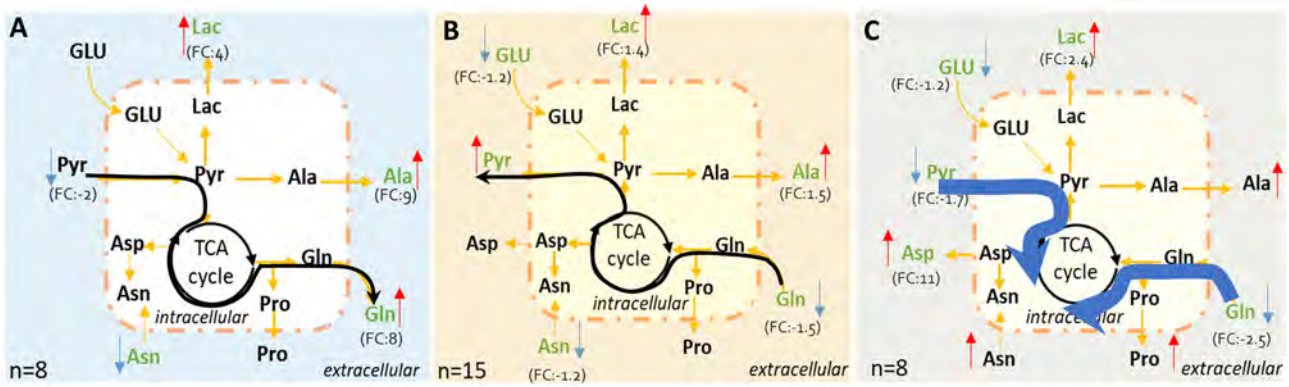

Figure 1: (abstract: FRI499): A) Metabolic pathway of primary BECs cultured with Human Cholangiocyte Medium (Celprogen); B) Metabolic pathway of iCCA cells; As shown, GLUTAMINE and PYRUVATE are metabolic sources that fuel central metabolism for both kind of cells. C) iCCA cells cultured with Human Cholangiocyte Medium highlighted their metabolic plasticity: iCCA cells used PYRUVATE when it was present in the medium.

complexity of the in vivo cellular interactions, metabolic activation pathways are largely unknown. We herein aim to elucidate the metabolic asset of both tumoral and non-tumoral primary BECs by profiling both the extra- and endo- metabolome.
Method: Primary non-tumoral BECS (NT-BECs) and tumoral iCCA BECs (iCCA-BECs) were isolated from 15 patients surgically resected at the Division of Hepatobiliary and General Surgery, Humanitas Clinical and Research Center. Both tumoral and non-affected BECs from the same donor were cultured until reaching 80% of confluence. Cells and their conditioned medium were analyzed by using mass spectrometry-based untargeted and targeted metabolomic approaches to explore the main metabolic processes. Moreover, primary iCCA BECs and Hucc-T1, human iCCA immortalized cell line, were seeded in 96-well plates to perform proliferation assay at different time point with different culture medium to detail the involvement of nutrients in iCCA-BEC proliferation.
Results: We observed that iCCA-BECs were characterized by higher mitochondrial activity compared to NT-BECs in all samples, in which glutamine and pyruvate act as metabolic sources to fuel central metabolism respectively. Importantly, iCCA-BECs exposed to different nutrient environments were able to reprogram nutrient uptake and utilization to boost central cellular metabolism. Furthermore, the proliferation assay showed that iCCA-BECs, when cultured in a different metabolic medium composition, were able to exploit the different metabolic sources to sustain cancer cell growth.
Conclusion: This observation raises the prospect that interfering with mitochondrial activity of iCCA cancer cells could make them more susceptible to cytotoxic drugs, opening new possibility to improve the outcomes of the iCCA patients.

Email: chiara.raggi@unifi.it

Background and Aims: Accumulating evidence indicates cancer stem cells (CSC) as a key target in cancer. Although metabolic reprogramming is considered an important feature of cancer cells, little is known about metabolic regulation in CSC derived from cholangiocarcinoma (CCA). This study investigated the role of mitochondria-dependent metabolism and of the related signaling pathways in the maintenance of a stem-state in CCA.
Method: Stem-like subset was enriched by sphere culture (SPH) in established human intrahepatic CCA cells (HUCCT1, CCLP1). Extracellular flux analysis was examined by Seahorse technology. Mitochondrial membrane potential and mitochondrial mass were assessed by MitoTracker Red and MitoTracker Green, respectively. Glucose uptake was quantified by incorporation of (U-14C)-D-Glucose. Gene set enrichment analysis (GSEA) and correlation with overall survival (OS) (log rank/Mantel-cox statistics) and time to recurrence (TTR) (Gehan-Breslow Wilcoxon test) were carried out from a transcriptome database of 104 CCA patients.
Results: In contrast to parental cells grown as adherent monolayers (MON), metabolic analyses by Seahorse revealed a more efficient respiratory phenotype in CCA-SPH, due to mitochondrial oxidative phosphorylation. In addition, CCA-SPH retained high mitochondrial membrane potential and elevated mitochondrial mass, as well as over-expression of PGC-1α, a master regulator of mitochondrial biogenesis. In vitro targeting of mitochondrial complex I by metformin impaired the ability to form SPH, expression of CSC-associated genes, and genes related to pluripotency and epithelial mesenchymal transition. In an in vivo model in immunocompromised mice, growth of tumors derived from CCA-SPH was suppressed by metformin. Furthermore, PGC-1α silencing highly reduced the expression of stem-like markers in CCA-SPH, and reduced sphere-formation and cell invasion. Notably, GSEA analysis showed that patients with with high levels of mitochondrial complex II had a worse prognosis in terms of OS ($p = 0.036$) and TTR ($p = 0.029$). In addition, PGC-1α was significantly correlated with mitochondrial complex II and stem-like genes in CCA patients.
Conclusion: Our data indicate a pivotal role of mitochondrial oxidative metabolism in the biology of the stem-like subset in CCA.

Montpellier, France; [3]University of Dundee, Centre for Gene Regulation and Expression, College of Life Sciences, United Kingdom*
Email: mlmartinez@cicbiogune.es

Background and Aims: Neddylation is a reversible posttranslational modification similar to ubiquitination that conjugates to target

proteins promoting their stabilization. NEDDylation is implicated in the regulation of almost every biological process. Liver cancer is the sixth most common cancer diagnosed and the fifth with the highest mortality worldwide in 2018, being hepatocellular carcinoma (HCC) the most common subtype. Due to the high mortality of HCC rate and the lack of effective, new strategies must be developed. Neddylation levels increase in HCC and correlated with those patients with a worse prognosis. Therefore, understanding the molecular basis for the observed defects in protein NEDDylation in tumors will not only assist the use of NEDD8 inhibitors in the clinic but could also potentially identify new therapeutic targets within the NEDD8 pathway. In this context emerges NEDD8 specific protease 1 (NEDP1), a protease that processes NEDD8 and catalyzes the de-neddylation of substrates. Therefore, the potential deregulation of this protease (NEDP1) will be evaluated in liver cancer patients.
Method: Preclinical animal models of liver cancer as well as human hepatocytes and hepatoma cells have been used in this study.
Results: NEDP1 levels are significantly reduced in mice model liver tumours, correlated with the increase in hepatic global Neddylation in comparison with a healthy liver. Interestingly, Senp8 (NEDP1 gene) does not show any transcriptional regulation suggesting posttranslational mechanisms underlying this modulation. Likewise, levels of NEDP1 in human liver cancer cell lines decrease, accordingly with increases in protein neddylation. In C elegans and human cells, NEDP1 induction upon DNA damage converts NEDD8 poly-chains (K11/K48) into mono-NEDD8. This promotes the activation of HSP70, which subsequently allows the oligomerization of APAF1 into the apoptosome, inducing apoptosis. More studies are required to understand the role of NEDP1 in HCC.
Conclusion: NEDP1 could act as a tumor suppressor in liver cancer.

Email: nataliya.rohr-udilova@meduniwien.ac.at

Background and Aims: PIDDosome is a multiprotein complex involved in regulation of hepatocyte ploidy by caspase-2-mediated MDM2 cleavage followed by p53 stabilization and cell cycle arrest. Here, we aimed to investigate the role of the PIDDosome in hepatocellular carcinoma (HCC) using animal models combined with analysis of human patient samples.
Method: HCC was induced by intraperitoneal DEN injection in wild type animals (*wt*) as well as in mice deficient in one of the three PIDDosome proteins CASP2, RAIDD/CRADD or PIDD1. Tumor load was assessed 10 months after DEN injections. Hepatic ploidy was evaluated by DNA staining and flow cytometry, morphometric analysis and bulk sequencing. Proliferation was assessed by Ki-67. Public TCGA expression data sets were interrogated to correlate mRNA tumor levels of *CASP2, RAIDD* and *PIDD1* with proliferation, survival as well as with disease stage of HCC patients. Moreover, morphometric assessment of nuclear size and spatial density as a surrogate for ploidy in human HCC's and corresponding non-tumoral tissues was performed in explant livers from a cohort of 172 patients that underwent liver transplantation.
Results: PIDDosome deficiency increased polyploidy in hepatocytes and reduced DEN-induced tumors in mice. Specifically, tumor multiplicity was significantly decreased in Casp2−/−, Raidd−/− and Pidd1−/− mice as compared to wild type. Irrespective of the genetic background, all tumors contained fewer binucleated cells than the corresponding non-tumoral tissues. CASP2 protein was upregulated in both mouse and human HCCs and correlated with increased Ki-67 levels and with reduced survival, identifying CASP2 as a cell cycle regulated gene. Since liver ploidy in non-tumoral tissue of patients varied with age and with etiology, we defined a tumor ploidy index adjusted for non-tumoral tissue of each patient. Patients with lower ploidy in the tumor as compared to non-tumoral tissue presented with shorter overall (OS) and recurrence-free survival.
Conclusion: The PIDDosome regulates hepatic ploidy and thereby impacts on hepatocarcinogenesis by promoting HCC tumor development from low-ploidy cells as well as on HCC progression and patient OS. Morphometric assessment of the ploidy index may represent a prognostic tool to predict survival in patients with HCC.

FRI504
TERT promoter mutations and liver carcinogenesis: identification and quantification of mutation status by digital PCR analysis on formol-fixed paraffin-embedded samples
Paisley Sarah[1], Ba Ibrahima[2], Beaufrère Aurélie[1], Miguel Albuquerque[1], Olivier Soubrane[1], Kannengiesser Caroline[2], Valérie Paradis[1]. *[1]Hospital Beaujon AP-HP, Clichy, France; [2]Bichat-Claude Bernard Hospital, Paris, France*
Email: valerieprds@gmail.com

Background and Aims: Liver carcinogenesis follows a sequential process with the development of dysplastic nodules (DN) associated with accumulation of genetic abnormalities, which may progress to hepatocellular carcinoma (HCC). The hotspot mutations of the Telomerase Reverse Transcriptase promoter (pTERT) (main mechanism of telomerase reactivation) are the most observed genomic alterations (20% and 60% of dysplastic nodules and HCC, respectively). As differential diagnosis between DN and HCC is challenging, especially on biopsy specimen, we aimed to detect the pTERT hotspot mutations from paraffin sections of macronodules <2 cm developed on cirrhosis in order to identify those already engaged in the process of malignancy, whatever their morphological classification.
Method: 167 macronodules developed on cirrhotic liver in 33 patients were retrieved, reviewed and morphologically classified as HCC, high grade DN, low grade DN and regenerative nodule. The hotspot (−124), (−146) and (−57) mutations were searched by digital droplet PCR (ddPCR) from macrodissected formalin-fixed macronodules.
Results: Among the 167 macronodules, pathological diagnosis was HCC (64, 38%), high grade DN (18, 11%), low grade DN (15, 9%), and regenerative nodules (27, 16%). In 10 nodules (6%), the diagnosis was difficult (HCC vs high grade DN). For each patient, a cirrhotic nodule (nodule control) was selected for molecular analysis. A total of 52 nodules had a pTERT mutation including 48 in position (−124), 2 in position (−146) and 2 in position (−57). Sixty percent of patients (n = 21) had at least one mutated nodule. Mutated nodules morphologically corresponded to HCC (45.72%), high grade DN

(3.16%), low grade DN (1.7%), regenerative nodule (1.4%) and cirrhotic nodule (1.3%). Of the 10 nodules difficult to classify, one (high grade vs HCC) was mutated (−124). In the set of mutated nodules, the mean allelic frequency of the mutation (−124) was 28.7%, 23.5% for the mutation (−146) and 16% for the mutation (−57).
Conclusion: This study demonstrates the feasibility of ddPCR for searching pTERT mutations from fixed macronodules (including biopsy), and reports for the first time mutation in position (−57). This approach may help to better discriminate the macronodules <2 cm already engaged in the process of malignancy, regardless of their morphological classification.

The role of insulin degrading enzyme in gender disparity of hepatocellular carcinoma progression and sorafenib response

Yu Pan[1,2], Shunjie Xia[1,2], Junjie Xu[1], Xiujun Cai[1,2]. *[1]Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Department of General Surgery, Hangzhou, China; [2]Key Laboratory of Laparoscopic Technology of Zhejiang Province, Hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: Hepatocellular carcinoma (HCC) occurs more frequently and aggressively in men than women. However, the underlying mechanistic of the gender disparity in HCC is obscure. Several candidate genes including insulin degrading enzyme (IDE) were screened. In this study we aimed to identify the role of IDE in gender disparity of hepatocellular carcinoma progression and sorafenib response.

Method: The expression of IDE in sorafenib-resistant HCC cells was analyzed using quantitative real-time PCR and western blot analysis. The prognostic role of IDE was evaluated in data from HCC patients in The Cancer Genome Atlas (TCGA) database and validated in male HCC patients treated with sorafenib. Effects of IDE in sorafenib-resistant HCC cells were analyzed in the half maximal inhibitory concentration (IC50) and proliferation. Association between IDE and androgen receptor (AR) signal pathway was assessed in western blot, immunofluorescence and immunoprecipitation assays. The therapeutic value of agent targeting IDE to combat HCC in combination with sorafenib was investigated in vitro and in vivo.
Results: IDE was found enriched in sorafenib-resistant HCC cells. Male HCC patients with increased IDE were associated with poor prognosis. Knockout of IDE in sorafenib-resistant HCC cells decreased the IC50 for sorafenib. Gene Set Enrichment Analysis suggested IDE was associated with the AR signal pathway, which was confirmed by western blot, immunofluorescence and immunoprecipitation assays. Knockout of IDE in sorafenib-resistant HCC cells suppressed the proliferation and was rescued by overexpression of AR. Bacitracin (BAC), an inhibitor of IDE, synergistically increase the efficacy of sorafenib in vitro and in vivo.
Conclusion: IDE represents a useful biomarker to predict sorafenib sensitivity in male patients with HCC, which provides novel insights into gender disparity. Agent targeting IDE represents a novel sex-specific therapeutic strategy for enhancing the efficacy of sorafenib.

FRI507

A pro-inflammatory variant in the TLR5 gene is associated with hepatocellular carcinoma in patients with cirrhosis due to steatohepatitis.

Hans Dieter Nischalke[1], Janett Fischer[2], Benjamin Krämer[1], Bettina Langhans[1], Felix Stickel[3], Jacob Nattermann[1], Ulrich Spengler[1], Thomas Berg[2], Christian Strassburg[1], Philipp Lutz[1]. *[1]University of Bonn, Department of Internal Medicine I, Bonn, Germany; [2]University Hospital Leipzig, Department of Gastroenterology, Leipzig, Germany; [3]University Hospital of Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland*
Email: philuweltweit@web.de

Background and Aims: Intestinal bacteria frequently possess flagella, whose structural protein, flagellin, is sensed by the human toll-like receptor 5 (TLR5). Bacterial translocation from the gut is an important mechanism of liver disease progression by stimulating immune response. We wondered whether a variant in a functional TLR5 polymorphism affects development of hepatocellular carcinoma (HCC).
Method: Healthy controls, patients with alcohol abuse but without significant liver disease, and three cohorts of patients with cirrhosis due to alcohol-related or non-alcoholic steatohepatitis with and without HCC were genotyped for the non-synonymous rs5744174 polymorphism in the TLR5 gene. Levels of inflammatory cytokines were measured by ELISA in the serum of patients and in supernatant of stimulated monocytes from healthy controls.
Results: Frequency of the TLR5 rs5744174 TT genotype was similar in healthy controls (n = 212; 33%), controls with alcohol abuse (n = 382; 34%), and patients with alcohol-related cirrhosis in the discovery cohort (n = 372; 28%), the validation cohort (n = 355; 33%) and the cirrhosis cohort of non-alcoholic steatohepatitis (NASH) (n = 139; 28%). However, when patients were stratified according to presence of HCC (n = 79; n = 132; and n = 61 in the respective cohorts), prevalence of the TT genotype was significantly higher in cirrhotic patients with compared to without HCC in the discovery (41% vs 25%), the validation (39% vs 29%) and the NASH cohort (39% vs 22%) (each $p < 0.05$). The association between presence of the TT genotype and HCC remained significant (OR = 1.8; CI 1.1–2.7; $p = 0.01$) after multivariate correction for age (OR = 1.09/year; CI 1.06–1.12; $p < 0.0001$), gender (OR = 3.4; CI 1.9–5.9; $p < 0.0001$), diabetes (OR = 2.2; CI 1.5–3.5; $p < 0.001$), and carriage of the PNPLA3 148M variant (OR = 2.2; CI 1.4–3.5; $p = 0.001$). Interleukin-8 response of flagellin-stimulated monocytes from healthy controls was enhanced in carriers of the TT genotype ($p = 0.02$). Patients with alcohol-related liver cirrhosis carrying the TT genotype had higher serum levels of interleukin-8 (mean 177 vs 61.8 pg/ml; $p = 0.02$) and of CXCL1 (mean 418.1 vs 220 pg/ml; $p = 0.03$).
Conclusion: The TT genotype of the rs57544174 polymorphism in the TLR5 gene is associated with an increased risk for HCC in cirrhosis due to steatohepatitis, which may be linked to enhanced immune response to translocated flagellin.

FRI509

Hepatitis B virus surface antigen inactivates the hippo pathway and thereby increases the hepatic expression of oncogene BMI1

Xufeng Luo[1], Mengji Lu[2], Hideo Baba[3], Guido Gerken[1], Heiner Wedemeyer[1], Ruth Broering[1]. *[1]University Duisburg-Essen, Medical faculty, Department of Gastroenterology and Hepatology, Essen, Germany; [2]University Duisburg-Essen, Medical faculty, Institute for Virology, Essen, Germany; [3]University Duisburg-Essen, Medical faculty, Institute for Pathology, Essen, Germany*
Email: ruth.broering@uni-due.de

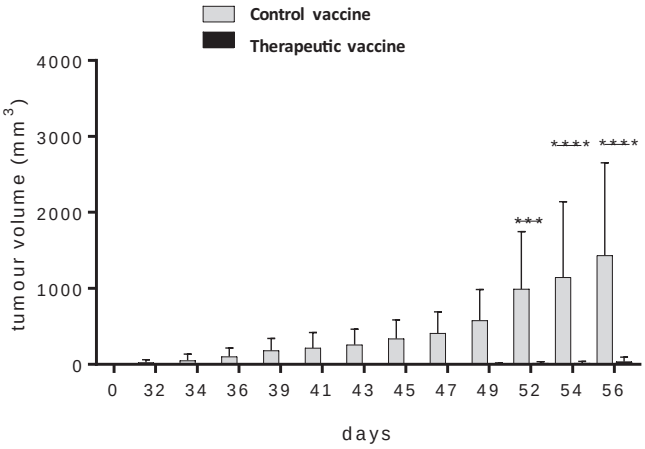
Background and Aims: Chronic hepatitis B virus (HBV) infection is a key risk factor for the development of hepatocellular carcinoma. Our previous work showed that BMI1 is upregulated in (I) the liver of HBV surface antigen (HBsAg)-transgenic mice, (II) HBV-exposed primary murine hepatocytes (PMH) and (III) HBV-related hepatocellular carcinoma tissue sections. We here investigated the relation between Hippo signalling and BMI1 expression in HBsAg mediated hepatocarcinogenesis.
Method: Reanalysis of GEO (GSE84429) data was performed to search for eligible pathways associated with HBsAg overexpression. PMH were isolated from HBsAg-transgenic or wildtype mice and analyzed by flow cytometry and western blot. Immunocytochemistry staining was performed to intracellularly locate YAP and BMI1 proteins. Dual-luciferase reporter (DLR) assay, chromatin immunoprecipitation (ChIP) was performed to prove the direct regulation of the *Bmi1* promoter by the YAP/TEAD4 transcription factor complex. Short hairpin RNA (shRNA)-induced gene knockdown and overexpression of selected factors were investigated.
Results: Reanalysis of Chip data showed that genes associated with Hippo signalling, cell cycle, centrosomal function and DNA repair/replication were altered in HBsAg-transgenic mice liver. Quantitative PCR and western blot results confirmed that downregulation of MST1/2 is accompanied by loss of YAP phosphorylation and induction of BMI1 expression. Immunohistochemical staining of HBsAg-transgenic mice liver further indicated that expression of HBsAg induced an increase of YAP and BMI1, which resulted in cell proliferation and the abnormal nucleus morphology. Flow cytometry revealed that ploidy and aneuploidy also occurred in PMH of HBsAg-tg mice. Bioinformatic analysis of *Bmi1* promoter indicated the presence of several TEAD4 bind sites. ChIP assay and binding site mutated DLR assays confirmed that YAP/TEAD4 transcription factor complex bound and activated the *Bmi1* promoter. Hepa1-6 cell line was transfected with an RFP-reporter plasmid containing the Bmi1 promoter region, herein knockdown of Yap or Tead4 led to decreased RFP signals.
Conclusion: The Hippo signalling pathway plays a vital role in cell homeostasis. Our findings led to suggest that HBsAg-mediated Hippo pathway inactivation results in BMI1 expression, possibly promoting hepatocarcinogenesis through alteration in cell cycle and chromosomal stability.

FRI510

Natural killer cells target XPO1: a therapeutic opportunity for HCC

Pauline Rettman[1], Matthew Blunt[1], Leidy Bastidas-Legarda[1], Rebecca Fulton[1], Ralf Schittenhelm[2], Salim Khakoo[1]. *[1]University of Southampton, Southampton, United Kingdom; [2]Monash University, Clayton, Australia*
Email: s.i.khakoo@soton.ac.uk

Background and Aims: Despite extensive recent developments in cancer immunotherapy, hepatocellular carcinoma (HCC) remains difficult to treat. Natural killer cells are well known to directly recognise cancerous cells, can regulate the tumour micro-environment and have an emerging therapeutic potential. However, the underlying mechanisms of how NK cells can recognise HCC are still unclear. Our goal was to identify new mechanisms by which NK cells could recognise HCC and explore the therapeutic potential for NK cells in HCC.
Method: MHC class I peptides were eluted from the HUH7 cell line to identify peptides that would bind and activate NK cells. In vitro peptide binding assays and assays of NK cell phenotype and function were performed. Mice were vaccinated with a novel NK cell targeting-DNA vaccine and activation of NK cells assessed using flow cytometry and functional assays. A xenograft model of HCC was used for adoptive transfer experiments of NK cells from vaccinated mice.
Results: From over 6000 peptides sequenced we identified one peptide with the potential to activate NK cells. This peptide, NAPLVHATL, was derived from the nuclear export protein XPO1, which is upregulated in approximately one third of HCCs, and also in other cancers including myeloma, lung, breast and prostate cancer. In vitro, binding of NAPLVHATL to HLA-C was confirmed and it was shown to bind the activating NK cell receptor KIR2DS2 using a tetramer assay. This peptide specifically activated KIR2DS2+ NK cells



NSG mice were inoculated subcutaneously with HUH7 cells and natural killer cells from vaccinated or control vaccinated mice adoptively transferred. Tumour size was monitored (n=4-5 per group)

Figure: (abstract: FRI510)

and siRNA knockdown of XPO1 in HUH7 cells reduced activation of KIR2DS2. Vaccination of KIR-transgenic mice with a KIR2DS2-targeting DNA vaccine increased activation of NK cells in both spleens and livers as determined by KLRG1 expression ($p < 0.01$), and this was most marked on mature CD11b+CD27-KIR2DS2+ NK cells ($p < 0.01$). NK cells from vaccinated mice had peptide–specific NK cell responses in vitro, which were not observed in peptide control vaccinated mice. Adoptive transfer of NK cells from vaccinated mice led to impaired growth of HUH7 cells in NOD/SCID/γ_c KO mice, as compared to NK cells from mice vaccinated with a control vaccine.
Conclusion: We describe the first known HLA class I restricted tumour associated antigen to be targeted specifically by NK cells. We also demonstrate proof-of-concept for an NK cell targeting peptide vaccination strategy for HCC.

FRI511

Myeloid IRE1a deletion alters hepatic macrophage phenotype and attenuates experimental non-alcoholic steatohepatitis-related hepatocellular carcinoma

Sanne Van Campenhout[1], Laurentijn Tilleman[2], Sander Lefere[1], Astrid Vandierendonck[1], Anja Geerts[1], Xavier Verhelst[1], Filip Van Nieuwerburgh[2], Hans Van Vlierberghe[1], Lindsey Devisscher[3]. [1]*Ghent University, Internal Medicine and Pediatrics, Gent, Belgium;* [2]*Ghent University, Pharmaceutics, Ghent, Belgium;* [3]*Ghent University, Basic and Applied Medical Sciences, Ghent, Belgium*
Email: Sanne.VanCampenhout@UGent.be

Background and Aims: Obesity, diabetes and associated non-alcoholic steatohepatitis (NASH) are characterized by adipose tissue and hepatic fat accumulation and inflammation and are rising causes of hepatocellular carcinoma (HCC). Macrophages are important immune cells involved in inflammation and tumour development. Inositol-requiring enzyme 1 alpha (IRE1a) has shown to be involved in macrophage cytokine production and myeloid-specific IRE1a knock-out (mKO) mice showed reduced weight gain during high fat diet feeding. However, the effect of myeloid-specific IRE1a deletion on NASH and subsequent HCC development has not been examined.
Method: Mice with non-functional myeloid IRE1a were created by crossing IRE1a floxed mice with LysM-Cre mice. Two-day old mKO and wild type (WT) mice were subcutaneously injected with streptozotocin (STZ) or PBS as control and male mice were fed a high-fat, -sucrose, -cholesterol diet (Western diet, WD) or control diet from the age of 4 weeks until 21 weeks. Mice were evaluated for obesity, diabetes, NASH and HCC. The macrophage population was evaluated by flow cytometry and RNA sequencing on FACS isolated cells.
Results: STZ+WD feeding resulted in impaired glucose tolerance, advanced NASH with fibrosis and HCC development. mKO STZ mice showed lower fasting glucose levels at the start of WD feeding, and an improved glucose tolerance and attenuated HCC development after 17 weeks of WD feeding despite a similar degree of liver steatosis and inflammation compared to WT mice. Transcriptomic analysis of liver Kupffer cells (KCs), macrophages and monocytes revealed phenotypical changes in NASH-HCC. Myeloid IRE1a deletion in healthy mice resulted in an altered transcriptomic profile with downregulation of pathways involved in immune system activation in KCs and macrophages, downregulation of metabolic pathways in KCs, whereas pathways involved in cell division and metabolism were upregulated in monocytes. Macrophages showed both up- and downregulated metabolic pathways. NASH-HCC attenuated the differential gene expression profile of mKO and WT liver isolated macrophages.
Conclusion: Our results show that myeloid-specific IRE1a deletion results in an altered transcriptional profile of hepatic macrophages and attenuates diabetes induction and NASH-related HCC development.

FRI512

TAK1 is a novel therapeutic target for hepatocellular carcinoma and contributes to sorafenib resistance

Shunjie Xia[1], Yu Pan[1], Junjie Xu[2], Xiujun Cai[1]. [1]*Key Laboratory of Laparoscopic Technology of Zhejiang Province, Department of General Surgery, Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, China;* [2]*Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Department of General Surgery, Hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: TAK1 has a dual role in cancer development and is associated with drug resistance in HCC. The upregulation and activation of TAK1 in intermediate and advanced HCC remains unclear. Mechanistically, little is known about K48-linked ubiquitination and proteasomal degradation of TAK1. This article aims to uncover the mechanism of TAK1 overexpression and its contribution to sorafenib resistance in HCC, and to verify whether targeting TAK1 pharmacologically could be a promising combinational therapy with sorafenib.

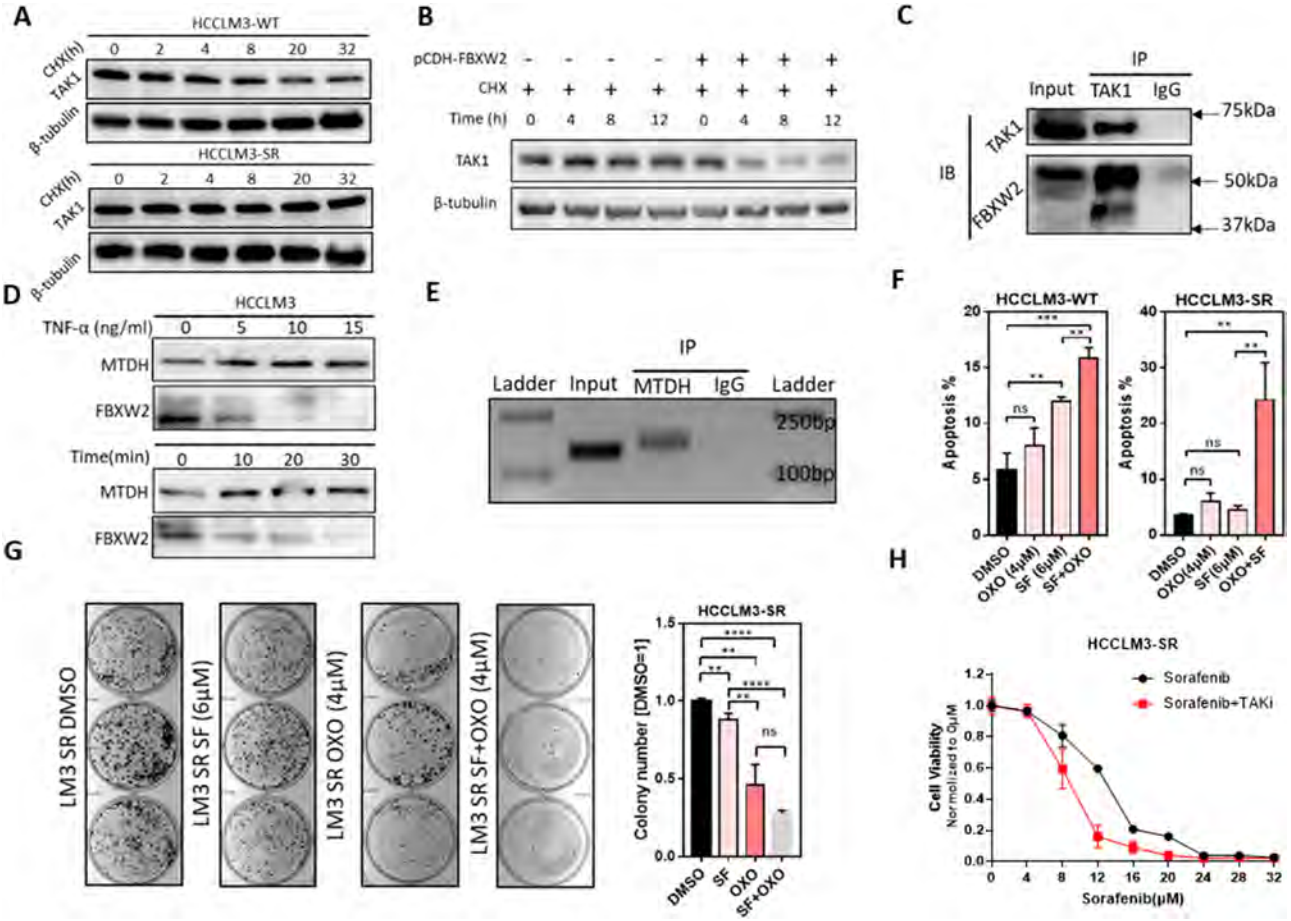


Figure: (abstract: FRI512)

Method: The expression level of TAK1 has been estimated in HCC cell lines and HCC patients by western blot. The prognostic prediction value of TAK1 has also been estimated in HCC patients receiving sorafenib treatment. CHX assay and Co-Immunoprecipitation has been conducted to measure the half-life of TAK1 protein and to determine the physical binding of TAK1 and its E3 ligase. Multiple in vitro and in vivo assays have been conducted to determine the synergistic effects and the involved mechanism between the combination of TAK1 inhibition and sorafenib.
Results: We found that TAK1 was overexpressed in HCC cell lines and HCC patients. High expression of TAK1 in patients receiving sorafenib was associated with unfavorable outcomes. Sorafenib induced apoptosis via inhibiting the phosphorylation of TAK1 in HCC cell lines, while suppressed ubiquitin-mediated degradation of TAK1 potentiated the development of sorafenib resistance. We identified FBXW2 downregulated in sorafenib-resistant cells as a novel E3 ligase binding to TAK1 via specific motif TSXXXS. Moreover, MTDH that has been widely involved in chemotherapy resistance negatively regulated the stability of FBXW2 mRNA. In turn, TAK1/CEBPB increased the expression of MTDH, forming a positive feedback loop in promoting NF-κB pathway. At last, treatment with 5Z-7-Oxozeaenol, a TAK1 inhibitor, significantly induced apoptosis of HCC cell lines and restored sorafenib sensitivity in sorafenib-resistant cells. Sorafenib and Takinib, a specific TAK1 inhibitor, had synergetic effect killing HCC cells.
Conclusion: Our data uncovered the underlying mechanism of suppressed degradation of TAK1 in HCC and sorafenib resistance. The striking synergetic effect of TAK1 inhibitors and sorafenib may promote innovative combination therapies for HCC.

FRI513

Exposing the regulation of MDM2 expression by ADAR-mediated A-to-I editing in human hepatocellular carcinoma: application of a large-scale on-step predicting platform in oncology research

He-ming Wang[1], Zhen Dai[2], Yicheng Zhao[3], Guangqi Song[1].
[1]Zhongshan Hospital of Fudan University, Department of Gastroenterology, Shanghai, China; [2]Hannover Medical School, Gastroenterology, Hepatology and Endocinology, Hannover, Germany; [3]Changchun University of Chinese Medicine, Clinical Medical College, Changchun, China
Email: song_guangqi@fudan.edu.cn

Background and Aims: Adenosine-to-inosine (A-to-I) editing induced by ADAR family proteins is one of the most common endogenous modifications during post- and co-transcription. This modification on double-stranded RNA may disturb normal mRNA translation, alternative splicing and miRNA-3′UTR binding, and further affect multiple cellular process and functions. Previously, several studies have demonstrated that a disrupted A-to-I editing balance has biological implication in hepatocellular carcinoma (HCC) development. However, the regulatory mechanism of A-to-I editing in HCC still needs to be elucidated via accurate large-scale bioinformatics analysis.
Method: RNA high-seq data from 35 pairs of human HCC patients were analysed to identify the A-to-I editing events using REP, our predicting platform which can automatically distinguish all A-to-I editing events by their potential downstream effects, and eliminate the editing sites without downstream function. The downstream effects of these functional editing sites on each gene were further analysed.

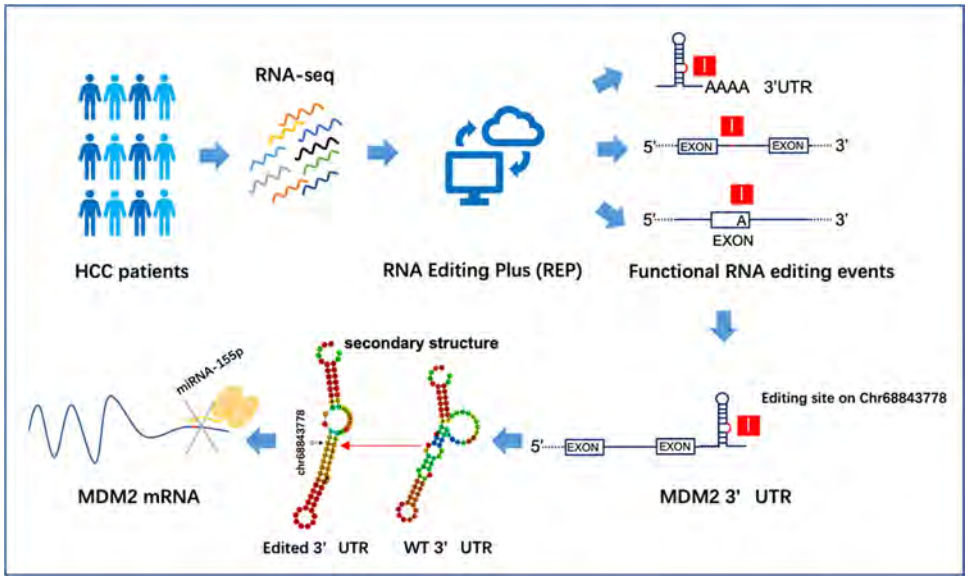

Figure: (abstract: FRI513)

Results: The results showed that the expression level of ADAR1 and the A-to-I editing level in HCC tissues significantly higher than para-carcinoma tissues. Top 5 genes (METTL7A, VHL, MDM2, APOL6, XIAP) with the highest level of A-to-I editing were identified. After removing the editing events without downstream effects, we obtained 5 genes (METTL7A, MDM2, APOL6, XIAP, PAICS) with the highest level of functional editing. Most of these 5 genes are reported oncogene or tumor suppressor. Previously, Qi et al. has reported the downregulation of METTL7A by ADARs promote HCC development. Here, we performed an in-depth analysis of all of functional editing sites that occurred on MDM2, the second frequently edited gene in HCC. Importantly, our results showed that the expression of MDM2 in HCC cells is positively correlated with the level of A-to-I editing at site chr68843778 which located in 3′UTR region of MDM2. This novel editing on chr68843778 leads to the secondary structure change in 3′ UTR region, resulting in alteration of miRNA-155p-MDM2 targeting efficiency. Besides, non-classical regulatory manner was also detected. The increased expression of MDM2 enhances the proliferation and migration of HCC cells.
Conclusion: Our data confirm that A-to-I editing is closely related to the development of HCC, and will provide a basis for the research of the regulatory mechanism of A-to-I RNA editing in HCC.

FRI514
Androgen receptor sensitized sorafenib efficacy via enriched EPCAM stemness in hepatocellular carcinoma

Hsueh-Chou Lai[1,2], Wen Lung Ma[3,4], Wei-Min Chung[3], Chun-Mien Chang[5], Chun-Chieh Yeh[6,7], Long-Bin Jeng[6,7]. *[1]China Medical University Hospital, Taichung, Taiwan, Section of Hepatobiliary, Division of Hepato-gastroenterology, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan, Taichung, Taiwan; [2]China Medical University, Taichung, Taiwan, School of Chinese Medicine, China Medical University, Taichung, Taiwan, Taichung, Taiwan; [3]China Medical University, Taichung, Taiwan, Sex Hormone Research Center, Graduate Institute of BioMedical Sciences, and Graduate Institution of Cancer Biology, China Medical University, Taichung, Taiwan, Taichung, Taiwan; [4] Asia University, Taichung, Taiwan, Department of Nursing, Taichung, Taiwan; [5]UT Southwestern Medical Center, Dallas, Texas, 75390, USA., Department of Internal Medicine, Dallas, Texas, United States; [6]China Medical University Hospital, Taichung, Taiwan, Department of Surgery, Taichung, Taiwan; [7]China Medical University, Taichung, Taiwan, School of Medicine, Taichung, Taiwan*
Email: t674233@ms54.hinet.net

Background and Aims: Androgen Receptor (AR) bimodal function has been discussed in Hepatocellular carcinoma (HCC) that promote initiation and suppress progression. However, the translational value of AR roles in HCC is unknown. Sorafenib, the multiple kinase inhibitor, is considered as the standard adjuvant therapy for unresectable HCC patients. This study aimed to evaluate the impact of AR in Sorafenib intervention in HCC laboratory models.
Method: AR cDNA was introduced in HCC cells to test AR function, cancer characteristics, and Sorafenib cytotoxic I.C.50. Knockout hepatic AR in carcinogen and HBV-induced HCC mouse models to examine AR effect on marker gene expressions. Quantitative PCR and immunoblot for testing AR effect on gene expressions. Cell sorting with stemness surface antigens to examine Sorafenib effect in vitro and in vivo. At last, bioinformatics for associating AR or EPCAM expressions with prognosis.
Results: Using in vitro model, AR cDNA stable expressing cells exhibited excellent transactivation function, better colony and sphere forming activities, and facilitated tumorigenicity capacity compared to parental HCC cells. While examining stemness markers, EpCAM was dramatically increased upon AR expression. Consistently, EpCAM+ cells was significantly decreased in spontaneous HCC AR knockout HCCs, compared to that of wildtype littermates. AR also ablated Sorafenib downstream signals, e.g., ERK, AKT, and p38MAPK, while they were been upregulated in parental cells. As for Sorafenib cytotoxic effect, the AR expressing cells are vulnerable to treatments. Moreover, sorting EPCAM or CD133 from HCC sphere cells, the IC.50 of Sorafenib were drastically lowered in AR+/EPCAM+ compared to AR–/EPCAM–. Strikingly, Sorafenib IC.50 are similar between AR+/CD133+ vs. AR–/CD133+ cells. Besides, Sorafenib regimen was robust suppress tumor growth in AR+/EPCAM+, but not AR–/EPCAM– implanted cells. At last, bioinformatics analysis revealed EPCAM is prognostic biomarkers in Asian and non-alcohol consumption HCC patients, suggesting a targeting value in those patients.
Conclusion: AR+/EPCAM+ could be therapeutic responsiveness marker for HCC patients receiving Sorafenib, particularly in Asian and non-alcohol related HCC. It's important to conduct an prospective survey associating AR/EPCAM expression to therapy outcomes.

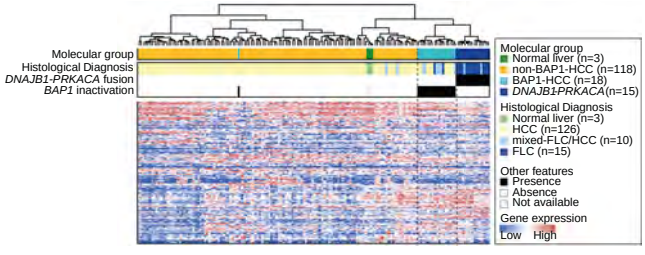
Email: theo.hirsch@polytechnique.org

Background and Aims: Fibrolamellar carcinoma (FLC) is a rare subtype of hepatocellular carcinoma (HCC). In adolescents and young adults, all FLC are driven by a specific *DNAJB1-PRKACA* fusion inducing an over-activation of the cAMP-dependent protein kinase (PKA) pathway. However, tumors harbouring mixed histological features of HCC and FLC (mixed-FLC/HCC) also occur in older patients and their genomic landscape remains to be explored.
Method: In this French multi-centric study, histological reviewing was performed in 151 selected liver tumors including 126 HCC, 15 FLC, and 10 mixed-FLC/HCC. RNAseq and whole-genome- or whole-exome-sequencing was performed on all 151 tumors, and 340 non-selected tumors from the TCGA cohort were used for validation. Genomic discoveries were validated with western-blot and immunohistochemistry.
Results: Hierarchical clustering on the transcriptomic data identified a subgroup of 17 tumors all harboring a biallelic inactivation of the *BAP1* tumor suppressor (BAP1-HCC) and regrouping most of the mixed-FLC/HCC (Figure). Compared to non-BAP1-HCC, BAP1-HCC shared a lot of features with FLC, at the clinical level (enrichment in females, lack of chronic liver disease), at the histological level (high intratumor fibrosis) and at the molecular level (significant exclusion with the classical HCC drivers such as *CTNNB1*, *TP53* and *TERT* promoter, expression of markers of hepato-pancreatic progenitors). However BAP1-HCC patients were older and had a poorer prognosis than FLC patients. BAP1-HCC were devoid of the *DNAJB1-PRKACA* fusion but instead showed recurrent gains / amplifications of the *PRKACA* locus, together with a loss of the *PRKAR2A* locus (coding for the inhibitory subunit of PKA), leading to a high PRKACA/PRKAR2A ratio at the mRNA and protein levels.



Conclusion: *BAP1* loss, found in around 5% of HCC, defines a homogeneous group of tumors with fibrolamellar-like features and an alternative dysregulation of the PKA pathway through copy-number alterations. This common over-activation of PKA could explain the similarities between BAP1-HCC and *DNAJB1-PRKACA* FLCs, and could extend the number of liver tumors susceptible to future PKA-targeted therapies.

PPEF2 suppresses hepatocellular carcinoma by inhibiting c-Myc signal pathway

Nuoqing Weng[1], Lisi Zeng[2], Yinlian Cha[3], Guoliang Huang[4], Shijuan Mai[1], Meiyin Zhang[1], Huizhong Zhang[5], Yaojun Zhang[6], Da Fu[7], Huiyun Wang[1]. *[1]Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center For Cancer Medicine, Guangzhou, China; [2]Affiliated Cancer Hospital & Institute of Guangzhou Medical University, Guangzhou, China; [3]Huizhou Municipal Central Hospital of Guangdong Province, Department of Medical Oncology, Huizhou, China; [4]Guangdong Medical College, Sino-American Cancer Research Institute, Dongguan, China; [5]Sun Yat-Sen University Cancer Center, Department of Pathology, Guangzhou, China, Guangzhou, China; [6]Sun Yat-Sen University Cancer Center, Department of Hepatobiliary Oncology, Guangzhou, China; [7]Shanghai Tenth People's Hospital, Tongji University School of Medicine, Central Laboratory for Medical Research, Shanghai, China*
Email: wanghy@sysucc.org.cn

Background and Aims: Primary liver cancer ranks the sixth most commonly diagnosed cancer worldwide, of which hepatocellular carcinoma (HCC) is the major type. The outcome of HCC is very poor, and the development mechanism still is not fully understood. In a previous study, we performed a genome-wide loss of heterozygosity (LOH) analysis on 104 HCCs with microsatellite genotyping and found that D4S2964 locus has a 50% LOH. Then we conducted another LOH analysis on 112 HCC samples with a custom single nucleotide polymorphism (SNP) genotyping microarray and identified PPEF2 gene with 64.5% LOH in D4S2964 locus. In this study, we aimed to explore the clinical significance, biological function and mechanism of PPEF2 in HCC.
Method: Taqman PCR was conducted to detect the DNA copy number of PPEF2. Quantitative real-time reverse transcription-PCR (qRT-PCR) was performed to measure PPEF2 mRNA expression level in fresh HCC and non-cancer liver samples. Immunohistochemistry (IHC) staining was used to examine PPEF2 protein expression in three cohorts of HCC cases and the relationship between PPEF2 and clinical characteristics was analyzed. The biological functions of PPEF2 in hepatocarcinoma cells were explored in vitro and in vivo. The co-immunoprecipitation assay was conducted to ensure the interaction between PPEF2 and c-Myc. The alteration of c-Myc and downstream target was examined by western blot.
Results: The LOH of PPEF2 was detected in 86.1% (68/78) of HCC patients and the mRNA expression of PPEF2 was significantly down-regulated in HCC tissues, which is associated with poor prognosis in HCC patients. PPEF2 protein level also is notably reduced in HCCs compared with matched liver tissues as showed by western blot and IHC detection. Importantly, PPEF2 protein expression measured by IHC is significantly correlated with overall survival and disease-free survival in 3 cohorts of HCC patients. PPEF2 suppressed the proliferation of hepatocarcinoma cells in vitro, and inhibited the colony formation and induced the G1/S arrest of HCC cells. Mechanistically, PPEF2 protein, which mainly located in cytoplasm, is interacted with c-Myc and reduces its protein level by accelerating the ubiquitinated degradation of c-Myc protein, which caused negative regulation of cyclins and cyclin dependent kinases (CDKs).
Conclusion: PPEF2 expression is a potential prognostic biomarker in HCC patients and suppresses HCC cell proliferation by down-regulating c-Myc protein level.

Email: yoshiaki.sunami@uk-halle.de.

Background and aims: Hepatocellular carcinoma (HCC) is the most prevalent primary liver cancer, accounting for 80–90% of cases. Mutations are commonly found in the signaling regulating the Akt pathway, leading to oncogenic cell proliferation and survival. Key transcription factors that are negatively regulated downstream of PI3K/Akt are members of the forkhead box O family (FOXO). FOXOs were initially considered as tumor suppressors by inducing cell cycle arrest and apoptosis. However, there is increasing evidence showing that FOXOs, especially FOXO3, can support tumorigenesis.

Method: To understand the roles of FOXO3 in liver tumorigenesis and hepatocarcinogenesis, we analyzed HCC patient specimens and also established a doxycycline-regulated transgenic mouse model with hepatocyte-specific FOXO3 expression in a constitutively active form.

Results: We found that FOXO3 protein is significantly overexpressed and activated in livers of HCC patients. Hepatic activation of FOXO3 induced extensive hepatic damage and elevated gene expression of several HCC-associated factors. Furthermore, FOXO3 expression enhanced hepatotoxicin-induced tumorigenesis. Mechanistically, FOXO3 activation caused oxidative stress and DNA damage and triggered positive feedback-loop for Akt activation as well as mTORC2 activation. Interestingly, FOXO3 activated not only reactive oxygen species (ROS)-promoting pathways, but also ROS-eliminating systems, which can be associated with the activation of the pentose phosphate pathway.

Conclusion: FOXO3 is a master regulator of ROS. On one side, FOXO3 supports in protecting from ROS and may avoid cellular crisis but FOXO3 can also promote ROS signaling on the other side and support hepatocellular carcinogenesis.

Lipoprotein lipase deletion induces a proinflammatory phenoytpe in liver-infiltrating monocytes during non-alcoholic steatohepatits

Anja Koop[1], Joerg Heeren[2], Ansgar W. Lohse[1], Johannes Kluwe[1]. [1]*University Medical Center Hamburg-Eppendorf, I. Department of Internal Medicine, Hamburg, Germany;* [2]*University Medical Center Hamburg-Eppendorf, Institute of Biochemistry and Molecular Cell Biology, Hamburg, Germany*
Email: a.koop@uke.de

Background and Aims: While absent in the healthy liver, hepatic expression of lipoprotein lipase (LPL) is upregulated during non-alcoholic steatohepatitis (NASH). The functional consequence is unclear, however. We have previously shown that LPL deficiency in myeloid cells leads to a more severe NASH phenotype. Published evidence suggests that LPL may influence macrophage polarization. The aim of our current study was to evaluate if LPL deficiency affects myeloid cells during NASH progression.
Method: C57BL/6J mice heterozygous for lysozyme2-cre recombinase were crossed with LPL floxed mice to generate mice with a myeloid cell-specific LPL knockout ($LPL^{\Delta LysM}$) and wild type-like littermates ($LPL^{fl/fl}$). Mice were fed a high cholesterol, high fat, high caloric diet for 26 weeks to induce a NASH. The NASH phenotype was characterized by histology, qPCR and transaminases. Liver cells were isolated and analyzed by flow cytometry.
Results: We could reproduce our previous finding that myeloid cell-specific LPL knockout aggravates the NASH phenotype with enhanced fibrosis and inflammation in $LPL^{\Delta LysM}$ mice. Immune cell phenotyping showed increased number of CD8+ T cells in the livers of $LPL^{\Delta LysM}$ NASH mice compared to $LPL^{fl/fl}$ NASH mice. LPL deficiency in myeloid cells did not influence the frequency of different myeloid cell populations in liver or blood. The percentage of neutrophils (Ly6Ghigh), monocytes (Ly6Gnegative, Ly6Chigh) and liver resident macrophages (F4/80high) remained on a comparable level in both NASH groups. Liver monocytes produced more iNOS indicating a stronger proinflammatory phenotype in liver infiltrating LPL-deficient monocytes in NASH. In contrast, the immunophenotyping of liver resident macrophages and peripheral monocytes did not show any differences between $LPL^{fl/fl}$ and $LPL^{\Delta LysM}$ NASH mice.
Conclusion: LPL deficiency in myeloid cells aggravates NASH progression. In NASH, LPL appears to restrict a proinflammatory phenotype in liver-infiltrating monocytes but not in liver resident macrophages.

SAT002

A translational mouse model for NASH and advanced fibrosis in association with atherosclerosis

Anita M. van den Hoek[1], Nicole Worms[1], Anita van Nieuwkoop[1], Christa de Ruiter[1], Aswin Menke[1], Sridhar Radhakrishnan[2], Martine C. Morrison[1], Kanita Salic[1], Robert Kleemann[1]. [1]*The Netherlands Organization for Applied Scientific Research (TNO), Department of Metabolic Health Research, Leiden, Netherlands;* [2]*Research Diets, Inc., New Brunswick, United States*
Email: a.vandenhoek@tno.nl

Background and Aims: Non-alcoholic steatohepatitis (NASH) is a fast-growing liver disorder in the Western world and is associated with an increased incidence of cardiovascular disease and type 2 diabetes. Animal models adequately mimicking this condition and that display both the metabolic and histological features of human NASH are scarce. We herein investigate whether Ldlr−/−.Leiden mice on a high fat diet represent a suitable NASH model.
Method: Ldlr−/−.Leiden mice were fed high-fat diets (no added cholesterol) containing lard or milk fat for 28 weeks. Effects on body weight, plasma and liver biochemical variables, liver histology, adipose tissue (inflammation) and atherosclerosis (aortic root) were assessed. Additionally, disease induction at earlier timepoints in the milk-fat group were investigated by taking a liver biopsy at t = 12 weeks and sacrifice at t = 22 weeks. The response to treatment (week 18–28) with 10 mg/kg/d FXR agonist obeticholic acid (OCA) on NASH and fibrosis was also evaluated.
Results: Both high-fat diets induced obesity, hyperlipidemia, hyperinsulinemia, and increased ALT and AST levels. Mice on both diets developed progressive macro- and micro-vesicular steatosis, hepatic inflammation and fibrosis. OCA treatment significantly reduced hepatic inflammation and fibrosis in both models. Lard-fat diet group had more severe hyperinsulinemia and adipose tissue inflammation, while milk-fat diet group had more severe hepatic inflammation with advanced bridging fibrosis (F3) in all mice after 28 weeks. Another longitudinal study with the milk fat diet revealed that after 22 weeks on the diet fibrosis was significantly induced, but primarily in F1-F2 stage with occasionally bridging fibrosis. In addition, milk-fat diet induced severe atherosclerotic lesions (primarily type IV and V based on AHA classification) in the aortic root area after 22 weeks.
Conclusion: Ldlr−/−.Leiden mice fed high-fat diets recapitulate features of the metabolic syndrome and NASH with progressive liver fibrosis and simultaneous atherosclerosis development. By adaptation of the fat content of the diet, either insulin resistance and adipose tissue inflammation (lard-based diet) or hepatic inflammation and fibrosis (milk-fat diet) can be emphasized. This represents a novel translational animal model of fibrosing NASH in association with atherosclerosis that can be used to investigate the effects of new drugs, alone (or drugs in combination).

ELSEVIER

Background and Aims: Chronic hepatitis C virus (HCV) infection is a major cause of hepatic steatosis and metabolic disease. We previously demonstrated that HCV infection impairs protein tyrosine phosphatase receptor type delta (PTPRD), a candidate tumour suppressor associated with poor prognosis and enhanced signal transducer and activator of transcriptions (STAT3) transcription (Van Renne, Roca Suarez et al. Gut 2018). Since HCV-induced STAT3 activity perturbs peroxisomal beta-oxidation (Lupberger et al. Gastroenterology 2019) and somatic mutations of PTPRD associate with diabetes type II (Chen et al., Oncotarget 2015), we aim to study the role of PTPRD as regulator of hepatocyte metabolism and liver disease.
Method: Based on liver transcriptomic data, non-infected normal and obese patients were classified according to hepatic PTPRD expression levels and diabetic blood markers. Gene set enrichment analysis (GSEA) was performed in order to identify signalling pathways associated with low PTPRD expression. Results were validated in primary human hepatocytes (PHH) by RNAi and western blotting, and in livers of PTPRD-deficient mice following 8 weeks of choline-deficient high-fat diet (CD-HFD) feeding.
Results: Livers of normal patients with low PTPRD expression exhibit an enrichment of genes associated with peroxisomal function, inflammation and glucose metabolism suggesting PTPRD as regulator of hepatic fat metabolism and insulin signalling. Indeed, silencing PTPRD in PHH impairs Akt phosphorylation following insulin stimulation. Livers of PTPRD-deficient mice (Ptprd+/–) mice exhibit higher STAT3 phosphorylation levels and present hepatic transcriptional changes similar to healthy patients with low PTPRD levels. Moreover, induction of liver disease in PTPRD-deficient mice using CD-HFD cause a diabetic phenotype including increased fasting blood glucose levels in absence of weight gain in Ptprd+/– animals. In obese patients with low hepatic PTPRD expression, we found increased blood levels of fasting glucose, glycated haemoglobin (HbA1c) and elevated insulin resistance scores (HOMA2).
Conclusion: Our data suggests an important regulatory role of the hepatic PTPRD-STAT3 axis in fatty acid and glucose homeostasis, which is associated with clinical manifestations of metabolic disease. We suggest that targeting PTPRD downstream signalling represents a potential strategy to restore metabolic pathways and hepatic steatosis in risk patients.

SAT004
LncRNA-H19 as a marker of liver progression from steatosis to hepatocellular carcinoma

Email: mromerogomez@us.es

Background and Aims: The main aims of this study were: a) Isolation, characterization and analysis of the epigenetic profile of liver cancer stem cells (LCSC) b) Assessment of *H19* in a NAFLD-HCC animal model c) Validation of *H19* as a diagnostic biomarker in HCC patients.
Method: a) *In vitro* LCSC were isolated from a Huh7.5 cell line by FACS ($EpCAM^+CD133^+$) and *H19* expression was evaluated by qPCR b) A total of 31 6w-old male C57BL/6J were fed with a HFHCC diet (40% Kcal-fat, 1%cholesterol and 42 g/L glucose/fructose in drinking water) (n = 26) or standard diet(n = 5) for 52w. Histological, biochemical and metabolic profiles were measured and *H19* liver expression was assessed by qPCR c) *H19* levels were determined in 14 liver tissues from cirrhotic patients, with HCC (n = 7) or without (n = 7). Circulating *H19* was evaluated in 67 patients; 26 with liver cirrhosis without HCC at baseline (of them, 6 developed HCC during follow-up) and 41 suffering from HCC. Total RNA was isolated from plasma and the quantification of *H19* copies was performed by using digital droplet PCR (ddPCR).
Results: a) An increase in size and number of spheroids was observed in $EpCAM^+CD133^+$ cells (LCSC *vs.* Huh7.5: fold-sphere number: 2.15 ± 0.96; p = 0.004 and fold-size μm^2: 3.04 ± 1.93; p < 0.001). LCSC showed higher expression of *H19* levels than Huh7.5 (fold-2.18 ± 0.32; p = 0.003) b) HFHCC-diet induced steatosis within the first 39w and NASH at 52w. Nodules were detected in 33% of mice, being classified into adenomas or well-differentiated HCC. *Gpc3*+ expression was significantly raised in presence of HCC (p < 0.0001). *H19* was upregulated in NASH and HCC liver tissue when compared to steatosis (p = 0.05 and p = 0.001) and control group (p = 0.011 and p = 0.016). Also, *H19* was increased in ballooning (p = 0.003), oval cells proliferation (p < 0.001) and advanced fibrosis (p = 0.010). There was not found association with steatosis and lobular inflammation c) *H19* was found significantly increased in liver tissue from HCC patients compared to cirrhotic patients (fold-4.0 ± 2.55; p = 0.020). In addition, *H19* was found upregulated in plasma from HCC *vs.* cirrhotic patients without development of HCC (2.60 ± 2.29 *vs* 1.02 ± 0.58 copies/µL; p < 0.001). Cirrhotic patients who developed HCC during the follow-up period showed higher levels of *H19* compared to non-HCC cirrhotic patients (4.42 ± 3.96 *vs* 1.02 ± 0.58, copies/ul p = 0.089).
Conclusion: H19 was found to be increased in LCSC, promoters of the carcinogenesis. Also, it was found upregulated in both NASH and tumors in a NAFLD preclinical model, as well as in liver tissue and plasma from HCC patients. Therefore, H19 could constitute a biomarker of disease progression from liver steatosis to HCC.

SAT005
The lipid composition of the liver: assessing differences in obese patients with and without non-alcoholic steatohepatitis

Anna Hernández-Aguilera[1], Helena Castañé[2], Montserrat Fibla Simó[1], Gerard Baiges[2], Salvador Fernández-Arroyo[1], Jordi Camps[1], Jorge Joven[1]. *[1]Institut d'Investigació Sanitària Pere Virgili, Unitat de Recerca Biomèdica, Hospital Sant Joan de Reus, Reus, Spain; [2]Universitat Rovira i Virgili, Unitat de Recerca Biomèdica, Reus, Spain*
Email: anna.hernandeza@gmail.com

Background and Aims: Obesity and associated co-morbidities are reaching pandemic proportions in developed countries. Non-alcoholic steatohepatitis (NASH) is the hepatic co-morbidity of this disease and is gaining interest due to the metabolic importance of the liver. The aim of our study was to assess the lipid composition of the liver from patients with obesity and with or without NASH.
Method: Obese patients were divided into NASH group (n = 50) or non-NASH group (n = 50) depending on their non-alcoholic steatohepatitis activity score (NAS). To assess the liver lipid composition, 10 mg of liver were homogenized and lipids were extracted by using a solution of chloroform – methanol (2: 1 proportion). After different centrifugation, the apolar phase was dried, reconstituted in methanol – MTBE (9: 1 proportion) and placed into vials for the UHPLC-ESI-QTOF-MS.
Results: Cholesterol esters were the main lipid species in the liver composition. The lipid categories present in the livers were similar in patients with and without NASH. However, their concentrations and therefore percentages were different: especially note cholesterol esters, which were statistically increased in obese patients with NASH (70.9% in non-NASH vs 89.8% in NASH) (Figure 1A). We observed that all lipids were generally increased in livers with NASH, except phospatidylcholines, which were all decreased (Figure 1B). In a

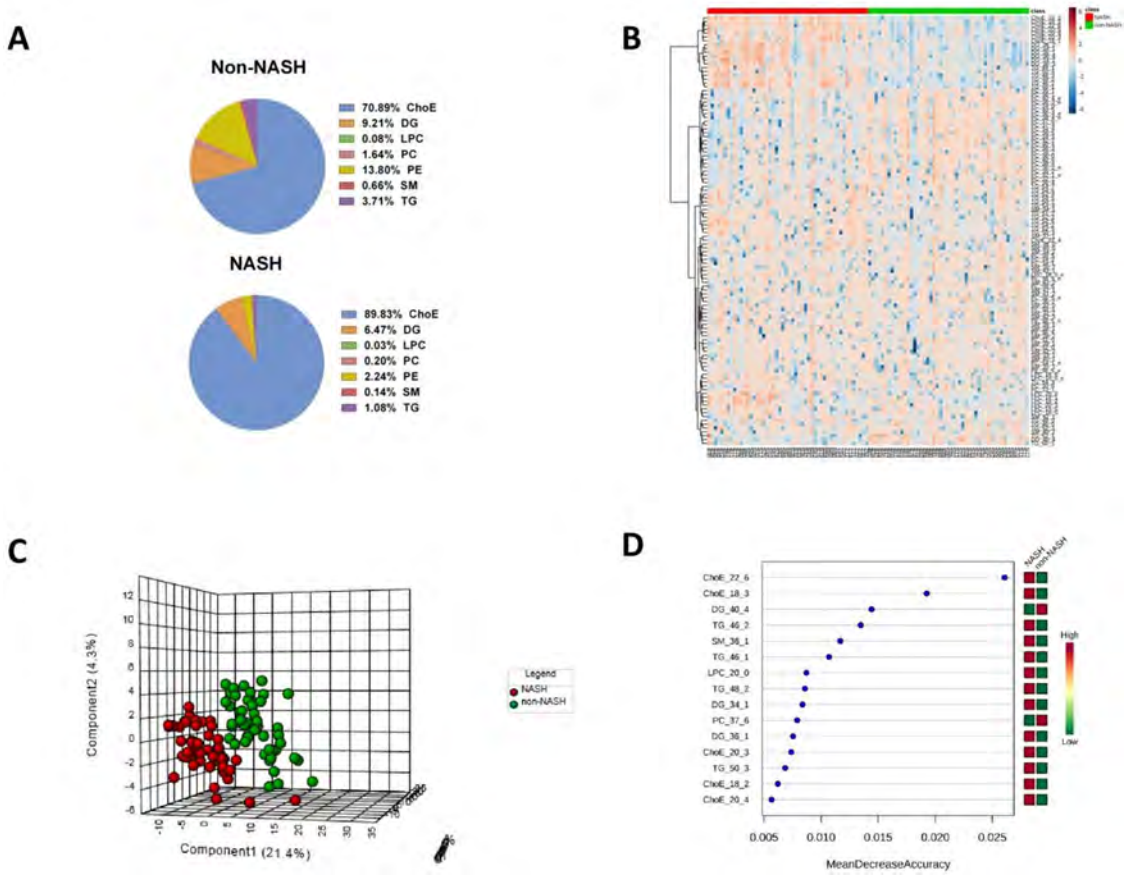

Figure: (abstract: SAT005)

PLSDA, the combination of liver lipid compounds allowed a correct separation of patients with and without NASH (Figure 1C). Finally, by using a random forest analysis, we saw that two cholesterol esters were the lipid species with the best discriminant capacity between NASH and non-NASH patients: Cholesterol esters 22:6 and 18:3.
Conclusion: The lipid composition of the liver is different when obese individuals suffer from NASH. These changes in lipid concentration could point to new possible molecular mechanisms of this disease which may be related to lipid dysregulation.

SAT006

AXL inhibition prevents NAFLD progression in mice with soluble AXL as marker of the NAFLD to NASH transition

Anna Tutusaus[1], Estefanía de Gregorio[1], Blanca Cucarull[1], Isabel Graupera[2], Mar Coll[2], Sturla M Grondal[3], Gro Gausdal[4], James B Lores[3], Pablo Garcia de Frutos[1], Albert Morales[1,5], Montserrat Marí[1]. *[1]IIBB-CSIC/IDIBAPS, Cell Death and Differentation, Barcelona, Spain; [2]Unidad de Hepatología, Hospital Clinic, IDIBAPS, CIBEREHD, Barcelona, Spain; [3]Centre for Cancer Biomarkers, University of Bergen, Department of Biomedicine, Bergen, Norway; [4]BerGenBio AS, Bergen, Norway; [5]Barcelona Clinic Liver Cancer (BCLC), Barcelona, Spain*
Email: monmari@clinic.cat

Background and Aims: TYRO3, AXL and MERTK are receptor tyrosine kinases activated by the ligand GAS6. AXL signalling is increased in NASH patients, promotes fibrosis in hepatic stellate cells and inflammation in Kupffer cells, while GAS6 protects hepatocytes against lipotoxicity via MERTK. Recent data has shown that the AXL kinase inhibitor bemcentinib, by blocking AXL signalling and increasing GAS6 levels, reduces experimental NASH. However, AXL's role in the NAFLD/NASH transition has not been addressed. Identifying mechanisms responsible for NAFLD progression into NASH could provide early markers and novel therapeutic targets.
Method: Mice were fed a high-fat methionine-restricted choline-deficient (HFCD) diet for 2 and 4 weeks, and a high-fat diet with fructose (HFF) for 4 months to induce different degrees of NAFLD/NASH. Mouse Gas6, soluble levels of Axl (sAXL) and Mertk were measured by ELISA. Human GAS6, sAXL and MERTK were measured by ELISA in control and patient serum, and compared with biochemical and histological data. Transaminases and triglycerides were measured at the Hospital Clinic Core. The collagen content was measured by staining with Sirius Red and quantified by imaging software. H&E staining was performed and NAS score evaluated. Transcriptomic analysis of genes related to liver inflammation and fibrosis were measured in commercial microarrays and by qPCR.
Results: After 4 weeks feeding with HFCD diet, early NASH was detected featuring liver steatosis, liver inflammation, hepatocellular ballooning and fibrosis. AXL inhibition with bemcentinib for 2 weeks reduced all these hepatic anomalies, including triglyceride serums levels and liver steatosis, preventing NAFLD progression. After 2 weeks of HFCD diet, mice presented fatty liver without fibrosis; however, transcriptomic analysis evidenced strong upregulation of pro-fibrotic and pro-inflammatory genes, while soluble Axl levels were already increased. Of note, one week bemcentinib administration not only reduced specific inflammatory and fibrotic genes such as *Ccr2* or *Col1a1*, but also hepatic steatosis and NAS score. In contrast, in HFF-fed mice only liver steatosis was observed, without evidence of fibrosis or inflammation nor changes in sAxl levels. Interestingly, previous and on-going clinical data show significant sAXL increase in clinical patients with only diagnosed liver steatosis, showing no histological signs of inflammation or fibrosis. These results justify

further transcriptomic patient evaluation and possible evolution depending on sAXL levels.
Conclusion: sAXL levels reveals as a potential NAFLD-NASH transition marker, indicative of the initiation of liver inflammation and fibrosis before histological detection. Early treatment with bemcentinib prevented experimental NASH appearance, pointing to AXL antagonism as possible strategy for future clinical trials.

SAT007

Efficacy and safety of an acetyl CoA carboxylase inhibitor are improved in combination with PPAR agonists in a dyslipidemic rat model

Archana Vijayakumar[1], Isabel Olson[1], Ting Wang[1], David Hollenback[1], Maria Toteva[1], James Trevaskis[1], David Breckenridge[1], Jamie Bates[1].
[1]*Gilead Sciences, Foster City, United States*
Email: archana.vijayakumar@gilead.com

Background and Aims: Firsocostat (FIR), a liver-directed acetyl-CoA carboxylase inhibitor (ACCi) is under investigation in NASH patients with F3/F4 fibrosis. FIR reduces hepatic steatosis and liver biochemistry in NASH patients but raises plasma triglycerides (TG) in some patients with high baseline TG. ACCi combination (combo) with fenofibrate (Feno, a peroxisomal proliferator-activated receptor (PPAR) α agonist (ag)) mitigates the plasma TG increase. Here we evaluated the safety (plasma TG reduction) and efficacy (liver TG reduction) of ACCi combo with PPAR ag with different selectivity profiles: Feno, Elafibranor (Ela, PPARα/δ ag), Seladelpar (Sela, PPARδ ag) and Lanifibranor (Lani, pan PPAR ag).
Method: Male rats were fed a fast food diet containing high fat, cholesterol and sugar for 28 days and were treated with Vehicle (Veh) or PPAR ag from Day 8–28, and ACCi from Day 15–28. ACCi alone (30 mg/kg) was compared to ACCi combo with Feno (1, 5, 15 mg/kg), Ela (1, 3, 10, 30 mg/kg), Sela (0.2, 1, 5, 15 mg/kg) and Lani (1, 3, 10, 30 mg/kg) (n = 10/dose group). Top doses of PPAR ag were determined from the literature. Plasma TG (absolute and normalized to baseline TG per animal), and hepatic TG and gene expression were assessed.
Results: PPAR ag differentially lowered plasma TG (37–54%, Feno; 43–70%, Ela; 11–52%, >1 mg/kg Sela; 12%, 30 mg/kg Lani; $p < 0.05$ vs Veh) while ACCi raised plasma TG by 43–129% ($p = 0.02$ vs Veh) after 1 week of monotherapy. While addition of ACCi slightly raised plasma TG in the combo groups, they were maintained at or below baseline in animals receiving Feno, Ela, >5 mg/kg Sela and 30 mg/kg Lani. Hepatic Apoc3 expression (PPARα target) was reduced dose-dependently with Feno (26–74%), Ela (50–97%) and Sela (<27%), and unchanged with Lani (vs Veh). ACCi lowered liver TG by 41–49% ($p < 0.05$ vs Veh). Further reductions were seen in combo arms with 15 mg/kg Feno (63% vs Veh, $p < 0.001$) and >10 mg/kg Ela (64–76% vs Veh, $p < 0.001$). Liver TG in the Lani and Sela combo arms did not improve or showed a trend to dose-dependently increase respectively, compared to ACCi alone.
Conclusion: At least one dose of all PPAR ag tested in combo with ACCi maintained plasma TG at or below baseline, mitigating the ACCi-induced rise in plasma TG. However, while Feno and Ela improved efficacy of ACCi to reduce liver TG, Lani and Sela did not alter or worsened steatosis. These studies support the use of PPARα ag to improve efficacy and safety of FIR in NASH patients.

SAT008

PBI-4050 restores liver and adipose tissue metabolic homeostasis, and decreases fibrosis in a high-fat-diet mouse model of non-alcoholic fatty liver disease

Brigitte Grouix[1], Jean-Christophe Simard[1], Jean-Francois Thibodeau[1], Mikaël Tremblay[1], Alexandre Laverdure[1], François Sarra-Bournet[1], Ramon Corpuz[1], Lyne Gagnon[1]. [1]*Liminal R&D BioSciences Inc., Laval, Canada*
Email: b.grouix@prometic.com

Background and Aims: Non-Alcoholic Fatty Liver Diseases (NAFLD), characterized by fatty acid and glucose metabolism dysregulation, has become a major global health concern. PBI-4050 is a free fatty

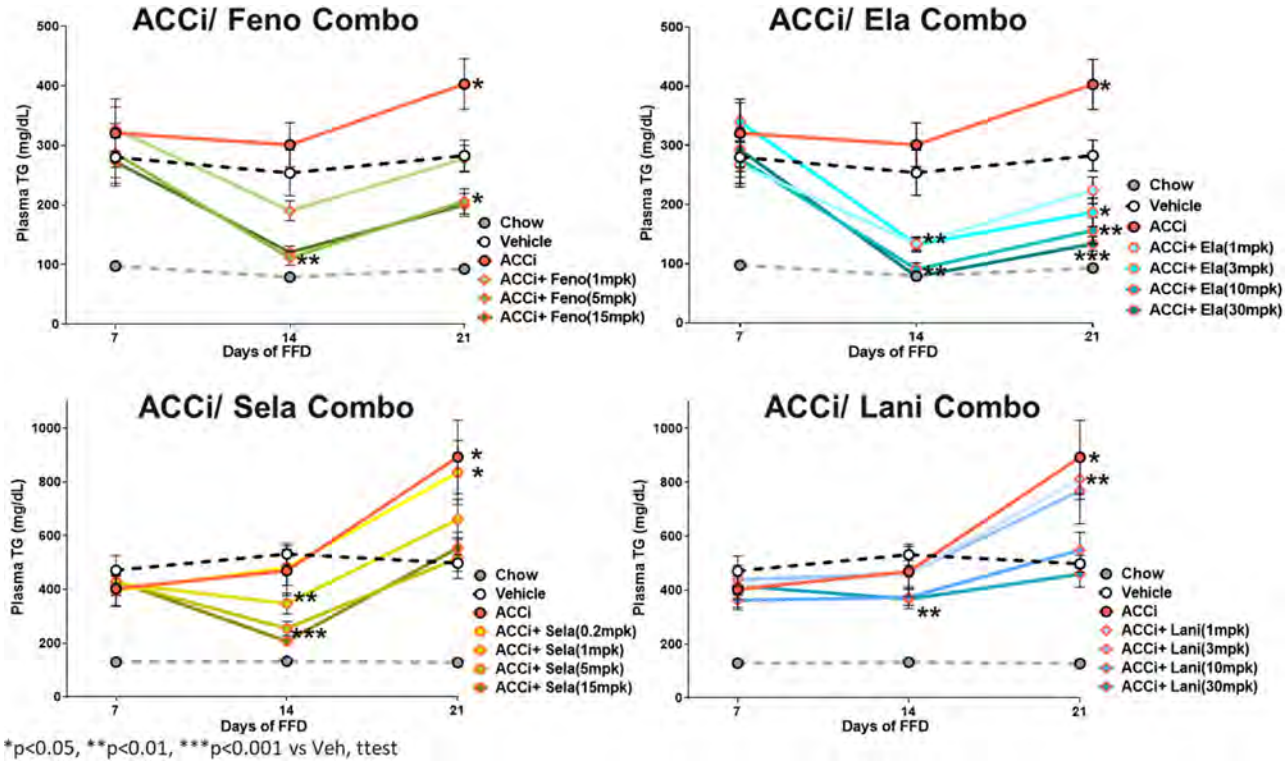

Figure: (abstract: SAT007)

acid mimetic with GPR40 agonist and GPR84 antagonist activities. It was previously shown to possess pleiotropic activities and to reduce fibrosis in different rodent models. PBI-4050 has also completed open label, non-placebo controlled, phase II clinical trials for the treatment of Idiopathic Pulmonary Fibrosis and Alström syndrome. In the present study, we used a high-fat diet (HFD) mouse model to evaluate the efficacy of this compound in preventing NAFLD progression, metabolic dysregulation, and the development of fibrosis in liver and white adipose tissue (WAT).

Method: C57BL/6 mice were fed with either a standard or a high-fat diet for 14 weeks. Mice fed with the HFD were then treated or not with PBI-4050 (200 mg/kg, oral once a day) for 6 weeks. Clinical manifestations of NAFLD, including hepatic steatosis, ballooning and inflammation, were monitored. Moreover, levels of fibrosis, a sign of NAFLD progression, were evaluated in liver and WAT. Glucose and fatty acid metabolism were also analyzed. ^{1}H-NMR hepatic metabolomic studies were used to quantify liver metabolites. Effect of PBI-4050 on mitochondrial respiration and glycolysis were measured *in vitro* in HepG2 hepatocytes using a Seahorse XF96 analyser.

Results: Histological analysis revealed that PBI-4050 treatment led to a significant reduction of hepatic steatosis, ballooning and total NAFLD score. PBI-4050 also led to a reduction in interstitial fibrosis which correlated with decreased gene levels of *Col1a1*, *Col3a1*, *Ctgf*, *Timp1* and *Mmp2*. In WAT, PBI-4050 significantly reduced immune cell infiltration and collagen deposition as well as expression of pro-fibrotic and inflammatory genes. Serum adiponectin levels were also increased by PBI-4050. Metabolomic study from liver extracts revealed that PBI-4050 restored normal levels of amino acids and energy-related metabolites that were dysregulated by HFD. Interestingly, endogenous level of glucose and ATP was decreased while NAD+ was increased by treatment with PBI-4050. mRNA expression of uncoupling proteins (*Ucp3* in liver and *Ucp1* in WAT) were also increased by PBI-4050 suggesting that PBI-4050 could affect mitochondria and increase energy expenditure. Moreover, mitochondrial oxygen consumption and acidification rate were reduced in HepG2 hepatocytes by PBI-4050 treatment *in vitro*, while in the presence of palmitate we observed an increase in fatty acid oxidation.

Conclusion: These results indicate that PBI-4050 offers the potential as a novel therapy for NAFLD, diabetes and associated metabolic syndrome.

SAT009

Adipose tissue macrophages acquire a pro-inflammatory phenotype which is associated to liver fibrogenesis in an experimental model of NAFLD in mice

Celia Martínez Sánchez[1], Octavi Bassegoda[2], Silvia Ariño Mons[1], Beatriz Aguilar-Bravo[1], Elisa Pose[2], Virginia Hernandez-Gea[3,4], Pau Sancho-Bru[1], Pere Ginès[1,2,4], Isabel Graupera[1,2,4], Mar Coll[4]. *[1]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [2]Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain; [3]Hospital Clínic de Barcelona, Hepatic Hemodynamic Laboratory, Liver Unit, Barcelona, Spain; [4]Centro de Investigación Biomédica Red de enfermedades hepáticas y digestivas (CIBEREHD), Barcelona, Spain*
Email: celiamartinezsa@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NALFD) associated with obesity is characterized by a hypertrophy of adipose tissue (AT) accompanied by increased macrophage recruitment. It has been reported that pro-inflammatory mediators produced by AT macrophages (ATM) might induce hepatic inflammation in NAFLD. However, there is lack of information on the role of ATM on liver fibrosis. The aim of the present study was to elucidate the role of ATM in fibrogenesis associated to NAFLD.

Method: 15 mice were randomized into 3 groups, receiving a choline deficient supplemented with high fat diet (CDAHFD; NASH model), high fat diet (HFD) or control diet for 9 weeks. ATM and liver macrophages accumulation was quantified by using F4/80 IHC. Stromal vascular fraction enriched in macrophages was isolated from total AT and ATM phenotype and their response to pro-inflammatory mediators (INFg and LPS) was evaluated by qPCR. Hepatic fibrosis was assessed by Sirius red. Kupffer cells (KCs) were isolated using magnetic beads and its phenotype was characterized by qPCR. Primary human hepatic stellate cells (HSC) were exposed to conditioned medium of human AT from patients with obesity and fatty liver (basal and stimulated with LPS) for 24 hours.

Results: At hepatic level, NASH-mice presented a higher degree of steatosis, inflammation and fibrosis compared to animals fed with HFD or control chow. AT from NASH-mice did not display hypertrophy neither a significant infiltration of macrophages compared to HFD. However, ATMs from NASH-mice, presented a higher basal expression of pro-inflammatory cytokines and displayed an exacerbated response to pro-inflammatory stimuli mediated by CCl2. Expression levels of CCl2 in ATMs strongly correlated with the hepatic expression of fibrosis markers and with the area of collagen deposition in liver tissue samples. KC isolated from NASH mice displayed a pro-inflammatory profile with an enhanced expression of CCL2 which correlated with CCL2 levels expressed by ATMs. Finally, human AT secretome (basal and stimulated with LPS) induced activation of human HSC in-vitro.

Conclusion: In experimental NASH, ATM shows a pro-inflammatory phenotype which is associated with an increased liver inflammation and fibrogenesis and human secretome from AT activate HSC. These results suggest that modulating the pro-inflammatory phenotype of ATM might be a good strategy to mitigate inflammation and fibrosis in NAFLD.

SAT010

Intermittent hypoxia featuring the obstructive sleep apnea syndrome contributes to hepatosteatosis by upregulating the intrahepatic expression of fatty acid translocase CD36 and lipogenic genes

Esther Rey[1], Brittany Beeler[1], Patricia Marañon[1], Pedro Landete[2], Stephania Chavez[2], Ramon Farre[3], Isaac Almendros[3], Águeda Gónzalez-Rodriguez[1], Carmelo Garcia-Monzon[1]. *[1]Santa Cristina University Hospital, Instituto de Investigacion Sanitaria Princesa, Liver Research Unit, Madrid, Spain; [2]La Princesa University Hospital, Instituto de Investigacion Sanitaria Princesa, Respiratory Medicine, Madrid, Spain; [3]School of Medicine, Barcelona University, CIBERes, IDIBAPS, Biophysics and Bioengineering Unit, Barcelona, Spain*
Email: cgmonzon@salud.madrid.org

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) comprises varied grades of hepatic lipid accumulation, inflammation, ballooning and fibrosis; the most severe cases result in cirrhosis and liver failure. Recent evidence has linked obstructive sleep apnea syndrome (OSAS) to hepatic lipid accumulation. As OSAS is featured by periods of intermittent hypoxia (IH) during sleep, it has been suggested that IH alters hepatic lipid metabolism and could contribute to NAFLD development in OSAS patients, but little is known about the molecular mechanisms underlying increased hepatic lipid accumulation due to IH. The aim of the present study was to elucidate the molecular mechanisms by which excessive lipid accumulation occurs within the liver in conditions of IH.

Method: Histopathology and triglyceride content were assessed in livers from mice submitted to an IH protocol. Furthermore, expression of genes related to lipid synthesis (Fasn, Scd1), β-oxidation (Cpt1a, Ppara), and fatty acid uptake (Cd36) was tested by real-time PCR, Western-blot and immunohistochemistry. In addition, prevalence of NAFLD was evaluated in 90 patients with clinical and polygraphic features of OSAS and in 30 subjects with normal lung function tests by using a blood-based metabolomic assay (OWLiver test) capable to discriminate between simple steatosis, NASH and normal liver. None of patients and controls studied drank more than 20 g of alcohol per day.

Results: Grades of steatosis and triglyceride contents were significantly higher in livers from mice exposed to IH conditions than in their control littermates. Furthermore, an increased intrahepatic expression of the fatty acid translocase CD36 and lipogenic genes, such as Fasn and Scd1, was also found in hypoxic mice with respect to their normoxic controls. Noteworthy, in livers from mice submitted to IH, CD36 expression was largely restricted to the plasma membrane of hepatocytes whereas it was mainly observed within hepatocyte cytoplasms in normoxic mice. Interestingly, metabolomics profile compatible with NAFLD were significantly more frequent in OSAS patients than in subjects with normal lung function (80.7% vs 53.2%, respectively, $p < 0.05$), being NASH the most frequent metabolomic diagnosis in OSAS patients (49%).
Conclusion: NAFLD is highly prevalent among OSAS patients and IH featuring OSAS could contribute to NAFLD setup by inducing fatty acid uptake and lipid synthesis within the liver.

The symbiotic supplementation modulate gut microbiota, regulation beta-catenin expression and prevents weight gain in ob/ob mice with non-alcoholic fatty liver disease (NAFLD)

Sebastião Mauro Bezerra Duarte[1], Jose Tadeu Stefano[2], Lucas A. M. Franco[3], Roberta Cristina Ruedas Martins[3], Denise Frediani Barbeiro[4], Junia Marielle Teixeira Rodrigues Neri[1], Bruno Cogliati[5], Ester Cerdeira Sabino[3], Flair Jose Carrilho[1,2], Claudia Oliveira[1,2]. *[1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brasil; [2]Laboratório de Gastroenterologia Clínica e Experimental (LIM-07) do Departamento de Gastroenterologia e Hepatologia do Hospital das Clínicas HCFMUSP da Faculdade de Medicina da Universidade de São Paulo, São Paulo, SP, Brasil; [3]Departamento de Doenças Infecciosas e Instituto de Medicina Tropical, Faculdade de Medicina FMUSP, Universidade de Sao Paulo, Sao Paulo, SP, Brazil; [4]Laboratório de Investigação Médica (LIM-51), Faculdade de Medicina, Universidade de São Paulo (FMUSP), São Paulo, Brasil; [5]Departamento de Patologia, Escola de Medicina Veterinária e Ciência Animal, Universidade de São Paulo (USP), São Paulo, Brasil*
Email: cpm@usp.br

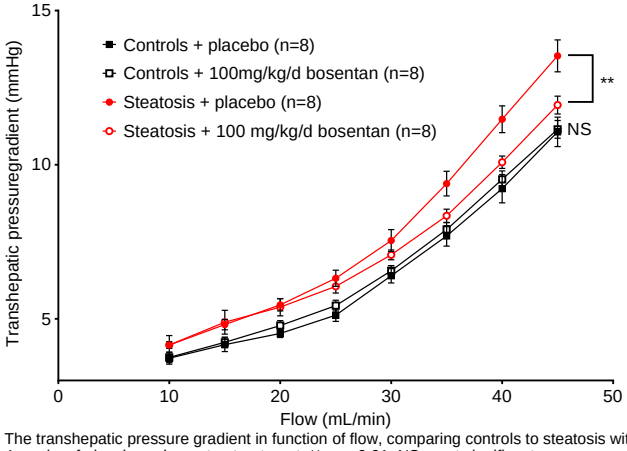
Background and Aims: Recent evidences suggest that symbiotic supplementation could modulate the gut microbiota, gene expression and improve metabolic disorders, including NAFLD. The aim of this study was to examine the symbiotic supplementation in ob/ob mice.
Method: 20 ob/ob mice were divided into four groups with 5 animals: Treated Obese (SBT), Control Obese (SBN), Treated Lean (SBTN) and Lean Control (SBCN). The SBT and SBTN groups received a combination of probiotics (L. acidophilus, L. rhamnosus, L. paracasei, Bifidobacterium lactis) and prebiotic (FOS) in water and standard diet for 8 weeks. The SBN and SBCN groups received water and standard diet. After 8 weeks, all animals were sacrificed, and liver and gut tissue were collected for mRNA isolation and histological analysis. SREBP1, MTTP, CPT1-α, PPAR-α, TLR4 and IL-6 gene expression were evaluated in liver tissue and beta-catenin, occluding, caderin and zonulin was evaluated in gut tissue by RT-qPCR. Microbiome DNA was extracted from stool samples and sequenced using the Ion PGM Torrent platform.
Results: The symbiotic supplementation reduced body weight gain in all treated animals (obese and lean) comparing with no treated animals (obese and lean) according the initial and final ($p = < 0.0001$; $p = 0.0012$, respectively). An increase of Cyanobacteria ($p = 0.047$), Enterobacteriaceae ($p = 0.005$) and decrease of Clostridiaceae ($p = 0.026$), Turicibacter ($p = 0.005$) and Coprococcus ($p = 0.047$) was verified in obese treated group (SBT) when compared to obese control group (SBN). A significant reduction of Sutterella bacteria ($p = 0.009$) and Turicibater ($p = 0.005$) was observed in lean treated group (SBTN) compared to lean control group (SBCN). The beta-catenin was significantly decreased in gut from obese treated group (SBT) ($p \leq 0.0001$) when compared to other groups. No changes were observed in occluding, caderin and zonulin gene expression in gut tissue as well as genes related to lipid metabolism, mitochondrial oxidation and inflammatory response in liver tissue.
Conclusion: The symbiotics supplementation prevents excessive weight gain, modulated the gut microbiota and reduces beta-catenin expression, an important gene involved in tight junction signaling, inflammation and proliferative status in NAFLD. Our results provide evidences the beneficial effects of symbiotics supplementation in NAFLD treatment.

SAT012

Treatment with the endothelin receptor inhibitor bosentan alleviates the NAFLD-associated increased intrahepatic vascular resistance and reduces steatosis and liver damage in a rat model of early NAFLD

Denise van der Graaff[1,2], Wilhelmus Kwanten[1,2], Peter Michielsen[1,2], Joris De Man[1], Benedicte De Winter[1], Sven Francque[1,2]. *[1]University of Antwerp, Laboratory of Experimental Medicine and Pediatrics, Antwerp, Belgium; [2]Antwerp University Hospital, Division of Gastroenterology and Hepatology, Edegem, Belgium*
Email: denise.vandergraaff@uantwerpen.be

Background and Aims: The intrahepatic vascular resistance (IHVR) is increased in early non-alcoholic fatty liver disease (NAFLD), impairing hepatic blood flow and potentially causing tissue hypoxia and disease progression. We previously demonstrated that this increase in IHVR is in part mediated by vascular hypersensitivity to endothelin-1 (ET-1), which could be blocked by ET-A receptor inhibition (Van der Graaff, Hepatol 2018;68(Suppl):1011A). The aim of this study was to analyse the potential benefit of bosentan (BOS, an ET-A and -B receptor blocker) on liver haemodynamics and concurrent severity of disease in early NAFLD.
Method: The effects of ET-1 inhibition were studied in male Wistar rats (n = 8/group) fed a methionine-choline-deficient (MCD) diet, which induces severe steatosis after 4 weeks, or a control diet. Rats were daily gavaged with 100 mg/kg BOS or placebo during the complete 4 weeks of diet as preventive treatment or during the second 2 weeks of diet as curative treatment. The IHVR was studied by measuring the transhepatic pressure gradient (THPG) in an *in situ ex vivo* perfusion model at different flows (10–45 mL/min). Blood samples were collected before liver perfusion to determine ALT levels and liver tissue was harvested for histology.



The transhepatic pressure gradient in function of flow, comparing controls to steatosis with 4 weeks of placebo or bosentan treatment. ** = p<0.01, NS = not significant

Results: The basal THPG in steatotic livers confirmed the significant increase compared to controls (Fig), as previously demonstrated (Van der Graaff, Lab Invest 2018). Preventive BOS treatment significantly decreased the THPG in steatotic livers, without affecting the THPG in

controls (Fig). Moreover, despite comparable weight evolution (MCD 199.6 ± 3.5 g and MCD + BOS 200.3 ± 3.3 g at W4, p = 0.898), liver weight and liver-to-total-body-weight (TBW) ratio were lower in preventive BOS-treated (4.6 ± 0.1% liver/TBW) compared to placebo-treated rats (5.2 ± 0.3% liver/TBW, p < 0.01) with steatosis. The degree of steatosis, expressed as % fat of total liver surface, was significantly lower in preventive BOS-treated rats (from 52.2 ± 0.7% placebo to 47.1 ± 2.0% BOS, p < 0.05). ALT significantly increased in MCD fed rats (94.9 ± 14.0 U/L), whereas preventive BOS-treated rats showed ALT levels comparable to control rats (48.4 ± 3.0 U/L, p < 0.05). In curative BOS-treated rats, we observed a similar significant decrease in THPG, liver and liver/TBW ratio and ALT level. The degree of steatosis showed an insignificantly decreased trend (results not shown). In controls, none of the parameters were affected by BOS treatment.

Conclusion: BOS treatment significantly decreased the elevated THPG observed in steatosis. This effect goes along with a decrease in steatosis, lower liver weight and liver/TBW-ratio and normalisation of ALT in the absence of any effect on body weight. These findings strongly support the role of ET-1-related vascular alterations in NASH pathogenesis and its potential as a therapeutic target.

SAT013

Liver sinusoidal endothelial cell-specific RUNX-1 gene knockdown decreases hepatic inflammation and myeloid cells infiltration in pre-clinical animal models non-alcoholic steatohepatitis

Dinesh Mani Tripathi[1], Savneet Kaur[1], Impreet Kaur[1], Sumati Rohilla[2], Abhishak Gupta[1], Vegi Naidu[3], Subham Banerjee[3], Shiv Kumar Sarin[4].
[1]Institute of Liver and Biliary Sciences, Liver Physiology and Vascular Biology, Molecular and Cellular Medicne, Delhi, India; [2]Gautam Buddha University, Greater Noida, India; [3]National Institute of Pharmaceutical Education and Research, Guwahati, India; [4]Institute of Liver and Biliary Sciences, Hepatology, Delhi, India
Email: savykaur@gmail.com

Background and Aims: Our recent studies have reported an increased expression of Runt-related transcription factor (RUNX1) in liver sinusoidal endothelial cells in patients with non-alcoholic steatohepatitis (NASH). Here, we further dissected the role of RUNX1 in NASH by in vitro and in vivo studies.

Method: In vitro, RUNX1 gene expression was downregulated in LSECs using RUNX1-siRNA followed by analysis of their angiogenic gene expression and functions by RT-PCRs and matrigel assays. In vivo, RUNX1 was silenced in LSECs in methionine choline deficient (MCD) diet-induced NASH mice by using a nanodelivery system consisting of nanolipocarrier encapsulated RUNX1-siRNA (RUNX1-NLC). After characterization of the RUNX1-NLC (both in vitro and in vivo), liver cells and liver infiltrating lymphocytes (LILs) were analyzed to study expression of RUNX1 and other angiogenic/adhesion molecules by RT-PCRs and flow cytometry. MCD mice treated only with nanolipocarriers without RUNX1 siRNA served as vehicle.

Results: Results: An in vitro knock-down of RUNX1 gene in LSECs (>50%) resulted in substantial downregulation of their angiogenic and adhesion gene expression and also angiogenic properties. In vivo, a knock-down of about 40% was achieved in the expression of RUNX1 gene in CD31+ liver endothelial cells of RUNX1-NLC treated mice, which showed a reduced expression of adhesion molecules, VCAM1 and ICAM1 in comparison to the vehicle mice. RUNX1-NLC treated mice showed marked reduction of CD45+CD3+ T cells in the liver as compared to vehicle (25.8 + 1.8 vs 39.6 + 2.5%). Also, percentages of CD11b+F4/80+ inflammatory monocytes/macrophages were significantly lower in RUNX1-NLC mice as compared to that seen in vehicle mice (5.9 + 1.1 vs 21.9 + 2.6%). A decrease in inflammatory cells in liver was also well evident in the H & E liver sections of the RUNX1-NLC mice versus vehicle animals. Hepatic TNF-α and CCL2 levels showed significant reduction in RUNX1-NLC mice in comparison to that of the vehicle mice (p < 0.05).

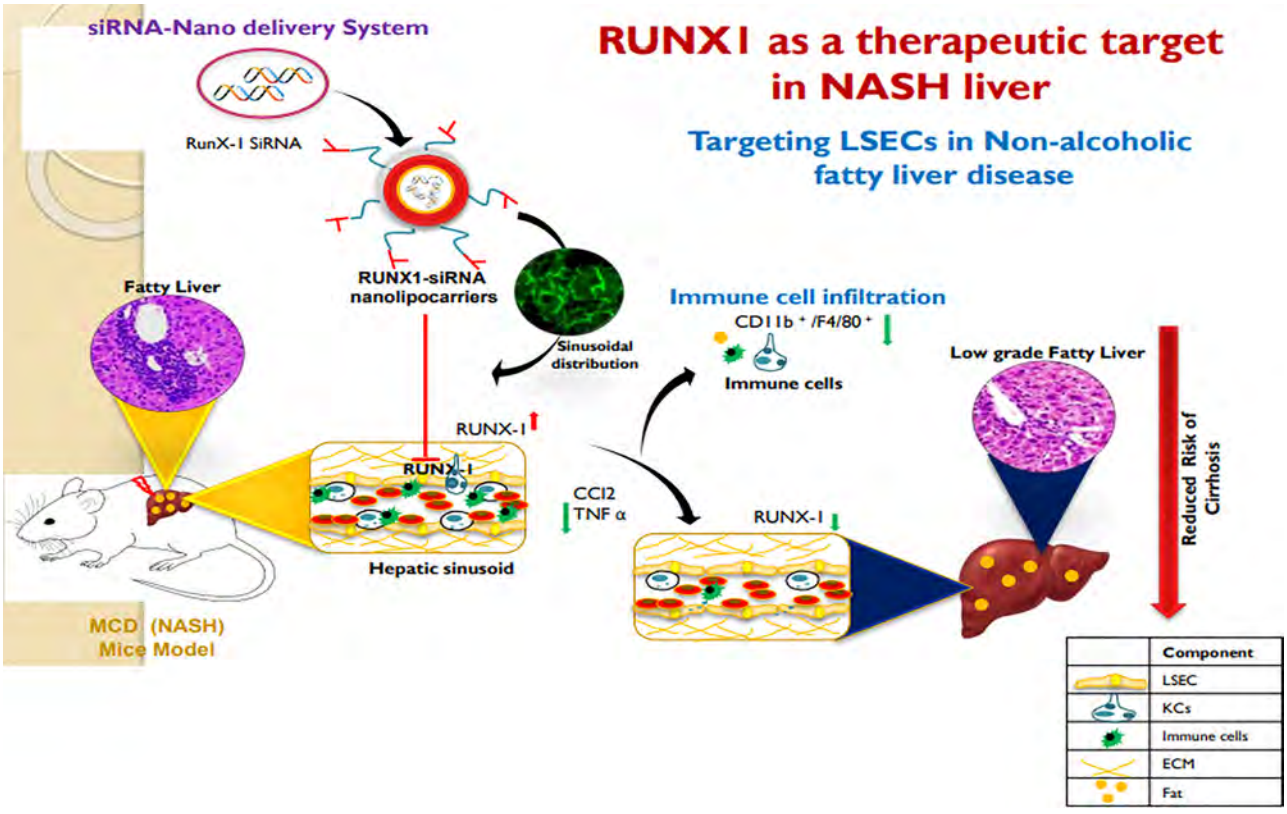


Figure: (abstract: SAT013)

Conclusion: A decrease in RUNX1 expression in LSECs reduces their expression of adhesion molecules, causing decreased infiltration of myeloid and T cells in liver, decreasing inflammation in NASH liver. The study highlights the significance of a nanodelivery system for in vivo cell-specific gene silencing and proposes it as a strategy to target LSEC-associated inflammation in NASH.

SAT014

Identification of novel biomarkers and therapeutic targets for steatohepatitis and advanced fibrosis in patients with non-alcoholic fatty liver disease (NAFLD): an in silico analysis

Douglas Maya-Miles[1,2], Rocío Gallego-Durán[1,2], Rocio Munoz Hernandez[1,2], Angela Rojas[1,2], Antonio Gil-Gomez[1,2], Rocío Montero-Vallejo[1,2], Sheila Gato[1,2], Maria Giraldez-Jimenez[1,2], Javier Ampuero[1,2], Manuel Romero Gomez[1,2]. [1]*Seliver Group, Instituto De Biomedicina De Sevilla (IBiS), Hospital Universitario Virgen Del Rocío/CSIC/Universidad De Sevilla;* [2]*Centro De Investigación Biomédica En Red De Enfermedades Hepáticas y Digestivas (CIBEREHD)*
Email: mromerogomez@us.es

Background and Aims: To integrate multiple gene expression datasets from liver biopsies to search for novel biomarkers and/or therapeutic targets for advanced fibrosis and steatohepatitis in NAFLD patients.
Method: Data was obtained from Gene Expression Omnibus or other public repositories and integrated using R studio. Expression data was quantile normalized using *RMA* (*oligo* package version 1.48.0) and *BrainArray* (version 23.0.0) probe/gene mappings to increase precision and accuracy. Probes that were not present in all arrays were excluded from the analysis. After *RMA* pre-processing, array data with a different provenance (from different studies/platforms) were cross-platform normalized (aka merged) using *Combat* method (*InSilicoMerging* package version 1.14.0) to remove batch effects. The search for biomarkers and therapeutic candidates of NASH was performed using data from six cohorts (N = 317) by pairwise comparisons between healthy individuals (n = 82) or patients with simple steatosis (n = 90) with individuals with NASH (NAS score ≥5) (n = 145). The search for advanced fibrosis markers was performed using exclusively individuals diagnosed with NAFLD (3 cohorts, N = 188) that had either mild (F0-F1, n = 152) or advanced (F3-F4, n = 36) fibrosis according to Kleiner Score. Changes in gene expression were considered significant when the FDR corrected p-value was ≤ 0.05 and the Fold Change (FC) ≥ 1.4. The behaviour of genes identified was further explored in two additional gene expression datasets that compared: 1) human primary hepatocytes exposed or not to conditions that promote inflammation and fat accumulation (0.5 mM mixture of palmitic/oleic acid + TNF-α) and; 2) Quiescent Human Primary Hepatic Stellate cells isolated from the liver of healthy patients that were exposed to conditions that promote their activation.
Results: Comparison between healthy and NASH patients showed 5 genes that changed significantly their expression: ME1 (FC: 1.53), CXCL10 (FC: 1.53), FABP4 (FC: 1.49), FST (FC: −1.45), P4HA1 (FC: −1.49). ME1 was also highly expressed in primary human hepatocytes subject to the treatment with fatty acids and TNF-α (FC: 1.53 FDR: 3.92×10^{-4}). Comparison between mild and advanced fibrosis revealed 69 genes with a significant change in their expression levels. One of these genes, which we have named as Advanced Potential Fibrosis Candidate 1 (APFC1) (FC: 1.75 FDR: 4.94×10^{-7}), has not been previously associated to advanced fibrosis and was also more expressed in activated human hepatic stellate cells compared to quiescent cells (FC: 3.72 FDR: 2.11×10^{-5}).
Conclusion: The integration of multiple expression datasets allowed us to identify a new potential candidate for advanced fibrosis in NAFLD patients, APFC1. The expression of this gene is higher in activated human hepatic stellate cells compared to quiescent cells suggesting a possible role for this gene during fibrogenesis.

SAT015

Liver-chip: a model for understanding diet-induced liver disease and drug efficacy assessment

Dwayne Carter[1], Grasiella Andriani[1], Sushma Jadalannagari[1], Sauveur Jeanty[1], John Sauld[1], Sannidhi Joshipura[1], Jamie Bates[2], Saritha Kusam[2], Diego Miranda[2], Ayse Okesli Armlovich[2], Archana Vijayakumar[2], Kyung-Jin Jang[1], Geraldine Hamilton[1], Katia Karalis[1], James Trevaskis[2]. [1]*Emulate, Inc, Boston, United States;* [2]*Gilead Sciences, Inc., Foster City, United States*
Email: dwayne.carter@emulatebio.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is a progressive condition initially characterized by increased lipid accumulation in the liver (steatosis) and can develop into non-alcoholic steatohepatitis (NASH). There is an unmet need for a human-relevant *in vitro* model to enable successful development of therapies.
Method: To address this unmet need, we utilized our human Liver-Chip, which retains key characteristics of native liver function over long-term culture. To induce steatosis, chips were treated with saturated (palmitate) or unsaturated (oleate) fatty acids, alone or in combination. TGF-beta was used as a positive control for hepatocellular injury and stellate cell activation. To assess therapeutic efficacy against steatosis, chips were treated for two days after initiating steatosis (therapeutic), or co-treated (prophylactic) with a liver-targeted analogue of firsocostat, a known inhibitor of acetyl-CoA carboxylase (ACC - i). Morphological evaluation of the hepatocytes and AdipoRed™ staining was used to evaluate steatosis. Quantification of triglycerides released in the media was used to evaluate lipid removal, and alpha-SMA staining was used to assess stellate cell activation.
Results: We demonstrated induction of steatosis in hepatocytes in a concentration-dependent manner following continous exposure to oleate, palmitate, or in combination. Withdrawal of fatty acids significantly diminished the steatotic phenotype as well as levels of triglycerides released in accordance with relevant human *in vivo* data. Administration of TGF - beta resulted in increased stellate cell activation, hepatocellular injury, and lipid accumulation compared to the vehicle controls. Chips treated with the ACC - i demonstrated a concentration-dependent reduction in lipid accumulation in both the therapeutic and prophylactic paradigms when compared to steatosis induced controls.
Conclusion: In this study we provide preliminary data supporting the potential application of the Liver-Chip for modelling NAFLD-like phenotypes and conducting human-relevant therapeutic efficacy assessment using clinically relevant endpoints.

SAT016

AKR-001, an engineered Fc-FGF21 variant, directly modulates human liver and adipose tissue physiology, exerting beneficial metabolic, anti-inflammatory, and anti-fibrotic effects without FGFR4 agonism

Erik Tillman[1], Monika Kijanska[2], Tim Rolph[1]. [1]*Akero Therapeutics, South San Fransisco, United States;* [2]*InSphero AG, Schlieren, Switzerland*
Email: tim@akerotx.com

Background and Aims: Non-alcoholic steatohepatitis (NASH) is a progressive liver disease with complex etiology. Pathophysiology results from the accumulation of liver fat due to increased adipose tissue lipolysis, excess calories directed to the liver, and increased hepatic *de novo* lipogenesis. Accumulating fat drives lipotoxicity, endoplasmic reticulum stress, and oxidative stress in hepatocytes, leading to apoptosis, inflammation, and fibrosis. FGF21 acts as both an endocrine and a paracrine hormone, integrating whole body responses to nutritional changes and protecting cells against various stressors. To understand the potential for AKR-001, a clinical-stage FGF21 analog, to mitigate each of the core processes underlying NASH pathology and progression, its activity has been profiled in different human *ex vivo* tissue models relevant to NASH pathology described

above. Additionally, we sought to characterize the relative contributions of different FGF receptors to the actions of AKR-001 using a panel of endocrine FGF analogs with different FGFR selectivity profiles.

Method: Various endocrine FGF analogs have been profiled using 2D and 3D *ex vivo* human liver and adipose models, under conditions which mimic fed and fasted states by varying media glucose, insulin, and glucagon concentrations. The biological activity of different endocrine FGF analogs was characterized using transcriptomics and candidate protein expression analysis. We used a functional co-culture 3D liver model to understand direct hepatic effects of FGF21 activity on steatotic, inflammatory, and fibrotic readouts.

Results: FGF21 and AKR-001 suppress TGF-b-induced fibrogenic gene expression in a human hepatic stellate cell line. In 3D liver microtissues consisting of primary hepatocytes and various nonparenchymal cells, FGF21 and AKR-001, but not FGF19, suppress DNL and triglyceride accumulation. In this 3D human liver cell co-culture model, FGF21 and AKR-001 also suppress inflammatory activation by LPS to a greater extent than FGF19, while also suppressing fibrogenesis. Unbiased transcriptome profiling of these 3D liver microtissues, and of human adipocytes differentiated *in vitro*, demonstrated that AKR-001 recapitulates FGF21's regulation of key metabolic pathways supporting its potential for use as a therapeutic in NASH patients.

Conclusion: FGF21 and AKR-001 exert direct actions in human adipocytes, hepatocytes, and liver non-parenchymal cells consistent with suppression of steatosis, inflammatory activation, and fibrogenesis. These actions appear to be mediated by FGF21's canonical receptors FGFR1c/2c/3c, since agonism of FGFR4 does not seem to contribute additional efficacy in these tissues. This supports the appealing pharmacology of AKR-001, which has been reported to have favorable effects on markers of glycemic control and lipid metabolism and to be well-tolerated in humans.

SAT017

Propionate intervention attenuates NASH while negatively affecting cognition

Eveline Gart[1,2], Anouk Tengeler[3], Martine C. Morrison[1], Robert Kleemann[1], Amanda Kiliaan[3]. *[1]TNO, Metabolic Health Research, Leiden, Netherlands; [2]Wageningen University, Human and Animal Physiology, Wageningen, Netherlands; [3]Radboud university medical center, Department of Anatomy, Donders Institute for Brain, Cognition and Behavior, Nijmegen, Netherlands*
Email: eveline.gart@tno.nl

Background and Aims: There is an increasing interest to elucidate the health effects of short-chain fatty acids (SCFAs) on metabolism, obesity and brain function. Obesity is often associated with the development of non-alcoholic steatohepatitis (NASH) and cognitive impairment. We herein investigated potential health effects of the SCFA propionic acid (PA) on NASH development and brain function including cognition and behaviour readouts.

Method: During 17 weeks of run-in, LDLR−/−.Leiden mice received either high-fat diet (HFD) to establish obesity or chow as control. Obese mice were matched into groups (n = 15/group) and treated with propionic acid (PA+HFD), or a reference fatty acid (caproic acid; CA+HFD), or HFD without supplements (HFD). Cognitive and behavioral effects, as well as metabolic and inflammatory risk factors, were assessed prior to and after 12 weeks of treatment. At endpoint, liver, adipose and brain tissue were histologically and biochemically analyzed.

Results: PA, but not reference CA, reduced body weight and this effect was independent of food intake. PA also reduced fasting insulin levels and plasma cholesterol levels relative to the start of intervention. In addition, PA reduced total and subcutaneous fat mass, but did not affect WAT inflammation. Histopathological analysis of the liver demonstrated that PA reduced macrovesicular steatosis, hypertrophy and inflammation. Consistent herewith, PA reduced the inflammatory marker serum amyloid A and lowered the hepatic collagen content. PA treatment did not affect behavior in the open field test but mice showed impaired spatial memory, i.e. the latency to find the platform in the Morris water maze was increased. In line with these findings, we observed alterations in tissue integrity and gene expression in the hippocampus, a brain region important in memory consolidation. The reference fatty acid CA exerted no effects on the above readouts.

Conclusion: PA treatment during obesity had favorable metabolic effects, reducing body weight gain, improving metabolic risk factors and reducing the development of NASH and associated fibrosis. Simultaneously, PA had detrimental effects on the brain, reducing synaptogenesis signaling and affecting spatial memory. Altogether, the results from this study indicate that while the beneficial metabolic effects of PA treatment seem promising, it can also have negative effects on brain functioning and cognition, and should therefore be treated with caution.

SAT018

A shortcut from non-alcoholic fatty liver disease to HCC: c-Myc, a promising theranostic target

Feifei Guo[1], Kang Zheng[2,3], Raquel Benedé[1], Marius Woitok[4], Olga Estévez Vázquez[1], Philip Kaye[5], Christian Liedtke[4], Francisco Javier Cubero[2,3], Yulia A. Nevzorova[1,3,4]. *[1]Department of Genetics, Physiology and Microbiology, Faculty of Biology, Complutense University, Madrid, Spain; [2]Department of Immunology, Ophthalmology & ENT, Complutense University School of Medicine, Madrid, Spain; [3]12 de Octubre, Health Research Institute (imas12), Madrid, Spain; [4]Department of Internal Medicine III, University Hospital RWTH Aachen, Aachen, Germany; [5]Department of Pathology, Nottingham University Hospitals NHS Trust, Queen's Medical Centre Campus, Nottingham, UK, Nottingham, United Kingdom*
Email: feirguo@163.com

Background and Aims: Non-Alcoholic Fatty Liver Disease (NAFLD) has rapidly risen as one of the leading etiologies for HCC and represents a large societal and health problem. Many factors are responsible for the high risk of NAFLD-related HCC development. Lately, oncogenes have been suggested to be determinant; however, their role still remains unknown.

Here we analysed the impact of the proto-oncogene *c-MYC* in the development of murine NAFLD and NAFLD-associated HCC.

Method: Transgenic mice bearing overexpression of c-*MYC* in hepatocytes (alb-MYC^{tg}) were studied at baseline conditions (36 weeks, 1 year) as well as after application of Western diet (WD).

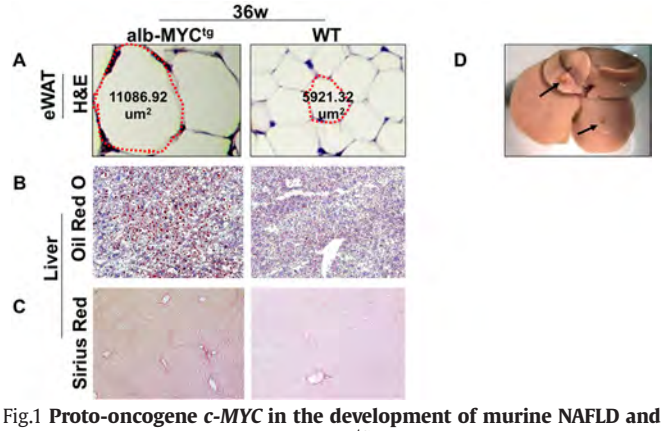

Fig.1 **Proto-oncogene *c-MYC* in the development of murine NAFLD and NAFLD-associated HCC**. (A-C) alb-MYC^{tg} mice exhibited profound spontaneous changes at 36 weeks: (A) hypertrophia of eWAT cells; (B) macrovesicular steatosis and (C) significant collagen accumulation in liver; (B) Multiple tumour nodules in alb-MYC^{tg} mice livers after 10 months of WD feeding.

Results: Mild obesity (Fig.1A), spontaneous hyperlipidaemia, glucose intolerance and insulin resistance were characteristic of 36 week-old

alb-MYC^{tg}. Moreover, alb-MYC^{tg} mice exhibited profound hepatic changes at baseline, characterized by significant macrovesicular steatosis (Fig.1B), hepatocellular ballooning and increased triglyceride content, compared to WT littermates. Liver injury and inflammation associated with elevated serum transaminases, marked infiltration of CD45 and F4/80 positive cells, increased caspase-3 activity, up-regulation of the ER-stress response and ROS production, significant collagen accumulation (Fig.1C) and compensatory proliferation were apparent in transgenic animals at 36 weeks. In agreement with earlier studies, 20% of alb-MYC^{tg} mice developed HCC at 1 year of age. Importantly, the application of WD exacerbated metabolic abnormalities, steatohepatitis, fibrogenesis and substantially enhanced the tumor incidence and tumor growth resulting in the formation of multiple tumour nodules after only 10 months of feeding in 100% of alb-MYC^{tg} mice (Fig.1D).

Conclusion: In the present study, we identified a novel function of *c-MYC* for the progression from NAFLD to HCC. It can be speculated that targeting of *c-MYC* in patients with NAFLD could reduce the risk of HCC development. However, further analysis is needed to uncover the underlying mechanisms and risk factors.

SAT019

Sex differences of adipose tissue dynamic changes in NASH progression of morbid obese patients: a preliminary study

Gerard Baiges[1], Elisabet Rodríguez-Tomàs[1], Anna Hernández-Aguilera[2,3], Helena Castañé[1], Salvador Fernández-Arroyo[2,3], Montserrat Fibla Simó[3], Jordi Camps[2,3], Jorge Joven[2,3]. *[1]Rovira i Virgili University, Tarragona, Spain; [2]Hospital Universitari Sant Joan de Reus, Reus, Spain; [3]Fundación Instituto de Investigación Sanitaria Pere Virgili, Tarragona, Spain*
Email: gerardbaiges93@gmail.com

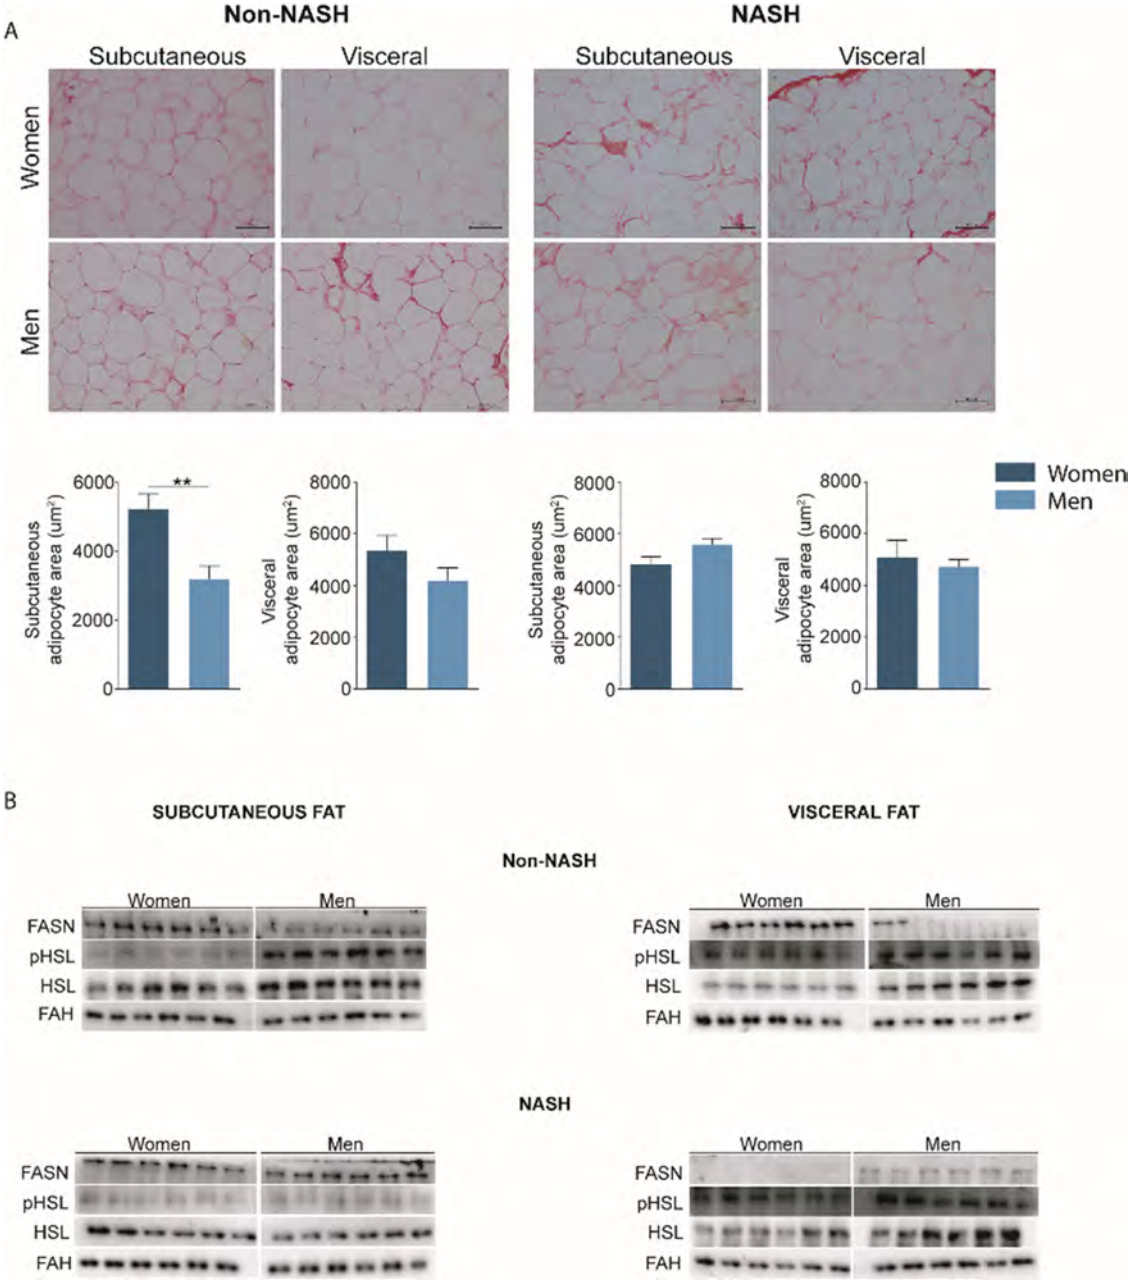

Figure: (abstract: SAT019)

Background and Aims: The prevalence of obesity has increased drastically in the last decades and this phenomenon constitutes today a serious health public problem. This obesogenic environment is characterized by an increase in adipose tissue mass. However, the adipocyte metabolism differs within (anatomical localization) and between individuals. The magnitude of adiposity is influenced by their potential growth (hypertrophy and/or hyperplasia) and their ability to triglyceride turnover. In fact, under a dysfunctional subcutaneous adipose tissue may result in the ectopic fat deposition in important metabolic organs such as visceral adipose tissue and liver. Progressively the hepatocyte loses the ability to metabolize the excess of lipids and can evoke to an inflammatory response and thereby progress to steatohepatitis (NASH). Our study aimed to assess adipose tissue metabolism and their metabolic changes during the development of NASH.
Method: Sixteen women and sixteen men with morbid obesity candidates to bariatric surgery were classified into the non-NASH group (n = 8 per sex) and NASH group (n = 8 per sex). Visceral and subcutaneous abdominal adipose tissue samples were immediately recollected before bariatric surgery. Histological analysis and immunoblot were performed to assess the adipose tissue dynamic and their impact on NASH progression according to sex.
Results: We found that in terms of hypertrophy only in Non-NASH group, the women had a significant increase in subcutaneous adipocyte size. However, the activity of adipocyte showed be heterogeneous according to the tissue and the sex. Of note, that in Non-NASH group the women showed an adipose tissue much more lipogenic in both tissues. By contrast, the adipose tissue of men showed a higher capacity to removal the triglycerides by enzymatic hydrolysis (lipolysis). Nevertheless, in the NASH group only we observed that the men visceral adipose tissue showed an increase of lipogenesis.
Conclusion: Adipose tissue is a heterogeneous organ where the adipocytes have a sex-specific metabolism and thereby the response under the same pathological condition is different.

Hepatocyte-specific deletion of ERK5 worsens insulin resistance in a murine model of non-alcoholic fatty liver disease (NAFLD)

Giovanni Di Maira[1], Giulia Lori[1], Benedetta Piombanti[1], Maria Letizia Taddei[1], Paola Chiarugi[1], Elisabetta Rovida[1], Cathy Tournier[2], Fabio Marra[1]. *[1]University of Florence; [2]University of Manchester*
Email: giovanni.dimaira@unifi.it

Background and Aims: The extracellular signal-regulated kinase 5 (ERK5) is a member of the Mitogen-Activated Protein Kinases family highly expressed in hepatocytes, macrophages and stellate cells, and we recently generated hepatocyte-specific ERK5 knock-out mice (ERK5ΔHep). The aim of this study is to investigate the role of hepatocyte ERK5 in a murine model of NAFLD.
Method: ERK5ΔHep and control mice were fed with a high-fat diet (HFD) for 16 weeks. For glucose tolerance test (GTT) mice were injected with 1 g/kg BW glucose i.p. Insulin tolerance test (ITT) was performed by injecting 0.8 U/kg BW of regular insulin i.p. A murine hepatocyte cell line (MMH) was silenced using lentiviral vectors encoding shRNA for the ERK5 gene. Mitochondrial depolarization was assayed using the TMRE staining protocol. OXPHOS metabolism was measured by Seahorse.
Results: ERK5ΔHep mice exhibited impaired glucose tolerance and reduced insulin sensitivity in comparison to the control group. Body weight and food consumption were similar, while visceral fat was increased in ERK5ΔHep. MMH stably silenced for ERK5 showed reduced Akt activation following insulin stimulation. When cells were challenged with palmitic acid and then stimulated with insulin, Akt activation was completely abrogated in MMH/shERK5. In addition, measurement of mitochondrial membrane potential indicated a strong depolarization in MMH/shERK5 cells, which also showed an impairment of mitochondrial OXPHOS, indicating a profound impact of ERK5 deficiency on mitochondrial functions. In MMH/shERK5 cells, expression of peroxisome proliferator-activated receptor-gamma coactivator-1α (PGC-1α), a pivotal regulator of mitochondrial biogenesis and function, was up-regulated. Additionally, expression of TRIB3, a negative regulator of insulin signaling (through inhibition of Akt) under the control of PGC-1α was higher in MMHshERK5 cells, and its expression was further enhanced by palmitic acid. Increased expression of PGC-1α protein and TRIB3 was also observed also in liver tissues from HFD-fed ERK5ΔHep mice.
Conclusion: We have elucidated a novel pathway connecting expression of ERK5 in hepatocytes to the regulation of insulin sensitivity through PGC-1α, TRIB3, and Akt, which is relevant to the pathogenesis of NAFLD.

MicroRNAs involved in the progression of non-alcoholic fatty liver

Guillermo Nahúm López-Sánchez[1], Eduardo Montalvo-Javé[2], Misael Uribe Esquivel[3], Norberto Carlos Chávez-Tapia[1,3], Natalia Nuño-Lambarri[1]. *[1]Medica Sur Clinic & Foundation, Translational research unit, Mexico City, Mexico; [2]General Hospital of Mexico, General, gastrointestinal and hepatobiliary surgery, Mexico City, Mexico; [3]Medica Sur Clinic & Foundation, Obesity and Digestive Diseases Unit, Mexico City, Mexico*
Email: nlambarri@gmail.com

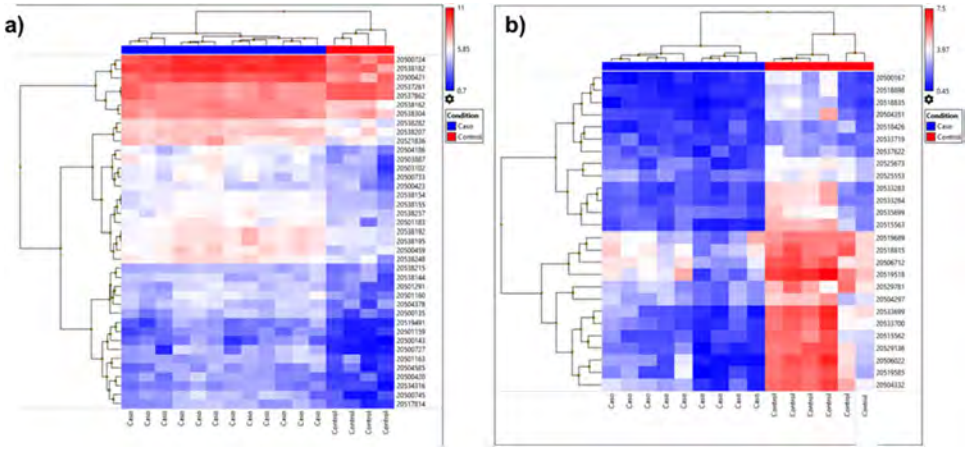

Figure: (abstract: SAT021): **Microarrays heat maps.** a) NAFLD patients compared to controls, b) NASH patients compared to controls.

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease in the world; its prevalence has increased recently, accompanied by global obesity pandemic. It is a complex entity that arises from numerous genetic, environmental, behavioral and social factors. Non-alcoholic steatohepatitis (NASH) is part of the disease progression and is a preamble to more severe complications such as cirrhosis and hepatocellular carcinoma. Currently, the only tool to diagnose NASH is liver biopsy. The aim is to identify the different microRNAs (miRNAs) involved in NAFLD progression.
Method: 117 patients were recruited; liver biopsy and a blood sample were obtained; 30 were submitted to microarray assays and classified according to controlled attenuation parameter (CAP) and NAFLD activity score (NAS). Patients with CAP ≤ 232 dB/m, 0-point NAS and histopathological report without alterations, were the control group; with CAP ≥ 290 dB/m, NAS with 1 to 3 points and histopathological report with steatosis in more than 5% of hepatocytes, were the NAFLD group, and patients with CAP ≥290 dB/m, NAS ≥5 points and histopathological report with steatosis accompanied by inflammatory ballooning and infiltration, were the NASH group. From blood samples, liver function tests, as well as fasting cholesterol, triglycerides, and glucose levels, were determined. RNA was extracted from liver tissue to analyze the miRNAs differential expression using the GeneChip miRNA 4.0 microarray; expression levels were compared with the Affymetrix TAC software using a fold change parameter ≥2 and ≤−2; FDR ≤ 0.05 and $p \leq 0.001$.
Results: Regarding the anthropometric characteristics, BMI had a statistical difference between control 27.8 kg/m^2, NAFLD 29.1 kg/m^2 and NASH 39.1 kg/m^2 $p \leq 0.0001$; liver function profile, circulating lipids and fasting glucose did not change. The microarray analysis revealed a differential expression of 24 miRNAs in the NAFLD group, 23 were upregulated and 1 downregulated; miR-122-3p was expressed 9 times more than the control, followed by the miR-140-5p that showed almost 6 times more expression, the miR-200a-3p was 5 times more expressed, but also the miR-148b-3p and the miR-148a-5p were 4 times more expressed than the control; while the miR-6089-2 shows 2-fold drop expression compared to the control group. While NASH results disclosed 21 differentially expressed miRNAs compared to controls, miR-297, miR-3064-5p, miR3148 and miR-7844-5p showed more than 20 times decrease expression compared to the control group.
Conclusion: The results suggest that miRNAs differential expression could be used as potential NAFLD diagnostic and progression biomarkers; however, the mechanism by which these miRNAs are involved in the pathogenesis needs further investigation.

SAT022

Simultaneous intra-operative sampling from multiple anatomical sites reveals pro-inflammatory liver homing T cells in liver, adipose tissue and peripheral blood in patients with NASH

James Brindley[1], Falguni Tailor[1], Karthik Chandrasekharan[1], Kathryn Waller[1], Anja Versteeg-de Jong[1], Kalpana Devalia[2], Sanjay Agrawal[2], Francesca Rosini[3], John Loy[2], William Alazawi[1].

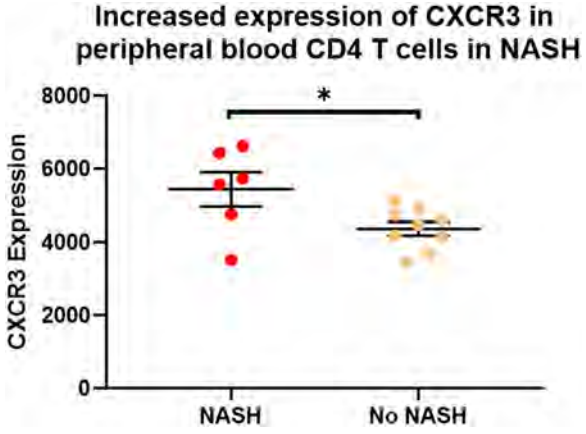
Email: halbrindley@gmail.com

Background and Aims: Non-alcoholic steatohepatitis (NASH) is an inflammatory liver disease that can lead to fibrosis, cirrhosis and end stage liver disease. NASH has a multi-directional relationship with metabolic syndrome. Emerging evidence suggests an increase in peripheral blood T helper 1 (Th1) cells in NASH. However, the number and phenotype of T cells sampled simultaneously from adipose and liver tissue and peripheral blood in obese patients with NASH has not been studied to date. Here we test the hypothesis that a Th1 phenotype is dominant in all anatomical compartments.
Method: Patients undergoing bariatric surgery with NAFLD underwent simultaneous sampling of liver, visceral and subcutaneous adipose tissue and peripheral blood mononuclear cells for immunoprofiling by flow cytometry.
Results: We included 15 bariatric patients (median age 54); 6 with biopsy-proven NASH and 9 non-NASH. NASH patients had greater median BMI 49.8 (IQR 48.1–52.9) than non-NASH 42.0 (36.6–43.7), with mean ALT 91 vs 23 ($p < 0.001$) and median CAP score 374 dB/m vs 278 dB/m with a trend towards raised median liver elastography 11.2 Kpa (IQR 6.6–11.5) vs 7.7 Kpa (IQR 5.7–10.0). In peripheral blood, there was significantly greater CXCR3+ expression in CD4+ T cells in NASH (MFI 5447 vs 4377, $p < 0.05$) with a trend towards increased interferon gamma expression following stimulation with PMA. Overall expression of the liver homing marker CXCR6 was increased across all peripheral T cells in NASH by multiple linear regression analysis ($p = <0.05$). In particular, there were significantly more CD4 +CXCR6+ T cells in NASH versus non-NASH. Among CD45+ cells extracted from liver tissue, patients with NASH had significantly more cytotoxic CD8+ Tcells ($p = 0.01$). In the visceral adipose compartment, Th2 cells (CD4+CRTH2+) sampled from obese non-NASH patients had significantly higher levels of CXCR6 expression compared to patients with NASH. Conversely there was a trend towards higher expression of CXCR6 on Th1 cells (CD4+CXCR3+) sampled from patients with NASH compared to those without ($p = 0.059$).
Conclusion: To our knowledge, this is the first study of immune cell phenotype in multiple anatomical compartments in this patient group. We find evidence of a pro-inflammatory, liver-homing phenotype in peripheral blood and adipose tissue and a dominant type I immune phenotype in all 3 compartments. Further investigation of the role of the adaptive immune system in the pathogenesis of NASH is warranted.



SAT023

The influence of obesity, non-alcoholic steatohepatitis and bariatric surgery on plasma lipid profile

Helena Castañé[1], Anna Hernández-Aguilera[2], Montserrat Fibla Simó[2], Gerard Baiges[1], Salvador Fernández-Arroyo[2], Jordi Camps[2], Jorge Joven[2]. *[1]Universitat Rovira i Virgili, Unitat de Recerca Biomèdica, Hospital Sant Joan de Reus, Reus, Spain; [2]Institut d'Investigació Sanitària Pere Virgili, Unitat de Recerca Biomèdica, Hospital Sant Joan de Reus, Reus, Spain*
Email: helena.castanev@gmail.com

Background and Aims: Obesity is often accompanied by non-alcoholic steatohepatitis (NASH). NASH is characterized by hepatic fibrosis, lipid accumulation and inflammation. Bariatric surgery (BS),

the gold standard treatment for obesity, has shown improvements in global health of obese individuals, but their effect on plasma lipid profile is still unknown. Our main aim was to assess changes in lipid profile of control population, obese patients with and without NASH and obese patients that undergone BS and were followed-up 12 months.

Method: Plasma samples were obtained from the participants and a lipid extraction was fulfiled. Then, we performed a lipidomic analysis by UHPLC-ESI-QTOF-MS. Results were compared in five different ways: healthy controls (n = 50) *vs* obese patients without NASH (n = 50) (obesity effect), obese patients with (n = 50) and without (n = 50) NASH (NASH effect), obese patients 12 months after BS (n = 50) *vs* obese patients with and without NASH (effect of BS in obese patients). Healthy individuals were also compared to obese patients 12 months after BS to assess possible restoration of healthy lipidome.

Results: Most lipid concentrations were statistically decreased in non-NASH obese patients than in healthy controls. Besides, obese patients with NASH had increased lipid concentrations compared to non-NASH obese patients. With that, we found few possible lipid candidates that could differentiate NASH from non-NASH, as seen in ROC curves of ChoE 18:1 and TG 50:1. However, multivariant analysis did not allow a complete distinction between groups. The effect of BS was different depending on the presence of NASH. If obese patients had NASH, BS altered much more lipid concentration than in obese patients that were non-NASH. Regarding obese patients and their follow-up after BS, we observed a different behaviour in the analysed lipid categories. Moreover, we observed that BS was not able to recover a healthy lipidome.

Conclusion: Obesity and mainly NASH are linked to a specific plasma lipidome. There are some lipids that are extremely different between obese patients with and without NASH that could lead to future non-invasive NASH biomarkers. Bariatric surgery improves clinical and biochemical characteristics of obese patients; however, it reduces plasma lipid concentrations even more than those concentrations found in healthy controls, probably due to the absorption modification after surgical intervention.

SAT024

Growth differentiation factor 11 promotes progression of non-alcoholic fatty liver disease

Jan Fröhlich[1], Kristina Kovacovicova[1], Tommaso Mazza[2], Michelangelo Foti[3], Cyril Sobolewski[3], Marion Peyrou[4], Francesc Villarroya[4], Melchiorre Cervello[5], Francesca Bonomini[6], Manlio Vinciguerra[1]. *[1]FNUSA-ICRC, CTM-EMA, Brno, Czech Republic; [2]Fondazione Casa Sollievo Della Sofferenza Istituto Mendel, Bioinformatics Unit, Roma, Italy; [3]University of Geneva-Faculty of Medicine, Department of Cell Physiology and Metabolism, Geneva, Switzerland; [4]Institute of Biomedicine of the University of Barcelona, Department of Biochemistry and Molecular Biomedicine, Barcelona, Spain; [5]National Research Council, Institute for Biomedical Research and Innovation, Palermo, Italy; [6]University of Brescia, Department of Clinical and Experimental Sciences, Brescia, Italy*
Email: jan.frohlich@fnusa.cz

Background and Aims: GDF11 (Growth Differentiation Factor 11) is a member of the TGF-beta superfamily and several recent papers implicated GDF11 as an antiaging factor. Nonetheless, its role in liver diseases is not fully clarified. Our aim was to evaluate the role of GDF11 in the progression of nonalcoholic fatty liver disease (NAFLD) to non-alcoholic steatohepatitis (NASH).

Method: We performed transcriptomic and lipidomic analyses in hepatoma cells treated with recombinant GDF11, to determine effected signaling pathways after GDF11 treatment. We administered recombinant GDF11 to *ob/ob* mice with NAFLD by daily intraperitoneal injection for 14 days to monitor the overall pathological changes in the liver. We also analyzed liver biopsies from a cohort of 33 morbidly obese Caucasian adults with biopsy-proven NAFLD (n = 20) or NASH (n = 13). We determined mRNA expression levels of GDF11 and other genes involved in NAFLD to NASH progression and we assessed correlations between obtained expression levels and clinico-pathological and histological features.

Results: In hepatoma cells, GDF11 treatment caused ALK5-dependent SMAD2/3 nuclear translocation, promoted accumulation of long acyl chain diacylglycerols and triacylglycerols and up-regulated TGF-beta activated genes involved in the deposition of extracellular matrix. In obese mice treated with recombinant GDF11 we observed

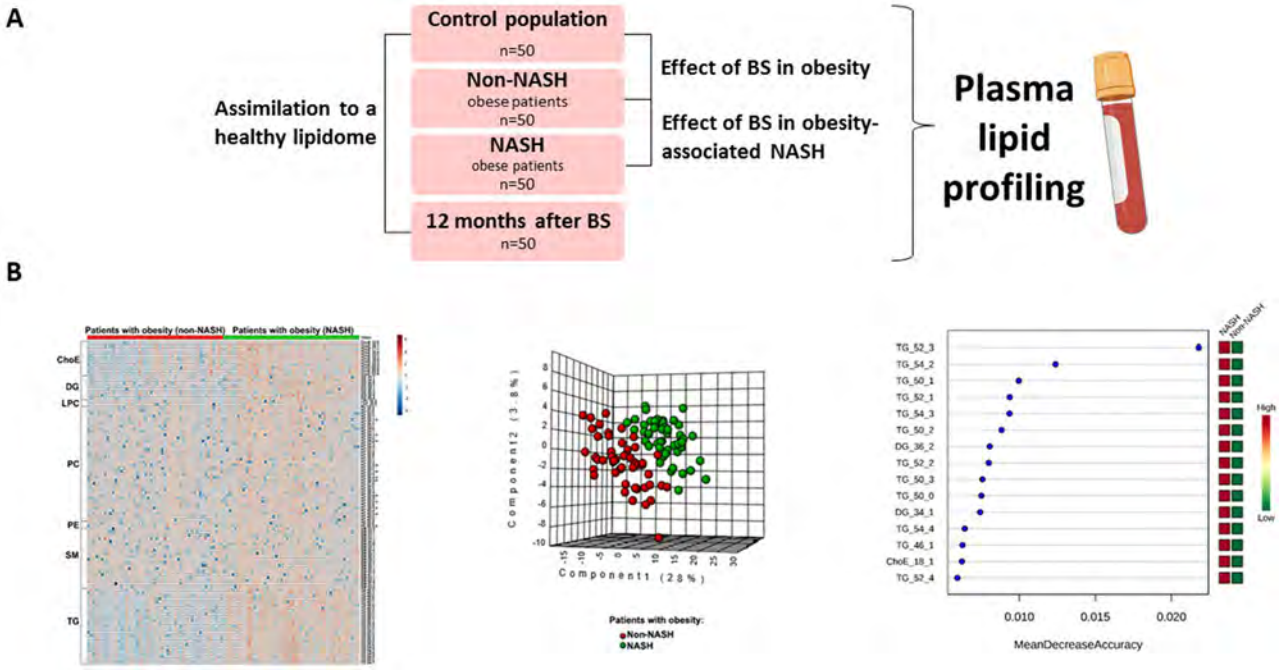


Figure: (abstract: SAT023)

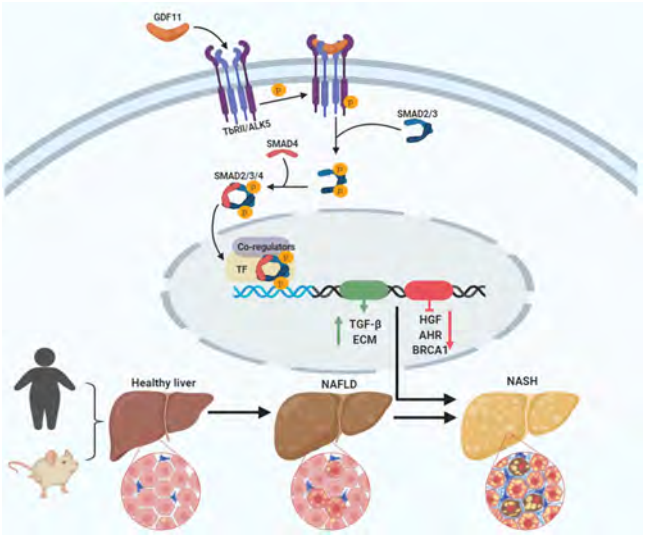
exacerbated liver fibrosis without changes in total liver lipid amount and composition. GDF11 mRNA levels showed significant positive correlation with Kleiner score (NAFLD activity score) in all patients but correlations between GDF11 expression levels and those of genes CPT1, PPAR-gamma, SREBP1 and Col1A1 were significant only in morbidly obese patients with NASH (not in the NAFLD subgroup).



Conclusion: The use of GDF11 is harmful in the context of obesity dependent NAFLD as its supplementation leads to the promotion of liver fibrosis in both *in vitro* and *in vivo*. Taking into the account the high prevalence of NAFLD in the developed countries (up to 30% of the general population), caution should be taken when considering therapies based on GDF11 regulation or supplementation.

SAT025

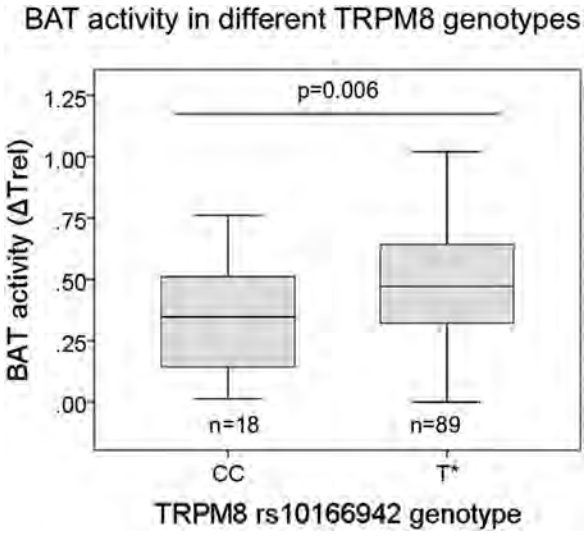
The influence of TRPM8 variant on brown adipose tissue activity and contribution to increased susceptibility to non-alcoholic fatty liver disease among South Asians

Jane Chalmers[1,2], Declan Wayne[3], Jane Grove[1,2], Michael Symonds[3], Helen Budge[3], Harold Sacks[4], Leena Mohan[5,6], KT Shenoy[5], Guruprasad Aithal[1,2]. *[1]Nottingham University Hospitals NHS Trust and the University of Nottingham, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom; [2]University of Nottingham, Nottingham Digestive Diseases Centre, School of Medicine, Nottingham, United Kingdom; [3]University of Nottingham, Division of Child Health, Obstetrics and Gynaecology, School of Medicine, Nottingham, United Kingdom; [4]VA West Los Angeles Healthcare System; [5]Population Health and Research Institute, Thiruvananthapuram, Kerala, India; [6]Holistic Health and Research Institute, Thiruvananthapuram, Kerala, India*
Email: jane.grove@nottingham.ac.uk

Background and Aims: South Asians are at risk of developing non-alcoholic fatty liver disease (NAFLD) and diabetes at a lower BMI than Caucasians. Brown adipose tissue (BAT) activity is linked to whole-body energy expenditure, body fat and it's associated metabolic complications. We recently demonstrated that native Indians have lower BAT activity than Caucasians. The single nucleotide polymorphism encodes a cold receptor with a putative role in physiological thermoregulation and adaption to cold environments. We hypothesise that presence of the TRPM8 variant influences BAT activity and may contribute to the susceptibility of South Asians to the metabolic syndrome including NAFLD.

Method: BAT activity was assessed in 24 native Indian (10 NAFLD, 14 control), 32 UK South Asian (17 NAFLD, 15 control) and 51 UK Caucasian (21 NAFLD, 30 control) male participants using a thermal imaging method measuring the change in temperature within the supraclavicular fossa relative to a reference point (Trel), following cold stimulus. TRPM8 rs10166942 genotyping was performed using real-time PCR.

Results: T allele frequency among Caucasians and South Asians was 0.8 and 0.48 respectively. Presence of T allele was strongly associated with increased BAT activity (0.49+/−0.22 vs 0.33+/−0.21 p = 0.006). On univariate analysis, T allele was associated with higher BMI (27.2 vs 24.7 p = 0.017), prevalent diabetes (41.6% vs 16.7% p = 0.046), but lower likelihood of NAFLD (39.3% vs 72.2% p = 0.01). Through multiple logistic regression modelling, adjusting for BMI, presence of diabetes and BAT activity, T allele was negatively associated with NAFLD (odds ratio 0.06 (0.008, 0.43; p = 0.005)).



Conclusion: Possession of the TRPM8 T allele variant is associated with increased BAT activity. Environmental factors interacting with a lower prevalence of T allele may result in reduced BAT activity among South Asians and hence, account for increased risk of NAFLD and other metabolic consequences observed in this community.

SAT026

Combinatorial effect of ezetimibe and empagliflozin in non-alcoholic fatty liver disease in a mouse model and a liver organoid for disease modeling of hepatic steatosis

Dongyun Kim[1], Kyu Sik Chung[2], Heon Yung Gee[1], Jun Yong Park[3,4]. *[1]Yonsei University Graduate School of Medicine, Department of Pharmacy, Seoul, Korea, Rep. of South; [2]Yonsei University Graduate School of Medicine, Department of Medicine, Korea, Rep. of South; [3]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [4]Severance Hospital, Yonsei Liver Center, Seoul, Korea, Rep. of South*
Email: drpjy@yuhs.ac

Background and Aims: Sodium-glucose cotransporter 2 inhibitor (SGLT2i) and ezetimibe, a cholesterol-lowering drug by targeting NPC1L1, have shown therapeutic potential for non-alcoholic fatty liver disease (NAFLD). SGLT2i and ezetimibe have different pharmacological mechanism, we hypothesized the combination of empagliflozin (selective SGLT2i) and ezetimibe could improve NAFLD additively

Method: We used the choline-deficient high fat diet (CD-HFD)-induced murine model of NAFLD that has key features of human metabolic syndrome. 6-week-old C57BL/6J mice were fed a CD-HFD for 8 weeks. Then these mice were divided into four groups: vehicle, ezetimibe (10 mg/kg), empagliflozin (10 mg/kg), and ezetimibe

(10 mg/kg) + empagliflozin (10 mg/kg). After 8 weeks, mice were sacrificed and subjected to blood measurements, and tissues for RNA isolation, lipid measurements and histology.
Results: Ezetimibe, empagliflozin, and combination therapy significantly reduced liver steatosis. However, the histological NAFLD activity score (NAS) was most improved in the ezetimibe/empagliflozin group (0.667) than in the ezetimibe group (2.0, P = 0.032) or empagliflozin group (3.33, P = 0.043). Hepatic lipid contents were also significantly lower in the ezetimibe/empagliflozin group compared to other groups. Hepatic expression of lipogenesis genes such as FAS (Fatty Acid Synthase), ACC1 (Acetyl-CoA carboxylase 1) were significantly decreased in the ezetimibe/empagliflozin group. For in vitro study of ezetimibe and/or empagliflozin, we utilized murine liver organoids and provided them with fatty acid to induce hepatic steatosis. Lipid accumulation was observed in liver organoids treated with fatty acid compared with control. When liver organoids with fatty acid were also treated with ezetimibe and/or empagliflozin, lipid accumulation was most diminished in the ezetimibe/empagliflozin group by measuring fluorescence intensity.
Conclusion: Our data suggested that combined administration of empagliflozin and ezetimibe can additively improve NAFLD by decreasing lipogenesis. These results provide new insight into pathogenesis and strategies for treatment of the NAFLD.

SAT027
Deviations of the peripheral blood and intrahepatic immune cell landscape between NAFLD patients and healthy controls
Tom Diedrich[1], Andreas Drolz[1], Ansgar Lohse[1], Johannes Kluwe[1], Julian Schulze Zur Wiesch[1]. *[1]University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany*
Email: julianszw@gmail.com

Background and Aims: Multiple factors are involved in the pathogenesis of NAFLD, but the exact immunological mechanisms that cause inflammation and fibrosis of the liver remain enigmatic. Several immune cells including cytotoxic T cells, Th17 cells, regulatory T cells (Tregs), mucosal associated invariant T (MAIT) cells, γδT cells, iNKT cells and natural killer (NK) cells have been found as being altered in the lobar inflammation of NAFLD patients. However, the significance and directionality of these differences are still controversially discussed, especially with respect to human NAFLD.
Method: In this study, we present 16-color flow cytometric data of a cohort of NAFLD patients (PBMC: n = 27, liver samples: n = 15) in comparison with healthy individuals (PBMC: n = 26, liver samples: n = 3) assessing the frequency and phenotype of 23 immune cell subtypes that were correlated with clinical data.
Results: PBMC of NAFLD patients showed decreased frequencies of total CD3+, CD8+ T cells, CD56dim NK cells and MAIT cells, but elevated frequencies of CD4+ T cells and Th2 cells compared to healthy controls. IHL of NAFLD patients showed decreased frequencies of total T cells, total CD8+ T cells, Vd2+ gamma delta T cells, and CD56bright NK cells, but elevated frequencies of Vdelta2- gamma delta T cells and CD56dim NK cells compared to healthy controls. The activating receptor NKG2D was significantly less frequently expressed among iNKT cells, total NK cells and CD56dim NK cells of PBMC of NAFLD patients compared to healthy controls. More strikingly, hepatic fibrosis as measured by fibroscan elastography negatively correlated with the intrahepatic frequency of total NK cells (r^2 = 0,3737, p = 0,02). Hepatic steatosis as measured by controlled attenuation parameter (CAP) value negatively correlated with circulating NKG2D+ iNKT frequency (r^2 = 0,3365, p = 0,0047).
Conclusion: Our data provide an overview of the circulating and intrahepatic immune cell composition of NAFLD patients, and point towards a potential role of NK cells and iNKT cells in the regulation of hepatic fibrosis and steatosis in NAFLD.

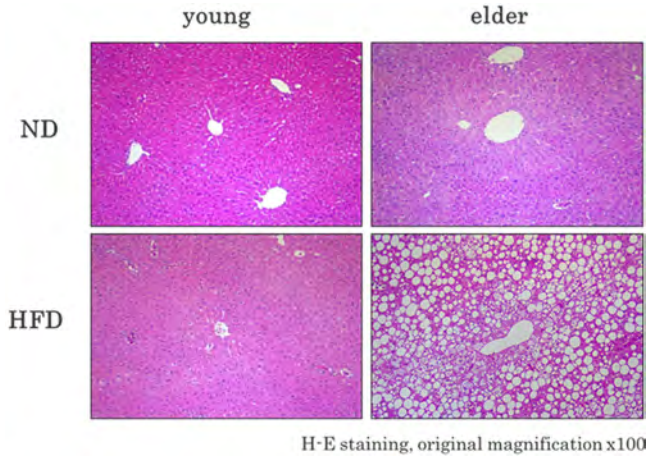
Schattenberg[6], Vlad Ratziu[7], Elisabetta Bugianesi[8], Ann K Daly[1], Quentin Anstee[1,9]. *[1]Newcastle University, Translational and Clinical Research Institute; [2]Newcastle University, Bioinformatics Support Unit; [3]Newcastle University, Biosciences Institute; [4]Linköping University; [5]Sorbonne Université, INSERM Nutriomique Research Unit; [6]University Medical Center Mainz, Metabolic Liver Research Program, I. Department of Medicine, Mainz, Germany; [7]University Paris-Diderot, Assistance Publique-Hôpitaux de Paris; [8]University of Turin, Department of Medical Sciences, Division of Gastro-Hepatology; [9]Newcastle upon Tyne Hospitals NHS Trust, Newcastle NIHR Biomedical Research Centre*
Email: katherine.johnson@ncl.ac.uk

Background and Aims: The current gold standard of non-alcoholic fatty liver disease (NAFLD) diagnosis is based on histological scoring of liver biopsies. Disease activity can be graded using the NAFLD activity score (NAS), calculated as the sum of Kleiner inflammation, ballooning and steatosis scores. Liver biopsies carry inherent risks and so circulating biomarkers are needed to circumvent the requirement for such invasive procedures. MicroRNAs (miRNAs) are small (~22 nt) non-coding RNA molecules that post-transcriptionally regulate gene expression and are known to be expressed in serum. Circulating miRNAs have been characterised as diagnostic biomarkers for a range of diseases. Accordingly, we sequenced over 2,000 serum miRNAs in a discovery cohort of patients across the NAFLD spectrum to establish a profile of circulating miRNAs from which novel disease biomarkers could be identified.
Method: miRNA libraries, using 15 µl serum for each of 183 NAFLD patients and ten healthy controls, were generated by HTG EdgeSeq and sequenced by Illumina NextSeq. Limma in the R software environment was used to perform analyses on the data. Data were normalised and corrected for batch effects. MiRNAs with a mean counts per million of >=100, a log2 fold-change (logFC) of >=0.3 and an adjusted *p* value of <=0.05 were classified as differentially expressed.
Results: Seven miRNAs were differentially expressed in severe disease activity (NAS5-8) relative to mild (NAS1-4), with miR-193a being the most significant (logFC = 0.68, *p* = 3.0 × 10^−07, AUROC = 0.71). Additionally, miR-193a was the most significant (logFC = 1.5, *p* = 3.5 × 10^−10, AUROC = 0.94) of 121 differentially expressed miRNAs above a more stringent logFC threshold of >=1 in NAFLD patients relative to controls. Distilling NAFLD into steatosis and non-alcoholic steatohepatitis (NASH) with fibrosis stage (F0-F4) confirmed a consistent and significant upregulation of miR-193a in each of the classifications relative to the controls.
Conclusion: We have identified a potentially clinically significant differentially expressed circulating miRNA, which appears to primarily reflect NAFLD grade and activity. Quantification of miR-193a may facilitate non-invasive NAFLD diagnoses. This, along with other significantly differentially expressed miRNAs, is currently being validated in an independent cohort of samples using qPCR.

SAT029
Ageing causes lipid metabolism imbalance and exacerbates steatohepatitis in high-fat diet-fed mice
Kazuyoshi Kon[1], Kei Ishizuka[1], Hyeon-Cheol Lee[2], Kumiko Arai[1], Akira Uchiyama[1], Hiroo Fukada[1], Shunhei Yamashina[1], Takehiko Yokomizo[2], Kenichi Ikejima[1]. *[1]Juntendo University Graduate School of Medicine, Department of Gastroenterology, Tokyo, Japan; [2]Juntendo University Graduate School of Medicine, Department of Biochemistry, Tokyo, Japan*
Email: kazukon@juntendo.ac.jp

Background and Aims: Aging is an independent risk factor for the progression of nonalcoholic steatohepatitis (NASH); however, the role of aging in lipotoxicity, a major contributor to NASH, has not been fully understood. We investigated the impact of aging on lipotoxicity using aged mice.
Method: Male C57BL/6J mice aged 8 and 55 w.o. (young and elder, respectively) were fed either high-fat diet (HFD) or normal diet for 8 wks. Liver tissues were stained by immunohistochemistry for 4-hydroxynonenal (4-HNE) and Sirius-Red. Hepatic lipid composition was comprehensively analyzed using liquid chromatography coupled to tandem mass spectrometry. The expression of mRNA was determined by RT-PCR.
Results: Following HFD-feeding, elder mice developed massive steatohepatitis with hepatocyte ballooning and pericellular fibrosis, whereas young mice only developed mild steatosis (Figure). Serum ALT levels following HFD feeding were much higher in elder mice than in young mice (192 ± 17 IU/L vs. 34 ± 4 IU/L). Antioxidant enzymes such as superoxide dismutase-1, -2 and catalase mRNA were significantly decreased following a HFD in elder mice compared to young mice. In contrast, the expression of mRNA for heme oxygenase 1, tumor necrosis factor alpha, IL-6, and transforming growth factor beta following an HFD was more increased in elder mice than young mice. Higher expression of 4-HNE was also observed in elder mice fed an HFD. Lipidomics analysis revealed that HFD-feeding increased triacylglycerol and diacylglycerol predominantly containing 18:1n-9 and decreased phospholipids containing poly unsaturated fatty acid such as 22:6n-3 and 22:5n-3 in liver of elder mice compared to young mice. The HFD-induction of sterol regulatory element-binding transcription factor 1c (SREBP1c) mRNA was significantly enhanced in elder mice compared to young mice. Carnitine palmitoyltransferase IA (CPT1A) mRNA levels were increased following HFD-feeding in young mice; however, the levels were reciprocally decreased in elder mice. Peroxisome proliferator-activated receptor alpha mRNA levels were also decreased following HFD significantly in elder mice. The expression of elongation of long chain fatty acids family member 6 (ELOVL6) mRNA was equally enhanced in both young/elder mice following HFD. In contrast, fatty acid desaturase (FADS) 1 and 2 mRNA were significantly decreased in elder mice fed an HFD as compared to young mice.



H-E staining, original magnification x100

Conclusion: Elder mice developed severe steatohepatitis following diminished antioxidant enzymes as compared to young mice by same period of HFD feeding. Our findings indicated that imbalance among lipogenesis/lipolysis/lipid desaturation against HFD causes lipotoxicity by altering the lipid composition of neutral lipids and phospholipids. Correction of lipid metabolism imbalance is a potential therapeutic target for preventing exacerbation of steatohepatitis by aging.

SAT032

Anti-inflammatory and anti-fibrotic activity of TERN-201, a semicarbazide-sensitive amine oxidase inhibitor, in a rat choline-deficient high-fat diet non-alcoholic steatohepatitis model

Kevin Klucher[1], Christopher Jones[1], Zhou Zhou[2], Martijn Fenaux[1].
[1]Terns Pharmaceuticals, Inc., Foster City, United States; [2]Terns China Biotechnology Co., Ltd, Shanghai, China
Email: kklucher@ternspharma.com

Background and Aims: Infiltration of leukocytes into the liver is a characteristic of non-alcoholic steatohepatitis (NASH), leading to tissue inflammation and liver injury. Semicarbazide-sensitive amine oxidase (SSAO), also known as vascular adhesion protein 1 (VAP-1), is a dual function cell adhesion molecule with a unique amine oxidase ecto-enzyme activity significantly increased in patients with NASH and independently associated with liver fibrosis stage. SSAO catalyses the oxidative deamination of aliphatic and aromatic primary amines, generating toxic products that increase systemic oxidative stress and damage the vasculature, mediating leukocyte entry into inflammatory sites. TERN-201, a novel, selective SSAO inhibitor currently in clinical development for NASH, was tested in a rat choline-deficient NASH model.
Method: Male Wistar rats were fed with a choline-deficient high fat diet (CDHFD) for 4 weeks followed by tri-weekly intraperitoneal sodium nitrite ($NaNO_2$) treatment to induce fatty liver disease and fibrosis, respectively. TERN-201 dosing was administered for 8-weeks concomitant with the start of $NaNO_2$ treatment. Serum lipids, liver enzymes and liver tissue were then analysed for changes from baseline. RNA levels of genes known to be involved in liver inflammation or fibrosis were also measured as biomarkers of drug activity.
Results: In CDHFD rats chronically treated with $NaNO_2$, treatment with TERN-201 increased the plasma concentration of methylamine indicating on-target SSAO inhibition. TERN-201 strongly reduced liver inflammation ($p < 0.001$) and gene expression associated with inflammation. Fibrosis related gene expression was also strongly reduced in the liver with TERN-201 treatment ($p < 0.005$), concomitant with a reduction in the histological fibrosis score ($p < 0.05$). TERN-201 treatment reduced GGT levels ($p < 0.05$), a marker of liver injury. As expected for an anti-inflammatory agent, TERN-201 did not induce changes in liver steatosis or serum lipids.
Conclusion: TERN-201 strongly inhibited liver inflammation in a rat model of NASH. A reduction in liver fibrosis markers was also seen, supporting the further development of this drug in patients with NASH.

SAT033

Cognitive dysfunction occurs early in experimentally induced NAFLD and is associated with systemic inflammation

Kristoffer Kjærgaard[1], Anne Catrine Daugaard Mikkelsen[1], Annie Landau[2,3], Peter Lykke Eriksen[1], Stephen Hamilton-Dutoit[4], Rajiv Jalan[5], Nils Erik Magnusson[6], Raj Mookerjee[1,5], Cecilie Bay-Richter[3], Karen Louise Thomsen[1,5]. *[1]Aarhus University Hospital, Department of Hepatology and Gastroenterology, Aarhus N, Denmark; [2]Aarhus University Hospital, Department of Nuclear Medicine and PET-Centre, Aarhus N, Denmark; [3]Aarhus University, Translational Neuropsychiatry Unit, Aarhus C, Denmark; [4]Aarhus University Hospital, Department of Pathology, Aarhus N, Denmark; [5]University College London, UCL Institute of Liver and Digestive Health, London, United Kingdom; [6]Aarhus University Hospital, Medical Research Laboratory, Aarhus N, Denmark*
Email: krikje@clin.au.dk

Background and Aims: A key factor now recognized in non-alcoholic fatty liver disease (NAFLD) is impaired cognition, which may affect up to 70% of NAFLD cases with significant socio-economic impacts. Chronic low-grade systemic inflammation is well described in NAFLD. The aim of this study was to address the importance of chronic low-

grade systemic inflammation in the development of cognitive dysfunction in NAFLD.

Method: Using a well-established model of NAFLD representing "western diet," 20 male Sprague Dawley rats were fed either a high-fat, high-cholesterol (HFHC) diet for 16 weeks or standard diet (10 per group). These animals were assessed for behavioural changes using previously validated neuropsychological tests, and inflammation studied through a broad panel of cytokines. Liver histology was assessed to stage NAFLD severity.

Results: The HFHC diet resulted in significant behavioural changes compared to standard diet: HFHC rats manifest a depressive affect evidenced by a significant reduction in survival behaviour ($p = 0.031$) and increased immobility ($p = 0.011$) in Porsolt's Swim Test. Moreover, the Novel Object Recognition test showed that HFHC rats displayed cognitive impairment, with impaired memory of previously encountered objects ($p = 0.047$). Chronic low-grade inflammation was confirmed in HFHC rats with significant increases in IFN-γ, GRO/KC, IL-1a, IL-2, IL-6, IL-10, IL-13, IL-17, MIP-1a, RANTES and MCP-1 (all $p < 0.05$). Histopathological assessment confirmed early NAFLD with extensive steatosis and lobular inflammation but no fibrosis in HFHC rats

Conclusion: This study shows that cognitive impairment and depression-like behaviour is present in a preclinical model of early NAFLD. These neurobehavioural changes were accompanied by chronic low-grade inflammation which may contribute to neuroinflammation, as is observed in many neurodegenerative diseases. Our observations, if extrapolated to humans, suggest a substantial disease burden and potential socio-economic impact of cognitive dysfunction in early NAFLD, even before fibrosis progression. These findings require further validation in patients.

SAT034

Thr ß-selective agonist MGL-3196 improves NAS score and plasma lipoprotein profile in the liver-humanized FRGN KO NASH model

Lander Foquet[1], Edward Henson[1], Markus Grompe[2], Rob Copenhaver[1]. [1]*Yecuris, Portland, United States;* [2]*Oregon Health & Science University, Portland, United States*
Email: landerfoquet@yecuris.com

Background and Aims: Current preclinical rodent models of NAFLD and NASH are inadequate at predicting human clinical responses to pharmaceutical intervention because they do not show the full pathology of human disease and are incapable of modeling the role of specific genotypes known to influence disease progression within the context of human cellular signaling pathways.

Building on the liver-humanized FRGN mouse platform, we previously established an in vivo model, that recapitulates NAFLD/NASH with only high-fat diet fed to animals repopulated hepatocytes from a PNPLA3-148M homozygous donor. This I148M variant is significantly associated with a high risk of NASH development.

Method: FRGN KO mice were transplanted with human hepatocytes from a donor homozygous for the G allele on the minus strand of rs738409 in PNPLA3. After near complete repopulation of the liver with human hepatocytes, animals received a diet with 40 kcal% Fat, 20 kcal% fructose, and 2% cholesterol.

As a proof-of-concept, liver-humanized animals on HFD were treated during eight weeks with MGL-3196, a first-in-class, orally-administered, small molecule, liver-directed, thyroid hormone receptor (THR) ß-selective agonist.

Results: Both control and NASH-induced liver-humanized animals remained highly repopulated over the course of the study. Body weight and liver to body weight ratios increased in humanized mice on HFD compared to controls.

Liver-humanized mice show a lipid chemistry profile similar to humans (LDL/HDL ratio of ~1.6). After four weeks, the humanized animals on HFD had cholesterol levels significantly higher than control humanized animals. From week 8 to week 24, key NASH characteristics were increasingly detectable in the HFD fed animals: steatosis, hepatocyte ballooning, Mallory bodies, collagen deposition, and bridging fibrosis.

During the intervention study, liver-humanized FRGN KO mice were dosed with MGL-3196 for 8 weeks after inducing NASH for 8 weeks. The animals continued to receive HFD during the study.

Animals dosed with MGL-3196 showed a smaller liver compared to controls. Blood LDL was reduced by 14.3%. A 2-point reduction in NAS (NAFLD activity score) of 2.17 vs 4.25 was observed. This was mainly due to a reduction in steatosis. Fibrosis was not affected by the treatment and ranged from mild to perivenular/ pericellular (score 1 to 2).

Conclusion: FRGN KO mice repopulated with human PNPLA3-148M hepatocytes and fed HFD developed key aspects of NASH. Unlike current rodent models, the blood lipid profiles resembled those in humans with NAFLD. Histological analysis showed time-dependent progressive accumulation of typical NASH features.

As a proof-of-concept, FRGN KO mice were dosed with MGL-3196. Steatosis was reduced as shown by a significant reduction in the NAS score.

These results suggest that liver-humanized FRG KO mice fed an HFD may be a superior model for NASH.

SAT035

TM6SF2/PNPLA3/MBOAT7 loss-of function genetic variants impact on NAFLD development and progression both in patients and in in vitro models

Miriam Longo[1,2], Marica Meroni[1,3], Veronica Erconi[1], Anna Alisi[4], Luca Miele[5], Raffaela Rametta[1], Anna Ludovica Fracanzani[1,3], Luca Valenti[3,6], Paola Dongiovanni[1]. [1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, General Medicine and Metabolic Diseases, Milano, Italy;* [2]*Università degli Studi di Milano, Department of Clinical Sciences and Community Health, Milano, Italy;* [3]*Università degli Studi di Milano, Department of Pathophysiology and Transplantation, Milano, Italy;* [4]*"Bambino Gesù" Children's Hospital IRCCS, Research Unit of Molecular Genetics of Complex Phenotypes, Roma, Italy;* [5]*Fondazione Policlinico Universitario A. Gemelli IRCCS, Area Medicina Interna, Gastroenterologia e Oncologia Medica, Roma, Italy;* [6]*Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Trasfusional Center-Translational Medicine, Milano, Italy*
Email: longo.miriam92@gmail.com

Background and Aims: The I148M *PNPLA3* and E167K *TM6SF2* variants alongside the rs641738 polymorphism in *MBOAT7/TMC4* locus represent the main genetic risk factors for non-alcoholic fatty liver disease (NAFLD). We previously generated a full knock-out (KO) of *MBOAT7* in HepG2 cells, homozygous for the I148M PNPLA3 (I148M MBOAT7$^{-/-}$). We aimed to 1) investigate the synergic impact of the 3 risk variants on liver injury and hepatocellular carcinoma (HCC) in NAFLD patients 2) create *in vitro* models of genetic NAFLD by silencing *TM6SF2* in I148M and I148M MBOAT7$^{-/-}$ cells.

Method: NAFLD patients (n = 1194) of whom 72 had HCC were stratified according to the presence of *PNPLA3*, *TM6SF2* and *MBOAT7* at risk variants as follows: 0 (none), 1 (1 variant in *PNPLA3*, *TM6SF2* or *MBOAT7*), 2 (2 variants) and 3 (patients carrying all the 3 variants). The additive weight of the mutations was correlated with liver disease severity. Finally, we silenced *TM6SF2* in HepG2 (I148M TM6SF2$^{-/-}$) and I148M MBOAT7$^{-/-}$ (I148M MBOAT7$^{-/-}$TM6SF2$^{-/-}$) through CRISPR/Cas9.

Results: At bivariate analysis, the co-presence of the 3 risk variants correlated with the grade of steatosis ($p < 0.0001$), lobular inflammation ($p = 0.009$), ballooning ($p = 0.004$) and fibrosis ($p < 0.0001$). At nominal logistic regression analysis adjusted for age, sex, BMI and T2D, patients carrying the 3 variants showed ~4-fold higher risk of fibrosis>2 ($p = 0.002$), cirrhosis ($p = 0.02$) and HCC ($p = 0.09$). In I148M TM6SF2$^{-/-}$ and I148M MBOAT7$^{-/-}$TM6SF2$^{-/-}$ cells, intracellular lipid droplets and TG content were higher than in I148M HepG2 ones ($p < 0.01$), and the expression of genes involved in *de novo* lipogenesis, cholesterol biosynthesis and β-oxidation was altered (p

< 0.05). Moreover, markers of endoplasmic reticulum (*XBP1*, *GRP78*) and oxidative stress, as well as lipid peroxidation and DNA damage were increased (p < 0.05). Cell injury was greater in I148M MBOAT7$^{-/-}$ TM6SF2$^{-/-}$ cells as they had the highest levels of XBP1, GRP78 and free radicals (p < 0.05). Finally, both models showed higher proliferation rate compared to control (p < 0.01), but still more in I148M MBOAT7$^{-/-}$TM6SF2$^{-/-}$ cells (p < 0.05).

Conclusion: We firstly generated an *in vitro* stable compound knockout of genetic NAFLD. The co-presence of the 3 risk variants impacts on NAFLD development and progression, in both human patients and experimental models. In particular, *TM6SF2* silencing alone or combined with I148M PNPLA3 and MBOAT7 KO contributes to hepatocellular damage and cell proliferation.

SAT036

Enhancing autophagy improves and slows the progression of non-alcoholic steatohepatitis disease

Maria Ruart[1], Nuria Suárez-Herrera[1], Genís Campreciós[1,2], Carla Montironi[3,4], Celia Martínez Sánchez[5], Erica Lafoz[1], Héctor García-Calderó[1,2], Tiago Da Silva Ramos[1], Marina Vilaseca Barceló[1], Anna Oncins[1], Pol Olivas[1,5], Mar Coll[2,5], Isabel Graupera[2,5], Scott Friedman[6], Juan Carlos Garcia Pagan[1,2,5], Virginia Hernandez-Gea[1,2,5]. *[1]Hospital Clínic-IDIBAPS. UB, Barcelona Hepatic Hemodynamic Laboratory, Liver Unit, Barcelona, Spain; [2]Centro de Investigación Biomédica Red de enfermedades hepáticas y digestivas (CIBEREHD), Madrid, Spain; [3]Hospital Clinic, Pathology Department, Barcelona, Spain; [4]IDIBAPS-Hospital Clínic, UB., Liver Cancer Translational Research Group, Liver Unit, Barcelona, Spain; [5] Hospital Clínic-IDIBAPS, Liver Unit, Barcelona, Spain; [6]Icahn Medical School at Mount Sinai, Division of Liver Diseases, New York, United States*
Email: vihernandez@clinic.cat

Background and Aims: Loss of endothelial cell (LSEC) phenotype, or endothelial dysfunction (ED), has been associated with the progression from non-alcoholic fatty liver disease (NAFLD) to non-alcoholic steatohepatitis (NASH). NASH is associated with defects in endothelial autophagy, which maintains LSEC phenotype. Spermidine (SPD) is a polyamine that activates autophagy and has beneficial effects on cardiovascular endothelium. Our hypothesis is that enhancement of autophagy with SPD could alleviate NAFLD progression.

Method: The impact of SPD treatment on autophagy and endothelial phenotype were evaluated in vitro in mouse LSEC (TSEC). Wild-type mice were pretreated with SPD (in drinking water) for two weeks and continued in a concomitant fashion with a 60% kcal fat-deficient choline diet (CDAAH, Br J Pharmacol. 2018) during 9 weeks. We evaluated autophagy levels and its impact on liver damage, ED, oxidative stress, inflammatory response and liver fibrosis.

Results: SPD activated autophagy in TSEC in vitro and in whole liver in vivo. NASH mice treated with SPD showed a decrease in adipose tissue mass as well as an improvement in basal glucose, consistent with amelioration of the metabolic phenotype. SPD had a hepato-protective effect with an improvement of ED and reduction of fibrosis degree. Changes in hepatocyte ballooning degree were observed but not in steatosis. SPD treatment reduced mitochondrial oxidative stress and activated the selective degradation of dysfunctional mitochondria (mitophagy), leading to an improvement in mitochondrial phenotype. Interestingly, SPD had also an anti-inflammatory effect in NASH mice, characterized by a deactivation of the NLRP3 inflammasome and a reduction of proinflammatory macrophage phenotype. No toxicity was observed. Finally, enhancement of autophagy by SPD improved endothelial response to oxidative stress by means of increased viability, reduced ROS production and improved mitochondrial phenotype.

Conclusion: Autophagy inducement by SPD promotes endothelial response to oxidative stress by eliminating dysfunctional mitochondria, improving ED, reducing inflammation and attenuating liver fibrosis during the progression of NASH disease and may be a new and attractive antifibrotic strategy.

SAT037

The PSRC1 rs599839 A > G variant disentangles the risk of coronary artery disease and hepatocellular carcinoma in Italian NAFLD patients

Email: paola.dongiovanni@policlinico.mi.it

Background and Aims: Several inherited variants that regulate hepatic lipid handling increase the susceptibility to develop nonalcoholic fatty liver disease (NAFLD) and progress to nonalcoholic steatohepatitis (NASH), fibrosis and hepatocellular carcinoma (HCC). Dyslipidemia and enhanced cardiovascular risk are typical features of NAFLD. The rs599839 A > G variant in the 3' UTR region of PSRC1, located in the CELSR2-PSRC1-SORT1 locus, has been previously associated with coronary artery disease (CAD) and reduced circulating lipids. Aim was to examine the impact of the rs599839 variant on metabolic traits and liver damage in a large histologically characterized cohort of patients at risk of NASH.

Method: We studied the impact of the rs599839 variant in 1224 Italian NAFLD patients (Liver Biopsy Cohort (LBC)), in 500,000 individuals (UK Biobank Cohort (UKBBC)) and in 366 HCC (The Cancer Genome Atlas (TCGA)). Hepatic expressions of PSRC1, SORT1 and CELSR2 genes were evaluated by RNAseq in a subset of patients (n = 125).

Results: The rs599839 G allele was associated with lower circulating LDL (beta: –0.19; 95%c.i.–0.3–0.09; p = 0.0003), higher HDL (beta: 0.07; 95%c.i. 0.03–0.10; p = 0.0008), reduced intima-media thickness (beta: -0.06; 95%c.i.–0.1–0.01; p = 0.008), decreased carotid plaques (OR: 0.23; 95%c.i. 0.04–1.3; p = 0.09) and hypertension (OR: 0.43; 95% c.i. 0.18–0.98; p = 0.04) in LBC and with the protection from dyslipidemia in UKBBC. Concerning the liver damage, G allele was associated with ballooning (beta: 0.26; 95%c.i. 0.01–0.51; p = 0.03) and HCC risk (OR: 1.92; 95%c.i. 1.06–3.50; p = 0.03; N = 72 cases) in LBC, but not in UKBBC. Carriers of G allele showed increased hepatic expression of PSRC1, SORT1 and CELSR2 (p < 0.0001). PSRC1 mRNA levels negatively correlated with those of genes involved in lipoprotein release (APOB and DGAT2) (p < 0.0001), while positively with those of genes implicated in cell proliferation (PCNA and TP53) (p < 0.0001). In TCGA, PSRC1 expression was associated with tumor stage worsening (beta: 0.40; 95%c.i. 0.05–0.27; p = 0.006), advanced histological grade (beta: 0.17; 95%c.i. 0.05–0.29; p = 0.005) and tumor extension (beta: 0.17; 95%c.i. 0.06–0.28; p = 0.003). As in LBC, PSRC1 expression negatively correlated with that of APOB and DGAT2, and positively with SORT1, CELSR2 and PCNA (p < 0.01).

Conclusion: The PSRC1 rs599839 A > G variant disentangles the risk of CAD and HCC in Italian NAFLD patients, likely by modulating PSRC1, SORT1 and CELSR2 expressions.

SAT038

The FASN inhibitor TVB-2640 is efficacious in a new 3D human liver microtissue model of NASH

Marie O'Farrell[1], Doug Buckley[1], George Kemble[1]. [1]*Sagimet Biosciences, San Mateo, United States*
Email: marie.ofarrell@sagimet.com

Background and Aims: Fatty acid synthase (FASN) is a central mediator of de novo lipogenesis (DNL) which converts dietary sugar into the fatty acid palmitate, a key signaling molecule and building block for long chain fatty acids. Increased hepatic DNL increases liver fat content, a hallmark of NAFLD (non alcoholic fatty liver disease). TVB-2640 is an oral, selective and reversible inhibitor of FASN. In a recent Ph1b study in men with characteristics of metabolic syndrome, with BMI's from 33 to 44, TVB-2640 dose-dependently reduced fasting hepatic DNL by up to 90%. FASN inhibitors reduce steatosis, inflammation and fibrosis in diseased livers of diet induced obese (DIO) murine NASH models. TVB-2640 is currently being tested in a Phase 2 study in patients with NASH, with a primary endpoint of liver fat content by MRI-PDFF imaging (NCT03938246).
Method: To better evaluate the mechanisms underlying the activity of FASN inhibitors in NASH we used a human liver tissue 3D model recently developed by InSphero (3D Insight Human Liver MicroTissue NASH Model (LMT). This model incorporates the critical primary human liver cell types including hepatocytes, Kupffer cells, hepatic stellate cells and hepatic endothelial cells and can be stimulated and tuned to recapitulate the continuum of NASH in 10 days. We report the testing of TVB-2640 in this model at dose levels from 30 nM to 3 uM, using the full complement of NASH inducers (fatty acids, sugars and LPS).
Results: Stimulation of LMTs with fatty acids, sugars and LPS induced changes consistent with NASH including steatosis, inflammation and fibrosis, with increased cellular triglycerides (TGs) and elevated cytokines. TVB-2640 was well tolerated with no observed toxicity. Following 5 days of treatment, TVB-2640 significantly reduced excess intracellular TGs by 57% ($p < 0.05$), compared to levels in non-NASH cultures; in contrast neither an ALK5 inhibitor (SB525334) nor a PPAR agonist (Elafibranor) reduced TGs significantly. TVB-2640 also decreased secreted IP-10 (IFNy-Inducible Protein-10) at all dose levels tested indicating decreased inflammatory signaling.
Conclusion: This model reproduces multiple hallmarks of liver tissue damage in NASH and the results recapitulate FASN inhibitor activity in DIO mouse models. The current study will evaluate additional impacts on hallmarks of NASH by further analysis of secreted markers and immunohistochemistry. The LMT model may be very useful in dissecting the mechanism of action of TVB-2640 and can be used to assess mechanism-based rationale for combinations of NASH agents.

SAT039

SERPINB3 inhibition as a novel target therapy for non-alcoholic steatohepatitis

Andrea Martini[1], Gianmarco Villano[2], Santina Quarta[1], Cristian Turato[3], Mariagrazia Ruvoletto[1], Alessandra Biasiolo[1], Andrea Cappon[1], Erica Novo[4], Stefania Cannito[4], Maria Guido[1], Maurizio Parola[4], Patrizia Pontisso[1]. [1]*University of Padova, Department of Medicine, Italy;* [2]*University of Padova, Department of Surgery, Oncology and Gastroenterology, Padova, Italy;* [3]*Veneto Institute of Oncology, IOV-IRCCS, Italy;* [4]*University of Torino, Department of Clinical and Biological Sciences, Italy*
Email: martiniandrea86@gmail.com

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) and Non-Alcoholic Steatohepatitis (NASH) are increasingly relevant public health issues and their prevalence is predicted to increase in parallel with the increase of obesity and diabetes, but pharmacological treatments are still lacking. SerpinB3 is a serine protease inhibitor that progressively increases in the liver in relation to the extent of hepatic damage. In animal models of NASH, SerpinB3 transgenic mice display increased fibrosis and inflammation. 1-Piperidine Propionic Acid (PPA) has been recently identified as SerpinB3 inhibitor. The aim of this study was to evaluate the effect of PPA on NASH experimental models.
Method: Cell lines with different SerpinB3 expression have been incubated with PPA to assess its inhibitory activity. Real time cell proliferation was assessed using the xCELLigence instrument. Recombinant SerpinB3 (100 ng/ml) was also added to primary monocytes in the presence or absence of PPA. SerpinB3-transgenic and SerpinB3-KO mice and their control littermates were fed on MCD and CDAA diets to induce experimental NASH. Starting from the second and third month respectively, mice were injected daily with PPA (0,01 µg/g) and were sacrificed at week 8 (MCD diet) and 12 (CDAA diet). Liver pathology, IHC for F4/80, Sirius red staining, fibrosis and inflammation gene expression was carried out at sacrifice.
Results: In cell lines PPA was found to inhibit SerpinB3 mRNA expression in a dose dependent manner and these features were associated to a corresponding reduction of cell proliferation. In monocytes SerpinB3 induced overexpression of sCD163, a recognized marker of NASH, that was markedly inhibited by PPA. SerpinB3-KO mice showed significantly lower steatosis, inflammation and fibrosis after both dietary regimens, while opposite findings were observed in SerpinB3 transgenic mice. Treatment with PPA reverted these features, leading to liver profiles similar to controls. PPA significantly decreased gene expression of fibrosis and inflammation (alpha-SMA, IL-1beta, Collagen 1 and MCP-1) and lead to the activation of PPAR-gamma and PPAR-alpha.
Conclusion: SerpinB3 has been identified as a new druggable target for NASH and PPA proved to be an efficient compound that markedly reduces NASH through the inhibition of SerpinB3 and the activation of PPAR-gamma and alpha in the liver.

SAT040

Metabolism of human liver on a genome scale in non-alcoholic fatty liver disease

Department of Medicine, Mainz, Germany;* [7]*Cambridge University, United Kingdom*
Email: matej.oresic@oru.se

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a major risk factor leading to chronic liver disease and type 2 diabetes. By using patient-matched liver transcriptomics and serum metabolomics data from the EPoS European NAFLD Registry cohort, we conducted genome-scale metabolic modeling (GSMM) to dissect hepatic metabolism across the full spectrum of NAFLD, from steatosis (NAFL) to NASH-cirrhosis.
Method: We compared the genome-scale metabolic networks across different stages of NAFLD together with healthy controls (HC, n = 10), with the patients divided into three groups: steatosis (n = 60), NASH (n = 139; F0: n = 4, F1 n = 28, F2: n = 53, F3: n = 54) and cirrhosis (n = 14). Based on transcriptomics data obtained from the liver biopsy of the patients enrolled in the European NAFLD Registry, genome-scale metabolic models of the liver were developed and contextualized for these conditions. GSMM, as a scaffold, connects metabolic genes (i.e., enzymes) and metabolic pathways. Moreover, genome-scale networks can be constrained with multi-'omics' datasets, and thus connect an organism's genotype to phenotype.
Results: GSMM revealed that similar metabolic functions are perturbed in NAFL and NASH, while additional metabolic processes were regulated in advanced fibrosis/cirrhosis. The primary liver processes such as glycerophospholipid metabolism, chondroitin/heparan sulfate, bile acid and fatty acid biosynthesis and oxidation

(carnitine shuttle in mitochondria) were affected. Lipid precursors for VLDL particles were upregulated in NAFL. Integrative analysis of transcriptomics and serum metabolomics data also revealed that several microbial pathways are up-regulated in NAFLD and may contribute to pathogenesis.
Conclusion: A GSMM approach has identified common and specific liver metabolic pathways across different stages of NAFLD progression. Data were cross-validated by serum metabolomics, where in addition analysis also revealed that specific microbially-produced metabolites are elevated in NAFLD as compared to controls. These results provide important insights into the changes in hepatic metabolism occurring during NAFLD/NASH pathogenesis.

Email: mbafonso@ff.ulisboa.pt

Background and Aims: Necroptosis embodies an inflammatory cell death pathway dependent on receptor-interacting-protein kinase 3 (RIPK3) activity that may influence hepatocellular damage in non-alcoholic fatty liver disease (NAFLD). A signalling interplay between necroptosis and lipid metabolism is emerging. We aimed to evaluate the impact of RIPK3 signalling in lipid metabolism and in pathogenesis of human and experimental NAFLD.
Method: RIPK3 levels were evaluated in two independent cohorts of morbidly obese patients with biopsy-proven diagnosis of NAFLD (cohort A: n = 146; cohort B: n = 71), and correlated with clinical and biochemical parameters. C57BL/6 wild-type (WT) or RIPK3-deficient (*Rip3k*$^{-/-}$) mice were fed a choline-deficient L-amino acid-defined diet (CDAA; n = 14) or a control choline-sufficient L-amino acid-defined diet (CSAA; n = 14) for 32 and 66 weeks. Liver samples were processed for histological analysis. Relevant necroptosis, inflammation and fibrosis proteins and genes were also measured. Lipidomic analysis was performed and a profiler PCR array was used to evaluate expression of liver cancer-related genes.
Results: In cohort A, RIPK3 protein levels were increased in patients with more advanced fibrosis and higher NAS score, correlating with circulating hepatic transaminases. Similarly, RIPK3 mRNA was increased in cohort B NAFLD patients, comparing with healthy controls, correlating with the expression of collagen-1α1 and inflammatory and necroptosis-related proteins. In mice, RIPK3 deficiency ameliorated CDAA-induced inflammation and fibrosis. Intriguingly, *Rip3k*$^{-/-}$ mice displayed increased liver fat accumulation, body weight gain and circulating insulin levels, irrespective of the diet, when compared with WT mice. Lipidomics showed that deletion of RIPK3 shifted hepatic lipid species profiles, impacting on acyl chain length and saturation. In line with these metabolic changes, PPARγ was increased in the liver of *Rip3k*$^{-/-}$ mice. Finally, WT mice on the CDAA diet for 66 weeks developed preneoplastic nodules, which were reduced in *Rip3k*$^{-/-}$ mice. Indeed, microarray profiling and subsequent validation showed RIPK3 deficiency hampered tumourigenesis.
Conclusion: Hepatic RIPK3 correlates with NAFLD severity in humans and mice. RIPK3 plays an opposing role in controlling steatosis versus inflammation/carcinogenesis in CDAA-fed mice, suggesting that these two phenomena are dissociated events in NAFLD.

A novel FXR agonist EDP-297 exerts anti-inflammatory and hepatoprotective effects in human liver 3D microtissues and rodent NASH and liver injury models

Mary Chau[1], Manuel Roqueta-Rivera[1], Guoqiang Wang[1], Kelsey Garlick[1], Bindu Ramachandran[1], Kevin Mongeon[1], Nadya Bryan[1], Yat Sun Or[1], Bryan Goodwin[1]. [1]*Enanta Pharmaceuticals, Inc., Watertown, United States*
Email: bgoodwin@enanta.com

Background and Aims: The farnesoid X receptor (FXR) plays a central role in regulating bile acid and lipid homeostasis. In both preclinical and clinical settings, FXR agonists decrease liver steatosis and exert anti-inflammatory and anti-fibrotic effects, making FXR an attractive target for the management of non-alcoholic steatohepatitis (NASH). Here we report the identification of a novel, potent, FXR agonist EDP-297. The pharmacologic activity of EDP-297 was evaluated in multiple *in vitro* assays and further characterized in a human liver microtissue system and in rodent models of NASH and liver injury.
Method: Next generation sequencing of 3D InSight Human Liver Microtissue NASH model (InSphero, Schlieren, Switzerland) treated with vehicle or 1 μM EDP-297 for 10 days was performed for gene expression analysis. Male Sprague-Dawley rats that underwent sham or bile duct ligation (BDL) procedure (Charles River Laboratories, Wilmington, MA) were treated with vehicle or 1 mg/kg EDP-297, starting on Day 2 post surgery, for 5 days. Plasma biochemistry and cytokine levels were measured on the IDEXX Catalyst One analyzer or by Meso Scale Diagnostics assay (Rockville, MD). Male, biopsy-confirmed, AMLN diet-induced NASH mice (Gubra, Hørsholm, Denmark) were also treated with vehicle or EDP-297 for 12 weeks prior to sacrifice. Multiple markers of hepatic function and liver histology were evaluated.
Results: In a cell-based reporter assay, EDP-297 activated FXR with a half-maximal effective concentration (EC_{50}) of 0.2 nM. Expression of the bile salt export pump (*BSEP*) and other FXR target genes was induced with sub-nanomolar potency (EC_{50} = 0.72 nM) in the liver-derived cell line HepaRG. In 3D NASH microtissues, EDP-297 modulated multiple pathways associated with the pathogenesis of NASH. Specifically, decreased expression of genes encoding multiple lipogenic and inflammatory proteins was observed. Consistent with the anti-inflammatory effects observed *in vitro*, EDP-297-treated BDL rats showed significantly reduced expression of inflammatory (*Ccl2, Cxcl1)* and fibrotic genes (*Acta2*, *Col1a1)* and normalized circulating markers of liver injury, including ALT (76% reduction, $p < 0.001$), AST (83% reduction, $p < 0.001$) and GGT (76% reduction, $p < 0.001$). Histological analysis confirmed the hepatoprotective effects of EDP-297 with reduced immune cell infiltration and necrosis. Finally, EDP-297 was shown to be hepatoprotective in the dietary NASH model. Histological scoring, plasma and liver biochemistry will be discussed.
Conclusion: EDP-297 is a potent FXR agonist that exhibits hepatoprotective effects in rodent models of NASH and liver fibrosis. EDP-297 attenuates NASH-relevant pathways of steatosis, liver injury, inflammation, and apoptosis both *in vitro* and *in vivo.* These data support the further evaluation of EDP-297 for the management of NASH.

SAT044

Efficacy and safety of combination therapy with elobixibat and colestyramine for non-alcoholic steatohepatitis model mice

Michihiro Iwaki[1], Takaomi Kessoku[2], Anna Ozaki[3], Takashi Kobayashi[3], Yasushi Honda[3], Yuji Ogawa[3], Kento Imajo[3], Masato Yoneda[3], Satoru Saito[3], Atsushi Nakajima[2]. *[1]Yokohama City University Graduate School of Medicine., Gastroenterology and Hepatology, Yokohama city, Japan; [2]Yokohama City University Graduate School of Medicine., Gastroenterology and Hepatology; [3]Yokohama City University Graduate School of Medicine., Gastroenterology and Hepatology, Yokohama city, Japan*
Email: michihirokeidai@yahoo.co.jp

Background and Aims: Bile acids synthesis is accelerated, and serum bile acid levels are elevated in NASH patients. The phase 2 study of volixibat, an inhibitor of the apical sodium-dependent bile acid transporter (ASBT), for NASH was conducted but resulted in early termination due to lack of efficacy and occurrence of adverse events. It is known that bile acids increase the intestinal permeability. We speculate that ASBT inhibition may increase the portal blood concentration of endotoxin by increased colonic permeability, which accelerates the liver injury. Another problem on ASBT inhibitor is the severe bile acid diarrhea. In fact, elobixibat, another ASBT inhibitor, has been approved for the treatment of chronic constipation. Colestyramine, a bile acid sequestrants (BAS), is used for the bile acid diarrhea. Taking together, we hypothesized that co-administration of ASBT inhibitor and BAS might be effective by both reducing the serum bile acids and improving the diarrhea. The purpose of this study was to test our hypothesis using mice model.
Method: Eight-week-old male C57BL/6J mice were randomly distributed into 5 groups: a basal diet fed mice (group B), a high-fat high-fructose high-cholesterol diet (AMLN) fed mice (group A), AMLN+ elobixibat 10 mg/kg - fed mice (group E), AMLN + colestyramine 0.5 mg/kg fed mice (group C) and AMLN + elobixibat 10 mg/kg + colestyramine 0.5 mg/kg fed mice (group EC). The drugs were administered for 4 weeks. After administration, hepatic condition, intake, defecation status, intestinal permeability and gene expression of liver and ileum were examined.
Results: The significant decrease in serum ALT by 87%, in serum total cholesterol by about 30%, in serum free fatty acid by about 40%, was observed in group EC compared to that in monotherapy groups. Significant reduction of hepatic lipids, and hepatic histological improvement were observed in EC compared to monotherapy groups as well. Intestinal permeability measured by FITC dextran showed the twofold increase in group E comparison to A, but completely ameliorated in EC. Consisting these findings, serum LBP, lipopolysaccharide binding protein, in group E and A were shown to be more than twice higher than that in B and significantly ameliorated in EC, which suggested combination therapy improved steatohepatitis not only by higher reduction of serum bile acid but also by reducing the endotoxin levels elevated by elobixibat. Interestingly expression of ileum ASBT in C was the highest among 5 groups. Significant reduction of serum concentration of primary bile acid was observed in EC compared to other groups. Watery diarrhea observed in E was completely ameliorated in EC.
Conclusion: Our findings clearly suggest ASBT inhibition in combination with BAS provide the promising therapeutic strategy for NASH with higher reduction of serum bile acid and tolerability compared to ASBT inhibitor monotherapy.

SAT045

The role of RIPK3 in non-alcoholic fatty liver disease: a multi-omics perspective

Miguel Mateus-Pinheiro[1], Marta B. Afonso[1], Pedro Miguel Rodrigues[1,2], André L. Simão[1], Maria Manuela Gaspar[1], Sylvaine Di-Tommaso[3,4], Anne-Aurélie Raymond[3,4], Jean-William Dupuy[5], Frederic Saltel[3,4], Rui E. Castro[1], Cecília M. P. Rodrigues[1]. *[1]Research Institute for Medicines (iMed. Email: miguel-pinheiro@edu.ulisboa.pt

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is characterized by an excessive accumulation of triglycerides within hepatocytes, which can progress to non-alcoholic steatohepatitis (NASH). Genetic deletion of receptor-interacting protein kinase 3 (RIPK3) halts NASH development in mice fed a methionine and choline-deficient (MCD) diet, while exacerbating liver steatosis and adipose tissue inflammation in a high-fat diet model. Here, we aimed to further elucidate the role of RIPK3 in experimental NASH using a multi-omics approach.
Method: Liver samples from C57BL/6 wild-type (WT) or RIPK3-deficient (*Rip3k*$^{-/-}$) mice fed a choline-deficient L-amino acid-defined diet (CDAA; n = 14) or a control choline-sufficient L-amino acid-defined diet (CSAA; n = 14) for 32 and 66 weeks, were used for lipidomic and proteomic analysis, respectively. Lipidomic analysis was performed through ultra-high-performance liquid chromatography – mass spectrometry (UHPLC-MS). Formalin-fixed paraffin-embedded liver slices were cut by laser capture and the tissue obtained was used for protein extraction and LC-MS/MS analysis
Results: RIPK3 deletion halted NASH development in CDAA-fed mice, despite increasing liver fat accumulation in both NASH-inducing and control diets. In line to what has been shown in NAFLD patients, CDAA diet was associated with a reduced ratio between phosphatidylcholines and phosphatidylethanolamines (PC/PE), comparing with CSAA diet, in both *Rip3k*$^{-/-}$ and WT mice. Still, RIPK3 deficiency increased hepatic levels of diglycerides (DG) and triglycerides (TG) with shorter acyl chains and low unsaturation in mice fed the CSAA diet, while species with longer acyl chains and high number of double bonds were decreased in *Rip3k*$^{-/-}$ comparing to WT mice. These changes were also observed in CDAA-fed mice, although to a lesser extent, since the diet itself significantly increased TG and DG containing long and polyunsaturated fatty acids. In turn, *protein set enrichment analysis further* revealed that RIPK3 deficiency strongly modulated the levels of several proteins implicated in signalling pathways typically associated with NAFLD, including eIF2 signalling, mitochondrial dysfunction and oxidative stress response. These results were further validated by Western blot and suggest that mitochondria failure and protein translation impairment might be primal in the pathophysiology of NAFLD and important merging points between metabolism and cell fate.
Conclusion: In conclusion, RIPK3 deficiency shifts the lipidomic and proteomic landscape in a dietary NASH model. A throughout characterization of these molecular signatures will aid in pinpointing the specific mechanistic roles of RIPK3 in NAFLD pathogenesis.

Muscle fat is higher in NAFLD, and increases with fibrosis stage - a retrospective liver biopsy controlled magnetic resonance imaging-based body composition study

Mikael Forsgren[1,2,3], Mattias Ekstedt[4], Stergios Kechagias[4], Peter Lundberg[3,5], Olof Dahlqvist Leinhard[1,2,3]. [1]*AMRA Medical AB, Linköping, Sweden;* [2]*Linköping University, Department of Medical and Health Sciences, Linköping, Sweden;* [3]*Linköping University, Center for Medical Image Science and Visualization, Linköping, Sweden;* [4]*Linköping University, Department of Gastroenterology and Hepatology, Department of Medical and Health Sciences, Linköping, Sweden;* [5]*Linköping University, Department of Radiation Physics, Department of Medical and Health Sciences, Linköping, Sweden*
Email: mikael.forsgren@amramedical.com

Background and Aims: Sarcopenia, or adverse muscle composition, develops almost universally in subjects with cirrhosis. There is ample literature support that sarcopenia leads to more pre-, peri-, and post-operative complications, as well as lower post-operative survival in liver transplant settings, and also negatively impacts TIPS treatment outcome. Recent research shows that muscle volume in combination with muscle fat greatly improves function correlations compared to muscle volume alone. In addition, visceral adipose tissue (VAT) is strongly associated with adverse Non-Alcoholic Fatty Liver Disease (NAFLD) comorbidities such as coronary heart disease. Our aim was to analyze a well-described cohort with chronic liver disease retrospectively with respect to ectopic fat content using volumetrically assessed magnetic resonance (MR) images in relation to fibrosis stage and etiology.

Method: Abdominal 2-point Dixon MR images were analyzed retrospectively for VAT volume normalized to height^2 (VATi) and muscle fat infiltration (MFI) of the spinal erectors. The volumetric analysis was performed using AMRA® Researcher in a region limited by the top and bottom of the L1 vertebrae. Mann-Whitney U-test was used for statistical analysis. Liver needle biopsy-based fibrosis staging (grouped by F0-2 and F3-4) and diagnosis (NAFLD versus other etiologies [e.g. HCV, AIH, PSC]) were defined as previously described [Forsgren MF et al, PLoS Comp Biol 2019].

Results: 34 subjects had NAFLD (F0-2 n = 27; F3–4 n = 7); 56 subjects had other etiologies (F0-2 n = 43; F3–4 n = 13). The NAFLD group had higher VATi (Fig 1A) than the other etiologies ($p < 0.001$), but neither group was significantly associated with fibrosis (NAFLD $p = 0.22$; other etiologies $p = 0.46$). The NAFLD group had higher MFI (Fig 1B) than the other etiologies ($p = 0.002$), MFI was higher in F3–4 compared to F0–2 in the NAFLD group ($p = 0.004$). In contrast, no difference between the two fibrosis groups was observed in the other etiologies ($p = 0.57$).

Conclusion: Visceral adiposity is elevated in NAFLD compared to other chronic liver diseases but does not significantly increase with fibrosis stage. Another key ectopic fat compartment – muscle fat – is elevated in NAFLD. Interestingly, muscle fat is further elevated in NAFLD subjects with advanced fibrosis, which could indicate sarcopenic processes. Prospective validation with whole-body MR body composition analysis may be required.

SAT047

Adoptive cell transfer of regulatory T cells causes an exacerbation of hepatic steatosis in high-fat high-fructose diet-fed mice

Mikhail Van Herck[1,2], Luisa Vonghia[1,2], Wilhelmus Kwanten[1,2], Thomas Vanwolleghem[1,2], Didier Ebo[3,4], Peter Michielsen[1,2], Joris De Man[2], Benedicte De Winter[2], Sven Francque[1,2]. [1]*Antwerp University Hospital, Gastroenterology and Hepatology, Edegem, Belgium;* [2]*University of Antwerp, TWI²N, LEMP, Gastroenterology and Hepatology, Antwerpen, Belgium;* [3]*University of Antwerp, TWI²N, LEMP, Immunology, Antwerpen, Belgium;* [4]*Antwerp University Hospital, Immunology, Edegem, Belgium*
Email: mikhail.vanherck@uantwerpen.be

Background and Aims: Non-alcoholic steatohepatitis (NASH) is a multisystem condition, involving the liver, adipose tissue, and immune system. Regulatory T (Treg) cells are a subset of T cells that exert an immune-controlling effect. We previously demonstrated a reduction of Treg cells in the visceral adipose tissue (VAT) in high-fat high-fructose diet- (HFHFD) fed mice, which was associated with more severe liver disease. To further investigate the role of VAT Treg cells in NASH, we aimed to correct this immune disruption through adoptive cell transfer (ACT) of Treg cells.

Method: Male 8-week-old C57BL/6J mice were fed a HFHFD for 20 weeks. Subsequently, $CD4^+$ $CD25^+$ Treg cells were isolated from the spleens of healthy 8 to 10-week-old C57BL/6J mice and were adoptively transferred to the HFHFD-fed mice via intraperitoneal injection. HFHFD-fed mice injected with PBS served as controls. Mice were sacrificed three days after the injection. Plasma ALT and cholesterol levels were determined. Liver and adipose tissue was assessed histologically. Cytotoxic T (Tc) cells, Treg, T helper (Th) 1 cells and Th17 cells were characterized in liver, VAT, subcutaneous adipose tissue (SAT), blood, and spleen via flow cytometry. Data are presented as median (Q1 – Q3).

Results: Compared to controls, ACT of Treg cells increased the proportion of Treg cells in SAT, but not in any of the other investigated tissues. Moreover, in ACT mice Th1 cells were decreased in SAT, liver, blood, and spleen, while Tc cells and Th17 cells were not affected. Furthermore, the ACT increased the ALT levels and the histological degree of steatosis, while not significantly affecting bodyweight, cholesterol level, or liver inflammation.

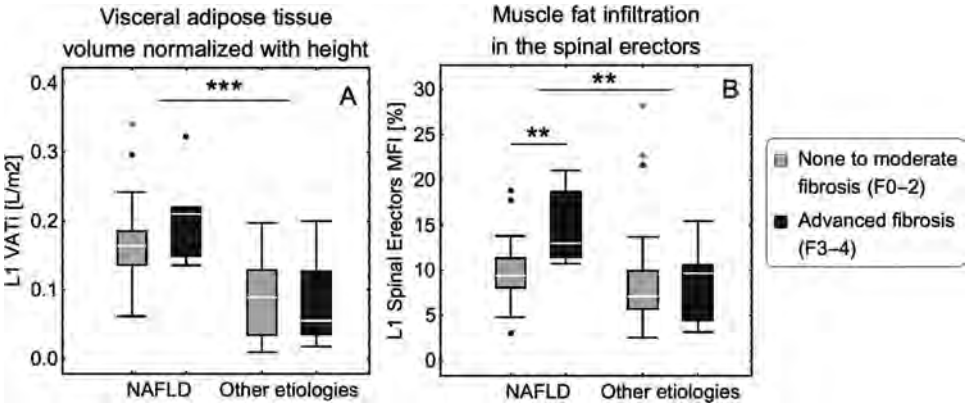

Figure: (abstract: SAT046)

Table: (abstract: SAT047)

	Control	ACT Treg cells	p-value
Liver Treg cells (% $CD4^+$ cells)	3.5 (3.5–6.7)	3.6 (1.9–7.1)	0.536
VAT Treg cells (% $CD4^+$ cells)	10.3 (7.4–12.1)	10.2 (8.0–14.1)	0.779
SAT Treg cells (% $CD4^+$ cells)	5.4 (4.3–5.8)	8.5 (7.5–10.7)	0.021
Blood Treg cells (% $CD4^+$ cells)	5.8 (5.1–9.1)	6.4 (5.9–7.9)	0.336
Spleen Treg cells (% $CD4^+$ cells)	9.9 (8.5–12.6)	11.5 (7.0–12.6)	0.662
Liver Th1 cells (% $CD4^+$ cells)	5.2 (2.6–9.0)	0.3 (0.1–3.3)	0.035
VAT Th1 cells (% $CD4^+$ cells)	2.2 (0.9–6.1)	0.7 (0.5–2.2)	0.094
SAT Th1 cells (% $CD4^+$ cells)	4.5 (2.0–6.5)	0.1 (0.7–1.1)	0.021
Blood Th1 cells (% $CD4^+$ cells)	5.4 (3.9–8.4)	2.0 (1.7–2.3)	0.021
Spleen Th1 cells (% $CD4^+$ cells)	2.2 (1.9–7.2)	0.5 (0.5–1.2)	0.026
Bodyweight (gram)	51.2 (44.3–53.9)	50.7 (48.6–53.7)	0.867
Cholesterol (mg/dL)	165 (126–173)	178 (158–188)	0.397
ALT (U/L)	12 (6–69)	77 (35–111)	0.049
Steatosis (%)	36 (31–41)	44 (42–49)	0.019
Liver inflammation (foci per mm^2)	16 (7–17)	13 (10–19)	0.715

Conclusion: Surprisingly, ACT of Treg cells in HFHFD-fed mice caused an exacerbation of hepatic steatosis. This was accompanied by an increase of Treg cells in the SAT and a general decrease in Th1 cells, while it did not correct the previously described HFHFD-induced reduction in VAT Treg cells.

SAT048

Synergic effect of a combined treatment with atorvastatin and ambrisentan in a rat model of NASH

Miren Bravo[1,2], Imma Raurell[1,2], Salvador Augustin[1,2], Joan Genesca[1,2], María Martell[1,2]. *[1]Liver Unit, Department of Internal Medicine, Hospital Universitari Vall d'Hebron, Institut de Recerca Vall d'Hebron (VHIR), Universitat Autonoma de Barcelona, Barcelona, Spain; [2]Centro de Investigacion Biomedica en Red de Enfermedades Hepaticas y Digestivas (CIBEREHD), Instituto de Salud Carlos III, Madrid, Spain*
Email: miren.bravo@gmail.com

Background and Aims: Early stages of non-alcoholic steatohepatitis (NASH) are associated with endothelial dysfunction. The decrease in vasodilators (NO, nitric oxid) and increase in vasoconstrictors (ET-1, endotheli-1) released by sinusoidal endothelial cells (LSEC), induce hepatic stellate cells (HSC) contraction, increasing intrahepatic resistance (IHVR) and thus portal pressure (PP), even before fibrosis development. Statins have been described to increase NO synthesis in LSEC, while ambrisentan is a selective endothelin receptor A antagonist. We aimed to analyse the combined effects of atorvastatin and ambrisentan on liver hemodynamics and histology, together with assessing the contraction ability of HSC from the different study groups.
Method: Sprague-Dawley rats were fed with high fat diet with a glucose-fructose beverage (HFGFD), or control-diet (CD) for 8 weeks. Then, HFGFD animals were treated with atorvastatin (10 mg/kg/day) (HFGFD-Ato), ambrisentan (2 mg/kg/day) (HFGFD-Amb), combination of both drugs (HFGFD-AA) or remained untreated (HFDGF-Veh) for 2 more weeks. Hemodynamic parameters were registered and liver histology and serum biochemical determinations were analysed. Three-dimensional collagen lattice contraction of HSC isolated from all groups were performed.
Results: Biochemical analysis revealed a significant rise of alanine aminotransferase (ALT) levels in HFGFD animals ($p < 0.001$), indicating an alteration in hepatic function. These values were reduced to normal with all tested treatments. Atorvastatin alone was more efficient than ambrisentan improving NAS activity, although their combination showed clearly the best result reducing the number of rats with histological NASH (NAS > 3) by more than a 75%. Both atorvastatin and ambrisentan independently reduced PP (HFGFD-Veh: 10,8 mmHg vs. HFGFD-Ato: 9.42 mmHg, $p = 0.0001$; HFGFD-Amb: 9.62 mmHg, $p = 0.004$), without affecting systemic hemodynamic, but only the combined treatment was able to reduce PP to levels comparable to those of the control diet group (CD-Veh: 8.45 mmHg vs. HFGFD-AA: 9.05 mmHg). This was associated with a reduction in IHVR in the groups treated with ambrisentan either alone or in combination (HFGFD-Veh: 4.83 mmHg/mL·min·100 g vs. HFGFD-Amb: 3.69 mmHg/mL·min·100 g, $p = 0.005$; HFGFD-AA: 3.33 mmHg/mL·min·100 g, $p < 0.001$), but again, only the group treated with the combination showed indistinguishable IHVR values from those of the control group (CD-Veh: 2.86 mmHg/mL·min·100 g vs. HFGFD-AA: 3.33 mmHg/mL·min·100 g). Furthermore, HSC from the combined treatment group showed a reduced collagen lattice contraction, even under in vitro ET-1 treatment.
Conclusion: In our NASH model rats, the combination of ambrisentan and atorvastatin exerts a potent inhibition of HSC contractility, and thus intrahepatic resistance, resulting in decreased portal pressure.

SAT049

Obesity and non-alcoholic steatohepatitis: assessing lipid diversity in adipose tissue

Montserrat Fibla Simó[1], Anna Hernández-Aguilera[1], Helena Castañé[2], Gerard Baiges[2], Salvador Fernández-Arroyo[1], Jordi Camps[1], Jorge Joven[1]. *[1]Institut d'Investigació Sanitària Pere Virgili, Unitat de Recerca Biomèdica, Hospital Sant Joan de Reus, Reus, Spain; [2]Universitat Rovira i Virgili, Unitat de Recerca Biomèdica, Hospital Sant Joan de Reus, Reus, Spain*
Email: montsefiblasimo@yahoo.es

Background and Aims: Obesity, an increasing disease reaching pandemic proportions, is characterized by fat accumulation in adipose tissue. When adipose tissue exceeds its storage capacity, lipids reach the bloodstream and this leads to ectopic fat accumulation and inflammation in locations like the liver giving rise to non-alcoholic steatohepatitis (NASH). The aim of our study was to assess changes in histological features and in the lipid composition of visceral and subcutaneous adipose tissue (VAT and SAT) in obese patients with and without NASH.
Method: Obese patients were classified into NASH group (n = 50) and non-NASH group (n = 50). Three different comparisons were performed to analyse possible alterations in histology and lipid composition of adipose tissue during obesity and NASH development. Histological evaluation of visceral and subcutaneous fat was carried out using two stainings (Haematoxylin-Eosin and Sirius Red). To assess specific lipid signatures in VAT and SAT, a non-targeted lipidomics approach was used.
Results: Adipocyte area was higher in subcutaneous adipose tissue and in NASH obese patients. When analysing lipid differences between VAT and SAT, we observed that in general, most of the

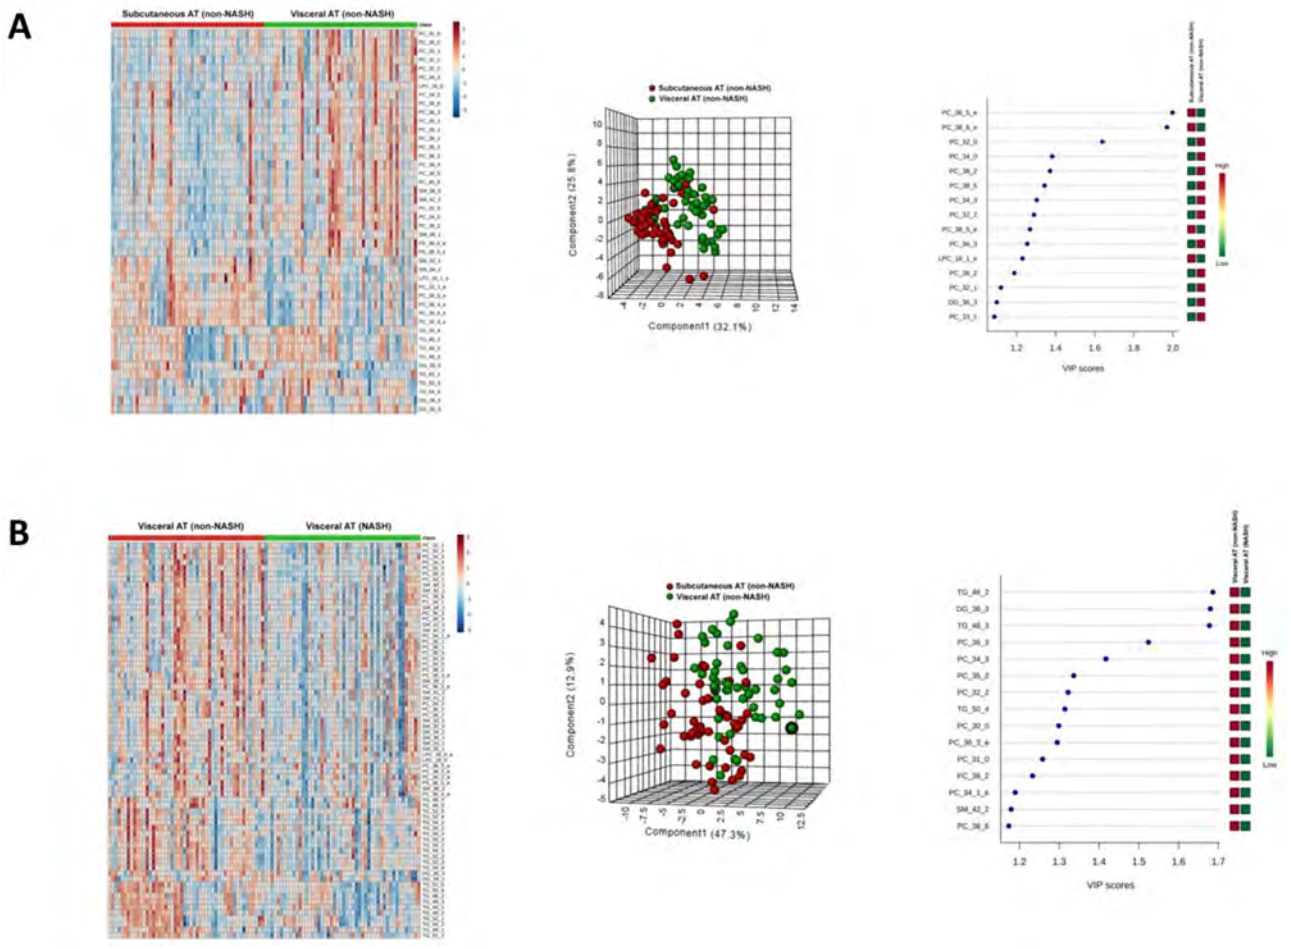

Figure: (abstract: SAT049)

significantly different lipids were increased in VAT compared to SAT of non-NASH patients (Figure 1A). When searching for NASH-specific lipid changes in VAT, we found that 68 species were significantly different and all were decreased in visceral depots of NASH obese patients compared with VAT from non-NASH patients (Figure 1B). Lastly and surprisingly, the analysis of SAT between NASH and non-NASH patients did not reveal any significant change in lipid composition.

Conclusion: Adipocyte area is higher in SAT than in VAT and is also higher in NASH group compared with non-NASH patients. Non-targeted lipidomics revealed tissue-specific lipid profiles in VAT and SAT of obese without NASH. Moreover, lipid composition of VAT was modified in NASH patients, and contrarily, SAT lipid composition was not different.

Blocking IL-1 signaling in hepatocytes undergoing metabolic stress protects against metabolic inflammation and attenuates pro-coagulant factors

Nadine Gehrke[1], Beate Straub[2], Nadine Hoevelmeyer[3], Ari Waisman[3], Detlef Schuppan[4], Marcus-Alexander Woerns[1], Peter Galle[1], Jörn M. Schattenberg[1]. *[1]University Medical Center Mainz, I. Department of Medicine, Mainz, Germany; [2]University Medical Center Mainz, Institute of Pathology, Mainz,; [3]University Medical Center Mainz, Institute for Molecular Medicine, Mainz, Germany; [4]University Medical Center Mainz, Institute for Translational Immunology, Mainz, Germany*
Email: schatten@uni-mainz.de

Background and Aims: In non-alcoholic fatty liver disease (NAFLD), IL-1 signaling is induced rapidly in response to lipid overload, oxidative stress, exposure of cytokines including IL-1α/β itself, and gut-derived microbial metabolites, thereby driving sterile metabolic inflammation. The chronic inflammatory state in turn confers an increased risk of metabolic comorbidities. Aim of this study was to examine whether in vivo knockout of the IL-1 receptor type 1 (IL-1R1) on hepatocytes may prevent (extra)hepatic complications of NAFLD.

Method: 8–10-week-old male hepatocyte-specific IL-1R1 knockout (*Il1r1*$^{Hep-/-}$) mice and their wild-type (WT) littermates were fed a high-fat, high-carbohydrate diet (HFD) for 12 weeks to induce obesity-related NAFLD or a control diet.

Results: All mice fed the HFD developed a significant and comparable weight gain, hyperlipidemia, hyperglycemia, decreased adiponectin levels, and macrovesicular hepatic steatosis. Despite comparable metabolic stress induced by the HFD, levels of serum ALT, micro-vesicular hepatic steatosis, activation of c-Jun N-terminal and extracellular signal-regulated kinases (JNK, ERK) were significantly higher in the WT compared to *Il1r1*$^{Hep-/-}$ mice, suggesting attenuated liver injury. This was paralleled by an induction of peroxisome proliferator-activated receptor γ coactivator (PGC)-1α and farnesoid X receptor (FXR)-α in *Il1r1*$^{Hep-/-}$ livers, which was absent in WT mice. These findings were validated in a second model using the choline-deficient, L-amino acid-defined (CDAA) diet. Further analyses revealed that *Il1r1*$^{Hep-/-}$ mice on the HFD maintained physiological insulin sensitivity both at the level of the liver and the whole body, while WT mice exhibited impaired insulin

sensitivity (downregulation of hepatic insulin receptor and phospho-Akt expression, increased fasting insulin and HOMA-IR levels, reduced whole body-glucose tolerance testing) and increased adipose tissue inflammation, as assessed by F4/80+ macrophages, MCP-1 and IL-1RA expression. Moreover, WT mice on the HFD exhibited a clear reduction of serum thrombopoietin levels compared to *Il1r1*$^{Hep-/-}$ mice, whereas C-reactive protein was markedly increased, pointing to a suppressed pro-coagulatory state in the *Il1r1*$^{Hep-/-}$ mice.

Conclusion: This data suggests a pivotal role of hepatocyte IL-1R1 signaling in modulating whole body insulin sensitivity, metabolic inflammation and coagulation in the context of NAFLD, and supports of IL-1/IL-1R blocking approaches for the treatment of NAFLD and its comorbidities.

SAT052

Monocyte chemoattractant protein-induced protein 1 level negatively correlates with steatosis in fatty liver patients

Natalia Pydyn[1], Justyna Kadluczka[1], Piotr Major[2], Edyta Kus[3], Stefan Chlopicki[3], Andrzej Budzynski[2], Jolanta Jura[1], Jerzy Kotlinowski[1]. [1]*Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Department of General Biochemistry, Kraków, Poland;* [2]*Jagiellonian University Medical College, 2nd Department of General Surgery, Kraków, Poland;* [3]*Jagiellonian University, Jagiellonian Centre for Experimental Therapeutics, Kraków, Poland*
Email: natalia.pydyn@doctoral.uj.edu.pl

Background and Aims: Monocyte chemoattractant protein-1-induced protein-1 (MCPIP1) is an endonuclease that degrades selected mRNAs, viral RNAs and pre-miRNAs. The main function of MCPIP1 is a negative regulation of inflammation, through degradation of proinflammatory cytokines transcripts like IL-6 or IL-1beta. MCPIP1 inhibits also adipogenesis by degradation of C/EBPbeta mRNA and adipogenesis-related miRNA, however its role in the regulation of hepatic lipid homeostasis is unknown. Nonalcoholic fatty liver disease (NAFLD) is an umbrella term for a range of liver conditions affecting people who drink little to no alcohol. In the first stage, NAFLD is characterized by simple hepatic steatosis, that might eventually progress to nonalcoholic steatohepatitis, fibrosis, cirrhosis or hepatocellular carcinoma. The aim of this study was to analyze MCPIP1 level in liver biopsies and PBMCs of patients' who underwent bariatric surgery.

Method: For our study we enrolled 37 obese patients, excluding subjects infected with hepatitis viruses or drinking alcohol (more than 20 g and 30 g of ethanol per day for women and men, respectively). We have tested blood morphology, level of plasma components (i.e. CRP, lipid profile, liver enzymes) and amount of MCPIP1 protein in PBMC and liver samples. Liver histology analysis was performed to assess the level of steatosis (Oil Red O stain), fibrosis (Picrosirius Red) and inflammation (H&E).

Results: Body mass index (BMI) of 37 NAFLD patients enrolled to our study ranged from 38 to 58, liver steatosis was from 5% to 80% and NAFLD activity score from 3 to 7. We detected no changes in total protein, albumin nor ions (Na+, K+, Fe2+) concentrations in plasma samples. Similarly, lipid profile (total cholesterol, HDL, LDL and triglycerides) was within physiological range. CRP was above normal range in all subjects (9.14–87.59 mg/L, median 26.67 mg/L) and 90% of them had elevated levels of ALT and AST. We detected a nine fold variation of *ZC3H12A* gene expression in PBMC that resulted in negative correlation between MCPIP1 protein level with patients' BMI ($p = 0.01$). Additionally, MCPIP1 protein level in liver biopsies negatively correlated with steatosis ($p = 0.037$).

Conclusion: We demonstrated a negative correlation between MCPIP1 protein and NAFLD progression both in liver and PBMC. Thus, MCPIP1 can be considered as a new important player involved in the fatty liver progression.

SAT053

Ultrastructural changes in perfusion-fixed human non-alcoholic fatty liver disease biopsies

Pauline Verhaegh[1,2], Eddie Wisse[1], Toon De Munck[1,2], Jan W. Greve[3,4], Joanne Verheij[5], Robert Riedl[6], Hans Duimel[7], Ad Masclee[1], Daisy Jonkers[2], Ger Koek[1,2]. [1]*Academic Hospital Maastricht, Gastroenterology and Hepatology, Maastricht, Netherlands;* [2]*Faculty of Health, Medicine & Life Sciences, Maastricht University, Gastroenterology and Hepatology, Maastricht, Netherlands;* [3]*Atrium MC, Surgery, Heerlen, Netherlands;* [4]*Academic Hospital Maastricht, Gastro-Intestinal Surgery, Maastricht, Netherlands;* [5]*Academic Medical Centre, Pathology, Amsterdam, Netherlands;* [6]*Atrium MC, Pathology, Heerlen, Netherlands;* [7]*Faculty of Health, Medicine & Life Sciences, Maastricht University, Electron microscopy, Maastricht, Netherlands*
Email: pauline.verhaegh@gmail.com

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a widespread liver disease in Western society, but its multifactorial pathogenesis is not completely clear. Ultrastructural analysis of the liver showed defenestration (i.e. loss of fenestrae) of liver sinusoidal endothelial cells (LSECs) early in the course of NAFLD, promoting steatosis in animal models and *in vitro* studies. However, human data, especially on LSECs and their fenestrae, are scarce.

Applying recently developed methods for perfusion-type fixation in human samples, we aimed to explore ultrastructural changes in human liver biopsies of NAFLD patients with and without NASH, focussing on LSECs and their fenestration.

Method: We applied jet and injection fixation to needle and wedge liver biopsies of patients with NAFLD, as confirmed by routine pathologist's light microscopic (LM) diagnosis. A total of 39 samples were eligible for inclusion.

Results: In total, 37 samples were of sufficient quality for further analysis. Twelve of these had NASH (32.4%) based on the SAF (Steatosis, Activity, Fibrosis) score by LM. Comparing NASH with noNASH samples, significantly less defenestration and sinusoidal lipid embolisms were found in the NASH group (both $p < 0.05$). Other features, *i.e.* fenestrae size, presence of parenchymal and Kupffer cell lipolysosomes and megamitochondria did not differ between groups. Furthermore, newly described structures *i.e.* single cell steatonecrosis (SCSN) and inflammatory fat follicle (IFF) were seen in both groups.

Conclusion: This study showed that defenestration was more common in noNASH compared to NASH. Defenestration was not related to the degree of steatosis or fibrosis. We speculate whether this could be a protective mechanism in simple steatosis which is lacking in NASH. Sinusoidal lipid embolisms seen in the noNASH group and single cell steatonecrosis and inflammatory fat follicle seen in both groups suggest a feature of lipid overload in NAFLD.

SAT054

mIR-21 is increased in patients with NASH-associated HCC and contributes to hepatocarcinogenesis in mice with NAFLD

Email: pedro.rodrigues@biodonostia.org

Background and Aims: Molecular mechanisms governing the progression of NASH towards HCC remain elusive. We have recently shown that concomitant miR-21 ablation and FXR activation prevent NASH development in mice. Here, we aimed to evaluate the role of miR-21-dependent signalling in NASH-associated carcinogenesis.
Method: miR-21 expression was evaluated in liver biopsies and surgically resected tumors from two independent patient cohorts, which included obese patients with NAFLD (n = 200; SS cohort), HCC (n = 362) and NASH-associated HCC (n = 19) (TCGA cohort). WT and miR-21 KO mice were fed either a choline-sufficient, amino acid-defined control diet (CSAA; n = 28) or a choline-deficient, amino acid-defined diet (CDAA; n = 28) for 32 and 66 weeks. Liver samples were processed for histological analysis. miR-21 and dowstream targets, pro-inflammatory/pro-fibrogenic cytokines and metabolic relevant genes were also measured. A profiler PCR array was used to evaluate expression of liver cancer-related genes.
Results: In patients, miR-21 expression increased with NAFLD severity (steatosis, lobular inflammation, ballooning, fibrosis and the NAS score) in the SS cohort. Levels of miR-21 were markedly increased in the tumour tissue of both HCC and NASH-HCC patients compared with surrounding liver (TCGA cohort), and correlated with histological HCC markers (AFP, GPC3), disease stage and worse overall survival. WT mice fed the CDAA diet for 32 weeks developed NASH and fibrosis while CDAA-fed miR-21 KO mice exhibited increased activation of PPAR target genes and augmented mitochondrial activity. After 66 weeks, all WT mice on the CDAA diet had developed at least one preneoplastic nodule (~5.2 nodules/animal), with one animal developing trabecular HCC. miR-21 expression was significantly increased in CDAA-fed mice and further increased in HCC, concomitantly with decreased expression of PPAR. Livers presented hyperplastic foci, anisokaryosis as well as phenotypically altered and highly proliferative hepatocytes. Increased levels of pro-inflammatory/fibrogenic markers were particularly evident in pre-neoplastic liver tissues, alongside activation of oncogenic pathways. Strikingly, CDAA-fed miR-21 KO mice displayed serum ALT levels similar to control animals. The NAS score (<5), number of liver nodules (~2.3 nodules/animal), hepatocyte profliferation and expression of pro-inflammatory/fibrogenic markers and oncogenes were all significantly reduced, comparing with CDAA WT-fed mice.
Conclusion: Activation of miR-21-dependent pathways appears to contribute to NAFLD progression up to NASH-associated carcinogenesis, with its inhibiton halting HCC development. Targeting miR-21 may constitute an appealing therapeutic approach to ameilorate NASH and its progression towards HCC. SAT055

Inhibition of autotaxin-lysophosphatidic acid signaling pathway by a novel autotaxin inhibitor FP10.47 ameliorates non-alcoholic steatohepatitis in vivo

Richell Booijink[1,2], Fernando Salgado Polo[2], Büsra Özturk Ackora[1], Craig Jamieson[3], Anastassis Perrakis[2], Ruchi Bansal[1]. *[1]University of Twente, The Liver Lab, Department of Medical Cell BioPhysics, Technical medical centre, Faculty of Science and Technology, Enschede, Netherlands; [2]The Netherlands Cancer institute and Oncode Institute, Division of Biochemistry, Amsterdam, Netherlands; [3]University of Strathclyde, Department of Pure and Applied Chemistry, Glasgow, United Kingdom*
Email: r.s.booijink@utwente.nl

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is a growing cause of mortality worldwide. Due to the increasing incidence of obesity and diabetes, prevalence of NAFLD is rising exponentially. 30% of affected people develop non-alcoholic steatohepatitis (NASH) that further progresses to cirrhosis and hepatocellular carcinoma. Currently, there is an unmet need for the effective therapy for the treatment of NASH. Recently, upregulated serum levels of lysophosphatidic acid (LPA) and of autotaxin (ATX, ENPP2), the enzyme that generates LPA *in vivo* have been identified in NASH, suggesting the implication of the ATX-LPA axis in NASH progression. Hence, we hypothesized that the inhibition of the ATX-LPA signaling pathway might be a promising approach to attenuate NASH. The aim of this study is to investigate the therapeutic efficacy of a novel small molecule type IV ATX inhibitor FP10.47 in NASH.
Method: ATX gene and protein expression was examined in human diseased livers and *in vivo* in mouse models. *In vitro* effectivity of ATX

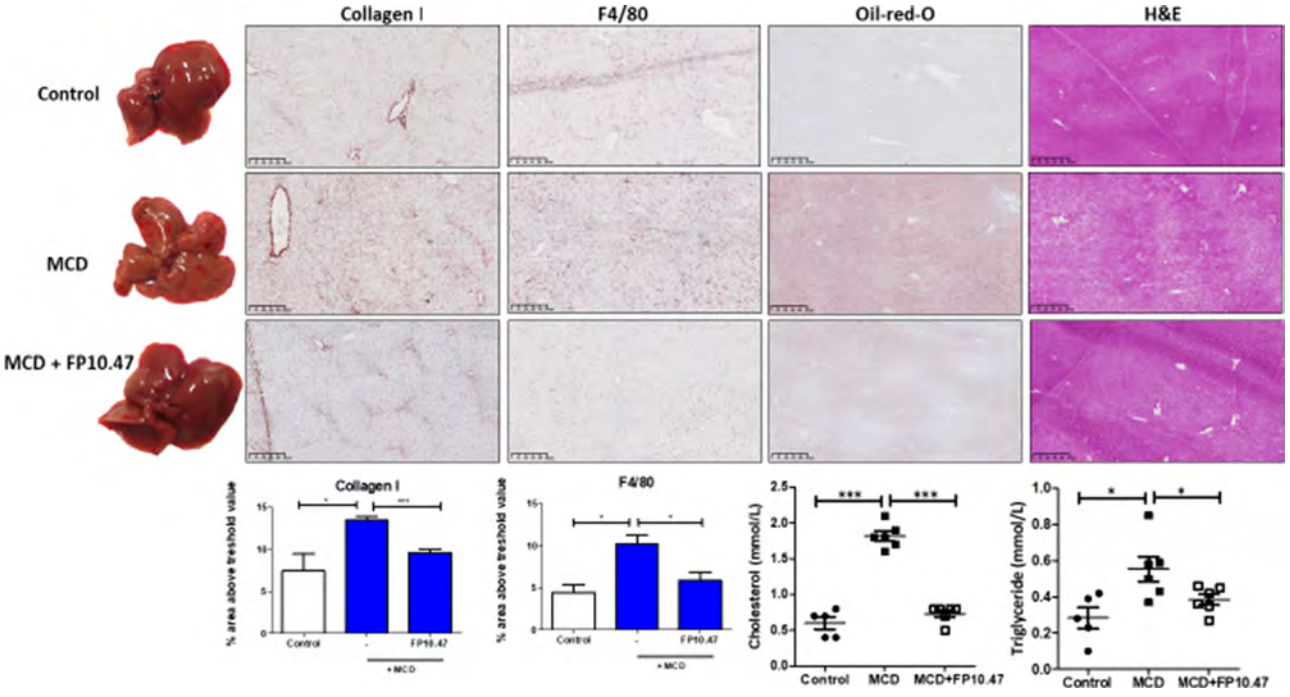

Figure: (abstract: SAT055)

inhibitor FP10.47 on fibrotic parameters, contractility and wound healing was evaluated in TGFβ-activated human HSCs. Furthermore, effects of FP10.47 on inflammatory parameters and migration was examined in M1-activated murine macrophages. Finally, FP10.47 was extensively investigated in a methionine-choline-deficient (MCD) diet-induced NASH mouse model.

Results: Upregulation of ATX expression was observed in human diseased livers with different etiologies and in murine models of NASH and alcoholic steatohepatitis (ASH). FP10.47 (1 μM) inhibited TGFβ-induced HSCs activation, contractility and migration. LPS/IFNγ-induced macrophage activation and migration was also reduced by FP10.47 (1 μM). Effects of FP10.47 were mediated via inhibition of the pERK1/2 signaling pathway. Importantly, FP10.47 didn't induce any toxicity in HSCs and macrophages. *In vivo*, in a NASH mouse model, post-disease intraperitoneal treatment with FP10.47 (5 mg/kg) strongly attenuated fibrosis, steatosis and inflammation, as observed histologically, and in gene expression profiles. Importantly, FP10.47 reduced total ALT, AST, cholesterol and triglyceride plasma levels.

Conclusion: The ATX-LPA pathway is a novel player in the pathogenesis of NASH, and inhibition of ATX is a promising therapeutic approach for the treatment of this disease.

Recombinant glutamine synthetase reduces ammonia and hepatic fibrosis in in vitro and in vivo models of non-alchoholic fatty liver disease

Antria Siakalli[1], Abeba Habtesion[1], Andrew Hall[1], Ewald Doornebal[2], Dr. Elena Palma[2], Tamara Nicolson[3], Shilpa Chokshi[2], Jane Macnaughtan[1], Rajiv Jalan[1]. [1]*UCL Institute for Liver and Digestive Health, London;* [2]*Institute of Hepatology, Foundation for Liver Research;* [3]*Thoeris GmBh, Vienna, Austria*
Email: rmgpsia@ucl.ac.uk

Background and Aims: The severity of fibrosis predicts risk of death in NAFLD. A causal association exists between hyperammonaemia and fibrosis in NAFLD. This occurs due to a stepwise reduction in expression and activity of urea cycle enzymes resulting in stellate cell activation and fibrosis. In NAFLD, hepatic glutamine synthase (GS) loses zonation and its activity is reduced. As GS can detoxify ammonia and also synthesise glutamine, which is important for gut and immune homeostasis, we aimed to determine whether replacing recombinant GS (AM-535), would reduce ammonia and hepatic fibrosis in NAFLD models.

Method: *In vitro precision cut liver slices (PCLS) model:* C57BL mice PCLS (n = 4/group) were administered a lipid mixture (50 μl; containing oleic, palmitic, linoleic and elaidic acid (final [2 mM]), and treated daily for 3-days with AM-535 (20 μg) in presence and absence of NH_4Cl (100 μm). *In vivo models*: (A) *Methionine choline deficient (MCD)* was administered to C57BL mice (5 g/25 g mice, n = 16) and treated with vehicle or AM 535 i.p. (30 mg/kg; 2x/w for 2w). Study was terminated at 3w. (B) *High fat high cholesterol diet (HFHC):* SD rats were fed with HFHC diet for 16w (25 g/250 g rat; n = 8), or normal chow (n = 4). HFHC rats were administered AM-535 i.p. (30 mg/kg, 2x/w) or vehicle from 8w and were terminated at 16w. Plasma ammonia levels, liver biochemistry, hepatic GS expression and severity of liver fibrosis were determined.

Results: *PCLS model:* A significant reduction in supernatant ammonia concentrations were observed from 357.5 ± 4.36 to 295.0 ± 12.91 μmol/L ($p < 0.05$) in the AM-535 treated group. *MCD model:* Ammonia concentration was significantly higher in the MCD animals compared with the chow fed animals and this was significantly reduced by AM-535 [(160.8 ± 74.3 vs 42.33 ± 16.4 μmol/L ($p < 0.05$)]. *HFHC model:* The collagen proportionate area (CPA) was significantly higher in untreated HFHC rats compared to naïve controls (4.38% vs 2.25%) ($p < 0.05$), which was reduced significantly in the AM-535 animals (CPA: HFHC vehicle: 4.38% vs 2.58%; HFHC AM-535: $p < 0.05$). In both models, hepatic immunohistochemistry for GS showed typical perivenular localisation of the administered AM-535 (Figure 1).

Conclusion: This study shows for the first time that administration of recombinant GS, AM-535 in a PCLS model and two models of NAFLD, effectively reduces ammonia and prevents progression of hepatic fibrosis providing a potential novel therapeutic approach for NAFLD.

SAT057

Absence of histidine triad nucleotide binding protein-2 (HINT-2) triggers mitochondrial dysfunction and aggravates steatosis

Raviprasadh Rajasekaran[1], Pavitra Kumar[2], Jean-François Dufour[1,3], Marie V. St-Pierre[1]. [1]*University of Bern, Department of Biomedical Research, Bern, Switzerland;* [2]*University of Bern, Department of Biomedical Research, Bern, Switzerland;* [3]*University Hospital Bern, University Clinic of Visceral Surgery and Medicine, Bern, Switzerland*
Email: jean-francois.dufour@dbmr.unibe.ch

Background and Aims: Mitochondrial dysfunction plays a role in the development hepatic steatosis. Histidine triad nucleotide-binding protein 2 (Hint-2) is a mitochondrial adenosine phosphoramidase expressed in hepatocytes. Hint2 knockout mice show hepatic steatosis and lysine hyperacetylation of mitochondrial proteins, which are features of respiratory chain malfunctions. We asked whether the absence of Hint-2 impairs mitochondria bioenergetics secondary to hyperacetylation.

Methods: *Hint2*$^{-/-}$ mice (C57Bl/6J) were generated using homologous recombination. Oxygen consumption rates (OCRs) was measured with the extracellular flux XF-24 bioanalyzer. Acetylation was assessed by immunoprecipitation and immunoblotting.

Results: *Hint2*$^{-/-}$ hepatocytes showed protein hyperacetylation, produced less ATP ($p < 0.001$) and generated a lower mitochondrial membrane potential than did *Hint2*$^{+/+}$ hepatocytes. The basal, ATP-linked and maximal OCRs were decreased in *Hint2*$^{-/-}$ hepatocytes ($p < 0.05$). Palmitate oxidation was reduced by 25% in Hint2$^{-/-}$ mitochondria and triglyceride content was higher in *Hint2*$^{-/-}$ than in *Hint2*$^{+/+}$ hepatocytes ($p < 0.005$). A high fat diet aggravated the hyperacetylation and steatotic phenotype in *Hint2*$^{-/-}$ livers. SNU-449 and HepG2 cells under- or over-expressing Hint-2 did not change protein acetylation. In Hint-2 overexpressing SNU-449 and HepG2 cells, the basal, ATP-linked and maximum OCRs were increased, whereas in Hint-2 silenced HepG2, OCR was decreased. LCMS/MS proteomics identified hyperacetylated proteins active in intermediary and ketone metabolism and in mitochondrial respiration, which were substrates of sirtuin3. Sirtuin3 deacetylase activity *in vitro* was unchanged. The global hyperacetylation status in *Hint2*$^{-/-}$ hepatocytes was partially reversed by recombinant sirtuin3 and NAD^+. Conversely, the acetylation reaction was enhanced *in vitro* in *Hint-2*$^{-/-}$ hepatocytes. An excess of acetyl-CoA (10 mM) increased acetylation 2-fold in *Hint2*$^{-/-}$ hepatocytes relative to *Hint2*$^{+/+}$. In addition, blocking fatty acid oxidation with etomoxir increased acetylation only in *Hint2*$^{-/-}$ hepatocytes.

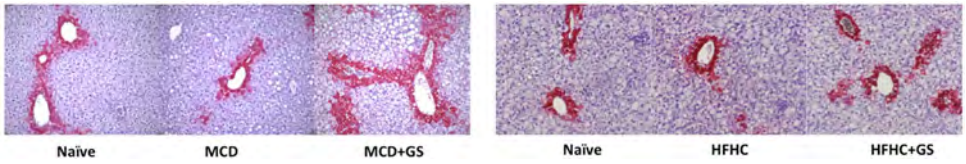

Figure: (abstract: SAT056): Glutamine synthetase (GS) immunohistochemistry (x20) in MCD (A) and HFHC (B) models.

Conclusion: The absence of Hint-2 provokes bioenergetics defects, independent of the global increase in protein acetylation. Our findings support the notion that conditions favoring enhanced acetylation rather than impaired deacetylation are operative in *Hint2*$^{-/-}$ hepatocytes. The bioenergetic deficit in hepatocytes lacking Hint-2 likely leads to the secondary outcome of steatosis.

SAT058

GPNMB modulates hepatic steatogenesis and liver cancer

Yan Gao[1], Zeribe Nwosu[1], Matthias Ebert[2], Steven Dooley[1], Seddik Hammad[1,3]. [1]*Medical Faculty Mannheim, Heidelberg University, Molecular Hepatology Section, Department of Medicine II Mannheim, Mannheim, Germany;* [2]*Medical Faculty Mannheim, Heidelberg University, Department of Medicine II Mannheim, Mannheim, Germany;* [3] *South Valley University, Department of Forensic Medicine and Veterinary Toxicology, Faculty of Veterinary Medicine, Qena, Egypt*
Email: seddik.hammad@medma.uni-heidelberg.de

Background and Aims: Lipid accumulation in liver cells predispose to non-alcoholic fatty liver disease (NAFLD) including its severe disease types non-alcoholic steatohepatitis (NASH) and hepatocellular carcinoma (HCC). Hepatocyte (HC)-derived glycoprotein non-metastatic melanoma B (Gpnmb) was recently reported as regulator of fat metabolism in adipose tissue, however, its role in the pathogenesis of NAFLD-related HCC is not clear.
Method: Results: To get insight, we started with an analysis of published microarray data from human patients and found Gpnmb upregulated in NAFLD/NASH and HCC, as compared to healthy livers. We next confirmed a progressively increasing expression of GPNMB in fatty livers (6, 8 and 12 weeks) and HCC stages (20 weeks) of STAM mice, a NASH-based HCC mouse model. With IHC, we locate GPNMB expression to hepatocytes and HC-derived cancer cells. In line, *in vitro* modeling of steatosis by supplementing oleic acid (OA) to mouse hepatocytes (pmHC) and AML-12 cells induces GPNMB expression at mRNA and protein levels. We next modulated GPNMB expression in pmHC and AML12 cells with or without OA-treatment and investigated the fatty hepatocyte phenotype. *Gpnmb* depletion increases triglycerides (TG) accumulation, and mRNA expression of lipogenic genes namely, Sterol regulatory element-binding protein-1c (*Srebp-1c*), Peroxisome proliferator-activated receptor alpha (*Ppar-alpha*), Peroxisome proliferator-activated receptor gamma (*Ppar-gamma*), Fatty acid synthase (Fasn) and stearoyl-CoA desaturase 1 (Scd1). Unexpectedly, Carnitine palmitoyltransferase I (*Cpt1*) and acyl-CoA oxidase 1 (*Acox1*), members of antioxidant genes, are also upregulated. Complementary results were obtained upon GPNMB overexpression. Moreover, in Huh7, HLE and HLF liver cancer cells, GPNMB facilitates cell death signals as measured by time-lapse live cell imaging and caspase assay. Mechanistically, GPNMB facilitates cell death via interfering with AKT phosphorylation dependent survival signals.
Conclusion: GPNMB is a consistently upregulated target in NASH and HCC. GPNMB is expressed in HC and HC-derived cancer cells. In fatty liver, GPNMB is upregulated to tone down lipogenesis. In liver cancer cells, GPNMB acts as a tumor suppressor by providing cytostatic effects. The German Federal Ministry of Education and Research (BMBF) Project LiSyM supported this study.

TM6SF2 E167K variant increases the severity of NAFLD in high fat diet-fed mice

Shousheng Liu[1], Baokai Sun[1], Jie Zhang[1], Qing Zhang[1], Yongning Xin[1]. [1]*Qingdao Municipal Hospital, Infectious Disease, Qingdao, China*
Email: xinyongning@163.com

Background and Aims: Genetic factors contribute to the development and progression of non-alcoholic fatty liver disease (NAFLD). Accumulated studies had been conducted to explore the association of Tm6sf2 E167 K with the risk of various liver diseases which includes NAFLD. Although the role of Tm6sf2 E167 K in NAFLD is relative doubtless, the detailed mechanism of Tm6sf2 E167 K in the

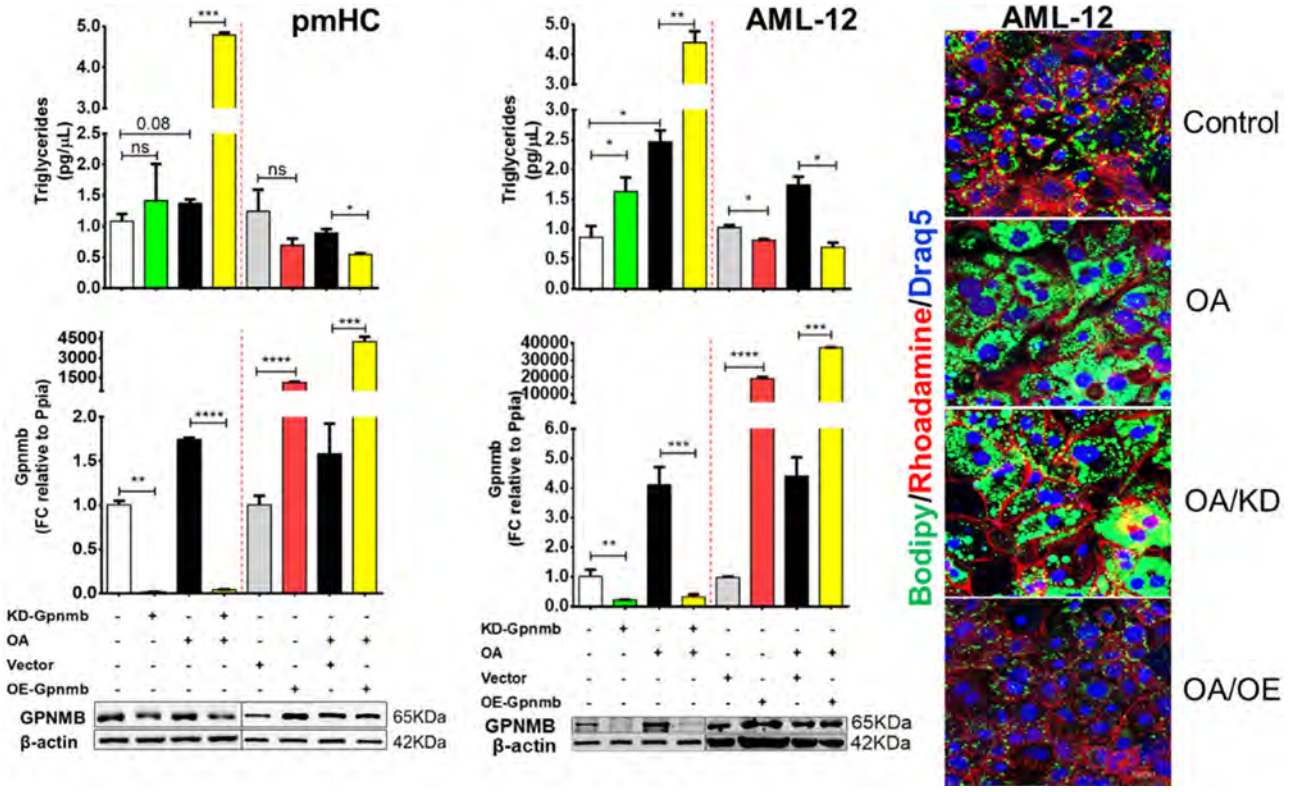

Figure: (abstract: SAT058): Modulation of Gpnmb expression is associated with lipid accumulation in pmHC and AML-12.

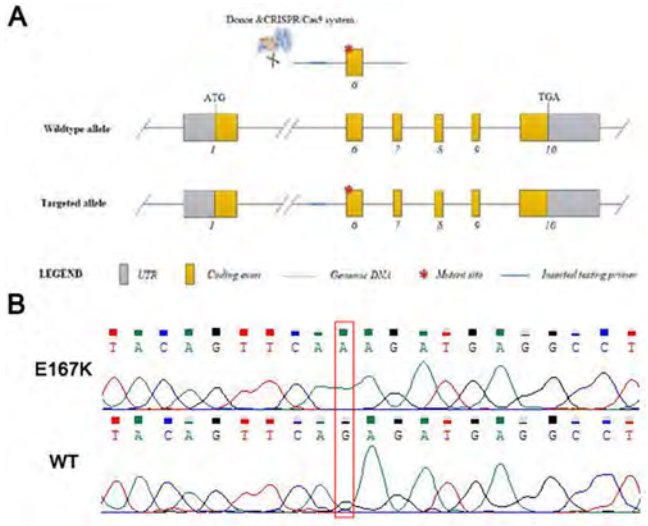
development of NAFLD was remains unclear. The aim of this study was to investigate the mechanism of Tm6sf2 E167 K in the development of NAFLD in mouse.

Method: We constructed the Tm6sf2 E167 K mutational C57BL/6 mouse model. The mice were divided into Tm6sf2$^{167E/E}$ group (n = 7) and Tm6sf2$^{167K/K}$ group (n = 7). Mice in each group were fed with chow diet or high fat diet for 8 weeks and 16 weeks. The body weight of each mouse was recorded weekly. Blood and liver of each mouse were sampled, and the liver weights were recorded and the liver indexes were calculated. Hematoxylin-eosin (HE) staining and oil red O staining were conducted to investigate the liver pathological characteristic and lipid accumulation. The HOMA-IR values were calculated to explore the insulin resistance of mice in each group.



Results: Tm6sf2 E167 K mutational C57BL/6 mouse model was constructed successfully. No significant difference of body weights was observed between Tm6sf2$^{167E/E}$ and Tm6sf2$^{167K/K}$ mice when fed with chow diet, but HFD-fed mice were more weight than CD-fed mice, and HFD-fed Tm6sf2$^{167K/K}$ mice were more weight than HDF-fed Tm6sf2$^{167E/E}$ mice. The liver index of Tm6sf2$^{167K/K}$ mice is significant higher than Tm6sf2$^{167E/E}$ mice after fed with HFD for 16 weeks. HE staining and oil red O staining showed that exacerbated hepatosteatosis and more lipid droplets were existed in the HFD-fed Tm6sf2$^{167K/K}$ mice compared to the HDF-fed Tm6sf2$^{167E/E}$ mice. The serum lipid profiles in the HFD-fed Tm6sf2$^{167K/K}$ mice were also significant higher than in the HDF-fed Tm6sf2$^{167E/E}$ mice. Homeostatic model assessment for insulin resistance (HOMA-IR) indexes was augmented by Tm6sf2$^{167K/K}$ variant. CD-fed Tm6sf2$^{167K/K}$ mice developed a more severe form of glucose intolerance than HDF-fed Tm6sf2$^{167E/E}$ mice at 8 weeks and 16 weeks.

Conclusion: Tm6sf2 E167 K variant increases the severity of NAFLD in the mouse after fed with HFD significantly. The detailed mechanism of Tm6sf2 E167 K variant in the development of NAFLD is studying at the present.

SAT060

Unrevealing the HDL lipidome in NAFLD: a possible explanation for the increased CVD risk of these patients

Sofia Kartsoli[1], Christina Kostara[2], Vasilis Tsimihodimos[3], Dimitrios Christodoulou[1], Eleni Bairaktari[2]. *[1]University of Ioannina, Department of Gastroenterology, Medical School, Ioannina, Greece; [2]University of Ioannina, Laboratory of Clinical Chemistry, Medical School, Ioannina, Greece; [3]University of Ioannina, Department of Internal Medicine, Medical School, Ioannina, Greece*
Email: skartsoli@outlook.com.gr

Background and Aims: Recently, Non-alcoholic Fatty Liver Disease (NAFLD), the most common chronic liver disease, has been appointed as an independent cardiovascular disease (CVD) risk factor. No specific and sensitive biomarker for the diagnosis and progression of the disease has been found as yet. Recent data suggest that the quality of HDLs affect their structure and physicochemical properties, and possibly their ability to protect against atherosclerosis.

The aim of this study was the investigation of the alterations occurring in the HDL lipidome in NAFLD by ^{1}H NMR spectroscopy, in order to identify new biomarkers for the early diagnosis of the disease and to compare it with that recorded from patients with coronary heart disease, in order to elucidate the mechanisms of the increased CVD risk of these patients.

Method: Serum samples were collected from overall 60 cases, out of which 20 patients with NAFLD (diagnosed with abdominal ultrasound), 20 patients with established coronary heart disease and 20 healthy controls. The lipid profile of the HDL lipoproteins was investigated by proton nuclear magnetic resonance (^{1}H NMR) spectroscopy.

Results: Patients with NAFLD exhibited significant changes in HDL lipidome compared to healthy subjects largely attributed to the phospholipid pattern (glycerophospholipids and sphingolipids). Specifically, patients with NAFLD showed reduced % content of phosphatidylcholine and phosphatidylinositol compared to controls and increased sphingolipid content mainly due to increased content of ceramides. The average chain length of fatty acids and the % content of polyunsaturated fatty acids such as arachidonic, eicosapentaenoic and docosahexaenoic acid were found to be reduced in patients with NAFLD compared to the control group. Compared to CVD patients, those with NAFLD showed an increased content of sphingolipids, sphingomyelin, ceramides and reduced content of phosphatidylinositol.

Conclusion: The changes observed in the phospholipid pattern and fatty acids of HDLs in NAFLD patients compared to healthy controls follow the lipid changes observed in hepatocytes of NAFLD patients and possibly reflect the lipid metabolism abnormalities involved in the pathophysiology of NAFLD. Thus, the altered lipidome of HDL may serve as potential biomarker of disease progression. Additionally, these changes seem to affect the atheroprotective properties of HDLs and may partly explain the increased risk of CVD in NAFLD patients.

SAT061

A novel small molecule modulating the mitochondrial NEET (CISD) proteins activity improves inflammation and fibrosis in a diet-induced model of non-alcoholic steatohepatitis

Stéphanie Le Corre[1], Lines Laetitia[1], Sampson Diane[1], Karmi Ola[2], Margault Henri-Baptiste[2], Rossignol Rodrigue[3], Amoedo Nivea[3], Nechushtai Rachel[2], Raphaël Darteil[1], Jacky Vonderscher[1], De Chassey Benoit[1], Meldrum Eric[1]. *[1]ENYO Pharma SA, Lyon, France; [2]The Hebrew University of Jerusalem, The Alexander Silberman Life Science Institute, Jerusalem, Israel; [3]Cellomet, Bordeaux, France*
Email: slc@enyopharma.com

Background and Aims: Non-alcoholic steatohepatitis (NASH) is a disease characterized by excessive fat accumulation, inflammation and fibrosis in the liver with periportal inflammation having been identified as a marker of disease severity. Here, we present a novel chemistry that regulates the function of 3 mitochondrial proteins called the NEET proteins to target the periportal region of the liver. These proteins perform an important role in mitochondrial Fe/ROS homeostasis and the regulation of mitochondrial metabolism. Previous literature reports have highlighted the therapeutic importance of NEET proteins in metabolic disease, so we assessed the possible effects of ENYO's lead NEET protein modulator on the pathology associated with a diet-induced obesity model of NASH in mice and compared those effects with OCA treatment.

Method: NEET proteins are unique in their ability to reversibly bind two [2Fe-2S] clusters allowing protein function to be evaluated by a

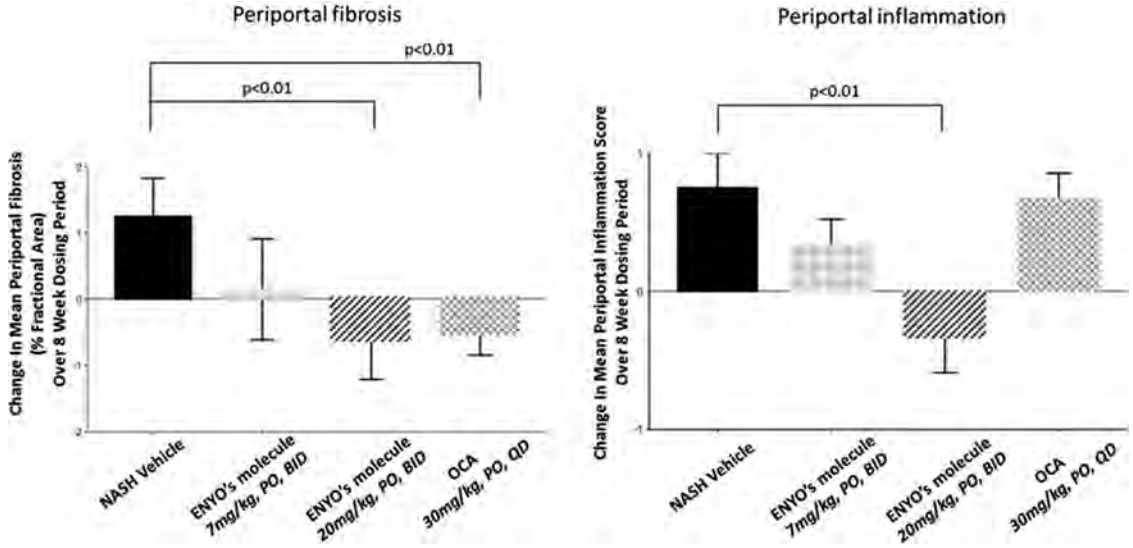


Figure: (abstract: SAT061)

cluster binding assay. Effects on mitochondrial activity were assessed by evaluating (1) mitochondrial respiration by high-resolution respirometry, (2) the activity of electron transport chain complexes by enzymology and finally (3) mitochondrial membrane potential by measuring TMRM probe incorporation by flow cytometry. The effect of ENYO's molecule was investigated *in* vivo by 8 weeks of oral administration in a mouse diet-induced NASH model. For comparison, a mouse group was also administered OCA daily.

Results: ENYO's lead molecule was shown to enhance release of the bound [2Fe-2S] cluster of purified NEET proteins and partially inhibit Electron Transport Chain Complex I and oxidative phosphorylation. Consistent with this effect, mitochondrial membrane potential and mitochondrial ATP levels of treated cells were decreased. In vitro, the molecule showed potential for anti-inflammatory effects by inhibiting NFKB activation in a reporter cell line and IL6 expression in bone marrow-derived macrophages. In vivo, therapeutic administration of ENYO's lead NEET protein modulator was shown to resolve both portal inflammation and portal fibrosis in a dose-dependent manner. Effects seen on portal inflammation were superior to OCA, which showed little effect on portal inflammation.

Conclusion: Our molecule offers a novel approach for regulating the activity of a family of proteins of critical importance in mitochondrial biology and could offer new perspectives in the treatment of NASH and other diseases with an important inflammatory component.

SAT062

Evaluation of pharmacological intervention using a deep learning approach for histopathological scoring in a diet-induced obese and biopsy-confirmed mouse model of NASH with fibrosis

Agnete Overgaard[1], Casper G Salinas[1], Christian Eschen[2], Michael Feigh[1], Denise Oro[1], Sanne Veidal[1]. *[1]Gubra, Hørsholm, Denmark; [2]Visiopharm A/S, Hørsholm, Denmark*
Email: ssv@gubra.dk

Background and Aims: The primary endpoint in clinical trials for non-alcoholic steatohepatitis (NASH) is the NAFLD-activity score (NAS) including fibrosis staging in a liver biopsy. Histopathological disease scoring systems are, however, subjective and prone to inter- and intra-observer variation. The present study aimed to develop deep learning applications (APPs) to obtain a more accurate and objective method for staging disease in mouse models of NASH. Further, we evaluated the effect of elafibranor or semaglutide in a diet-induced obese (DIO) biopsy-confirmed mouse model of NASH using the deep learning APPs.

Method: Segmentation of liver biopsy sections stained for H&E and Picro Sirius Red (PSR) from DIO NASH mice and lean controls was performed using the Artificial Intelligence (AI) software from Visiopharm. Hepatocytes with and without steatosis and inflammatory cells were annotated in H&E sections. In PSR sections, portal triads and central veins were segmented using AI. Portal, sinusoidal, and bridging fibrosis were identified using Bayesian image analysis. APP outputs were postprocessed into the corresponding scores (AI scores).

Digital slides were acquired from DIO-NASH mice (C57Bl/6J mice fed AMLN diet) with different stages of steatosis, inflammation and fibrosis (n = 110) to validate the AI scores. Additionally, pharmacological intervention was evaluated on DIO-NASH mice (n = 12–14/group) before (prebiopsy) and after 8 wks treatment with vehicle, elafibranor (30 mg/kg) or semaglutide (30 nmol/kg). AI scores (steatosis, inflammation and fibrosis) were obtained using the deep learning APPs.

Results: The deep learning APPs successfully recognized hepatocytes with and without steatosis, inflammatory cells and portal, sinusoidal and bridging fibrosis in DIO-NASH mice. APP outputs were successfully translated into steatosis, inflammation and fibrosis scores with weighted kappa values of 0.95, 0.81 and 0.74 respectively. Treatment with elafibranor or semaglutide significantly improved steatosis. In addition, animals treated with elafibranor showed no worsening of fibrosis as compared to vehicle. AI scores correlated well with previous reported efficacy data of elafibranor and semaglutide.

Conclusion: We here demonstrate a deep-learning based approach to obtain the NAS and fibrosis scores in a translational DIO-NASH mouse model. A deep-learning approach for pattern recognition allows unbiased and reproducible quantification of histological NASH parameters.

SAT063

MET409, a potent, non-bile acid sustained FXR agonist, improves NAFLD activity score and exerts anti-fibrotic effects in a diet-induced obese mouse model of biopsy-confirmed fibrosing NASH

Sanne Veidal[1], Michael Feigh[1], Kirstine Tølbøl[1], Nicholas Smith[2], Brandee Wagner[2]. *[1]Gubra, Hørsholm, Denmark; [2]Metacrine, Inc., San Diego, United States*
Email: ssv@gubra.dk

Background and Aims: The farnesoid X receptor (FXR) is a ligand activated transcription factor highly expressed in the liver and intestinal tract. Sustained FXR activation has shown efficacy in

clinical trials for non-alcoholic steatohepatitis (NASH); notably in conjunction with anti-fibrotic action. The present study aimed to explore the effect of MET409, a potent non-bile acid sustained FXR agonist, on metabolic, biochemical and histopathological endpoints in a diet-induced obese (DIO) mouse model of biopsy-confirmed NASH with fibrosis.

Method: Male C57BL/6J mice were fed Gubra Amylin NASH (GAN) diet high in fat, fructose and cholesterol for 35 weeks prior to liver pre-biopsy. Only animals with biopsy-confirmed steatosis (≥2) and fibrosis (≥F1) were included and stratified into treatment groups. DIO-NASH mice received vehicle (PO, QD), MET409 (3 mg/kg, PO, QD) or MET409 (10 mg/kg, PO, QD) for 8 weeks. Pre-post liver biopsy histology was performed for within-subject evaluation of changes in NAFLD Activity Score (NAS) and fibrosis stage. Additionally, terminal quantitative liver histology, blood and liver biochemistry was assessed. Finally, whole liver RNAsequencing for transcriptomic profile was analyzed.

Results: MET409 low and high dose treatment induced a weight loss of 14% and 19%, respectively, in DIO-NASH mice. Compared to vehicle, MET409 dose-dependently reduced plasma levels of liver enzymes (ALT, AST) and lipids (triglycerides, cholesterol) after 4 weeks of treatment, being sustained at termination. In addition, MET409 markedly reduced liver triglyceride and cholesterol content. MET409 treatment profoundly reduced quantitative levels (% fractional area) of liver fat and inflammation and improved composite NAS (pre-to-post) for all MET409-treated animals, driven by reduction in steatosis and lobular inflammation scores. For fibrosis, MET409 high dose treatment decreased liver collagen 1a1 content, along with a non-significant improvement in fibrosis stage (pre-to-post). Notable, MET409 treatment reduced liver α-SMA deposition. Finally, MET409 treatment led to consistently lowered expression of hepatic genes associated with inflammation and fibrogenesis.

Conclusion: MET409 is a potent, systemic, sustained FXR agonist that improved metabolic, biochemical and histopathological parameters in biopsy-confirmed DIO-NASH mice. FXR agonists with profiles similar to MET409 are promising drug candidates for improvement in liver pathology by improving fibrosing NASH and preventing fibrogenesis.

SAT064

S1pr2 is a key mediator of endoplasmic reticulum stress in NAFLD/NASH pathogenesis

Luciana Petti[1], Ana Lleo[2,3], Silvia Restelli[4], Giusy Sammarco[4], Matteo Donadon[5,6], Giulia Rizzo[6], Vincenzo Arena[7], Guido Carpino[8], Paola Corsetto[9], Roberto Ceriani[3], Angela Maria Rizzo[9], Alessio Aghemo[3,6], Stefania Vetrano[4,6]. *[1]Humanitas Clinical and Research Center-IRCCS, IBD Center, Laboratory of Gastrointestinal Immunopathology, Rozzano, Italy; [2]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy; [3]Humanitas Clinical and Research Center-IRCCS, Division of Internal Medicine and Hepatology, Department of Gastroenterology, Rozzano, Italy; [4]Humanitas Clinical and Research Center-IRCCS, IBD Center, Laboratory of Gastrointestinal Immunopathology, Rozzano, Italy; [5]Humanitas Clinical and Researtch Center-IRCCS, Department of Hepatobiliary & General Surgery, Rozzano, Italy; [6]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy; [7]Università Cattolica del Sacro Cuore, Area of Pathology, Department of Woman and Child Health and Public Health, Fondazione Policlinico Universitario A. Gemelli IRCCS, Istituto di Anatomia Patologica, Rome, Italy; [8]University of Rome "Foro Italico", Division of Health Sciences, Department of Movement, Human and Health Sciences, Rome, Italy; [9]Università Degli Studi di Milano, Department of Pharmacological and Biomolecular Sciences, Milan, Italy*
Email: stefania.vetrano@humanitasresearch.it

Background and Aims: The pathogenesis of non-alcoholic fatty liver disease (NALD), particularly the mechanisms whereby a minority of patients develop a more severe phenotype characterised by hepato-cellular damage, inflammation, and fibrosis is still incompletely understood. Endoplasmic reticulum (ER) stress is a feature of acute and chronic liver diseases through its involvement in inflammatory responses, steatosis, hepatocyte apoptosis, and fibrosis. However, the pathways activated by ER stress driving these processes are still poor unknown. The sphingosine-1-phosphate receptor 2 (S1PR2), one of receptors binding sphingosine-1-phosphate, plays an important role in promoting hepatic regeneration after liver injury and in regulating hepatic lipid metabolism. Nevertheless, its involvement in the NAFLD/NASH pathogenesis remains to be elucidated. Here we investigated the implication of S1PR2 the NAFLD/NASH pathogenesis.

Method: S1PR2 expression was analyzed in liver biopsies from 15 patients affected from NAFLD/NASH at different stages of disease progression and in non-tumoral liver samples from 5 patients with hepatocarcinoma as healthy controls by qRT-PCR. Experimental NAFLD model was carried out in S1PR2−/− (ko) and littermate wildtype (WT) mice by high fat diet (HFD)-feeding for 12 weeks. Body weight, metabolic parameters including total cholesterol, glucose and insulin were recorded. NAFLD activity score (NAS) and steatosis were evaluated by hystology. Inflammatory cytokines were analyzed by ELISA assay. ER stress was induced by a single injection of tunicamycin (TM) at a dose of 1 μg/g body weight intraperitoneally. Unfolded protein response (UPR) signaling was analyzed by qRT-PCR and western blot.

Results: Significant downregulation of S1PR2 was found in NAFLD/NASH patients compared to healthy controls, whereas no difference was observed among the different stages of disease. The genetic deletion of S1PR2 under HFD regime induced greater liver injury, apoptotic and inflammatory signaling, altered metabolic parameters such insulin resistence, reduced glucose level, lower total cholesterol and increased hepatic steatosis associated to a higher NAS score ($p = 0.017$) and to a greater presence of hepatocellular ballooning ($p < 0.001$) compared to WT mice. Significant increase of ATF6, ATF4 and CHOP levels were associated to ko mice compared to WT after HFD and TM treatment, whereas GRP78 levels drastically reduced. Furthermore, the loss of S1PR2 drove to lipid perturbations such as increased uptake of triglyceride and reduction of its oxidation.

Conclusion: These results suggest that S1PR2 is a key mediator of ER stress response, preventing an excessive and/or prolonged UPR activation, which leads to ER stress-induced damage and lipid perturbations. Overall, these observations identify S1PR2 as a novel therapeutic target for the treatment of NAFLD/NASH

SAT065

Infiltrative monocyte derived adenosine deaminase 2 promotes liver fibrosis via signaling through extracellular inosine

Shilpa Tiwari Heckler[1,2], Eric Yee[3], Jiwoon Park[4], Duc Nguyen[4], Wenda Gao[5], Michelle Lai[2], Robert Schwartz[4], Z. Gordon Jiang[2]. *[1]Heidelberg University Hospital, Division of Gastroenterology and Hepatology, Heidelberg, Germany; [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Gastroenterology and Hepatology, Boston, United States; [3]University of Arkansas for Medical Sciences, Department of Pathology, Little Rock, United States; [4]Weill Cornell Medical College, Division of Gastroenterology and Hepatology, New York City, United States; [5]Antagen Institute for Biomedical Research, Boston, United States*
Email: Shilpa.Tiwari-Heckler@med.uni-heidelberg.de

Background and Aims: Liver fibrosis in nonalcoholic fatty liver disease (NAFLD) is driven by infiltrated monocytes. However, the mechanism of this process is not fully understood. We have previously reported an association between liver fibrosis in NAFLD and circulating levels of adenosine deaminase 2 (ADA2), an enzyme produced exclusively by monocytes and macrophages that converts extracellular adenosine to inosine. Herein, we describe a novel mechanism by which infiltrated monocytes secret ADA2 to modulate the phenotype of hepatic macrophages and promote liver fibrosis in NAFLD.

Method: We examined ADA2 expression in 92 liver biopsies from a NAFLD registry. Recombinant human ADA2 was produced to study its function in modulating macrophage's phenotype *in vitro*. Transcriptome analysis in human monocyte-derived macrophages (MoMF) and primary human Kupffer cells were determined in response to wild-type and mutant ADA2 stimulation.
Results: In the human liver, ADA2 expression was noted in CD14+/CD16+ portal macrophages and Kupffer cells. ADA2+ portal macrophages were significantly associated with the degree of liver fibrosis as shown by a quantitative histological score. Notably, portal macrophages carried far more ADA2 transcripts than Kupffer cells as measured by RNAscope, suggesting a putative paracrine and autocrine nature of regulation. Upon ADA2 stimulation, human MoMF demonstrated a striking upregulation of pro-inflammatory and pro-fibrotic genes in our RNAseq analysis. These findings were validated in U937-derived macrophages and human MoMF from six independent donors. Among these differentially expressed genes, PDGF-BB transcription, a key pro-fibrotic cytokine, was upregulated in macrophages in response to ADA2 and its substrate adenosine. Particularly, inosine, the catalytic product of ADA2, stimulated significantly PDGF-BB expression in macrophages, suggesting a causal role of the deaminase activity. Furthermore, mutation at glutamic acid 359 in the catalytic active site of ADA2 resulted in diminished enzyme activity and a reduction in PDGF-BB gene-expression in macrophages compared to native form of ADA2. Finally, we tested the effect of ADA2 in a human-derived multicellular liver spheroid system and found a robust stimulation of PDGF-BB production from primary human Kupffer cells.
Conclusion: Infiltrative monocytes release ADA2 to promote liver fibrosis by augmenting a pro-fibrotic differentiation of hepatic macrophages via signaling through extracellular inosine. This pathway may provide alternative targets in modulating liver fibrosis in NAFLD.

SAT066

TERN-501, a potent and selective agonist of thyroid hormone receptor beta, strongly reduces histological features and biomarkers of non-alcoholic steatohepatitis associated pathology in rodent models

Thorsten Kirschberg[1], Christopher Jones[1], Yingzi Xu[1], Yujin Wang[1], Martijn Fenaux[1], Kevin Klucher[1]. [1]*Terns Pharmaceuticals, Foster City, United States*
Email: tkirschberg@ternspharma.com

Background and Aims: Liver inflammation and damage resulting from hepatic fat accumulation are key drivers in the progression of non-alcoholic fatty liver disease (NAFLD) to non-alcoholic steatohepatitis (NASH). Selective agonists of thyroid hormone receptor beta (THR-beta) have been shown to markedly reduce liver fat, hepatic inflammation, and damage. This drug class may also provide additional clinical benefits to NASH patients by lowering proatherogenic factors.
Method: THR agonist potency and selectivity were assessed biochemically using THR-beta or THR-alpha/RXR heterodimeric assays. Serum cholesterol lowering activity was assessed 24 hours after a single IP dose of TERN-501 in rats fed with a cholesterol rich diet for 14 days. TERN-501 was tested in a mouse NASH model using C57/Bl6J mice fed with a high fat diet prior to biweekly administration of carbon tetrachloride and daily oral drug treatment. Following 28 days of TERN-501 treatment, liver histology was used to assess steatosis, inflammation, ballooning and fibrosis; liver tissue and plasma/serum enzyme, lipid and triglyceride levels were analysed relative to vehicle treated control mice. Gene expression changes were determined by RT-qPCR and RNAseq.
Results: TERN-501 exhibited potent and selective THR-beta agonism (THR-beta EC_{50} = 100 nM; THR-alpha EC_{50} = 2,600 nM) with good PK properties in preclinical species. In a rat hypercholesterolemic model, a robust and dose-dependent reduction in total cholesterol of up to 71% at a dose of 30 mg/kg ($p < 0.0001$ vs. vehicle) was observed. In a NASH mouse model, steatosis in TERN-501 treated mice was profoundly reduced from untreated control mice. Significant reductions in serum total cholesterol, triglyceride and ALT levels were also observed at all dose levels tested. RT-qPCR and RNAseq analysis confirmed modulation of known THR-beta regulated genes. TERN-501 treatment strongly modulated expression of genes in multiple metabolic pathways relevant to NASH.
Conclusion: TERN-501 is a potent and selective THR-beta agonist. TERN-501 reduced serum cholesterol levels in a hypercholesterolemic rat model and significantly reduced liver steatosis, fibrosis, and serum markers of liver damage in a NASH mouse model, supporting further development of this drug for the treatment of NASH.

SAT067

Western diet induced nuclear NFATC1 activates pro-apoptotic endoplasmic reticulum (ER) stress signaling, and progresses NAFLD to NASH

Muhammad Umair Latif[1], Kristina Reutlinger[1], Geske Schmidt[1], Sercan Mercan[1], Julia Kitz[2], Raza-Ur Rahman[3], Shiv Kumar Singh[1], Philipp Ströbel[2], Volker Ellenrieder[1]. [1]*UMG, Institute for Gastroenterology and Gastrointestinal oncology, Göttingen, Germany;* [2]*UMG, Institute for Pathology, Göttingen, Germany;* [3]*UKE, Center for Molecular Neurobiology (ZMNH) Institute of Medical Systems Biology, Hamburg, Germany*
Email: umair.latif@med.uni-goettingen.de

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is one of the most common causes of chronic liver diseases worldwide having 20%-30% prevalence. It initiates with hepatocytes lipid

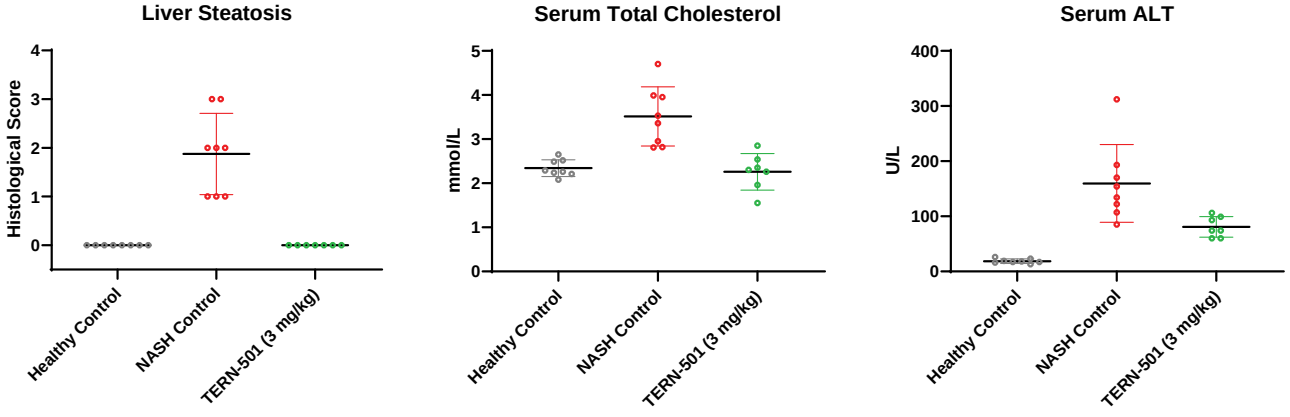

Figure: (abstract: SAT066): TERN-501 significantly reduced liver steatosis and serum total cholesterol and ALT in a mouse model of NASH.

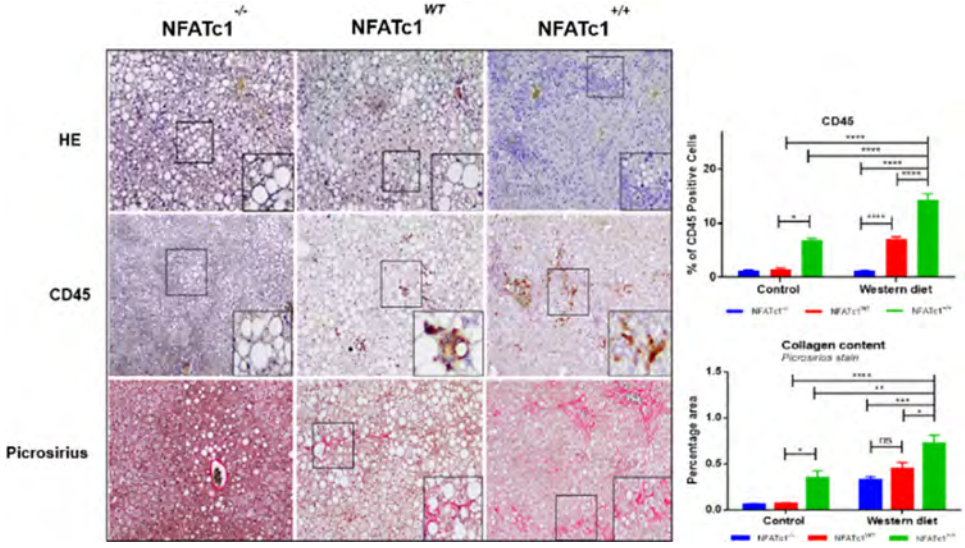

Figure: (abstract: SAT067)

deposition (steatosis) progressing to non-alcoholic steatohepatitis (NASH) and liver cancer. Numerous studies documented aberrant NFAT (nuclear factor of activated T-cells) signalling inducing inflammation and tumor development in other organs e.g. Pancreas. We tend to characterize NFATc1 mediated genes and signalling in NAFLD-NASH-HCC progression.

Method: Immunohistochemistry (IHC) confirmation of NFATc1 activation in NAFLD patients' biopsies. Analysis of palmitate induced NFATc1 expression in mouse primary hepatocytes and AML12 cells by western blot (WB) and immunoflouresence (IF). 8 weeks old C57BL/6 mice with hepatocyte specific constitutively active (NFATc1$^{+/+}$), knock-out and wild type NFATc1 expression (NFATc1^{WT}) were fed with normal and western diet for 20 weeks, respectively. Steatosis, inflammation and fibrosis were analyzed using Hematoxylin-eosin, IHC and picrosirius-red staining. RNA-seq was performed in AML12 cells after transfection with NFATc1$^{+/+}$ construct. Results were validated *in-vivo* and *in-vitro* using RT-PCR and WB. Cytokine profiling was performed in mouse liver tissue lysates.

Results: Western diet/Palmitate activates NFATc1 in hepatocytes both *in-vivo* and *in-vitro*. NFATc1 aberrant expression induced progressive hepatic inflammation and fibrosis in NFATc1^{WT} and NFATc1$^{+/+}$ mouse model. NFATc1$^{-/-}$ mice were protected against western diet induced inflammation and fibrosis. RNA-seq analysis in AML12 cells showed upregulation of pro-inflammatory and pro-apoptotic ER stress signaling after NFATc1$^{+/+}$ transfection, particularly PERK regulated C/EBP homologous protein (CHOP). CHOP leads to activation of caspase-1 mediated apoptosis and induction of pro-inflammatory cytokines IL1-alpha and IL1-beta. NFATc1 silencing protected CHOP induction and apoptosis as analyzed by TUNEL and WB. Mice pretreated with western diet showed similar effects along with NFATc1 dependent changes in cytokines/chemokines. we observed NFATc1 dependent NAFLD progression to NASH. Inhibition of ER stress with tauroursodeoxycholic acid significantly reduced inflammation and fibrosis upon western diet treatment in NFATc1^{WT} and NFATc1$^{+/+}$ mouse.

Conclusion: Together, our ongoing study proposes a model in which NFATc1 induction drives inflammation and fibrosis via inducing hepatocytes ER stress induced apoptosis and pro-inflammatory cytokines.

SAT069

Chorionic-plate-derived mesenchymal stem cells attenuate hepatic steatosis via restoration of mitochondrial function

Yun Bin Lee[1], Se-Mi Jung[1], Jae Yeon Kim[2], Minseok Albert Kim[1], Gi Jin Kim[2], Jung-Hwan Yoon[1]. [1]*Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South;* [2]*CHA University, Department of Biomedical Science, Seongnam, Korea, Rep. of South*
Email: yoonjh@snu.ac.kr

Background and Aims: Nonalcoholic fatty liver disease (NAFLD) is one of the most common chronic liver diseases worldwide, but its pathophysiology is not fully understood due to complexity of the mechanisms involved in the disease. Moreover, the pharmacological therapy for NAFLD is not yet available. We investigated the effects of chorionic-plate-derived mesenchymal stem cells (CP-MSCs) on hepatic steatosis and mitochondrial function.
Method: HepG2 cells were treated with palmitic acid (PA), and then co-cultured with CP-MSCs. Intracellular lipid accumulation was measured by oil red O staining and mitochondrial function was assessed by quantifying mitochondrial DNA (mtDNA) and fatty acid oxidation. Male C57BL/6J mice were chronically fed with high-fat diet (HFD). At week 29, mice were injected with either phosphate-buffered saline (NTx) or CP-MSCs (Tx; 1 × 106 cells, 8–10 passages). Four weeks later, liver histology and function were assessed.
Results: PA-induced intracellular lipid accumulation was attenuated when co-cultured with CP-MSCs (panel A). The mitochondrial mass was reduced by PA treatment and then was restored following co-culture with CP-MSCs (panel B). Expression of genes involved in regulation of mitochondrial function, such as PGC1 and sirtuins, was dynamically changed by PA treatment and CP-MSC co-culture. Cellular reactive oxygen species production was increased by PA treatment and then was attenuated after CP-MSC co-culture. The activity of superoxide dismutases (SODs) and the rate of mitochondrial β oxidation were suppressed by PA treatment and were restored by co-culture with CP-MSCs (panel C and D). Severe hepatic steatosis in HFD-fed mice was ameliorated following transplantation of CP-MSCs (panel E). Decreased activity of SODs was reverted to near the levels of normal diet-fed mice after transplantation of CP-MSCs (panel F).
Conclusion: Hepatic steatosis and mitochondrial dysfunction in NAFLD can be ameliorated by transplantation of CP-MSCs. Our study findings suggest the therapeutic potential of CP-MSCs in NAFLD and help understanding alterations in hepatic lipid metabolism which may be restored by CP-MSC transplantation.

SAT071

Iron loss-induced mitophagy via mitochondria ferritin suppresses NASH-related hepatocellular carcinoma

Yuichi Hara[1], Atsushi Tanaka[2], Izumi Yanatori[3], John Lemasters[4], Sohji Nishina[1], Kyo Sasaki[1], Keisuke Hino[1]. [1]*Kawasaki Medical School, Hepatology and Pancreatology, Kurashiki, Japan;* [2]*Yamagata University School of Medicine, Research Institute of Medical Sciences, Yamagata, Japan;* [3]*Nagoya University Graduate School of Medicine, Pathology and Biological Responses, Nagoya, Japan;* [4]*Medical University of South Carolina, Drug Discovery & Biomedical Sciences and Biochemistry & Molecular Biology, Charleston, United States*
Email: khino@med.kawasaki-m.ac.jp

Background and Aims: Mitochondrial dysfunction is known to play a critical role in nonalcoholic steatohepatitis (NASH) development and subsequent progression to cirrhosis and hepatocellular carcinoma (HCC). Mitochondrial quality is controlled by selective removal of defective mitochondria through autophagy (mitophagy). An iron chelator-mediated iron loss triggers mitophagy by a yet unknown mechanism and whether this could be used to improve mitochondrial function as a therapeutic strategy for NASH has not been tested. The aim of this study was to elucidate whether iron loss-induced mitophagy suppresses the HCC development in NASH-related mouse model and to clarify the mechanisms by which iron loss induces mitophagy.
Method: The effect of iron chelator, deferiprone (DFP), on mitophagy was examined using Huh7 cells, HepG2 cells, and NASH-related hepatocarcinogenic mouse models (STAM mice and 7,12-dimethylbenz(*a*)anthracene (DMBA)-treated mice fed a high fat diet).
Results: Iron loss induced by DFP suppressed NASH-related liver fibrosis and HCC development by inducing mitophagy in the mouse liver. Among the mitochondria-associated iron regulatory proteins, DFP treatment resulted in increased expression of mitochondrial ferritin (FTMT). In human liver cells, a transcription factor, SP1 and its regulator hypoxia inducible factor 1 alpha were necessary for DFP-induced increase in FTMT expression. FTMT is the mitochondrial protein that is synthesized as a precursor on cytosolic ribosomes, targeted to mitochondria, and then processed into functional protein.

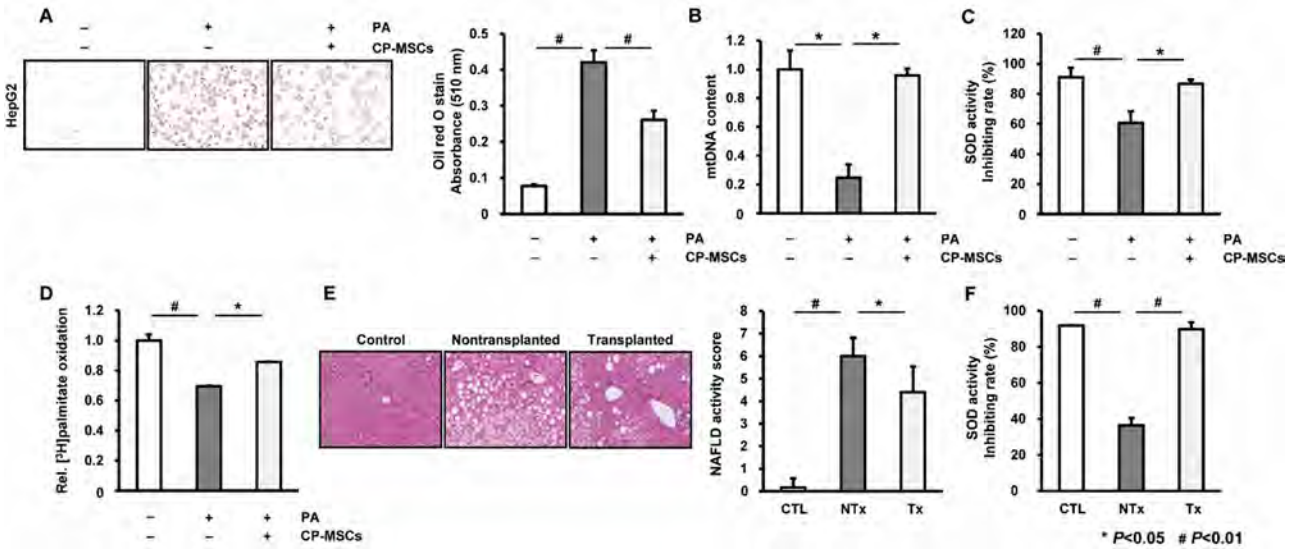

Figure: (abstract: SAT069)

DFP treatment accumulated FTMT on the outer membrane of defective mitochondria. FTMT specifically interacted with nuclear receptor coactivator 4, autophagic cargo receptor. Silencing FTMT abolished DFP-induced mitophagy. The hepatic iron decrease itself did not suppress HCC development since FTMT knockdown abrogated DFP-induced suppression of HCC. The expression of FTMT positively correlated with the number of mitophagosome-like structures and negatively correlated with the pathological severity and progression of nonalcoholic fatty liver disease (NAFLD) in liver biopsy specimens obtained from patients with NAFLD.
Conclusion: These results provide a rationale for targeting mitophagic activation as a therapeutic strategy against NASH-related liver fibrosis and HCC development.

Cirrhosis and its complications: Clinical

SAT076
Application of the new GLIM criteria for the diagnosis of malnutrition in patients with liver cirrhosis and usefulness of three different screening tools

Diego Casas Deza[1,2], Elena Betoré Glaria[1], Alejandro Sanz Paris[3], Vanesa Bernal Monterde[1,2], Eva Fernandez Bonilla[1], Javier Fuentes[1,2]. *[1]Hospital Universitario Miguel Servet, Gastroenterology and hepatology, Zaragoza, Spain; [2]IIS Aragón., Zaragoza, Spain; [3]Hospital Universitario Miguel Servet, Endocrinology and nutrition, Zaragoza, Spain*
Email: 630552@unizar.es

Background and Aims: Different scientific societies have proposed GLIM criteria (Global Leadership Initiative on Malnutrition) for the diagnosis of malnutrition. In patients with liver cirrhosis, however, the prevalence of such malnutrition has not been evaluated by applying these criteria. Our principal aim was to analyze the prevalence of malnutrition in a cohort of patients with liver cirrhosis according to the new GLIM criteria. As a secondary objective, to evaluate the capacity of the Liver Disease Universal Screening Tool (LDUST), Royal Free Hospital-Nutrition Priorizing Tool (RFH-NPT) and Mini Nutritional Assessment Short Form (MNA-SF) questionnaires as screening tools for malnutrition.
Method: Prospective study including consecutively all patients with liver cirrhosis in follow-up in Hepatology consultations at the Miguel Servet Universitary Hospital during the months of April and May 2019. Initially, a gastroenterologist applied the screening tools: LDUST, RFH-NPT and MNA-SF. Subsequently, the diagnosis of malnutrition was carried out according to GLIM criteria by an endocrinologist blind to the results of the screening tools. Sarcopenia was evaluated by bioimpedanciometry.
Results: 63 patients (38.1% women, mean age 63.11 ± 9.92) with cirrhosis (60.3% Child-A, 34.9% Child-B and 4.8% Child-C) were evaluated. The most frequent causes were alcohol (53%) and hepatitis C (23.8%). The prevalence of malnutrition according to GLIM criteria was 38.1% (15.9% moderate, 22.2% severe). The prevalence of sarcopenia was 14.3%. The most prevalent GLIM criteria were reduction in strength measured by hand grip (27%) and reduction in dietary intake (36.5%). Advanced stages of cirrhosis were associated with higher prevalence of malnutrition ($p = 0.033$). Considering GLIM as the gold standard, MNA-SF was the most accurate screening tool, being superior to RFH-NPT and LDUST (Table 1). It presented better sensibility than NFH-NPT (67% [0.45;0.84] vs 87% [0.67:0.97], $p = 0.031$) and better specificity than LDUST (97% [0.86; 0.99] vs 62% [0.44;0.76], $p < 0.001$) and than NFH-NPT (97% [0.86; 0.99] vs 82% [0.66;0.92], $p = 0.016$).

Table: Screening tools statistical measures

	LDUST	RFH-NPT	MNA-SF
Sensitivity % (IC)	83% (0.62;0.95)	67% (0.45;0.84)	87% (0.67:0.97)
Specificity % (IC)	62% (0.44;0.76)	82% (0.66;0.92)	97% (0.86; 0.99)
PPV % (IC)	57% (0.46;0.67)	80% (0.69; 0.88)	92% (0.81;0.97)
NPV % (IC)	85% (0.70;0.94)	70% (0.52;0.82)	95% (0.75;0.99)
Positive likelihood ratio	2,10 (1.40;3.34)	3.71 (1.79;7.69)	34.125 (4.90;237.60)
Negative likelihood ratio	0,27 (0.11;0.69)	0,41 (0.23;0.73)	0,1 (0.04;0.37)

Conclusion: According to the GLIM criteria, the prevalence of malnutrition in patients with cirrhosis is very high, being severe in 22% of the patients. The MNA-SF is the most accurate screening test, superior even to tools specifically designed for patients with cirrhosis.

SAT077
Automated low flow ascites (ALFA) pump effectively reduces the number of large volume paracentesis - data from a real world cohort

Adam Herber[1], Cornelius Engelmann[2], Niklas Aehling[1], Rhea Veelken[1], Dr. Sebastian Rademacher[3], Daniel Seehofer[3], Thomas Berg[1]. *[1]University Hospital Leipzig, Section Hepatology, Department of Gastroenterology and Rheumatology, Leipzig, Germany; [2]University College London, Royal Free Campus, Institute for Liver and Digestive Health, London, United Kingdom; [3]University Hospital Leipzig, Department of Visceral, Vascular, Thoracic and Transplant Surgery, Leipzig, Germany*
Email: adam.herber@medizin.uni-leipzig.de

Background and Aims: The alfapump is an implantable device which removes fluid from the peritoneal cavity into the urinary bladder and which is therefore used as a therapy for cirrhosis related refractory ascites and malignant ascites. The aim of our study was to analyze the safety and efficacy of the alfapump in a real life cohort.
Method: In this retrospective study we included all patients (n = 35) who underwent the alfapump implantation in the University Hospital Leipzig between June 2013 and September 2019. The major criteria to consider alfapump in our clinic are contraindication for TIPS and life expectancy of 6 months and more. The number of large volume paracenteses (LVP), clinical data and technical device reports were collected from patient records before and 1 week (±3 days) 3, 6, 12, 18, 24 months (±1 month) after implantation.
Results: Patients who underwent the procedure had a mean age of 62.3 ± 8.8 years and 77.1% were male. The main cause of ascites was liver cirrhosis (n = 32, 91.4%) and of those the majority had an alcoholic liver disease (n = 25, 78%). There were three patients with ascites unrelated to cirrhosis, caused by HCC in non-cirrhosis, mastocytosis and pancreas carcinoma (n = 1 each). At the time of implantation the median glomerular filtration rate (GFR) was 55 mL/min (20–112), mean MELD in cirrhotic patients was 13.4 ± 3.6. The median time the pump was functioning was 205 (29–933) days and the mean ascites volume removed was 740 ± 386 mL per patient/day. The LVP frequency per month could be reduced from 3.0 ± 1.1 to 0.8 ± 1.4 ($p = 0.001$). During the follow up wound complications such as dehiscence, cellulitis and local infection occurred in 11 (31.4%), technical issues such as catheter occlusion/kink and device defects in 9 (25.7%) patients. Overall 14/35 did not reach the targeted 6 months follow up (5 died due to progression of the liver disease, 7 pumps were explanted and 2 were implanted less than 6 months ago). Creatinine increased in 17/35 patients during the first week (mean 37.2 ± 38.7 µmol/L) and was significantly enhanced in patients with pre-existing renal insufficiency (GFR < 89 mL/min), 43.1 vs 14.8 µmol/L, $p = 0.01$. 4/7 patients (57.1%) fulfilling the AKI-criteria responded to

therapy. Overall 10 patients (28.5%) developed a spontaneous bacterial peritonitis (SBP), without difference between those, who had a history of SBP and those who developed SBP de novo (3/9 vs. 7/26, p = 0.6). Infections (local or systemic) led to pump removal in 12 (34.2%) patients, after a median time of 184 (46–555) days. Other reasons for explantation were ascites resolution (n = 3) and device defect (n = 3).

Conclusion: The alfapump significantly reduces the LVP-frequency and therefore is a relevant therapeutic option for patients with difficult to treat ascites. The management of renal function especially in patients with preexistent insufficiency and infection surveillance are crucial in the follow up period.

SAT078

Covered TIPSS does not improve long term survival in refractory ascites - a single- centre experience

Amritpal Dhaliwal[1,2], Laura McFarlane Majeed[1], Homoyon Mehrzad[3], Salil Karkhanis[3], Simon Olliff[3], Dhiraj Tripathi[1,2]. [1]*Queen Elizabeth Hospital Birmingham, Liver Unit, Birmingham, United Kingdom;* [2]*NIHR Birmingham Biomedical Research Centre, University Hospitals of Birmingham, Birmingham, United Kingdom;* [3]*Queen Elizabeth Hospital Birmingham, Department of Radiology, Birmingham, United Kingdom*
Email: adhaliwal85@gmail.com

Background and Aims: Refractory ascites is a serious complication of cirrhosis and portal hypertension with a 1 year survival rate of 50%. In selected patient treatment options include liver transplantation or TIPSS (transjugular intrahepatic portosystemic shunt). A recent trial showed better outcomes with covered TIPSS(1). The aim of this project was to assess the outcomes of patients who underwent a TIPSS compared to those who had large volume paracentesis (LVP).

Method: We performed a retrospective study of all patients who underwent a covered TIPSS for refractory ascites from April 2010 to November 2017 compared to all patients who underwent LVP (mean 1.28 ± 0.55 paracenteses per month) during a similar time period. We compared biochemical and clinical parameters. The primary outcome was transplant free survival.

Results: The ratio of patients in each group was 1:1.1 (n = 76 in TIPSS group, n = 86 in LVP group).

There was a male predominance of 53% and 60% respectively in the TIPSS and LVP group. The mean ages were 59 ± 9.5 & 61 ± 11.4 years. The most prevalent aetiology was alcohol related liver disease (75% TIPSS group; 56% LVP group).

The MELD score was significantly higher in the LVP group (11.5 ± 3.8 vs 15.6 ± 5.2, p < 0.05). 10 patients in the TIPSS group underwent liver transplantation versus 26 patients in the LVP group. There was no difference in spontaneous bacterial peritonitis presence between groups. Overall follow up was 20 ± 20.6 months.

Transplant free survival time at 6,12,24,60 months is as follow: TIPSS: 76%, 64%, 50%, 21%; LVP group 79%, 55%, 38%, 19% (p = NS, Figure 1). No clinical or biochemical variables were associated with survival on cox regressions analysis.

The TIPSS group (n = 76) was compared with a subset of patients in the LVP group (n = 48) who would be considered suitable for TIPSS based on the following parameters (platelet count ≥ 75 10^9/L, bilirubin ≤ 50 micromol/L, absence of pre-exist hepatic encephalopathy(2)). A further analysis of these groups showed transplant free survival remained similar in both groups.

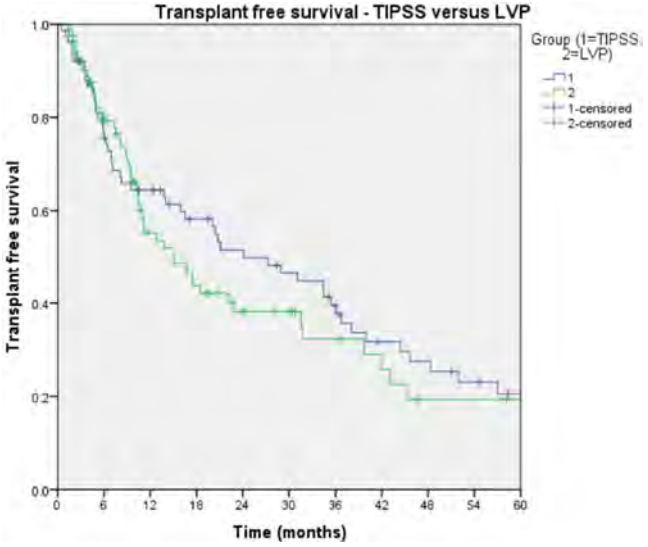

Figure: Transplant free survival (KP curve).

Conclusion: Our study shows that covered TIPSS did not result in improved transplant free survival when compared to LVP in a real-world cohort of patients with advanced liver failure. We can conclude that liver transplantation remains the best option for refractory ascites in selected patients. Further controlled studies to identify prognostic markers to assist clinicians in selecting appropriate candidates for TIPSS are required.

Comparison of skeletal muscle index (SMI) and transversal psoas muscle thickness (TPMT) for the diagnosis of sarcopenia in cirrhosis

Alessandra Pigliacelli[1], Manuela Merli[1], Barbara Lattanzi[1], Michael Praktiknjo[2], Jonel Trebika[3], Robert Schierwagen[3], Alessandro Di Gaeta[1]. [1]*Policlinico Umberto I, Roma, Italy;* [2]*UKB University of Bonn, Bonn, Germany;* [3]*University Hospital Frankfurt, Frankfurt am Main, Germany*
Email: alepigliacelli@yahoo.it

Background and Aims: Sarcopenia is a condition of progressive and generalized loss of muscle mass, strength and physical performance. Although physiologic in aging, sarcopenia represents an important burden in patients with liver cirrhosis due to its correlation with negative out-comes. Skeletal Muscle Index (SMI) is considered the gold standard for the diagnosis of sarcopenia and is calculated with computed tomography (CT) and specific due to these reasons, researchers have proposed different techniques, faster and easier, as the Trasversal Psoas Muscle Thickness (TPMT). The aim of this study is to analyze the differences among these two effective detecting sarcopenia tools.

Method: The abdominal CT of each patient has been studied to find both SMI and TPMT. SMI were taken at L3 level and the sarcopenia cut-off are: SMI ≤ 3 8.5 cm^2/m^2 for women and SMI ≤ 5 2.4 cm^2/m^2 for men. TPMT has been calculated at the level of the umbilicus and the sarcopenia cut-off are: TMPT ≤ 1 4 mm/m for women and TMPT ≤ 1 7.8 mm/m for men. Images have been studied with SliceOmatic V4.2 software, to find the total value of area.

Results: One-hundred eighty-one patients were included. A linear correlation showed these two tools are well correlated (r = 0,63 con p < 0,001), even considering only the male population (r = 0,62, p < 0,001) or the female one (r = 0,58, p < 0,001). Using SMI, we found 81 cases of sarcopenia, instead using TPMT 65 cases. The TPMT could not find out 22 cases of sarcopenia, and considered 6 patients more than SMI as affected by disease. Therefore, TMPT underestimates 27% of patients in the diagnosis, showing a sensibility of 73% and specificity of 94%.
We found both sarcopenia-SMI and sarcopenia-TPMT were significantly associated with mortality.
Conclusion: Due to lower sensitivity TPMT should not replace SMI for the diagnosis of sarcopenia in cirrhotic patients.

SAT080

PPIs can be discontinued in over 60% of patients with cirrhosis: long term impact of screening for hepatitis C drug interactions

Alison Boyle[1,2], Cecilia Fleming[1], Elaine Reilly[1], Janice McAvennie[1], Andrew Sommerville[1], Stephen Barclay[3], Fiona Marra[1,2]. *[1]NHS GGC, Pharmacy, Glasgow, United Kingdom; [2]University of Liverpool, Department of Pharmacology, Liverpool, United Kingdom; [3]NHS GGC, Glasgow Royal Infirmary, Glasgow, United Kingdom*
Email: alisonboyle2@nhs.net

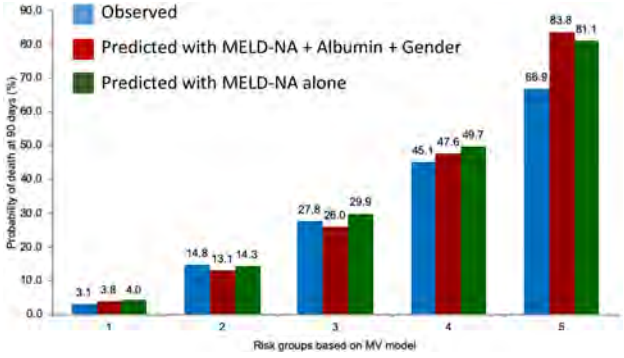
Background and Aims: Proton pump inhibitors (PPIs) are commonly prescribed in patients with cirrhosis. However, use of these drugs in this cohort has been associated with increased risk of spontaneous bacterial peritonitis and development of hepatic encephalopathy. Indications for long term use of PPIs in cirrhosis should be regularly reviewed and treatment discontinued wherever possible. PPIs can result in reduced absorption of some direct acting antivirals (DAAs) resulting in potentially sub-therapeutic levels which may impact on DAA efficacy. Frequently, it may be advised to reduce the dose or stop the PPI for the duration of HCV therapy to minimise the impact of this interaction.
We aimed to investigate whether temporary discontinuation or dose reduction of PPI therapy during HCV treatment as a result of a drug-drug interaction would result in long term rationalisation of the PPI prescription.
Method: Patients with cirrhosis commencing HCV treatment between April 2017 and March 2019, in Glasgow treatment centres were identified from the local HCV database. Information on co-prescription of PPIs was taken from pharmacy records and electronic patient records checked to confirm current prescribing status of PPI. Baseline data on age, gender, CP score, DAA regimens, PPI regimen and doses was collected. Management of the DDI was categorised as: PPI stopped and stayed off, PPI stopped and restarted after treatment, PPI dose reduced and remained low, PPI dose reduced and increased after treatment or no change to PPI.
Results: Seventy-three patients (70% male, mean age 52.3 (±SD) years) with cirrhosis co-prescribed PPIs were identified. Ten patients had decompensated liver disease (3 CPB, 7 CPC). Thirty-one patients (42.5%) were prescribed a combination of DAA and PPI which did not require discontinuation or adjustment of the PPI. Of 33 patients who stopped PPI therapy due to HCV treatment, 21 (63.6%) remained off PPIs once treatment completed. Nine patients had their dose of PPI reduced secondary to a potential DDI, with 5 (55.5%) staying on the reduced dose post treatment.
Conclusion: The majority of patients who stopped a PPI due to concerns of DDI with HCV DAAs were able to remain off the PPI once HCV treatment was completed. DDI assessment provides a valuable opportunity to rationalise medications that are potentially harmful in the context of advanced chronic liver disease, and provide an important benchmark for the feasibility of doing so.

SAT081

Building a better mousetrap: can MELD-Na be improved?

Allison Kwong[1], Ajitha Mannalithara[1], Paul Kwo[1], W. Ray Kim[1].
[1]Stanford University, Stanford, United States
Email: allison.kwong@gmail.com
Building a better mousetrap: Can MELD-NA be improved?

Background and Aims: MELD-NA is a well-established prognostic indicator for short term mortality in patients with end-stage liver disease (ESLD). It has been suggested that the predictive accuracy of MELD-NA has decreased recently with changing demographics of liver disease. The aim of the study is to utilize modern data in patients with ESLD and determine whether incorporation of additional variables may improve the accuracy of MELD-NA.
Method: This analysis is based on data from the US national registry of liver transplant candidates listed between Jan 2016 and Dec 2018. Patients were divided into model development (70%) and validation (30%) data sets. We develop a mortality prediction model using a multivariable Cox proportional hazards regression analysis incorporating additional prognostic variables. The impact of each variable on mortality was carefully modeled through variable transformation, thresholds, and interactions. Model discrimination was evaluated by concordance (c) statistics, and calibration was evaluated by comparing expected and observed mortality rates.
Results: The registry included 21,059 eligible liver transplant candidates with ESLD, divided into 14,742 for the development set and 6,317 for the validation set. After screening all potential predictors of mortality, two variables, namely sex and serum albumin, were found to be predictive of 90-day mortality, in addition to the four existing variables in MELD-NA. Statistically significant interaction was found between bilirubin and sodium, bilirubin and albumin, and sodium and INR. In the final optimized model, despite the addition of new variables and interactions, the c-statistic for the development cohort was not higher than MELD-NA alone (0.845 versus 0.846). In the validation data set, the new score predicted 90-day mortality quite well across all risk strata. However, the figure shows that the model's mortality prediction was not superior to MELD-NA. The c-statistics of the two models in the validation set were also comparable (both 0.857).



Conclusion: In contemporary ESLD patients awaiting liver transplantation, serum albumin and sex were statistically significant variables predictive of 90-day mortality independent of MELD-NA. However, incorporating these additional variables did not materially improve mortality prediction by MELD-NA. MELD-NA remains a robust and practical tool with which to predict short term mortality in patients with ESLD.

SAT082

Systemic inflammation is associated with cardiodynamic state in acute-on-chronic liver failure

Michael Praktiknjo[1], Sofia Monteiro[1,2], Josephine Grandt[3], Nina Kimer[3], Jan Lysgaard Madsen[4], Mikkel Parsberg Werge[3], Maximilian Joseph Brol[1], Laura Turco[5], Robert Schierwagen[6], Chang Johannes[1], Sabine Klein[6], Christian Jansen[1], Frank Uschner[7], Christoph Welsch[6], Richard Moreau[8], Filipo Schepis[5], Flemming Bendtsen[3], Lise Lotte Gluud[3], Søren Møller[4], Jonel Trebicka[6,9,10,11]. *[1]University of Bonn, Department of Internal Medicine I, Bonn, Germany; [2]Hospital Pedro Hispano, Department of Medicine, Porto, Portugal; [3]Hvidovre Hospital, University of Copenhagen, Gastrounit Medical Division, Copenhagen, Denmark; [4]Faculty of Health Sciences Hvidovre Hospital, University of Copenhagen, Department of Clinical Physiology and Nuclear Medicine, 239 Center for Functional and Diagnostic Imaging and Research, Copenhagen, Denmark; [5]Azienda Ospedaliero-Universitaria di Modena and University of Modena and Reggio Emilia, Division of Gastroenterology, Modena, Italy; [6]J.W.Goethe University Hospital, Department of Internal Medicine I, Frankfurt, Germany; [7]Hospital of the Goethe University Frankfurt, Department of Internal Medicine I, Frankfurt am Main, Germany; [8]Assistance Publique-Hôpitaux de Paris, Hôpital Beaujon, Département Hospitalo-Universitaire UNITY, Service d'Hépatologie;, Institut National de la Santé et de la Recherche Médicale and Université Paris Diderot, Centre de Recherche sur l'Inflammation, Paris, France; [9]European Foundation for Study of Chronic Liver Failure, Barcelona, Spain; [10]Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark; [11]Institute of Bioengineering Catalunya, Barcelona, Spain*
Email: amonteiro.sofia@gmail.com

Background and Aims: Acute-on-chronic liver failure (ACLF) is characterized by high short-term mortality and systemic inflammation (SI). Recently, different cardiodynamic states were shown to independently predict outcomes in cirrhosis. The relationship between cardiodynamic states, SI, and portal hypertension and their impact on ACLF development remain unclear. The aim of the present study was therefore to evaluate the interplay of cardiodynamic state and SI on fatal ACLF development in liver cirrhosis.
Method: At inclusion, haemodynamic measures including cardiac index (CI) and hepatic venous pressure gradient (HVPG) of 208 patients were measured. Patients were followed prospectively for fatal ACLF development (primary endpoint). SI was assessed by proinflammatory markers such as interleukins (ILs) 6 and 8 and IL-33 receptor - soluble ST2.
Results: Patients were divided according to CI (<3.2; 3.2–4.2; >4.2 L/min/m^2) in hypo- (n = 84), normo- (n = 69) and hyperdynamic group (n = 55). After a median follow up of 3 years, the highest risk of fatal ACLF was seen in hyperdynamic (35%) and hypodynamic patients (25%) compared to normodynamic (14%) (p = 0.011). Hyperdynamic patients showed the highest rate of SI. The detectable level of IL-6 was an independent predictor of fatal ACLF development.
Conclusion: Cirrhotic patients with hyperdynamic and hypodynamic circulation, have a higher risk of fatal ACLF. Therefore, the cardiodynamic state is strongly associated with SI, which is an independent predictor of development of fatal ACLF.

Preliminary results of the effects of beta-hydroxy-beta-methylbutyrate supplementation in patients with liver cirrhosis: a randomized controlled pilot study

Angelo Bruni[1], Barbara Lattanzi[1], Alessio Molfino[1], Maurizio Muscaritoli[1], Simone Di Cola[1], Nicoletta Fabrini[1], Alessandra Pigliacelli[1], Manuela Merli[1]. *[1]Viale dell'Università, 37, Roma, Italy*
Email: angelo_bruni@icloud.com

Background and Aims: Frailty is defined as a syndrome of physiological decline in late life. In patients with cirrhosis, the dysregulation of both catabolic and anabolic muscular pathways cause an increased risk of anticipated sarcopenia and frailty. Our goal is to evaluate the effects of a 3 g/die β-hydroxy-β-methylbutyrate (HMB) supplementation for twelve weeks (T1) on muscular mass and performance status in patients with cirrhosis.
Method: Clinical history and blood parameters were collected for each patient at the beginning of the study (T0). Furthermore, not only cognitive (Mini Mental State Examination, Psychometric Hepatic Encephalopathy Score, Animal Naming Test) and physical tests (Six Minute Walking Test, Five Chair Stand, Hand Grip Test) but also anthropometric measurements (using "Quadriceps femoris ultrasound" and Bioimpedentiometry) and Liver Frailty Index (LFI) was performed. Patients were randomized into a treatment group (3 g/die HMB supplementation for 12 weeks) and a control group (3 g/die sorbitol supplementation for 12 weeks). Both groups received nutritional counseling and indications of physical activity to carry out during the treatment period. At the end of the 12 weeks (T1) all the tests and measurements performed at T0 were repeated and the resulting data compared in each patient.
Results: 23 cirrhotic patients have been enrolled at present, 14 of the HMB Group and 9 of the Placebo Group. Patients receiving HMB showed a statistically significant improvement in muscular performance at FCS ranging from 14.5 (±5.4 DS) sec to 11.6 (±2.7 DS) sec, at 6MWT rising from 346.8 (±66 DS) m to 416 (±57 DS) m and LFI, decreasing from 4.0 (±0.4 DS) to 3.7 (±0.4 DS) with p value = 0,008. No significant variation between T0 and T1 were reported in patients assigned to the control group.
Conclusion: The preliminary results of this controlled randomized study suggest the efficacy of HMB supplementation in enhancing muscular performance and subsequently reducing frailty in cirrhotic patients.

SAT084

Optimizing nutrition in patients with cirrhosis may reduce hospital readmissions in medium and high risk groups: a quality improvement project

Angela Liaros[1], Christine Connolly[2], Lucy Potter[2], Lisa Jones[2], Tamsin Gledhill[1], Cyril Sieberhagen[1]. *[1]Aintree university hospital, Digestive diseases unit, Liverpool, United Kingdom; [2]Aintree university hospital, Nutrition and dietetics, Liverpool, United Kingdom*
Email: angieliaros@hotmail.com

Background and Aims: Malnutrition adversely affects prognosis in cirrhosis and is often recognized late. All cirrhotic patients should be screened for malnutrition yet this is variably performed. We evaluated assessment and management of nutrition in cirrhosis by comparing local practice to EASL guidelines, and explored patient outcomes after a focused intervention.
Method: Data was collected in 2 cycles. Cycle 1 retrospectively reviewed nutritional assessment of all patients admitted to gastroenterology during September-December 2018 with cirrhosis. An Inpatient Nutrition Proforma (INP) was introduced to record Child-Pugh (CP), anthropometrics, dietary intake, risk of malnutrition, and nutrition plan. Sarcopenia was assessed in high risk patients using handgrip strength (HGS). All CP-C and BMI <18.5 were high risk. Cycle 2 prospectively audited admissions after intervention (March-June 2019). Calorie-protein intake and HGS after intervention, readmissions and deaths were assessed at 4 months.
Results: 47 and 31 patients were identified in cycle 1 and 2 respectively. A Malnutrition Universal Screening Tool (MUST) was completed in 81% of cycle 1 patients. 47% did not trigger a dietetic referral on MUST scoring (44% medium risk and 33% high risk for malnutrition). All cycle 2 patients had a dietetic referral via the INP (26% medium risk and 71% high risk for malnutrition) and received dietary education with 77% requiring additional oral supplements and 10% nasogastric feeding. At follow-up, cycle 2 patients met higher caloric and protein requirements (average increase by 46% and 57% respectively versus 26% and 31% in cycle 1). HGS was measured in 74% in cycle 2 and 2% in cycle 1. Average HGS was 15.9 kg (cycle 2) and

improved by 9% on reassessment. There was a 12% reduction in hospital readmissions in cycle 2 compared to 7% increase in cycle 1 with similar mortality at 4 months.
Conclusion: MUST scores may be inadequate to identify all cirrhotic patients at risk of malnutrition. CP and BMI appear more accurate. A dedicated dietetic team and the INP enable early patient identification, thorough nutritional assessment and personalized plans, improving patient compliance and sarcopenia. Hospital readmission rates reduced over 4 months despite a higher proportion of high risk patients in cycle 2 versus cycle 1. 12 month follow-up data will be collected to assess mortality more accurately. Our intervention forms a platform for wider service development in this area that will help sustain quality improvement both in the inpatient setting and beyond.

SAT085

Adipopenia, among the nutritional parameters, is the rapid screening tool that best correlates with mortality in decompensated cirrhotic patients: results of a prospective study

Massimo De Luca[1], Luigi Addario[2], Anna Lombardi[3], Michele Imparato[3], Luca Fontanella[3], Marco Addario[4], Desiree Picascia[5], Giuseppe Di Costanzo[2], Antonio Ascione[3]. *[1]Liver Unit, AORN Cardarelli, Napoli, Italy; [2]Liver Unit, AORN Cardarelli, Napoli, Italy; [3]Centre for Liver Disease, Buon Consiglio, Fatebenefratelli, Napoli, Italy; [4]Liver Unit, Buon Consiglio, Fatebenefratelli, Napoli, Italy; [5]Hepato-Gastroenterology, Dpt of Precision Medicine - L. Vanvitelli University, Napoli, Italy*
Email: marcomax@tin.it

Background and Aims: patients with liver cirrhosis (LC) often have malnutrition (MN) which is associated with decompensation, infection and death. Nevertheless, nutritional status (NS) is rarely evaluated in clinical practice and there is no general agreement on definition and methods, especially in decompensated cirrhosis. Aims of this study were: 1) to investigate the prevalence of MN; 2) its impact on mortality in patients with LC and ascites and 3) relationship between MN and infectious ascites (SBP).
Method: NS was analysed in all cirrhotic patients with ascites consecutively admitted in two clinical Liver Centres between November 2014 and October 2016. The end of study was September 2019. The evaluation of NS was made using anthropometric parameters (weight, height, mid arm circumference, triceps skinfold thickness) and their derivate measurements: BMI according to Campillo, Upper Muscle Area (UMA), Upper Fat Area (UFA). All patients underwent diagnostic paracentesis and were followed up till the end of study to assess the outcome. An independent Ethical Committee approved the study.
Results: 110 patients were included and underwent NS assessment in addition to routine clinical procedures. They were: male 69.1%, median age 61 (range 26–85); aetiology of cirrhosis was: HCV 52.7%, Alcohol 33.6%, HBV 33.6%, Other 12.7%; Child-Turcotte-Pugh Class A 10.9%, B 64.5%, C 24.5%; MELD <14: 43.6%, 14–20: 33.6%, >20: 22.7%; SBP 27.3%. Prevalence of MN was: 30.9% according to corrected BMI, 67.3% according to UMA, and 40% according to UFA. During follow-up (median 10 months), 4 patients (3.6%) underwent OLT and were considered as death. Nineteen patients (17.3%) were lost to follow-up. The percentage of patients alive were: 68.1% at 3 months, 59.3% at 6 months, 45.1% at 12 months, 24.2% at the end of the study. At univariate analysis SBP, MELD, UFA, UMA and age were significantly associated with mortality. At multivariable analysis only SBP, MELD higher than 20, MELD higher than 14 and UFA were independently associated with mortality (OR = 3.09, 2.89, 2.35 and 2.22, respectively). There was a strong correlation between adipopenia and SBP ($p = 0.008$); but not with sarcopenia.
Conclusion: UFA, that measures the adipopenia, was abnormal in 40% of the cirrhotic population investigated and, among the parameters of malnutrition, was the only test independently associated with mortality (odds ratio 2.2).

SAT086

Leptin as a key player in insulin resistance of liver cirrhosis

Iva Košuta[1], Anna Mrzljak[2,3], Branko Kolaric[4,5], Maro Dragicevic[3], Egon Kruezi[6], Rafaela Novak[2], Marijana Vucic Loviencic[3], Dino Šisl[2]. *[1]Zagreb University Hospital Centre, Zagreb, Croatia; [2]School of Medicine, University of Zagreb, Zagreb, Croatia; [3]Merkur University Hospital, Zagreb, Croatia; [4]Andrija Stampar Teaching Institute of Public Health, Zagreb, Croatia; [5]School of Medicine, University of Rijeka, Croatia; [6]Sisters of Charity University Hospital Centre, Zagreb, Croatia*
Email: anna.mrzljak@gmail.com

Background and Aims: Insulin resistance is associated with increased risk of death and liver transplantation in the cirrhotic population independently of disease aetiology. However, factors accounting for insulin resistance in the context of cirrhosis are incompletely understood. This study aimed to investigate the association between adiponectin and leptin with insulin resistance in cirrhotic patients and to assess the influence of disease severity on insulin resistance and metabolic status.
Method: This cross-sectional study included 126 non-diabetic cirrhotic patients eligible for liver transplantation, who were classified according to Child-Pugh score. Homeostasis Model Assessment 2 model was used to determine insulin resistance index, and adiponectin, leptin, insulin, c-peptide, glucose, HbA1c, and lipid profile were analysed at fasting. We performed stepwise logistic regression to determine predictors of insulin resistance.
Results: Insulin resistance was detected in 83% of the subjects, and associated with higher levels of leptin, fasting plasma glucose and body mass index, and lower levels of triglycerides. Logistic regression analysis identified leptin and triglycerides as independent predictors of insulin resistance (OR 1.247, 95% CI 1.076–1.447, $p = 0.003$; OR 0.357, 95% CI 0.137–0.917, $p = 0.032$.). Leptin levels remained unchanged, whereas adiponectin levels progressively increased ($p < 0.001$) with disease progression, and inversely correlated with HbA1c ($\rho = -0.349$, $p < 0.001$).
Conclusion: Our results indicate that leptin resistance, as indicated by elevated leptin levels, can be regarded as an important contributing factor of insulin resistance in cirrhotic patients. The protective effect of triglycerides against insulin resistance was observed, while progressively increasing adiponectin levels elicited positive effect on glucose homeostasis, but not insulin sensitivity across liver cirrhosis stages.

SAT087

Femur fractures are associated with high morbimortality in patients with cirrhosis

Anna Brujats[1], Laura Gonzalez Gonzalez[1], Mireia Trias[1], Roger Rojas[2], Berta Cuyas[1], Edilmar Alvarado[1], Eva Roman[3,4], Julio De Caso[2], Carlos Guarner[1,4], German Soriano[1,4], Maria Poca[1,4]. *[1]Hospital de la Santa Creu i Sant Pau, Department of Gastroenterology, Barcelona, Spain; [2]Hospital de la Santa Creu i Sant Pau, Department of Orthopedic Surgery, Barcelona, Spain; [3]Universitat Autonoma de Barcelona, Sant Pau, University School of Nursing, Barcelona, Spain; [4]CIBERehd*
Email: annabrujats@gmail.com

Background and Aims: Patients with cirrhosis have an increased risk of falls and fractures. Fractures, especially femoral, and related surgical procedures are a common cause of decompensation and mortality in these patients. However, data evaluating the clinical impact of femur fractures in patients with cirrhosis are very scarce. The aim of this study is to evaluate the morbidity and mortality of patients with cirrhosis and femur fractures.
Method: Observational retrospective study including all patients with cirrhosis admitted for femur fracture to our hospital between 2007 and 2019. Patients were identified by the encoded diagnostics of the medical documentation department. Demographic data, clinical features, liver function, type of fracture, treatment, complications and in-hospital mortality were analyzed.

Results: One hundred and two patients were identified, 14 of whom were excluded because of lack of appropriate data, and 88 patients were thus analyzed (age 75.6 ± 11.0, 52.2% women). The main etiology was hepatitis C virus (48.9%), 43.2% had decompensated cirrhosis and MELD at admission was 11.8 ± 4.7. Fractures were the consequence of falls in 96.5% of patients, 97.7% were in proximal femur and 86.3% were operated. The time from admission to surgery was 5.3 ± 4.3 days. The incidence of complications during hospitalization was 56.8%, with infections (44.3%), renal insufficiency (35.2%), ascites (21.6%) and encephalopathy (20.4%) being the most frequent. In-hospital mortality was 18.2% (16/88), mainly due to infections. Mortality was significantly lower in patients who were operated on than in those who were not (13.1% vs 50% p = 0.007). In the multivariate analysis, independent predictive factors of in-hospital mortality were MELD (OR 1.146, 95% CI 1.018–1.290, p = 0.02) and the non-performance of surgery (OR 7.316, 95% CI 1.838–29.117, p = 0.005). Mortality among the five patients with MELD > 21 (all of them operated) was 80%. Neither age nor time between admission and surgery were predictive factors of mortality.
Conclusion: Patients with cirrhosis and femur fractures have a high risk of decompensation and in-hospital mortality. MELD score and the non-performance of surgery were independent predictive factors of mortality. Prevention of falls and multidisciplinary management of patients with fractures, including early assessment by hepatology units, may contribute to improve the prognosis of patients with cirrhosis.

SAT088

The presence of infection during hospitalization is associated with an increased risk of procedure-related bleeding in cirrhosis

Abhishek Shenoy[1], Wesley Yang[1], Zachary Henry[2], Stephen Caldwell[2], Patrick Northup[2], Nicolas Intagliata[2]. [1]*University of Virginia, Department of Medicine, Charlottesville, Virginia, United States;* [2]*University of Virginia, Division of Gastroenterology and Hepatology*
Email: nmi4d@virginia.edu

Background and Aims: Patients with decompensated cirrhosis frequently undergo procedures while hospitalized. Bleeding risk related to procedures is understudied and administration of empiric bleeding prophylaxis is common, yet lacks substantial evidence. We examined a cohort of hospitalized patients with decompensated cirrhosis who underwent non-surgical procedures to identify factors predictive of bleeding.
Method: Medical records of 707 hospitalized patients with cirrhosis over 2 years were examined. Patients were excluded if they had surgery, did not undergo a procedure or had non-procedure related bleeding. Bleeding was defined according to established criteria and was related to the procedure in time and location.
Results: 180 patients met inclusion criteria (40 with bleeding group (BG) and 140 in the non-bleeding group (NBG). General characteristics were similar between groups including MELD 26 (95%CI 22–25) BG vs. 23 (95%CI 22–25) NBG, p = 0.13. Traditional measures of coagulation were similar between groups including platelets 111 k/mL (95%CI 87–134) BG vs. 118 k/mL (95%CI 106–131) NBG, p = 0.50, fibrinogen 149 mg/dL (95%CI 118–178) BG vs.167 mg/dL (95%CI 147–189) NBG, p = 0.32, and INR 2.0 (95%CI 1.6–2.4) BG vs. 1.8 (95%CI 1.6–1.9) NBG, p = 0.25. Patients in the BG underwent significantly more procedures (3.6, [95%CI, 2.7–4.4]) than the NBG (2.1 [95%CI, 1.8–2.4]), p < 0.0001). The presence of infection at time of procedure was highly associated with bleeding on univariate analysis (OR 3.0, 95%CI 1.4–6.2, p = 0.0003). On multivariate analysis, infection (OR 2.4, 95% CI 1.1–5.3, p < 0.003), number of procedures performed (OR 1.3, 95% CI 1.1–1.5, p < 0.0001) and total admissions during the study period (OR 1.2, 95% CI 1.1–1.4, p = 0.0026) were independently associated with bleeding. Paracentesis was the most common procedure performed (Table 1). Among patients with bleeding, major bleeding was associated with a significantly larger decrease in hemoglobin and increased transfusion requirements compared to patients with minor bleeding.

Table: Bleeding Events

	Major Bleed (n = 26)	Minor Bleed (n = 14)
Bedside procedure 1. Paracentesis (21) 2. Thoracentesis (2) 3. Lumbar puncture (1)	16 (15.1%)	8 (7.5%)
Vascular (4)	3 (15.7%)	1 (5.3%)
Endoscopic (5)	4 (14.8%)	1 (3.7%)
Interventional radiology (4)	2 (15.4%)	2 (15.4%)
Other (3)	1 (6.7%)	2 (13.2%)

Conclusion: Infection is highly associated with risk of bleeding related to procedures. There is a higher risk of bleeding in patients with active infections who may benefit from personalized pre-procedure prophylaxis or special considerations. Multiple hospitalizations and more frequent procedures were also predictive of bleeding indicating that risk increases with a longer and more complicated hospital course. Future prospective studies are needed to create a predictive model in this population that will aid in accurate risk assessment.

SAT089

Role of urinary neutrophil gelatinase-associated lipocalin, kidney injury molecule-1 and cystatin C as markers of mild kidney function impairment in patients with liver cirrhosis

Anna Szymanek-Pasternak[1,2], Sylwia Serafińska[1,2], Monika Pazgan-Simon[1,2], Justyna Janocha-Litwin[1,2], Jolanta Zuwała-Jagiełło[3], Ewa Grzebyk[3], Simon Krzysztof[1,2]. Email: aszymanek7@gmail.com

Background and Aims: Renal function impairment worsens prognosis in patients with liver cirrhosis. Early diagnosis of chronic kidney disease poses a challenge for clinicians.
The aim of the study was to establish possible usefulness of urinary neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1) and cystatin C (CysC) as early markers of mild impairment of kidney function in patients with liver cirrhosis.
Method: Urine samples from 95 consecutive patients with liver cirrhosis of different etiologies were collected within 24 hours after admission to the 1st Department of Infectious Diseases Regional Specialistic Hospital, Wroclaw, Poland. Urinary concentrations of NGAL, KIM-1, CysC and proteinuria were mesured. eGFR according to Modification of Diet in Renal Disease equation was calculated and Child-Turcotte-Pugh score (CTP) was performed.
ANOVA and t-Student tests were used. P value 0.05 was considered statistically significant.
Results: According to CTP score 57 patients were in A group, 32 patients - B and 6 patients - C. Mean eGFR was 92.2 ml/min/1.73m^2 and did not differ significantly between CTP A, B and C groups (95.3, 87.4 and 88.2 respectively). Mean NGAL, KIM-1 and CysC concentrations between the group with higher eGFR (≥90 ml/min/1.73 m^2, N = 51) and lower eGFR (<90 ml/min/1.73 m^2, N = 44) did not differ significantly (NGAL: 33.87 pg/mL vs 32.32 pg/mL, KIM-1: 1.88 ng/mL vs 1.59 ng/mL, CysC: 27.77 ng/mL vs 22.4 ng/mL respectively). Patients with proteinuria (N = 30) had significantly higher urinary concentrations of NGAL (50.23 pg/mL) than patients without proteinuria (N = 65, mean NGAL = 24,82 pg/mL), p = 0.0056. KIM-1 and CysC were not statistically different in these groups (KIM-1: 2.67 ng/mL vs 1.35 ng/mL, CysC 36.2 ng/mL vs 19.7 ng/mL respectively). However in patietns with proteinuria there were no statistically

significant differences in NGAL concentrations between the subgroup with higher eGFR (≥90 ml/min/1.73 m^2, N = 19, NGAL = 53.57 pg/mL) and lower eGFR (<90 ml/min/1.73 m^2, N = 11, NGAL = 43,92 pg/mL).

Conclusion:

9. Urinary NGAL, KIM-1 and CysC possibly will not play a role as early makers of mild impairment of renal function in patients with liver cirrhosis.
10. Urinary NGAL, but not KIM-1 or CysC reflects proteinuria in patients with liver cirrhosis.
11. Urinary NGAL does not reflect renal function in patients with proteinuria and liver cirrhosis.

SAT090

Analysis of factors associated with the prognosis of cirrhotic patients who were treated with V2-receptor antagonist for hepatic edema

Akemi Tsutsui[1], Koichi Takaguchi[1], Masanori Atsukawa[2], Akihito Tsubota[3], Hidenori Toyoda[4], Motoh Iwasa[5], Tadashi Ikegami[6], Akito Nozaki[7], Haruki Uojima[8], Atsushi Hiraoka[9], Shinya Fukunishi[10], Hironao Okubo[11], Tsunamasa Watanabe[12], Norio Itokawa[13], Yasuhito Tanaka[14], Takashi Kumada[4]. *[1]Kagawa Prefectural Central Hospital, Hepatology, Takamatsu, Japan; [2]Nippon Medical School, Division of Gastroenterology and Hepatology, Tokyo, Japan; [3]Jikei University School of Medicine, Core Research Facilities, Tokyo, Japan; [4]Ogaki Municipal Hospital, Gastroenterology, Ogaki, Japan; [5]Mie University School of Medicine, Gastroenterology and Hepatology, Tsu, Japan; [6]Tokyo Medical University Ibaraki Medical Center, Gastroenterology, Ibaragi, Japan; [7]Yokohama City University Medical Center, Gastroenterological Center, Yokohama, Japan; [8]Kitasato University School of Medicine, Gastroenterology, kanagawa, Japan; [9]Ehime Prefectural Central Hospital, Gastroenterology Center; [10]Osaka Medical College, Second Department of Internal Medicine, Osaka, Japan; [11]Juntendo Nerima University Hospital, Gastroenterology, Tokyo, Japan; [12]St. Marianna University School of Medicine, Internal Medicine, Kawasaki, Japan; [13]Nippon Medical School Chiba Hokusoh Hospital, Gastroenterology, Inzai, Japan; [14]Nagoya City University, Graduate School of Medical Sciences, Virology & Liver Unit, Nagoya, Japan*
Email: k.takaguchi@chp-kagawa.jp

Background and Aims: V2-receptor antagonist named tolvaptan has not yet been added to the EASL guidelines. In Japan, a phase 3 clinical trial demonstrated the efficacy and safety of tolvaptan for cirrhotic patients with hepatic edema. Accordingly, in 2013, the use of tolvaptan for patients complicated by hepatic edema was approved. Contrary to the EASL guidelines, tolvaptan can be administered to patients resistant to treatment with conventional diuretics in Japan. We conducted a retrospective, multi-center collaborative study to identify the prognostic factors and clarify whether on-treatment factors, including conventional diuretic dosages and short-term response to tolvaptan, affect the long-term prognoses in cirrhotic patients with hepatic edema.

Method: Patients were initially instructed to receive salt-restricted diet therapy and conventional diuretics. When the BW of the patients remained unchanged on treatment, tolvaptan was orally administered at a dosage of 7.5 mg/day. Short-term responders to tolvaptan were defined as patients with BW loss of ≥1.5 kg from baseline to day 7.

Results: Patients consisted of 266 males and 141 females, with the median age of 68 years. The frequency of short-term responders to tolvaptan was 59.7%. In the Cox regression analysis, short-term response to tolvaptan, average dosages of furosemide and spironolactone during tolvaptan, Child-Pugh classification, and presence of hepatocellular carcinoma were independent factors associated with 1-year survival. The 1-year and long-term cumulative survival rates in short-term responders were significantly higher than those in non-responders (P = 0.011 and 0.010, respectively). Using a receiver operating characteristic curve analysis, the optimal cut-off values of average daily dosages of furosemide and spironolactone for predicting 1-year survival were 19 mg/day and 23 mg/day, respectively. The long-term cumulative survival rates in patients who received a mean dosage of spironolactone <23 mg/day during tolvaptan treatment period were significantly higher than those receiving a mean dosage of ≥23 mg/day (P = 0.001).

Conclusion: This study suggests that the short-term response to tolvaptan and low dosages of conventional diuretics during tolvaptan treatment improve the 1-year and long-term survival rates in cirrhotic patients with hepatic edema, irrespective of liver and kidney function and the presence of hepatocellular carcinoma.

SAT091

Combination of meld and lactates predicts early death in patients treated by salvage tips for refractory variceal bleeding

Aurélie Walter[1], Marika Rudler[2], Pol Olivas[3], Lucile Moga[4], Eric Trépo[5], Marie-Angèle Robic[6], Isabelle Ollivier-Hourmand[7], Anna Baiges[3], Olivier Sutter[1], Charlotte Bouzbib[2], Jean Marie Peron[6], Vincent Le Pennec[7], Nathalie Ganne[1], Juan Carlos Garcia Pagan[3], Maxime Mallet[2], Metivier Sophie[6], Thong Dao[7], Dominique Thabut[2], Virginia Hernandez-Gea[3], Jean Charles Nault[1], Christophe Bureau[6], Manon Allaire[7]. *[1]Jean-Verdier Hospital Ap-Hp, Bondy, France; [2]University Hospitals Pitié Salpêtrière - Charles Foix, Paris, France; [3]Hospital Clínic de Barcelona, Barcelona, Spain; [4]Hospital Beaujon AP-HP, Clichy, France; [5]Hospital Erasme, Bruxelles, Belgium; [6]Hospital Rangueil, Toulouse, France; [7]Hospital Center University Of Caen Normandie, Caen, France*
Email: aurelie.wal@gmail.com

Background and Aims: Few data are available about the short-term prognosis of salvage TIPS using covered stents for refractory variceal bleeding in cirrhotic patients in Baveno consensus IV/V/VI. The aims of this study were to assess survival and identify risk factors of early death in these patients.

Method: We retrospectively studied 164 cirrhotic patients from 5 centers, treated with salvage TIPS for refractory variceal bleeding between 2007–2017 divided in a derivation cohort (83 patients, 3 centers) and a validation cohort (81 patients, 2 centers). The association between clinico-biological variables the day of the TIPS, and 6-week mortality was assessed using uni and multivariable Cox models. A score including MELD and lactates was developed in the derivation cohort and evaluated in the validation cohort.

Results: Among the 83 patients of the derivation cohort, 78% were male with a median age of 55 years, 76% had alcoholic cirrhosis, 79.5% with esophageal varices, median MELD was 19 and median arterial lactates level 3.7 mmol/L. 77% of patients received vasopressors, 87% oral tracheal intubation and 17% renal replacement therapies. 11% of patients experienced acute pulmonary edema, 14.5% variceal rebleeding and 41% encephalopathy within the 6 weeks after TIPS.
The 6-week mortality was 42% (90% for MELD ≥3 0, 76% for lactates ≥ 5 mmol/L and 100% for lactates > 12 mmol/l). In multivariate analysis, the MELD score (OR = 1.1, 95%CI[1.06–1.14], p < 0.001) and lactates (OR = 1.1, 95%CI[1.08–1.17], p < 0.001) were independently associated with 6-week mortality. In the derivation cohort, we created a score combining MELD and lactates and a value > 3,53 was associated with 100% 6-week mortality (p < 0.001, AUROC 0.84).
The characteristics of the 81 patients of the validation cohort were not different compared to those of the derivation cohort (median MELD 18, median lactates 2,42 mmol/L). The 6-week mortality was 33% (87% for MELD > 30, 53% for lactates ≥ 5 mmol/L and 100% for lactates > 12 mmol/l). The 6-week mortality with a MELD-lactates score >3,53 was 87% and had higher predictive performances (AUROC = 0.70) than MELD (AUROC = 0.60) and lactates alone (AUROC = 0.66).

Conclusion: After salvage TIPS for refractory acute variceal bleeding, 6-week mortality remains high and can be predicted by a combination of MELD and lactates. This score can help to select a subgroup of patients with a better prognosis and use all resources available to prompt salvage TIPS in those patients.

SAT092

Esophageal varices recurrence after eradication: are there any predictors ?

Myriam Ayari[1], Yosra Zaimi[1], Shema Ayadi[1], Emna Bel Hadj Mabrouk[1], Leila Mouelhi[1], Radhouane Dabbeche[1]. [1]*Charles Nicolle Hospital, Gastroenterology, Tunis, Tunisia*
Email: ayari.myriam@hotmail.fr

Background and Aims: Esophageal varices (EVs) are a life-threatening complication of portal hypertension. Endoscopic variceal ligation (EVL) is the main instrumental treatment either on primary or secondary prophylaxis. But after varices eradication remains the risk of variceal recurrence (VR) and consequently the risk of bleeding. The aim of our study was to evaluate the recurrence rate of EVs and to determine the predictive factors of VR.
Method: We performed a single-center retrospective study analyzing data of patients with cirrhotic portal hypertension undergoing EVL for primary or secondary prophylaxis during 2010 to 2017. Patients aged under 17 years were excluded. Platelet count to spleen diameter ratio (PSR), AST-to-ALT ratio, APRI, FIB-4, Kings'score, Lok index, cirrhosis discriminant score, Goteborg University Cirrhosis Index (GUCI), MELD score were calculated for each patients at the first EVL. EVs recurrence was defined as an increase in EVs size to ≥ grade 1 after first eradication. Biochemical, endoscopic and imaging data was collected.
Results: Overall eighty-nine patients were included with a sex ratio M/F = 1.02. The mean age was 55.9 years ± 14.17. Child-Pugh class distribution was A (37%), B (51%), C (12%). A total of 267 EVL sessions were performed with an average number of banding sessions per patients of 3 sessions (1–7). Median follow-up was 53.5 months (mean: 68.7 months). Eradication was obtained in 89% of cases. Varices recurred in 41% of patients with a mean period of 28.9 ± 17.37 months after eradication. In univariate analysis secondary prophylaxis (OR 9.6; 95% CI 1.146–80.394; p = 0.017), portal thrombosis (OR 3.7; 95% CI 1,228–11,533; p = 0.03), *peri-esophageal collateral veins* (OR 9.7; 95% CI 2.486–38.021; p = 0.003), portal hypertensive gastropathy (OR 2.9; 95% CI 1.075–8.001; p = 0.03), APRI (p = 0.008), Fib-4 (p = 0.014), Lok index (p = 0.009), GUCI (p = 0.017) and PSR (p < 0.00001) were significantly associated with VR. In multivariate regression analysis only PSR (OR 0.99; 95% CI 0.996–0.999; p = 0.002) was an independent factor associated with VR. The area under the curve (AUC) of PSR as predictor of VR was 0.786 (95% CI 0.676–0.897; p < 0,00001). The optimal cutoff value of PSD predicting VR was 513 (sensibility 74%, specificity 75%).
Conclusion: PSR may be a reliable noninvasive predictor for recurrence of oesophageal varices. Thus we propose a cutoff of 513 to identify patients at high risk of variceal recurrence in order to optimize screening after eradication. PSR is a promising tool, requiring more studies in order to be integrated into a new risk score of variceal recurrence.

SAT093

Sarcopenia is associated with lack of therapeutic response and higher mortality in hepatocellular carcinoma patients

Hanaa Badran[1], Maha Elsabaawy[2,3], Amr Ragab[1], Aliaa Sabry[4], Ayman Elsebaey[3], Rasha Abdelwahaab[5]. [1]*National Liver Institute, hepatology, shebeen elkoom, Egypt;* [2]*national liver institute, hepatology, Egypt;* [3]*Menoufiya University, hepatology, shebeen elkoom, Egypt;* [4]*national liver institute, hepatology, shebeen elkoom, Egypt;* [5]*Menoufiya University, radiology, shebeen elkoom, Egypt*
Email: maha.ahmed@liver.menofia.edu.eg

Background and Aims: Hepatocellular carcinoma (HCC) is a dreadful complication of liver cirrhosis.
Aim: To study the effect of sarcopenia on treatment response, morbidities, and survival in patients with HCC.
Method: Two hundreds and sixty-two patients with HCC were included and subjected to different therapeutic modalities according to BCLC classification. Patients were followed for 12 months. Basal sarcopenia and follow up values were calculated by skeletal muscle index (SMI) through examination of psoas muscle at L3 by CT.
Results: patients with sarcopenia (43.1%) were older (61.18 ± 8.32: p = 0.006), mainly males (69.5%; p = 0.042), Child-Pugh class B (55.7%: p = 0.001). Patients with sarcopenia had lower survival than those without (10.09 vs. 11.72 months) p = 0.001. On pairwise comparison of patients with and without sarcopenia in the different time points between the baseline and 1, 3, 6 and 12 months; there was a statistically significant difference (p = 0.001) with higher values (cm^2/m^2) in patients without baseline sarcopenia (52.78 ± 8.32 vs. 44.12 ± 5.34), (51.80 ± 8.41 vs. 43.85 ± 5.77), (50.34 ± 8.12 vs. 43.9 ± 5.45), (49.54 ± 8.28 vs. 43.52 ± 5.31) and (49.28 ± 8.29 vs. 45.72 ± 13.23). On follow up patients with sarcopenia had higher incidence of ascites, compared to those without (45% vs. 20.4%), spontaneous bacterial peritonitis (21.7% vs. 11.6%), upper gastrointestinal bleeding (22.9% vs. 12.7%) and hepatic encephalopathy (28% vs. 11.5%) (p = 0.001). Patients with baseline sarcopenia compared to those without, had higher percentage of progressive HCC despite intervention in the first (29.2 vs. 16.1; p = 0.023), third (40.7 vs. 29.5; p = 0.001), sixth (51.4 vs. 30.6; p = 0.001) and the 12th months (32.1 vs. 25.7; p = 0.001). Recurrence rates at 1, 3,6, 12 months were (69%, 64.6%, 59.2% and 41.8%) for patients with sarcopenia and 57%,47.6%,40.9% and 31.3% for patients without sarcopenia, respectively (p = 0.001). Totally patients with sarcopenia compared to those without had higher (p = 0.001) percentage of progressive HCC (39% vs. 25.5%).

Conclusion: Sarcopenia is associated with lack of response to therapy, liver decompensation and higher mortality in hepatocellular carcinoma patients.

SAT094

A telephone survey to screen for frailty pre-liver transplant evaluation: validation of an easy to use survey

Bandar Aljudaibi[1], Katherine Dokus[1], Tina Galindez[1], Gwen Kendall[1], Nicholas Bartell[1]. [1]*University of Rochester, Rochester, United States*
Email: bandaraljudaibi@gmail.com

Background and Aims: Frailty is now an accepted predictor of mortality in the cirrhotic patient. Multiple screening modalities exist to determine patients who currently are frail, or are at future risk of developing frailty; however, they rely on an in-person assessment of the patient. Busy transplant centers currently have no reliable means to measure frailty prior to an initial visit with a provider. The aim of this study is to test the validity a telephone survey of frailty in pre-liver transplantation patients as compared to gold-standard in person assessments.
Method: Patients referred for consideration of liver transplantation at the University of Rochester Medical Center were screened for frailty using a telephone survey between March 2017 and October 2019. The telephone survey was adapted from a previously described telephone-based survey called the FRAIL scale. All patients then underwent frailty testing during their initial office visit using the gold-standard Fried Index. Results of the telephone survey and in-person assessment were then compared.
Results: A total of 79 patients were screened for frailty using the telephone survey prior to their initial in-person assessment. Of those 79 patients 33 (41.7%) were determined to be frail by the telephone survey, and 26 of those patients were found to be frail by the Fried Index for a positive predictive value of 78.8%. While 46 patients (58.3%) were determined to not be frail by the telephone survey, and 30 of those patients were found to not be frail by the Fried Index for a negative predictive value of 65.2%. The sensitivity and specificity of the telephone survey was 61.9% and 81.8% respectively.

	Frail by Fried Index	Not Frail by Fried Index	TOTAL
Frail By Phone Survey	26	7	33
Not Frail By Phone Survey	16	30	46
TOTAL	42	37	

Conclusion: This preliminary investigation indicates that a telephone survey is a useful tool to screen for frailty in pre-liver transplant patients. While not intended to replace gold-standard in person assessments, our telephone survey can be used a simple screen to easily find patients that may benefit from intensive nutrition and physical therapy interventions. Future refinements of this survey will allow for more accurate screening, and potentially improved outcomes for frail patients owing to the speed at which they can be identified.

SAT095

Risk factors associated with mortality in upper gastrointestinal bleeding in cirrhotic patients

Andra Barbulescu[1], Roxana Sirli[2], Sporea Ioan[2], Raluca Lupusoru[1], Mirela Danila[2], Alina Popescu[2], Hnatiuc Madalina[1], Iulia Ratiu[2].

[2]*Victor Babeş University of Medicine and Pharmacy, Timişoara, Romania*
Email: barbulescu.andra91@gmail.com

Background and Aims: Comparison of prognostic factors of bleeding in cirrhotic patients according to the etiology of bleeding.
Method: We performed a retrospective study on 647 cirrhotic patients with upper gastrointestinal bleeding, 352 men (54.4%) and 295 women (45.5%), with a mean age 54.56 ± 26.16 years. We divided the cohort into two groups, variceal bleeding (VB) and non-variceal bleeding (NVB), in order to find the prognostic factors for mortality using linear regression and logistic regression.
Results: From 647 patients, 200 (30.9%) had NVB and 447 (69.1%) had VB. The mortality rate was 17.2% in group with VB vs 10% in group with NVB, ($p < 0.0001$). We evaluated three predicting factors for mortality: liver failure defined as Child Pugh B and Child Pugh C class, severity of bleeding defined as severe anemia (Hb < 6 g/dl) and active upper GI bleeding (Table 1).
Conclusion: Liver failure in patients with all sources of bleeding is an independent risk factor for mortality in cirrhotics. Severe anemia turned out to be an independent risk factor for mortality in variceal hemorrhage, but not in patients with non-variceal bleeding. Active bleeding increases the mortality risk only in variceal hemorrhage, but it is not an independent factor.

Table: (abstract: SAT095) Univariate and multivariate analysis

	Overall N = 647		Variceal Bleeding N = 447		Non-variceal Bleeding N = 200	
Parameter	Univariate analysis	Multivariate analysis	Univariate analysis	Multivariate analysis	Univariate analysis	Multivariate analysis
Liver failure	P < 0.001	P = 0.01	P < 0.0001	P = 0.003	P < 0.0001	P < 0.01
Severity of bleeding	P = 0.02	P = 0.002	P < 0.0001	P = 0.01	P = 0.23	P = 0.84
Active upper GI bleeding	P = 0.03	P = 0.31	P = 0.04	P = 0.75	P = 0.41	P = 0.89

SAT096

Epithelial cell death markers M65 and M30 are significantly up-regulated in decompensated liver cirrhosis and decreased by correction of portal hypertension

Beatrice-Victoria Jahn[1], Felix Piecha[1], Anja Koop[1], Thomas Horvatits[1], Adina Pfeil[1], Ansgar W. Lohse[1], Johannes Kluwe[1]. [1]*University Medical Center Hamburg Eppendorf, I. Department of Internal Medicine, Hamburg, Germany*
Email: beatrice@v-jahn.de

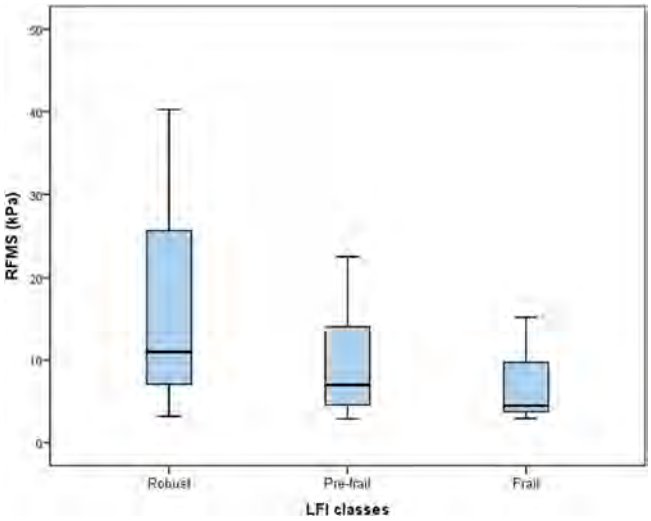
Background and Aims: In end-stage liver disease, epithelial cell death markers M30/M65 have been suggested as predictors for outcome. While the M30 ELISA detects caspase-cleaved keratin 18 as a marker for epithelial apoptosis, M65 detects keratin 18 (K18) as a global epithelial cell death marker. Both have been suggested as indicators of hepatocyte injury. This study evaluates the hypothesis that an elevated transhepatic pressure gradient promotes hepatocellular injury which can be reverted when portal hypertension is corrected by transjugular intrahepatic portosystemic shunt (TIPS) insertion.
Method: 42 cirrhotic patients with ascitic decompensation who received a TIPS and 9 patients with compensated cirrhosis were included in our prospective cohort study. Peripheral blood was collected before, 4–9 weeks (early follow-up) and 4–10 months (late follow-up) after TIPS insertion and in patients with compensated cirrhosis. Plasma levels of caspase-cleaved K18 were quantified using the M30 Apoptosense ELISA as an indicator for apoptosis. The M65 ELISA (Peviva) which measures total and caspase-cleaved K18 was used to assess the amount of epithelial cell death in plasma. Statistical analyses were performed by using Mann-Whitney test and t test, where applicable.
Results: Both, M30 and M65 were significantly higher in patients with ascitic decompensation compared to patients with compensated liver cirrhosis (p = 0,0034 and 0,0175, respectively). At late follow-up after TIPS insertion, M65 and M30 were both significantly decreased in patients with successful ascites control, indicating sufficient correction of portal hypertension. M65 plasma levels were lowered to the level of the compensated cirrhosis group.
Conclusion: Plasma markers of epithelial cell death are correlated with ascitic decompensation in liver cirrhosis. Therapeutic correction of portal hypertension by TIPS decreases M65 and M30 levels, suggesting a reduction of hepatocellular injury.

SAT097

Bidimensional shear wave elastography of the rectus femoris muscle in patients with cirrhosis

Chiara Becchetti[1,2], Giacomo Germani[1], Patrizia Burra[1], Jean-François Dufour[2], Annalisa Berzigotti[2]. [1]*Multivisceral Transplant Unit, Padua University Hospital, Department of Surgery, Oncology and Gastroenterology, Italy;* [2]*Hepatology, Inselspital, DBMR, University of Bern, University Clinic for Visceral Surgery and Medicine, Switzerland*
Email: becchettichiara@tiscali.it

Background and Aims: frailty is a frequent complication of cirrhosis, often related to skeletal muscle abnormalities, increasing mortality. Bidimensional shear wave elastography (2D-SWE) could offer new insights into biomechanical properties of skeletal muscle related to muscle quality. However, no research to date investigated the feasibility and reproducibility of 2D-SWE to assess skeletal muscle stiffness and its relationship with the severity of liver disease and global frailty.
Method: fasting outpatients with cirrhosis undergoing abdominal ultrasound were prospectively included in a single-center. Exclusion criteria were: transjugular intrahepatic portosystemic shunt, >75 years old, known peripheral artery disease, myopathy unrelated to liver disease. Liver Frailty Index (LFI) was used to test global frailty. Skeletal muscle stiffness was studied at the quadriceps femoris by using 2D-SWE (Aixplorer, Supersonic Imagine, France). Three sets of measurements of the rectus femoris muscle stiffness (RFMS) were performed.
Results: 39 patients (21 males; mean age 57 ± 10 years, 24 with alcoholic etiology) have been included. 19 patients were in the Child-Pugh Class A, 16 in class B and 4 in class C. 7 patients were compensated (no previous decompensation), and 32 decompensated. According to LFI classes 3 patients were robust, 28 pre-frail and 8 frail. Compensated and decompensated patients did not show significant differences in LFI classes. RFMS measurement was feasible in all patients, and the three measurements showed a high reproducibility (intraclass correlation coefficient: 0.96; 95% CI 0.93–0.98, p < 0.0001). Median RFMS was 6.4 kPa (IQR 10), with values ranging from 2.9 to 40.3 kPa. No correlation with Child and MELD score was observed. However, RFMS was higher in decompensated vs. compensated patients, in median: 7.4 (IQR 12) vs. 4.5 (IQR 3.3) kPa (p = 0.07), and differed among the LFI classes showing the lowest value in frail patients (11.0 vs. 7.0 vs. 4.5; p = 0.08; Figure).



Conclusion: RFMS measurement on 2D-SWE is feasible and reproducible in patients with cirrhosis and seems independent of liver function. RFMS is higher in decompensated patients, but lower in frail patients vs. pre-frail and robust. This finding, and the observed high variability within each of the LFI classes, suggest that RFMS could be further studied as a potential simple, quantitative non-invasive test to stratify muscle quality in patients with cirrhosis.

SAT098

Bacterial translocation-induced inflammation promotes liver fibrogenesis in patients with advanced chronic liver disease

Benedikt Simbrunner[1,2], Philipp Schwabl[1,2], Bernhard Scheiner[1,2], Rafael Paternostro[1,2], David JM Bauer[1,2], Alexander Stadlmann[1,2], Ernst Eigenbauer[3], Albert F Stättermayer[1,2], Matthias Pinter[1,2], Rodrig Marculescu[4], Michael Trauner[1], Thomas Reiberger[1,2], Mattias Mandorfer[1,2]. [1]*Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria;* [2]*Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Vienna, Austria;* [3]*Medical University of Vienna, IT-Systems & Communications, Vienna, Austria;* [4]*Medical University of Vienna, Department of Laboratory Medicine, Wien, Austria*
Email: mattias.mandorfer@meduniwien.ac.at

Background and Aims: The enhanced liver fibrosis (ELF) score comprises serum markers of matrix remodeling that might also reflect the dynamic process of liver fibrogenesis. A broad body of experimental evidence suggests that bacterial translocation-induced inflammation promotes liver disease progression, however, studies in humans are limited. Accordingly, we investigated whether markers of

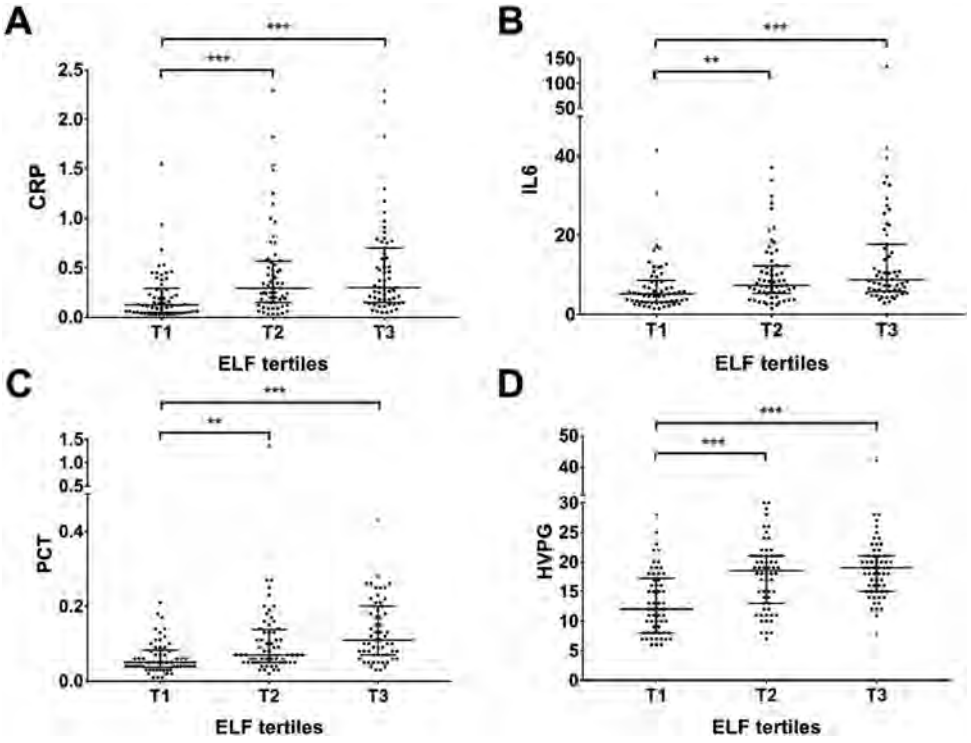


Figure: (abstract: SAT098)

systemic inflammation are linked to liver fibrogenesis in patients with advanced chronic liver disease (ACLD)/portal hypertension.

Method: ELF score, interleukin 6 (IL-6), procalcitonin (PCT), and C-reactive protein (CRP) were analyzed in 177 patients with a hepatic venous pressure gradient (HVPG) ≥6 mmHg recruited from the prospective VICIS study (NCT03267615). Patients with clinically stable ACLD and without pre- or post-hepatic portal hypertension, evidence of bacterial infection, hepatocellular carcinoma beyond Milan criteria, and history of liver transplantation were included.

Results: Serum levels of IL-6 (Spearman's $\rho = 0.358$; $P < 0.001$), PCT ($\rho = 0.486$; $P < 0.001$), and CRP ($\rho = 0.331$; $P < 0.001$) showed direct correlations with ELF score and stepwise increases with higher ELF tertiles (Figure; **P < 0.01 and ***P < 0.001).

Moreover, levels of IL-6 (6–9 mmHg: 5.45 [3.50–9.65] vs. 10–15 mmHg: 6.65 [3.44–12.48] vs. ≥16 mmHg: 7.75[5.34–13.76]; P = 0.015), PCT (6–9 mmHg: 0.06 [0.03–0.10] vs. 10–15 mmHg: 0.07 [0.04–0.16] vs. ≥16 mmHg: 0.09 [0.05–0.14]; P = 0.009), and CRP (6–9 mmHg: 0.19 [0.06–0.28] vs. 10–15 mmHg: 0.20 [0.08–0.41] vs. ≥16 mmHg: 0.29 [0.14–0.59]; P = 0.009) increased with portal hypertension severity. To investigate the association between markers of systemic inflammation and the dynamic process of liver fibrogenesis, we further stratified/adjusted our analysis by HVPG.

In patients with subclinical portal hypertension (i.e., HVPG 6–9 mmHg), only PCT showed a meaningful correlation with ELF. Interestingly, in patients with HVPG 10–15 mmHg/≥16 mmHg, IL-6 ($\rho = 0.304$; $P = 0.026$/$\rho = 0.353$; $P < 0.001$), PCT ($\rho = 0.488$; $P < 0.001$/$\rho = 0.406$; $P < 0.001$), and CRP ($\rho = 0.456$; $P = 0.001$/$\rho = 0.232$; $P = 0.020$) were directly correlated with ELF. Moreover, IL-6 ($B = 0.022$; $P = 0.006$) and PCT ($B = 7.841$; $P < 0.001$) were linked to ELF, even after adjusting for HVPG. Finally, IL-6, PCT, and HVPG were independent determinants of ELF in multiple linear regression analysis.

Conclusion: We observed a link between markers of systemic inflammation and ELF that is independent from portal hypertension severity, providing evidence for the role of bacterial translocation-induced inflammation as a key driver behind the dynamic process of liver fibrogenesis in humans.

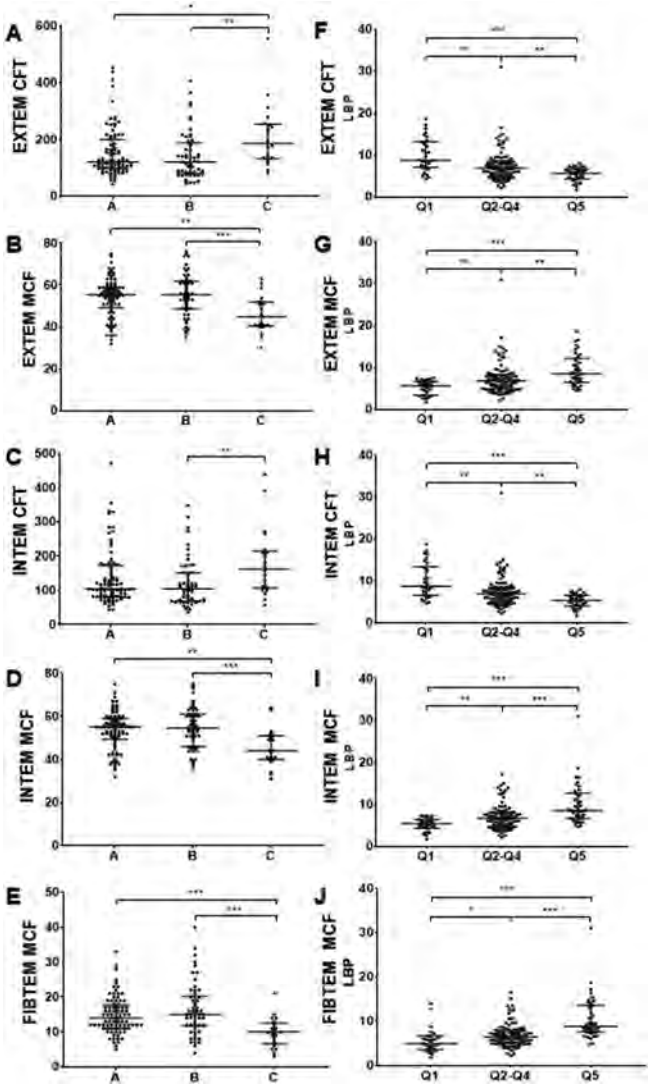
SAT099

Rotational thromboelastometry (rotem)-based assessment of coagulopathy in cirrhotic patients stratified by severity of portal hypertension

Benedikt Simbrunner[1,2], Pierre Raeven[3], Bernhard Scheiner[1,2], Philipp Schwabl[1,2], Alexander Stadlmann[1,2], Ernst Eigenbauer[4], Prof. Peter Quehenberger, MD[5], Michael Trauner[1], Joanna Baron-Stefaniak[3], David Baron[3], Mattias Mandorfer[1,2], Thomas Reiberger[1,2]. *[1]Medical University of Vienna, Department of Internal Medicine III, Division of Gastroenterology and Hepatology, Vienna, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Vienna, Austria; [3]Medical University of Vienna, Department of Anaesthesia, Intensive Care Medicine and Pain Medicine, Vienna, Austria; [4]Medical University of Vienna, IT-Systems & Communications, Vienna, Austria; [5]Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and Aims: Patients with advanced chronic liver disease (ACLD) exhibit complex coagulation disorders that confer increased risk for both bleeding and thrombosis. Conventional coagulation tests often do not reflect the hemostatic state. Rotational thromboelastometry (ROTEM) measures clot formation and dissolution in real-time. In this study, we systematically explored the impact of portal hypertension (PH) on ROTEM.

Method: ROTEM data, serum levels of C-reactive protein (CRP), procalcitonin (PCT), lipopolysaccharide binding protein (LBP), and epinephrine-stimulated platelet function assay (Epi-PFA) were analyzed in 159 consecutive patients with a hepatic venous pressure gradient (HVPG) ≥6 mmHg recruited from the prospective VICIS study (NCT03267615). Patients with clinically stable ACLD and without pre- or post-hepatic portal hypertension, hepatocellular carcinoma, or previous liver transplantation were included.



Results: Patients were stratified by PH severity, i.e. HVPG 6–9 mmHg vs. 10–19 mmHg vs. ≥20 mmHg. Neither EXTEM clot formation time (CFT, P = 0.804), EXTEM maximum clot firmness (MCF, P = 0.347), INTEM clotting time (CT, P = 0.561), INTEM CFT (P = 0.653), INTEM MCF (P = 0.271), or FIBTEM MCF (P = 0.921) differed between HVPG strata.

Child-C patients showed increased EXTEM CFT, INTEM CT, INTEM CFT, whereas EXTEM MCF, INTEM MCF, and FIBTEM MCF were significantly lower as compared to Child-A and/or Child-B patients (all P < 0.05; Figure A–E: *p < 0.05, **p < 0.01, ***p < 0.001).

In Child-A patients MCF progressively decreased with severity of PH (EXTEM MCF: 6–9 mmHg: 59 [54–68] vs. 10–19 mmHg: 56 [48–59] vs. ≥20 mmHg: 54 [45–58], P = 0.023; INTEM MCF: 6–9 mmHg: 57 [53–67] vs. 10–19 mmHg: 55 [48–59] vs. ≥20 mmHg: 52 [44–55], P = 0.009). Conversely, ROTEM results were similar in Child-B and Child-C patients across HVPG strata.

Patients with shortest CFT (EXTEM and INTEM, lowest quintile) had higher levels of LBP, CRP and PCT as well as shorter closing time on Epi-PFA (all P < 0.05). In line, serum levels of LBP (Figure F–J), CRP and PCT were higher and Epi-PFA closing time was shorter (all P < 0.05) in patients with highest MCF values (EXTEM and INTEM, highest quintile).

Conclusion: Results of ROTEM link the severity of portal hypertension to coagulation in compensated Child-A patients. Prolonged CFT and impaired MCF assessed by ROTEM are in agreement with previously reported bleeding tendencies in Child-C patients. Bacterial translocation and systemic inflammation are associated with a procoagulant state.

SAT100

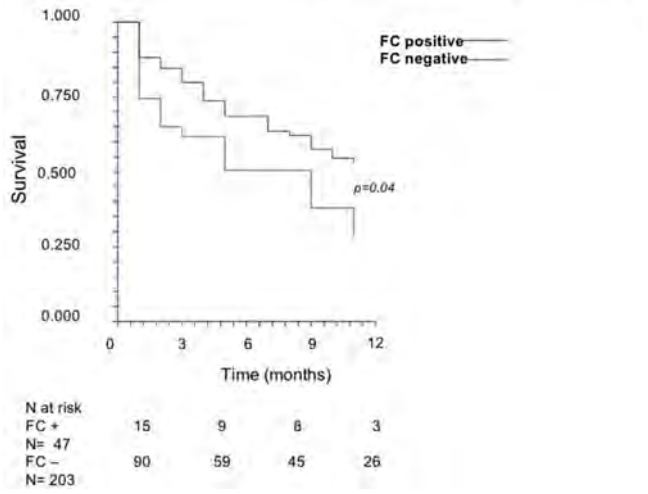
Impact of extended- spectrum- beta- lactamase faecal carrier on cirrhotic patients: a retrospective study on clinical outcomes before and after liver transplantation

Bianca Magro[1], Alessandra Mazzola[2], Mona Munteanu[3], Goumard Claire[4], Valérie Martinez[5], Denis Bernard[6], Olivier Scatton[4], Calogero Camma[1], Filomena Conti[2]. *[1]University of Palermo, Di.BIMIS Gastroenterology, Palermo, Italy; [2]Hôpital Pitié Salpêtrière, Unité Médicale de Transplantation Hépatique, Parigi, France; [3]Sorbonne Université, INSERM, Institute of Cardiometabolisme and Nutrition (ICAN), Parigi, France; [4]Hôpital Pitié Salpêtrière, Unité de Chirurgie Hépatobiliaire et Transplantation Hépatique, Parigi, France; [5]Hôpital Pitié Salpêtrière, Service des Maladies Infectieuses et Tropicales, Parigi, France; [6]Hôpital Pitié Salpêtrière, Anesthésie-réanimation, Parigi, France*
Email: bianca_magro@hotmail.it

Background and Aims: Infections are very common in cirrhotic patients and are associated with an increased risk of liver failure and liver-related complications, especially, in patients awaiting liver transplantation (LT). It is known that pre-LT colonization with Methicillin-Resistant-Staphylococcus-Aureus (MRSA) or Extended-Spectrum-Beta-Lactamase (ESBL) bacteria is an independent risk factor for infections after LT. The aim of this study was to evaluate the impact of MRSA and ESBLE fecal carriage at 6 and 12 months on infections and liver-related complications (LRC) during waitlist and on infections after LT.

Method: We retrospectively included 250 of 483 cirrhotic patients that underwent to LT from December 2015 to January 2018 in our liver transplant center, screened for MRSA or ESBL colonization at nasal and rectal swab, at the time of waitlist inscription and after LT.

Figura 5. Liver-related-complications-free-survival on waitlist according to fecal carriage



Results: 76% of patients (n = 109) were male with mean age of 57.5 ± 10, the most frequent cause of liver disease was alcoholic (39%, n = 99). The median of MELD score was 19 (12–28). Only 1 patient was positive for MRSA. Nineteen percent of patients (n = 47) were fecal carriers (FC) at the moment of inscription on waitlist and 15% (n = 37) after LT. The most isolated germ was E. Coli (53%). Infection free-survival on waitlist and after LT, according to FC was not statistically different between two groups [HR: 1.5, 95%; p = 0.28);

[HR 0.99; p = 0.9]. LRC-free-survival at 6 and 12 months was significantly lower in FC vs. No FC [HR 1; p < 0.04)]. MELD score >19 [HR 3; (p = 0.01)] and occurrence of infection <3 months on waitlist [HR 4.13; (p < 0.001)] were independent risk factors for LRC occurrence at multivariate analysis.
Conclusion: Our study is the first showing, in a cohort of cirrhotic patients waiting for LT, that LRC-free survival is lower in FC, but infection free survival is not different in the two groups.

SAT101

A randomized, double-blind study to evaluate the safety and tolerability of KB174, a novel synthetic glycan, in patients with well-compensated cirrhosis

Bal Raj Bhandari[1], Jeffrey Cehelsky[2], Yan Zheng[2], Mark Wingertzahn[2], Norma Palma[2], Robert S Mittleman[2]. *[1]Delta Research Partners, Monroe, United States; [2]Kaleido Biosciences, Lexington, United States*
Email: norma.alonzo-palma@kaleido.com

Background and Aims: Microbiome Metabolic Therapies (MMT™) are proprietary ensembles of novel synthetic glycans that have the potential to reverse the dysbiosis associated with hepatic encephalopathy (HE) and reduce the gut contribution to blood ammonia levels, that could lead to improved clinical outcomes for patients with cirrhosis. The MMT KB174 has been shown to reduce microbiota-associated ammonia in *ex vivo* testing of microbiome samples from patients with cirrhosis. Lactose-[^{15}N]-ureide tracer has been used to model changes in nitrogen metabolism of the microbiome by measuring ^{15}N recovery in urine, stool, and blood.
Method: Patients with well compensated cirrhosis (Childs-Pugh A or Childs-Pugh B) were randomized and double-blinded, 1:1, to KB174 or maltodextrin, a digestible control substance. KB174 was titrated to a peak dose of 36g bid for a total treatment duration of 28 days.
Three days prior to randomization and three days prior to the end of dosing, patients received an amino acid challenge followed by 4.5 mg/kg nitrogen tracer. Safety was assessed from first dose of study product through the post intake follow up period. Urine, stool, and blood were collected for tracer, as well as measures of safety and tolerability (Gastrointestinal Questionnaire (GITQ) and Bristol Stool Scale (BSS)).
Results: Forty patients were randomized. Ten pts were enrolled who had liver disease but did not meet the entry criterion threshold for cirrhosis as measured by transient elastography. Adverse events were generally GI-related and mild to moderate in severity in both groups. One patient in each group had transient interruption of study product. There was one unrelated serious adverse event in a patient receiving KB174. Gastrointestinal tolerability measures showed only small changes (max 0.2–0.4 units for GITQ and BSS scores with no significant differences between groups).
Conclusion: This is the first clinical study to report the effect of KB174 in patients with cirrhosis. KB174 titrated up to 72 g was shown to be well tolerated with no clinically significant safety signals observed in patients with well-compensated cirrhosis.

SAT102

Renal clearance measured by iohexol identifies cirrhotic patients with normal creatinine at risk of serious adverse events

Carlos González-Alayón[1], Natalia Negrín-Mena[2], Sergio Luis-Lima[2], Miguel Moreno[1], Dalia Morales Arraez[1], Esteban Porrini[2], Enrique Quintero[1], Manuel Hernandez-Guerra[1]. *[1]Gastroenterology Unit. Hospital Universitario de Canarias, Spain; [2]Research Unit Department. Hospital Universitario de Canarias, Spain*
Email: mhernandezguerra@gmail.com

Background and Aims: Renal dysfunction is a severe complication of advanced cirrhosis and even slight changes within normal serum creatinine are associated with greater morbidity and mortality. However, glomerular filtration rate (GFR) from creatinine leads to overestimation of renal function. Alternatively, GFR from exogenous substances is the gold standard for evaluation of renal function. However, there is a lack of data on its usefulness as predictors of the risk of serious adverse events (SAE). Our aims were to evaluate iohexol clearance as a predictive tool for SAE in cirrhotic patients with normal creatinine, and to identify characteristics associated with overestimation of GFR.
Method: Cirrhotic patients with normal creatinine (<1.4 mgr/dL) at the time of the study were offered to participate from May/2016 to Oct/2019. GFR was calculated in all patients from plasma clearance of creatinine and iohexol by dried blood spot method. The patients were grouped according to GFR-iohexol value: <90 ml/min (overestimated) and ≥90 ml/min (non-overestimated). Patients were followed up to identify hospital admissions and/or mortality defined as SAE.
Results: We included 125 patients (64.6 ± 8.2 years, 82% males): 76% alcoholic, Child 47% A, 42% B, 11% C, MELD 13.8 ± 5.3. Despite normal creatinine value (0.8 ± 0.2 mgr/dL), GFR was decreased (86.3 ± 28.3 ml/min). The overestimated group (n = 74) compared to the non-overestimated group (n = 51) was associated with: older age (65.9 vs 62.6 years; p < 0.024), female sex (26 vs 8%; p < 0.011), lower BMI (27 vs 30; p < 0.012), ascites (58 vs 37%; p < 0.038) and previous AKI (53 vs 28%; p < 0.005. In the multivariable model; female sex [OR: 4.06; 95% CI (1.29–12.77); p = 0.017], previous AKI [OR: 2.95; 95%CI (1.37–6.33); p = 0.006] and lower BMI [OR:0.89; 95%CI (0.81–0.98); p = 0.016] were predictors of overestimation. After a median follow-up of 18 [7–30] months, the overestimated group presented a higher rate of hospital admissions (43 vs 24%; p = 0.023), deaths (22 vs 14%; p = 0.26) and overall SAE (47 vs 29%; p < 0.045). In Cox regression model, the overestimated group presented higher risk of future admissions [HR: 2.24; 95%CI (1.15–4.37); p = 0.018] and SAE [HR: 1.94; 95%CI (1.06–3.58); p = 0.033].
Conclusion: Overestimation of renal function is associated with female sex, low BMI and previous AKI event. GFR with iohexol clearance allows the identification of cirrhotic patients with normal serum creatinine, at risk of SAE during follow-up.

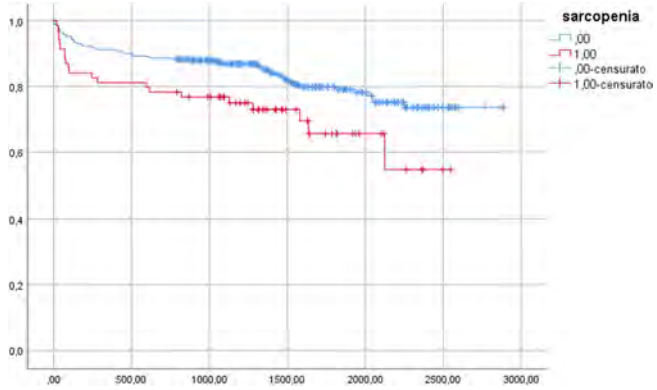
SAT103

Clinical relevance of sarcopenia in liver transplant candidates

Chiara Mazzarelli[1], Raffaella Viganò[1], Andrea De Gasperi[2], Ernestina Mazza[2], Angelo Vanzulli[3], Marcello Vangeli[1], Manlio Prosperi[2], Aldo Airoldi[1], Luca Saverio Belli[1]. *[1]ASST GOM Niguarda, Hepatology and Gastroenterology, Milano, Italy; [2]ASST GOM Niguarda, Intensive Care Unit, Milano, Italy; [3]ASST GOM Niguarda, Radiology Department, Milano, Italy*
Email: chiaramazzarelli@hotmail.com

Background and Aims: Sarcopenia, characterized by loss of skeletal muscle mass, affects 30 to 70% of cirrhotic patients. Sarcopenia has recently emerged as an independent factor associated with elevated mortality in end-stage liver disease (ESLD) patients and liver transplant (LT) candidates. Few studies have assessed the impact of sarcopenia on peri-transplant and post-transplant outcomes. Our study aimed to investigate the association between sarcopenia and peri-transplant and post-transplant outcomes in LT candidates.
Method: 410 cirrhotic patients, who received a LT at Niguarda Hospital, from January 2012 to December 2016 were enrolled. Skeletal muscle index at the third lumbar vertebra was measured by CT scan, and sarcopenia was defined using previously published gender and BMI –specific cutoffs.
Results: 365 patients (69%) were male, with a median age at LT of 54 years. The most common etiologies of cirrhosis were HCV (52%), alcohol (16%) and autoimmune diseases (6%). Sarcopenia was diagnosed in 69 patients (16%), and was more frequent in those with refractory ascites (p = 0.000), and a higher MELD score at LT (p = 0.000). While on waiting list, sarcopenic patients were more frequently admitted to the hospital for episodes of acute decompensation (p = 0.05), bacterial infections (p = 0.000) and to ICU to manage major cirrhosis complications (p = 0.000). Sarcopenic patients had longer ICU (p = 0.001) and hospital stays (p = 0.002) after receiving LT and a higher rate of bacterial and fungal infections

(0.001) post-transplant. Moreover, MDR infections, especially caused by Klebsiella Pneumoniae Carbapenemase-producing (KPC) bacteria were more represented in sarcopenic patients (p = 0.014). The median survival after LT was 1282 days for sarcopenic and 1411 for non-sarcopenic patients (P = 0.016). At multivariate analysis, older age at LT and pre-LT sarcopenia as well as post-LT MDR infections, use of CRRT and prolonged ventilation in ICU were all independently associated with mortality.



Conclusion: Sarcopenia is one of the most common complication in patients with cirrhosis and it is predictive of longer hospital stays, higher risk of waiting-list complications and post-LT bacterial infections, including MDR infections, and is associated with increased mortality after-LT.

SAT104

Impact of non-selective beta-blockers on hepatic encephalopathy in patients with liver cirrhosis

Christian Labenz[1], Nagel Michael[1], Gerrit Toenges[2], Yvonne Huber[1], Jens Marquardt[1], Peter Galle[1], Joachim Labenz[3], Marcus-Alexander Woerns[1]. *[1]University Medical Center of the Johannes Gutenberg-University Mainz, Department of Internal Medicine I, Mainz, Germany; [2]University Medical Center of the Johannes Gutenberg-University Mainz, Institute of Medical Biostatistics, Epidemiology and Informatics, Mainz, Germany; [3]Diakonie Klinikum Jung-Stilling, Department of Internal Medicine, Siegen, Germany*
Email: christian.labenz@unimedizin-mainz.de

Background and Aims: Non-selective β-blockers (NSBB) are routinely used for the treatment of portal hypertension and gastro-oesophageal varices in patients with liver cirrhosis; however prospective studies investigating the potential link between NSBBs and hepatic encephalopathy (HE) are still scarce. We investigated the relationship between NSBBs use and the presence of covert HE (CHE) as well as its potential association with the development of overt HE (OHE).

Method: In- and outpatients with an established diagnosis of liver cirrhosis treated between March 2017 and December 2018 at the University Medical Centre Mainz and the Diakonie Klinikum Siegen were included into this prospective cohort study and followed for a median of 364 days. Exclusion criteria were an OHE episode during the previous three months, current alcohol abuse, intake of psychotropic drugs, TIPSS, HCC or any active infection. CHE was diagnosed at study inclusion by pathological results in PHES. Predictors for the presence of CHE or the development of OHE during follow-up were analyzed using logistic regression or cox-regression models.

Results: 368 patients were screened and 224 finally included into the study. Median age was 60 years (IQR 52; 66). 56.7% were male and most patients had compensated stage of liver cirrhosis (Child A, B, C; 59%, 32%, 9%; Median MELD: 10). CHE was detected in 33.9% (n = 76) of patients at study inclusion and 39.3% (n = 88) were NSBB users. On logistic regression analysis, NSBB use (OR 1.88, 95% CI 1.03–3.42, p = 0.040), higher MELD score and a history of OHE were independently associated with the presence of CHE. Cumulative incidence of OHE was significantly higher in NSBB users than in non-users (p < 0.001). On cox-regression model, NSBB use (OR 3.07, 95% CI 1.66–6.56, p = 0.001), presence of CHE, lower albumin and higher MELD score were independently associated with the development of OHE.

Conclusion: NSBB use due to portal hypertension was associated with the presence of CHE as well as the development of OHE. Uncritical NSBB use should be avoided in patients with liver cirrhosis.

SAT105

Characterization of alterations in mechanical, thermal and pain sensitivity in cirrhotic patients with minimal hepatic encephalopathy

Dalia Rega[1], Mika Aiko[2], Nicolás Peñaranda[2], Juan José Gallego[1], Andrea Cabrera-Pastor[1], Amparo Urios[1], Franc Casanova[1], Alessandra Fiorillo[1], Carla Gimenez[3], Cristina Ipiens[2], Desamparados Escudero-García[4,5], Joan Tosca[4], Cristina Montón[4], María Pilar Ballester[1,4], Jose Ballester[4], Vicente Roig[1,6], María Pilar Rios[7], Lucía Durbán[7], Paula Cases[2], Vicente Felipo[3], Carmina Montoliu[1,8]. *[1]INCLIVA-Health Research Institute, Valencia, Spain; [2]Hospital Clínico Universitario de Valencia, Servicio de Neurofisiología, Valencia, Spain; [3]CIPF Centro de Investigación Príncipe Felipe; [4]Hospital Clinico Universitario de Valencia, Unidad de Digestivo, Valencia, Spain; [5]Universidad de Valencia, Departamento de Medicina, Valencia, Spain; [6]Hospital Clínico Universitario de Valencia, Valencia, Spain; [7]Hospital Arnau de Vilanova, Servicio de Digestivo, Valencia, Spain; [8]Universidad de Valencia, Departamento de Patología, Valencia, Spain*
Email: cmontoliu@incliva.es

Background and Aims: Hepatic encephalopathy (HE) associated to cirrhosis is a complex neuropsychiatric syndrome. Near 40% of cirrhotic patients have minimal hepatic encephalopathy (MHE) with mild motor and cognitive impairments.

Cirrhotic patients may have alterations in the peripheral nervous system, such as somatosensory perception. The perception of cold and heat pain is mediated by A-delta nerve fibers (myelinated, small diameter) and non-myelinated C fibers, respectively. The vibration is transmitted by myelinated larger diameter fibers (A-alpha). Alterations in thermal sensitivity have been described in patients with HE, which correlated with the degree of HE and with attention deficits.

The aim of this study is the evaluation and characterization of thermal sensitivity, vibration and heat-pain in cirrhotic patients and healthy controls, and to assess whether there are alterations associated to MHE.

Method: Sixty-five cirrhotic patients were included in the study, 41 without MHE and 24 with MHE, according to the PHES score (Psychometric Hepatic Encephalopathy Score) and 35 healthy controls. Selective and sustained attention were assessed using the Stroop and d2 tests. The evaluation and characterization of sensory thresholds was performed by quantitative sensory testing using a CASE IV device. The following sensory thresholds were measured: vibration detection threshold, which evaluates thick myelinated nerve fibers (A-alpha); cold detection threshold, which allows measurement of myelinated fine nerve fibers (A-delta) and heat-pain detection threshold that evaluates non-myelinated C fibers. The tests were performed on hand and foot.

Results: Results show that the thresholds of vibration and detection of cold in the foot are significantly higher in patients with MHE compared to those without MHE. This hyposensitivity correlates with attention deficits. Likewise, the reaction time is significantly longer in the tests of cold perception and heat pain when comparing patients with and without MHE. Finally, the total sum of the tests performed

out of the normal range by cirrhotic patients shows more significant differences with the control group when the hand is the test site, although the foot seems to be more affected by the presence of MHE.
Conclusion: Patients with MHE have a general decrease in cognitive and sensory abilities. Quantitative sensory tests could be used as an indicator of MHE and would allow studying the effects on the sensory system before and after a treatment.

SAT106

Role and prognostic value of routine doppler sonography in patients with severe liver disease - a prospective cohort study in an intensive care unit

Constantin Maier-Stocker[1], Johannes Vogg[1], Karsten Guelow[1], Martina Müller-Schilling[1], Stephan Schmid[1]. [1]*University Hospital Regensburg, Department of Internal Medicine I, Regensburg, Germany*
Email: constantin.maier-stocker@klinik.uni-regensburg.de

Background and Aims: Chronic liver disease is one of the major causes of morbidity and mortality. Inflammatory processes of the liver lead to hepatocellular damage and fibrosis of liver tissue. Due to the increase of resistance, hemodynamics of hepatic blood vessels alter. Ultrasound examination is of great importance in the evaluation of liver diseases. However, there is no sufficient data examining the precise role and prognostic value of routine Doppler sonography of liver perfusion in patients with severe liver disease. This study aims to determine the relation of the altering hepatic perfusion with the outcome of patients with severe liver disease in context of an intensive care treatment.
Method: Fifty patients with severe liver disease hospitalized in the internal intensive care unit of the Department of Internal Medicine I of the University Hospital Regensburg were examined with sonography at least twice a week. Liver perfusion was quantified by means of Doppler ultrasound to determine the hepatic artery resistance index (HARI) and the maximum portal vein velocity (PVv). For each patient the MELD (Model for End-Stage Liver Disease) score was calculated at the time of the study. In addition, clinical data such as the current catecholamine dose, the mean arterial blood pressure, ventilation and laboratory parameters were collected. Finally, the collected data, the duration of the intensive care treatment and the outcome of the patients were correlated with sonographic parameters.
Results: Analyses of the MELD score, the HARI and the maximum PVv in a scatter plot showed a linear, positive correlation between HARI and MELD score and a linear, negative correlation between maximum PVv and MELD score. Initial regression analyses quantify these correlations with a R2-value of 0,220 (HARI - MELD score) and 0.078 (PVv - MELD score). Furthermore, it appeared that the HARI increased in deceased patients on average by 1.6% with each examination, whereas it declined by 0.3% in non-deceased patients. On average, with each examination the maximum PVv increased by 1.8% in deceased patients and by 16.5% in non-deceased study participants.
Conclusion: The correlations of HARI and maximal PVv with the MELD score show that the development of liver perfusion is a prognostic factor. The routine assessment of HARI and the maximum PVv in patients with severe liver disease in the ICU should be further evaluated.

SAT107

Lack of evidence of significant tubular injury in patients with cirrhosis and persistent hepatorenal syndrome. implications for liver transplantation

Cristina Solé Martí[1,2], Elsa Solà[1,2,3,4], Marta Carol[2,4], Núria Fabrellas[2,4], Adria Juanola[1,2], Laura Napoleone[1,2], Patricia Huelin[1,2], Marta Cervera[2,4], Martina Perez[1], Emma Avitabile[1,2], Isabel Graupera[1,2,3], Elisa Pose[1,2,3], Pere Ginès[1,2,3,4]. Email: crissolemarti@gmail.com

Background and Aims: Hepatorenal syndrome (AKI-HRS) is a distinctive form of AKI that occurs in patients with advanced cirrhosis characterized by striking renal vasoconstriction in the setting of preserved tubular function. However, information on the status of kidney tubules in AKI-HRS is scarce and controversy exists as to whether persistent severe renal vasoconstriction leads to tubular injury. The aim was to assess the possible development of tubular injury during the natural course of AKI-HRS by assessing changes in urinary levels of neutrophil gelatinase-associated lipocalin (NGAL) and interleukin-18 (IL-18), markers of tubular injury.
Method: We analyzed a cohort of 48 patients prospectively collected from patients admitted to hospital for management of complications of cirrhosis, 22 with AKI-HRS and 26 with acute tubular necrosis (ATN). Only patients meeting the criteria of type-1 HRS were included. Urine was collected from all patients at diagnosis of AKI, and at days 3, 7, and 14 during hospitalization.
Results: Patients with AKI-HRS had advanced cirrhosis with markedly impaired liver and renal function tests. Eleven of the 22 (50%) patients had resolution of AKI-HRS during hospitalization; by contrast, in the remaining 11 patients there was no resolution of AKI-HRS. There were no significant differences between patients with resolution vs persistent AKI-HRS with respect to baseline characteristics. However, 3-month mortality was markedly higher in patients with persistent AKI-HRS (64% vs 9%, persistent vs resolution; $p = 0.026$). There were no significant differences in NGAL levels between the two subgroups at any time point studied. By contrast, urinary NGAL levels were remarkably higher throughout hospitalization in patients with AKI-ATN. The highest NGAL value among patients with persistent AKI-HRS at day ≥ 3 was 458 μg/g, but value in that particular patient decreased to <50 μg/g at day 14. All other NGAL values available in these patients were <200 μg/g, lower than those in patients with AKI-ATN. There were no significant differences in urinary IL-18 between the subgroups.
Conclusion: There is no evidence of development of significant tubular injury during the course of AKI-HRS, at least during a 14-day period, even in patients with persistent AKI-HRS. These findings may have important implications in management of patients with cirrhosis and AKI, particularly in the context of liver transplantation.

SAT108

Hepatic and splenic elastography: are they predictors of recurrence of esophageal varices after complete eradication?

Daniela Reis[1], Filipe de Sousa Damião[1], Ricardo Crespo[1], Carlos Noronha Ferreira[1], Luís Carrilho-Ribeiro[1], Maria Fatima Serejo L Silva[1], Rui Tato Marinho[1]. [1]*Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Gastroenterology and Hepatology, Lisbon, Portugal*
Email: daniela.ant.reis@gmail.com

Background and Aims: Endoscopic variceal surveillance combined with prophylactic banding decreases the incidence of variceal bleeding and it should be performed annually after successful eradication of esophageal varices (EV). The aim of this study was to assess which variables can be predictors of recurrence of EV after eradication, especially hepatic elastography (HE) and splenic elastography (SE), allowing to identify patients who may benefit from endoscopic control every two years.
Method: We retrospectively reviewed 99 consecutive patients who had complete eradication of EV after band ligation and underwent endoscopic surveillance for recurrence of EV or gastric varices, between February 2017 and October 2019. At time of control, HE and SE were performed and blood tests and abdominal ultrasound results were registered.

Results: Most patients were male n = 70 (70.7%). Mean age was 62.2 ± 10.5 years and mean body mass index (BMI) was 25.1 ± 8.1 Kg/m^2. The etiology of portal hypertension was cirrhosis in 87 (87.9%) patients and cavernoma in 12 (12.1%). Cirrhotic patients were mainly Child Pugh class A (92%) and had a mean MELD-Na$^+$ value of 10.7 ± 3.4 points. Concomitant beta-blocker therapy was observed in 68 (68.7%) patients. Mean value of hepatic elastography was 29.7 ± 20.6 kPa and mean value of splenic elastography was 69.7 ± 10.5 kPa.
Median time between complete eradication and endoscopic surveillance was 10 (1–1412) months. Recurrence of EV occurred in 25 (25.3%) patients, mainly small varices (n = 22). Gastric varices were observed in 12 (12.1%) patients, half of them with IGV1 type (n = 6). There was no statistically significant difference between patients with and without recurrent EV with respect to the following variables: age (p = 0.058), BMI (p = 0.458), time between eradication and control (p = 0.464), concomitant therapy with beta-blockers (p = 0.160), Child Pugh class (p = 0.329), MELD-Na$^+$ score (p = 0.643), ascites (p = 0.649), HE (p = 0.834) and SE (p = 0.986).
Conclusion: In this sample, most of patients who had recurrence of EV presented with small varices which suggest that these patients might benefit from a longer interval time between endoscopic surveillance (two years). Our study results suggest that hepatic and splenic elastography cannot replace upper endoscopy yet and patients with complete variceal eradication still need endoscopic screening.

SAT109

Risk of contrast-induced acute kidney injury in cirrhotic patients undergoing computed tomography: myth or reality?

Daniela Campion[1], Martina Rizzo[1], Paola Ponzo[1], Alessandro Risso[2], Ilaria Giovo[1], Felice Rizzi[1], Michele Roma[1], Alessandra Risso[1], Paola Caropreso[3], Gian Paolo Caviglia[4], Loredana Colla[5], Luigi Biancone[5], Aldo Manca[2], Giulio Mengozzi[3], Giorgio Maria Saracco[1], Carlo Alessandria[1]. *[1]Città della Salute e della Scienza, Gastroenterology and Hepatology, Torino, Italy; [2]Santa Croce e Carle Hospital, Gastroenterology, Cuneo, Italy; [3]Città della Salute e della Scienza, Clinical Chemistry, S.C. Baldi e Riberi, Torino, Italy; [4]University of Turin, Medical Sciences, Torino, Italy; [5]Città della Salute e della Scienza, Nephrology, Dialysis and Renal Transplant, Torino, Italy*
Email: carloalessandria@libero.it

Background and Aims: Cirrhotic patients have been considered at increased risk for iodinated contrast-induced acute kidney injury (CI-AKI), but evidence is scant, mainly encompassing retrospective studies with conflicting results. Our study aimed at clarifying the existence of an increased risk of CI-AKI in cirrhosis.
Method: An observational retrospective and a subsequent prospective study were undertaken, evaluating all the patients hospitalized from January 2018 to October 2019. Three cohorts were compared: cirrhotics (A) and non-cirrhotics (C) undergoing contrast-enhanced CT scan (CECT) and cirrhotics not exposed (B) to intravenous iodinated contrast media (ICM). Kidney function parameters were analyzed at T0 (24–48h before CECT for cohorts A/C; at enrollment for B) and after 2, 5 and 7 days (T1). CI-AKI was defined according to KDIGO criteria. Patients with any potential cause of impairment of clinical stability and of serum creatinine (sCr) increase between T0 and T1 were excluded.
Results: Overall, 294 patients were enrolled: 83, 95 and 116 in cohort A, B and C, respectively. CI-AKI incidence in cohort A did not differ from C (2.4 vs 2.6%, p = 0.48) or B (2.4 vs 1%, p = 0.94). All cases were stage 1a, except 1 case stage 1b, and all regressed spontaneously in few days. Mean sCr and eGFR (MDRD-4) did not change significantly after CECT neither in cohort A (T0 vs T1: sCr = 0.8 ± 0.3 vs 0.8 ± 0.2 mg/dl, p = 0.81; eGFR = 108 ± 38 vs 105 ± 32 ml/min/1.73 m^2, p = 0.29) nor C (T0 vs T1: sCr = 0.8 ± 0.2 vs 0.8 ± 0.3 mg/dl, p = 0.29; eGFR = 97 ± 33 vs 100 ± 34 ml/min/1.73 m^2, p = 0.16). In a subgroup of 69 consecutive cirrhotic patients urinary NGAL was measured, showing no significant changes from T0 to T1 in any patient neither in cohort A (26 ± 20 vs 24 ± 23 ng/ml, p = 0.48) nor B (30 ± 34 vs 31 ± 30 ng/ml, p = 0.86).
Conclusion: Cirrhosis per se does not appear to increase the risk of CI-AKI after CECT compared to the general population. AKI episodes were mild, rapidly reversible, with comparable incidence between CECT and non-CECT patients, hence likely attributable to spontaneous sCr fluctuations rather than to ICM. Even the assessment of NGAL, a sensitive marker of tubular damage, could not detect any sign of acute kidney injury after ICM exposure.

SAT110

Flash glucose monitoring system: a required tool to improve glycaemic control in patients with liver cirrhosis

Dalila Costa[1,2], Joana Lourenço[1], Ana Margarida Monteiro[3], Vera Fernandes[1,3], Sofia Silva Mendes[1,2], Raquel Gonçalves[2], Carla Rolanda[1,2]. *[1]Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal; [2]Gastroenterology Department, Braga Hospital, Braga, Portugal; [3]Endocrinology Department, Braga Hospital, Braga, Portugal*
Email: dc.dalilacosta@gmail.com

Background and Aims: Blood glucose dynamics in Liver Cirrhosis (LC) has been scarcely studied, however marked glycaemia fluctuations appear to be frequent, with a higher risk of postprandial hyperglycaemia and nocturnal hypoglycaemia, which are easily undervalued by standard monitoring tools. Flash glucose monitoring system (FGMS) is an improved subset of Continuous glucose monitoring with a recognized effectiveness on glycaemic control, recently validated by our group as a suitable option for monitoring Diabetes Mellitus (DM) in patients with LC. We aimed to characterize the glycaemic profile of this population and assess the clinical applicability of FGMS.
Method: A prospective, case-control study was performed in 61 ambulatory patients with LC and DM (LC, n = 31) or Type 2 DM (T2DM, n = 30). For 14 days, patients performed 4 assessments per day of self-monitoring of blood glucose (SMBG) followed by FGMS scanning (scheduled upon waking, 2 hours after the beginning of lunch and dinner and at bedtime). For a complete 24-hour glycaemic profile, a FGMS scan was performed once every 8 hours. Clinical and biochemical data were assessed, including the glycated haemoglobin (HbA1c).
Results: Patients with LC revealed significantly lower fasting glucose levels (p < 0.001), though no significant differences were detained regarding postprandial hyperglycaemia. The number of hypoglycaemia events were similar between the groups (p = 0,7), nonetheless a higher number of nocturnal hypoglycaemia episodes were detected in patients with LC (p = 0,008). FGMS recognized hypoglycaemia events in about 75% of the patients in LC group (median = 4; average duration 126 minutes) and SMBG exhibited a significantly lower hypoglycaemia detection rate (43,5%; p = 0,04). Most patients with LC revealed a normal value of HbA1c (median 6,0; IQR 2,0), which displayed a moderate correlation with postprandial hyperglycaemia ($\rho = 0.5$; $p < 0.001$) and no correlation with hypoglycaemia events ($\rho = -0.4$; $p = 0.07$).
Conclusion: Comparing to the standard tools (SMBG and HbA1c), FGMS revealed a greater performance in patients with LC, exhibiting a higher hypoglycaemia detection rate, mainly nocturnal hypoglycaemia events, frequently noticed in this population.

SAT111

Incorporation of frailty estimated by gait speed within MELD and the predictive potential for mortality in cirrhosis

You Deng[1], Lin Lin[2], Xiaofei Fan[3], Lijun Hou[3], Tianming Zhao[3], Chao Sun[3]. *[1]Tianjin Medical University General Hospital, Department of Gastroenterology and Hepatology, Tianjin, China; [2]Tianjin Medical University General Hospital Airport Hospital, Department of Gastroenterology, Tianjin, China; [3]Tianjin Medical University General*

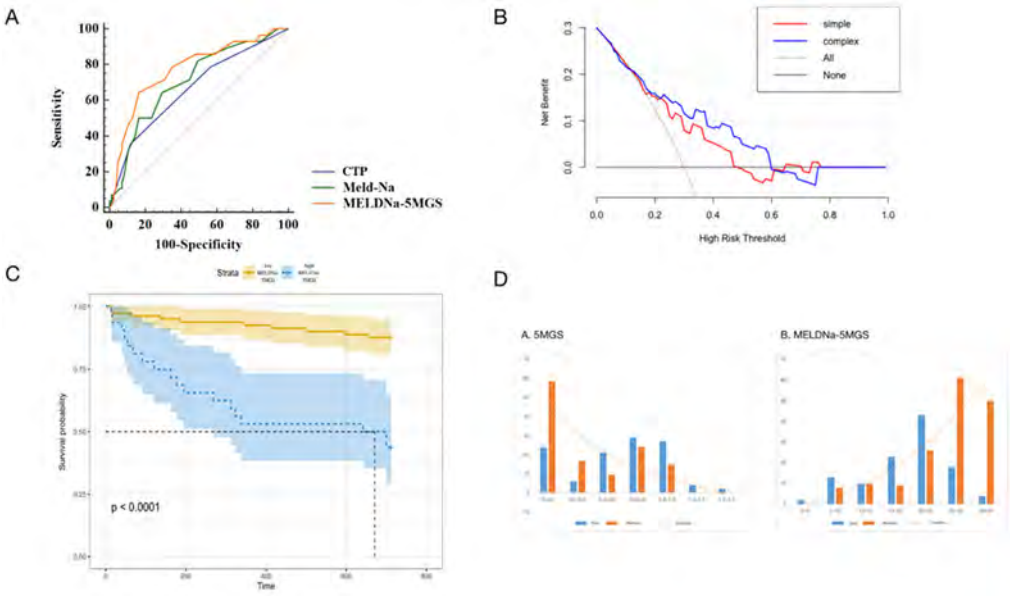

Figure: (abstract: SAT111)

Hospital, Department of Gastroenterology and Hepatology, Tianjin, China
Email: chaosun@tmu.edu.cn

Background and Aims: The five-meter gait speed (5MGS), a simple and reliable performance metric and surrogate indicator of frailty, consistently predicts adverse events in elders. Additionally, MELD-Na score fails to capture nutritional and functional decline of cirrhotic patients which may confer excess mortality. We hypothesized that 5MGS might be associated with all-cause mortality and inclusion of frailty assessment within MELD-Na could improve the prediction of mortality in cirrhosis.
Method: 5MGS were measured at baseline in 113 hospitalized cirrhotic patients. Survival status over two years and cirrhosis-related complications were recorded. We evaluated the prognostic value of 5MGS (as a continuous variable and as a dichotomous variable). The definition of slow versus preserved 5MGS was 0.8 ms^{-1} based on previous publication. Using Cox proportional hazards regression, a novel MELD-5MGS score was derived. ROCs estimated discrimination between new score model and established prognostic indices.
Results: The Continuous 5MGS and slow 5MGS were independent predictors of all-cause mortality (5MGS: HR 0.133 (0.047 to 0.347), $p < 0.001$; slow 5MGS: HR 4.805 (1.536 to 15.026), $p < 0.007$). The equation derived from Cox regression analysis was as follows: MELDNa-5MGS: MELD-Na score + 11 × slow 5MGS. Two-year mortality in patients with high MELD-5MGS score was significantly higher ($p < 0.001$). The discriminatory power was significantly better for MELDNa-5MGS than MELD-Na score (AUC: 0.802 vs 0.724, $p = 0.014$ for 12-month; 0.773 vs 0.709, $p = 0.044$ for 24-month).
Conclusion: In cirrhotic patients, 5GMS is an independent risk factor of mortality. Modification of MELD-Na to include frailty estimated by low 5GMS is related to improved prognostication of mortality.

SAT112

Serologically assessed fragments of type VI collagen are predictors of progression free survival and death in patients with hepatocellular carcinoma

Diana Julie Leeming[1], Mette Juul Nielsen[1], Signe Holm Nielsen[1,2], Raj Uchila[3], Mohammed Eslam[3], Roslyn Vongsuvanh[3], David Van Der Poorten[3], Morten Karsdal[1], Jacob George[3]. [1]*Nordic Bioscience, Research and Biomarkers, Herlev, Denmark;* [2]*Technical University of Denmark, Department of Biotechnology and Biomedicine, Kgs. Lyngby, Denmark;* [3]*Westmead Hospital, Storr Liver centre, Westmead, Australia*
Email: dianaleeming@gmail.com

Background and Aims: Serum alpha-fetoprotein (AFP) has suboptimal performance in the screening of hepatocellular carcinoma (HCC). During liver fibrosis and HCC development, collagen derived neoepitope fragments are released into circulation. Clinically, type VI collagen (COL6) a3 is known to relate to fibrosis, apoptosis and cell proliferation in HCC. We tested the ability of C6M a marker of matrix metalloprotease degradation of the a1 chain and PRO-C6 a COL6 formation marker of the a3 chain also known as the signaling fragment endotrophin (ETP) produced by fibroblasts, to predict outcome in HCC.
Method: Plasma C6M and PRO-C6 were assessed in 1) 86 biopsy-proven HCC patients, 2) 86 age and sex-matched cirrhotics, 3) 86 non-cirrhotics, and 4) 86 healthy controls. Data for clinical characteristics, liver related biochemistry and AFP were collected. Survival data were collected for up to 17-years after cirrhosis diagnosis. Progression free survival (PFS) was defined as time from diagnosis to tumor progression or death in HCC patients; overall survival (OS) was defined as all-cause mortality. Biomarker relations to survival was calculated by Kaplan-Meier analysis using median or quartiles(Q) as cut-off and by Cox Regression analysis.
Results: C6M was significantly related to disease severity ($p < 0.01$), however did not display significant difference between groups 1–4. In contrast, PRO-C6 was able to separate groups 2–4 from HCC patients ($p < 0.0001$, $p < 0.0001$ and $p = 0.007$, respectively). During follow-up, 75% of the cirrhotic patients experienced progression. Neither, $C6M_{median}$ or $C6M_{Q4vsQ1}$ were able to predict PFS, however were able to predict OS (median: Hazard Ratio (HR) = 2.4, $p = 0.02$; Q4 vs Q1-3: HR = 2.9, $p = 0.03$). $PRO\text{-}C6_{median}$ and $PRO\text{-}C6_{Q4vsQ1\text{-}3}$ were significantly associated with time to PFS (median: HR = 1.9, $p = 0.01$; Q4 vs Q1-3: HR = 2.3, $p = 0.01$) and to OS (median: HR = 2.4, $p = 0.003$; Q4 vs Q1-3: 3.2, $p = 0.004$). In comparison, AFP above the recommended cut-off (20 IU/mL) provided a HR = 1.87 ($p = 0.02$) for PFS and HR = 3.0 ($p = 0.002$) for OS. Only PRO-C6 was significant in a COX model including PRO-C6 and AFP for PFS (HR = 1.06 per unit change, $p = 0.020$). Both PRO-C6 and AFP were significant for OS (PRO-C6: HR

= 1.08 per unit change, p = 0.007; AFP: HR = 1.00 per unit change, p = 0.017).
Conclusions: Markers of COL6 relate to disease severity in patients with hepatic fibrosis and HCC. C6M, ETP and AFP were associated with progression and overall survival; while ETP was superior.

SAT113
Mechanical ventilation in patients with hepatopulmonary syndrome: prevalence, resource utilization, and prognosis: a nationwide analysis

Ahmad Khan[1], Muhammad Farhan Khaliq[2], Raseen Tariq[3], Khadija Naseem[4], Shailendra Singh[5]. *[1]West Virginia University Charleston Division, Charleston, United States; [2]Slidell Memorial Hospital, Internal Medicine, Slidell, United States; [3]Rochester General Hospital, Internal Medicine, Rochester, United States; [4]Services Institute of Medical Sciences, Lahore, Pakistan; [5]CAMC Memorial Hospital, Gastroenterology, Charleston, United States*
Email: drahmadk83@gmail.com

Background and Aims: Hepatopulmonary syndrome (HPS) is a frequent complication of liver cirrhosis, and liver transplantation is the only definitive therapy. Patients with HPS are often hospitalized with respiratory failure requiring invasive mechanical ventilation (IMV). There is limited data on the prevalence and hospital-related outcomes for these patients. We aimed to investigate the prevalence, resource utilization, and prognosis of patients with HPS requiring IMV.

Table: Demographics and outcomes of interests in patients with HPS with and without IMV

	HPS with MV *n* or *(%)*	HPS without MV *n* or *(%)*	*p* value
No. of patients	841	4794	
Patient Characteristics			
Female	357 (42.52%)	2384 (49.74%)	<0.001
Age in years (Mean)	56.73	56.27	<0.001
Race			<0.001
White	74.64	70.79	
Black	4.92	5.72	
Hispanic	14.84	17.52	
Other			
Charleston comorbidity index			<0.001
0	1.19	1.36	
1	3.51	7.79	
2	6.99	9.44	
3 or more	88.31	81.42	
Hospital Characteristics			
Hospital Teaching Status			<0.001
Teaching	21.2	22.35	
Non-Teaching	78.8	77.65	
Hospital size			<0.001
Small	8.91	9.98	
Medium	17.89	20.45	
Large	73.2	69.57	
Hospital Region			<0.001
Northeast	12.85	18.21	
Midwest	24.16	22.72	
South	28.46	34.1	
West	34.53	24.97	
Primary and Secondary Outcomes			
Total Hospitalizations	841	5,636	
Mortality n (%)	427 (50.77%)	310 (5.50%)	
Mean Length of Stay (Days)	15.77	8.9	
Mean Hospitalization Charges (USD)	279,012$	106,365$	

Method: We used the National Inpatient Sample (NIS) to identify patients with HPS who required IMV through ICD 9 CM codes between 2012–2014. Primary outcome included the rate of IMV requirement and secondary outcomes were inpatient mortality, length of stay (LOS) and hospitalization charges. We also used univariate and multivariate regression models to adjust for confounders to identify predictors of mortality.
Results: A total of 5,636 non-elective admissions were recorded for HPS between 2012–2014. Out of these, 2,739 (48.59%) patients presented with acute respiratory failure, and 14.92% patients required IMV. The mean age of patients requiring IMV was 56 years, 42.52% were females, and 74.64% were Caucasians (Table). The mortality among patients requiring IMV was 50.77% (427/841). Mean time to start IMV was recorded as 3.85 days. Patients in the IMV group had increased mean LOS 15.77 vs. 8.9 days, increased mean total hospitalization charges 279,012$ vs. 106,365$. We also found that IMV (OR 6.25, p < 0.01), age (OR 1.02, p = 0.04), acute kidney injury (2.81 p = 0.00), acute respiratory failure (3.2, p < 0.01) and sepsis (OR 2.76, p = 0.01) are independent risk factors for mortality in IMV group.
Conclusion: Our study shows that a large number of hospitalized patients with HPS will require IMV which is associated with resource utilization, and exceptionally high (51%) mortality. The requirement for IMV is an independent predictor for poor prognosis, and eligible patients should be prioritized for liver transplant allocations.

SAT114
Acute kidney injury: a predictor of worse outcomes in variceal bleeding

Ahmad Khan[1], Khadija Naseem[2], Nida Khalid[3], Nasir Saleem[4], Kamesh Gupta[5], Shailendra Singh[6]. *[1]West Virginia University Charleston Division, Charleston, United States; [2]Services Hospital, Lahore, Pakistan; [3]Rochester General Hospital, Rochester, United States; [4]University of Tennessee Health Science Center - Health Sciences Library, Memphis, United States; [5]Baystate Medical Center, Springfield, United States; [6]CAMC Memorial Hospital, Charleston, United States*
Email: drahmadk83@gmail.com

Background and Aims: Variceal Gastrointestinal Bleeding (VGIB) is a life-threatening emergency that can lead to significant morbidity and mortality. These patients are at risk of developing acute kidney injury (AKI) from inadequate fluid resuscitation due to the fear of third spacing. We aimed to investigate the prevalence and impact of AKI on in-hospital mortality and resource utilization in VGIB.
Method: We identified the patients with VGIB who had co-existing diagnoses of AKI using the ICD-9 CM codes in the National Inpatient Sample (NIS) database between 2009–2014. Primary outcome included the prevalence of AKI in VGIB with secondary outcomes as inpatient mortality, length of stay (LOS), total hospitalization charges, need for transfusion and mechanical ventilation, and prevalence of shock. We adjusted for confounding factors by performing univariate and multivariate regression models to identify predictors of mortality in these patients.
Results: A total of 23,314 VGIB related hospitalizations were identified, out of which 3,197 (13.71%) had AKI. Patients in this group were older (mean age 60.37 vs. 56.54 years) with a predominance of Caucasian males. In total, 1,360 patients died during the same admission, with 585 (43.01%) had co-existing AKI. These patients had higher mean LOS (6.8 vs. 4.68 days) as compared to the control group. Similarly, the inflation-adjusted mean total hospitalization charges (79,050$ vs. 42,520$) and cost (20,917$ vs. 11,729$) were also higher. After adjusting for confounding factors, AKI was turned out to be an independent predictor of mortality with aOR of 5.53 (p-value: <0.001 95% CI: 4.07–7.50).
Conclusion: Our study showed that AKI is an independent predictor for inpatient mortality and increased resource utilization in VGIB. Adequate volume resuscitation can prevent AKI and improve these outcomes.

Table: (abstract: SAT114) Demographics and outcomes associated with VGIB with and without AKI

	Acute VGIB with AKI *n* or *(%)*	Acute VGIB without AKI *n* or *(%)*	*p* value
Total hospitalizations	3,197 (13.71%)	20,117 (86.29%)

SAT115

The prospective prognostic values of diabetic conditions based on 75g oral glucose tolerance test in cirrhotic patients

Moon Young Kim[1], Seong Hee Kang[1], Soon Koo Baik[1]. [1]*Yonsei University Wonju College of Medicine, Gastroenterology and Hepatology, Wonju, Korea, Rep. of South*
Email: drkimmy@yonsei.ac.kr

Background and Aims: Disorders of glucose metabolism, such as impaired glucose intolerance (IGT) and diabetes mellitus (DM), occur frequently in cirrhosis. However, DM and IGT have not received enough attention and have been underestimated when fasting plasma glucose (FPG) levels are considered. we evaluated whether abnormal glucose metabolism, estimated by FPG and the oral glucose tolerance test (OGTT), influences the prognosis of patients with liver cirrhosis.
Method: This prospective observational study included 713 patients with either compensated or decompensated cirrhosis; these patients underwent a 75-g OGTT. The patients were divided into three groups: patients with normal glucose tolerance (NGT), patients with IGT ($100 \leq$ FPG < 126 mg/dL or $140 \leq$ 2-h OGTT < 200 mg/dL), and patients with newly diagnosed DM ($126 \leq$ FPG or 200 mg/dL $\leq$2-h OGTT).
Results: Among 713 patients, NGT was diagnosed in 139 (19.5%), IGT in 252 (35.3%), and DM in 322 (45.2%). During a median follow-up period of 42.0 months (interquartile range, 20.5–66.5 months), the cumulative survival rates of patients were as follows: NGT, 75.6%; IGT, 57.6%; and DM, 54.8%. Overall, IGT [adjusted hazard ratio (aHR) = 1.669; 95% CI = 1.050–2.653; P = 0.03] and DM (aHR, 1.723; 95% CI = 1.101–2.698; P = 0.017) were identified as independent predictors of mortality after adjustment for Child–Turcotte–Pugh (CTP) and MELD scores. In patients with compensated cirrhosis (CTP class A; n = 415), neither IGT nor DM conferred a higher risk for mortality. However, among patients with decompensated cirrhosis (CTP class B and C; n = 298), those with IGT (aHR, 2.279; P = 0.022) and DM (aHR, 2.211; P = 0.022) showed a worse survival rate than those with NGT. In addition, DM was identified as an independent risk factor for acute kidney injury (aHR, 2.247; P = 0.036) and infection (aHR, 2.801; P = 0.034).
Conclusion: Abnormal glucose tolerance in patients with IGT or DM is associated with an unfavorable prognosis in patients with cirrhosis, particularly in the decompensated state. Also, our results demonstrated that AKI and infection were more frequent in patients with DM than in those with NGT.

SAT116

PROSPER study reveals reduction in bed days per hospitalisation and decreased risk of mortality for patients observed on rifaximin-alpha 550mg compared to a cohort on standard of care

Dave Walker[1]. [1]*Norgine Ltd., Clinical Development, Harefield, United Kingdom*
Email: dwalker@norgine.com

Background and Aims: To provide real-world evidence on the effectiveness of rifaximin-alpha 550 mg (rifaximin) treatment in patients with persistent hepatic encephalopathy (HE) to reduce mortality and time in hospital compared to those patients who do not receive rifaximin (noted as standard of care (SOC), majority receiving lactulose alone).
Method: The Prospective Real World Outcomes Study of Hepatic Encephalopathy Patients' Experience on Rifaximin-α (PROSPER) clinical trial was a multinational, multicentre, observational study conducted under real-world clinical practice conditions combining a retrospective with a prospective approach. The study was conducted in centres in Australia, Belgium, Denmark, France, Germany, Netherlands, Sweden, Switzerland and UK. Patients with cirrhosis and persistent HE were enrolled, with a total of 389 observed cases. Management of patients remained unchanged beyond clinical practice. Patients underwent prospective observation for a minimum of 12 months and in some cases up to 26 months. The number of HE-related bed days, the number of bed days per hospitalisation, and the relative risk of mortality were compared between patients who received rifaximin versus patients who received SOC.
Results: The efficacy analysis set contained 280 cases in the rifaximin cohort and 89 cases in the SOC. The rifaximin treatment group had clinically meaningful advantages compared to the non-rifaximin group in all three performed analyses: HE-related bed days were reduced from (mean, 95% CI) 10.80 (9.12, 12.78) to 4.24 (2.95, 6.09) pre- and post-study enrolment respectively whereas the non-rifaximin cohort remained relatively stable at 9.72 (7.11, 13.29) and 9.56 (4.16, 21.94) pre- and post-study enrolment respectively. A comparison between these cohorts showed 60% benefit for the rifaximin cohort compared to SOC. Further post hoc analysis of bed days per hospitalisation event showed a 87% risk reduction in favour of rifaximin 550mg. Risk of mortality is significant for patients with HE and observations in these cohorts showed a relative risk reduction for patients taking rifaximin 550mg which ranged from 39% in the overall cohort and as high as 80% in selected high recruiting sites.
Conclusion: Descriptive comparisons between rifaximin and SOC cohorts highlighted demonstrable benefits for number of HE-related bed days, bed days per hospitalisation and a clinically meaningful reduction in mortality for patients taking rifaximin 550 mg.

SAT117

Hemodynamic effects of direct-acting antivirals in patients with hepatitis-C virus-associated cirrhosis and portal hypertension non responsive to beta-blockers

Edilmar Alvarado[1,2,3], Sabela Lens[2,4,5], Alba Ardevol[1,2,3], Marta García Guix[1], Anna Baiges[2,4,5], Ana Brujats[1,3], Laura Gonzalez Gonzalez[1,3], Zoe Mariño[2,4,5], Xavier Torras[1,2,3], Adolfo Gallego Moya[1,3], Virginia Hernandez-Gea[2,4,5], Xavier Forns[2,4,5], Juan Carlos Garcia Pagan[2,4,5], Candid Villanueva[1,2,3]. [1]*Hospital de la Santa Creu i Sant Pau, Gastroenterology and Hepatology, Barcelona, Spain;* [2]*Ciberehd, Madrid, Suriname;* [3]*Universitat Autònoma*

de Barcelona, Bellaterra, Spain; [4]Hospital Clínic de Barcelona, Hepatology, Barcelona, Spain; [5]University of Barcelona, Barcelona, Spain
Email: ealvaradot@santpau.cat

Background and Aims: Hemodynamic non-responders to non-selective β-blockers (NSBBs) are at high risk of unfavorable outcomes. Safe therapies to rescue non-responders are scarce. Whether etiologic treatment may achieve an additional decrease of portal pressure in these patients has not been clarified. Direct-acting antivirals (DAA) are safe and effective in patients with hepatitis-C virus-associated cirrhosis (HCV-cirrhosis) and offer a chance to clarify this issue. The present study aimed to assess the effect of DAA on portal hypertension (PH) in patients with HCV-cirrhosis and clinically significant PH (CSPH), according to the previous hemodynamic effect of chronic therapy with NSBBs.
Method: We performed an observational cohort study of patients with HCV-cirrhosis and CSPH treated with NSBBs for primary or secondary prophylaxis of PH-related bleeding before receiving DAA for HCV. Hepatic-venous pressure gradient (HVPG) was measured at baseline, and under chronic therapy with NSBBs before DAA and again after 24-weeks of achieving sustained virological response (SVR) with DAA.
Results: 51 patients were included, 17(33%) on secondary and 34 (67%) on primary prophylaxis. 32(63%) were Child-Pugh class A and 19(37%) class B, 27(53%) were compensated and 24(47%) had previous decompensation of cirrhosis. All were treated with NSBBs. : 30(59%) with propranolol (mean dose: 60 mg/d, IQR: 40–80) and 21 (41%) with carvedilol (mean dose: 18,5 mg/d, IQR: 12.5–25). 26 patients (51%) were hemodynamic responders to NSBBs (HVPG decrease ≥10% from baseline) and had. Baseline characteristics were similar baseline characteristics than non-responders. All patients had SVR. The HVPG-reduction achieved with DAA vs the baseline-HVPG, was greater in responders to NSBBs than in non-responders (20% ± 19% vs 7% ± 19%, P = 0.04). As compared to the HVPG-value under NSBBs, DAA achieved a significant HVPG-decrease in non-responders to NSBBs (from 16.8 ± 3 to 15.4 ± 3 mmHg, P = 0.001) but not in responders (from 15.9 ± 4 to 15.5 ± 4, P = 0.53), reaching a greater relative reduction (12% ± 11% vs 2 ± 22%, P = 0.05).
Conclusion: In patients with HCV-cirrhosis and CSPH receiving chronic prophylaxis with NSBBs, as compared with HVPG-value under NSBBs, DAA therapy has a greater HVPG-lowering effect in hemodynamic non-responders to NSBBs than in responders, although the final HVPG-decrease from baseline-HVPG was greater in hemodynamic responders to NSBBs. This suggests that hemodynamic non-responders to NSBBs may also achieve a benefit from etiological therapy in terms of HVPG-reduction.

SAT118

Improving nutritional care in patients with liver cirrhosis: a quality improvement project

Syazeddy Samani[1], Yen Miao[1], Sik Yeng Chan[1], Ka Kit Li[1], Jatinder Minhas[1]. *[1]University Hospitals of Leicester NHS trust, Digestive Disease Centre, Leicester, United Kingdom*
Email: eddysamani@gmail.com

Background and Aims: The nutrition status of patient with chronic liver disease is known to correlate with disease progression, complications and prognosis. This has resulted in the development of recent guidelines by both EASL and ESPEN on the management of clinical nutrition in liver disease. A liver nutrition care pathway was developed at the University Hospitals of Leicester, NHS Trust to facilitate the delivery of the highlighted recommendations with the aim of improving the quality of nutritional care in patients with cirrhosis. However, the adherence to this pathway has been poor. The aim of this quality improvement project (QIP) is to increase adherence to this pathway in the hepatology unit.
Method: All cirrhotic patients admitted are nutritionally assessed and commenced on the care pathway (see figure 1). Using the 'Plan, Do, Study, Act' (PDSA) QIP methodology, a multidisciplinary team was created to identify ways to improve adherence over a five week period. Three sets of data were prospectively collected on week one (week beginning 30th September 2019), three and five respectively with weeks two and four reserved for interventions. Some of the interventions undertaken included ward staff education, electronic prescribing for nutritional supplements, identification of a 'nurse champion' and promotion via the 'ward newsletter'. Data analysis were focused on adherence to key points including appendices filed, dry weight record, oral nutrition supplementation, food chart commencement and review at day four. Fisher's exact and Student's t-test were used for statistical analysis between week one and week five.
Results: Week 1 (n = 16):- mean age was 59 (SD 12) and 38% (n = 6) were female. Mean Child-Pugh score was 8.6 (SD 2). Number of appendices printed 0 (n = 16). 43.8% (n = 7) had high-energy protein (EP) supplements and 12.5% (n = 2) had carbohydrate (CB) offered. Dry weight estimate was measured in 12.5% (n = 2) of patients and food chart commenced in 75% (n = 12) of patients. Adequate day four food chart (FC) review was not performed in all patients. **Week 5** (n = 16):- mean age was 57 (SD 12) and 56% (n = 9) were female. Mean Child-Pugh score was 11 (SD 2). Percentage of appendices printed had improved to 75% of patients ($p < 0.001$). 87.5% (n = 14) of patients had EP supplements prescribed ($p = 0.023$) and 81.3% (n = 13) had CB offered ($p < 0.001$). There has also been an increase in documentation of dry weight (n = 2 vs n = 7, p = 0.046) and FC review (n = 0 vs n = 10, $p < 0.001$).
Conclusion: This ongoing QIP was successful in improving nutritional care for patients with cirrhosis over a short period. Significant improvement was achieved in appendices filed, dry weight estimate, oral nutrition including EP and CB supplementation and FC review. A key cofounder is the greater severity cirrhotic disease assessed on week five as compared to week one.

SAT119

90-day mortality is lower after as compared to before transjugular intrahepatic portosystemic shunt at the same model for end-stage liver disease score

Laurie Eicher[1], Andreas Umgelter[1,2], Alexander Hapfelmeier[3], Moritz Wildgruber[4,5]. *[1]Klinikum Rechts der Isar; 2nd Medical Department, Munich, Germany; [2]Vivantes Humboldt-Klinikum, Department of Emergency Medicine, Berlin, Germany; [3]Klinikum Rechts der Isar, Institute of Medical Statistics and Epidemiology, Munich, Germany; [4]Universitätsklinikum Münster, Institute of Clinical Radiology, Münster, Germany; [5]Klinikum Rechts der Isar, Institute of Diagnostic and Interventional Radiology, Munich, Germany*
Email: eicherlaurie@yahoo.com

Background and Aims: The Model for End-stage Liver Disease (MELD) score has originally been developed to predict 90-day mortality in cirrhotic patients after transjugular intrahepatic portosystemic shunt (TIPS). As the MELD score correlates with the severity of chronic liver disease, it is nowadays employed to stratify patients on a liver transplant waiting list according to urgency. TIPS reduces portal pressure at the cost of hepatic cellular function. It is unclear if the association between MELD score and 90-day mortality remains unaltered after placement of TIPS. MELD may be associated with a different mortality if measured after as compared to before TIPS.
Method: We retrospectively analyzed 179 consecutive patients with cirrhosis that received a TIPS procedure between 2004–2015. MELD scores before TIPS, and 30, 90 and 365 days after TIPS, as well as respective 90-day mortalities were calculated. Gender, age at TIPS insertion, time since TIPS procedure, MELD scores and timing of

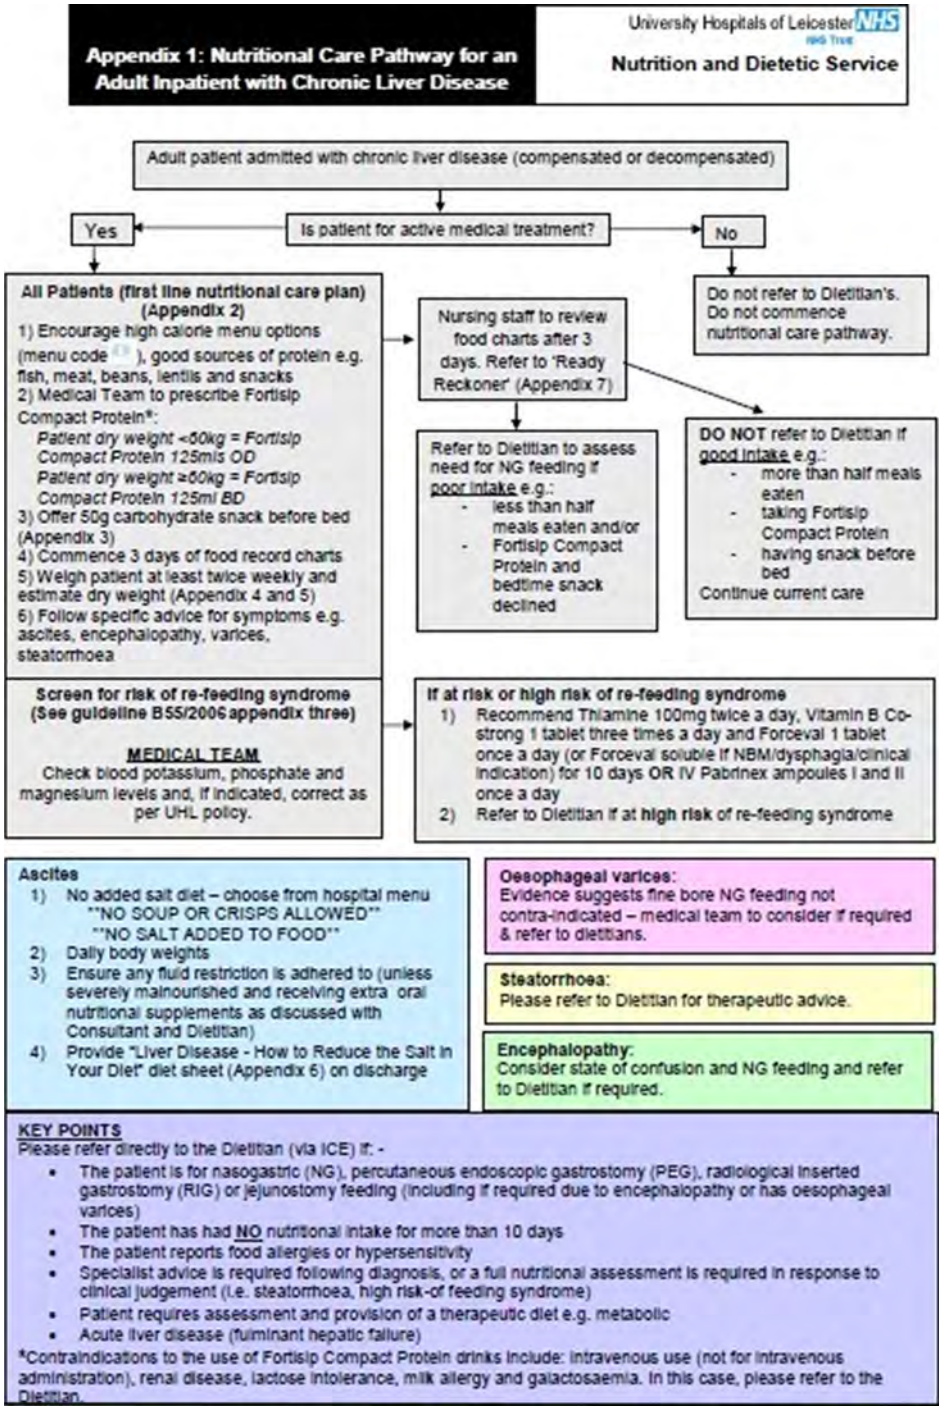

Figure: (abstract: SAT118): Local nutritional care pathway for an adult inpatient with chronic liver disease.

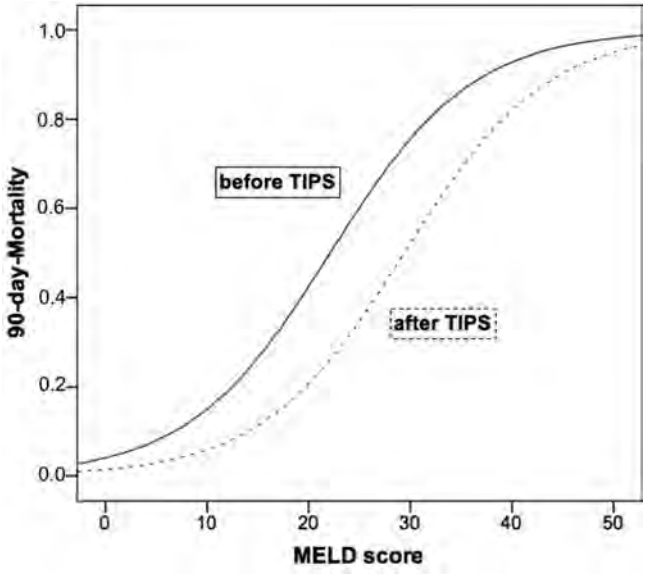
MELD score (before or after TIPS) were inserted as variables in a binary logistic regression with 90-day mortality as an end-point.

Results: Among the study population (n = 179), 69.4% were male, mean age was 60.3 ± 10.6 years and mean MELD score before TIPS was 16.0 ± 6.1. 76.0% underwent TIPS procedure because of ascites, 46.5% because of hemorrhage. In binary logistic regression analysis, only MELD score (p < 0,0001) and timing of MELD score before compared to after TIPS (p = 0,022) were significant predictors of 90-day mortality. Relative risk (95% confidence interval) for mortality per MELD point increase was 1.151 (1.10–1.20), for MELD before TIPS compared to after TIPS it was 0.457 (0.234–0.894). At MELD scores of 10, 20 and 30 mortality rates were 15% versus 6%, 42% versus 21% and 76% versus 52%, respectively, when measured before versus after TIPS insertion. The other variables were not significantly associated with mortality.

Conclusion: Our results suggest that the same MELD scores may be associated with a lower mortality if taken after as compared to before TIPS placement. This may have implications for liver allocation systems, as MELD scores of patients after TIPS may overestimate true waitlist mortality, unintentionally prioritizing these patients for liver transplantation.



SAT120

Long-term prospective study of development of hepatocellular carcinoma in compensated cirrhosis

Alessandra Pivetti[1], Paola Todesca[1], Federica Bertellini[1], Marcello Bianchini[1], Veronica Bernabucci[1], Barbara Lei[1], Mariagrazia Del Buono[1], Laura Turco[1], Filippo Schepis[1], Erica Villa[1].
[1]*Policlinico of Modena University Hospital of Modena, Gastroenterology, Modena, Italy*
Email: erica.villa@unimore.it

Background and Aims: Hepatocellular carcinoma (HCC) is the 5th most frequent incident solid tumor in males and the 2nd for mortality. Main risk factors for HCC development have been mostly identified in retrospective cohorts. With the aim of identifying clinical and biologic risk factors for HCC development, we started in 2013 a prospective study in patients with liver cirrhosis undergoing hepatic venous pressure gradient (HVPG) measurement (ClinicalTrials.gov Identifier: NCT03083002).
Method: 445 consecutive patients with liver cirrhosis (66.5% CP-A, 23.2% CP-B, 10.3% CP-C) undergoing HVPG measurement and transjugular liver biopsy at the Gastroenterology Unit, Modena, were enrolled in this prospective study starting July 2013. Patients were followed up every 6 months with US and blood tests. Those developing HCC in the first 6 months of follow-up were excluded. Data regarding etiology, portal vein, portal vein thrombosis, HVPG, presence and grading of esophageal varices, Child-Pugh and MELD Score, time of development of HCC were collected. Incident cases of HCC were biopsied for pathological and transcriptomic characterization. Independent risk factors for HCC were evaluated by Cox regression analysis.
Results: Median follow up was 40 months. 61 patients died during follow up, 35 developed HCC (M/F 29/6)(incidence 4–5% per year). Preliminary results of analysis of hepatic and circulating biomarkers of angiogenesis, portal hypertension and fibrosis as predictive factors for HCC development indicate marked activation of neoangiogenesis as related with HCC risk. At univariate analysis HVPG>15 (but not HVPG>10 or >20 mmHg), F2/F3 esophageal varices, viral vs. non-viral etiology, and albumin were statistically associated with HCC development (HVPG/F2-F3 varices collinear). In multivariate model with HVPG>15, none of these factors was significantly associated with HCC development while in the model with F2/F3 esophageal varices, presence of the latter was independently linked with HCC development (HR 2.258, 95% CI 1.135–4.494). Albumin only had borderline significance (0.586, CI%.337–1.018).
Conclusion: In this prospective cohort of patients with compensated liver cirrhosis, neither HVPG>10, >15 or >20 mmHg was independently associated with HCC development. Previous data indicating HVPG>10 as a significant risk factor for HCC were likely influenced by the cohort studied, which was free of varices at enrollment. In a cohort of compensated patients with liver cirrhosis not selected for absence of varices, more severe portal hypertension as indicated by F2/F3 varices was the only independent risk factor for HCC development. Presence of F2/F3 varices was related with activation of hepatic neoangiogenesis.

SAT121

First-line empirical antibiotics failed to control bacterial infections resistant to multi drugs in patients hospitalized with cirrhosis

Zhujun Cao[1], Yuhan Liu[1], Minghao Cai[1], Weijing Wang[1], Wei Cai[1], Hui Wang[1], Qing Xie[1]. [1]*Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Department of Infectious Diseases, Shanghai, China*
Email: xieqingrjh@163.com

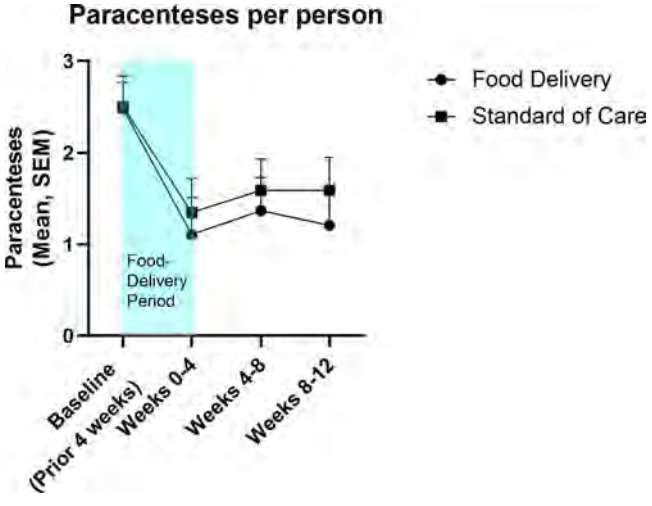
Background and Aims: Patients with cirrhosis are prone to developing bacterial infection due to immune-dysfunction and repeated hospitalizations. Recent data report a high prevalence of multidrug-resistance organism (MDRO) infection in patients with cirrhosis in Europe and other continents whereas data are limited in China. We aimed to characterize the prevalence, response to first-line empirical antibiotic and survival of MDRO infection in patients hospitalized with cirrhosis.
Method: We prospectively analyzed 155 episodes of infection in 129 consecutive hospitalized patients with cirrhosis in a tertiary center between June, 2016 and July 2018. Data on demographic, clinical, laboratory, microbiology, treatment were collected and analyzed. Treatment response and survival were compared between patients with and without MDRO infection and also between patients with and without accordance to the first-line empirical antibiotics, which was classified according to the Chinese guideline or the EASL guideline for the management of patients with decompensated cirrhosis.
Results: Pneumonia (43.9%), spontaneous bacterial peritonitis (18.7%) and urinary tract infections (7.7%) were the most frequently identified infections. Most of the infections were hospital-associated, including 39.4% of health-care associated and 46.5% of nosocomial infections. 40.6% of the infections were culture-positive, of which 38.8% were caused by MDRO with 65.4% of Enterobacteriaceae bacteria and others. Extended-spectrum beta-lactamase-producing Escherichia coli (38.5%) was the most frequent MDRO followed by Vancomycin-susceptible Enterococcus (15.4%), Carbapenem-resistant Klebsiella (11.5%) and Carbapenem-resistant Acinetobacter baumannii (7.7%). Patients with MDRO infections were closely (all $p < 0.001$) associated with poorer efficacy of first-line empirical antibiotic treatment, higher incidence of acute kidney injury and acute-on-chronic liver failure (ACLF), and lower 28- and 90-day transplant-free mortality comparing to those caused by non-MDRO infections. The accordance of the empirical antibiotic treatment with the national or international guideline did not significantly affect the clinical outcome. However, the failure of first-line empirical antibiotic treatment (sHR, 95%CI: 0.1, 0.02–0.36), presence of ACLF (sHR, 95%CI: 5.1, 2.6–10.0) and sepsis infection (sHR, 95%CI: 4.7, 2.4–9.0) were the most significant independent risk factor of 28-day transplant-free mortality.
Conclusion: MDRO is prevalent with negative impact on prognosis in our cohort from China. Currently recommended first-line empirical treatment by the national and International societies failed to control MDRO infections thereby leading to poorer survival. Specific local antimicrobial strategies need to be established.

SAT122

The SALTYFOOD trial: a randomized, controlled trial of home-delivered low-sodium meals for the management of refractory ascites

Elliot Tapper[1], Samantha Nikirk[1], Jad Baki[1], Anna Lok[1]. [1]*University of Michigan Hospital, Ann Arbor, United States*
Email: etapper@med.umich.edu

Background and Aims: Refractory ascites is a costly, morbid complication of cirrhosis. Re-accumulation of fluid after paracentesis is associated with risk of hospitalization and infection. Although low-sodium diet is central to the clinical management of ascites, its efficacy is limited by poor adherence. We aimed to determine the impact of home-delivered low-sodium meals on clinical and patient-reported outcomes.
Method: We enrolled 40 persons with cirrhosis and ascites at the time of their outpatient paracentesis or hospitalization with symptomatic ascites in a 1:1 randomized trial of standard-of-care (SOC) (an educational hand-out on low sodium diet) or home-delivered meals with <2000 mg of sodium, >2100 kilocalories, and ≥80 g of protein including a nocturnal protein supplement (Clinicaltrials.gov:NCT03493204). The food intervention took place from weeks 0–4. All patients were followed for 12 weeks with frequent phone assessments. The primary outcome was number of paracenteses performed during weeks 0–12. Baseline and end-of-study assessments included measures of liver function (MELD-Na, albumin), frailty/disability (hand-grip, ADLs, falls), and ascites specific quality of life (ASI-7 scores, range 0–28).
Results: Subjects were aged 54 (47–63), 46% female, 44% diabetic, 44% fully ADL-independent, with MELD-Na 18 (11–23) and albumin 2.7 (2.5–3.3). At baseline, subjects reported a median of 2 (1–3) paracenteses in the prior 4-weeks.
Outcomes: After 12 weeks, patients in the food-arm required fewer paracenteses than those in SOC, 0.34 (0.14–0.54) versus 0.45 (0.25–0.64) per week. Four patients (20%) in the SOC arm died while 2 (10%) and 1 (5%) in the food-arm died and were transplanted. Ascites specific quality of life was improved to a greater degree in the food-arm compared to SOC, by 25% (−11% −61%) versus 13% (−28% −54%). Frailty measures were unchanged.
Feasibility: The intervention was well received though patients with poor dentition or lactose intolerance suggested more meal choices. Adherence to the meal schedule was excellent save for when hospitalizations occurred.



Conclusion: A trial of home-delivered low sodium/high protein meals tailored to the needs of persons with ascites is feasible and potentially effective at reducing the need for therapeutic paracentesis and improving quality of life. Both arms experienced benefits, highlighting the role for improved education and closer monitoring in this challenging condition.

SAT123

The diagnosis of sarcopenia by quadriceps muscle ultrasound in patients with liver cirrhosis

Nicoletta Fabrini[1], Barbara Lattanzi[1], Angelo Bruni[1], Daria D'ambrosio[1], Stefania Gioia[1], Stefano Ginanni Corradini[1], Adriano De Santis[1], Alessandra Pigliacelli[1], Manuela Merli[1]. [1]*Viale del Policlinico; 37, Roma, Italy*
Email: fabrini.1598132@studenti.uniroma1.it

Background and Aims: A frequent complication in patient with liver cirrhosis is Sarcopenia, that is also associated with a worse prognosis. The diagnosis of sarcopenia is made by Computed Tomography (CT), that allows to calculate the skeletal muscle index (SMI). The quadriceps muscle thickness, measured by ultrasound, would be a bedside, less expensive, faster and easier tool in the detection of sarcopenia in cirrhotic patients. Our study had the aim to evaluate the role of quadriceps muscle thickness pressure index (TPI) in comparison to SMI.
Method: Consecutive cirrhotic patients, who had performed a CT scan within 8 weeks were included. Sarcopenia was evaluated at L3 using Carey et all. cut-offs. The TPI was performed in the middle point on a line connecting the patella with the upper anterior iliac spine. Three measurements with pressure to collapse the muscle were taken. TPI was obtained by the average of these measures normalized for the height.
Results: One-hundred patients were enrolled in the study (mean age 62,9 ± 10,9 years, mean BMI 26,1 ± 4.7 Kg/m², 80% male, 64% with diagnosis of HCC). According to CT imaging, 58% of these patients had a diagnosis of sarcopenia. Sarcopenic patients were older (65 ± 10.8 vs 59 ± 10; $p = 0.05$), with lower BMI (24.3 ± 3.6 vs 28.5 ± 4.9; $p < 0.001$). We found a positive correlation between SMI and TPI ($r = 0.58$; $r^2 = 0.34$; $p < 0.001$). The area under the ROC curve for TPI, considering sarcopenia by SMI the gold standard, was 0.72. The cut-off for the diagnosis of sarcopenia with TPI was 4.85 mm/m^2: the sensitivity was 57%, specificity 80%.
Conclusion: The US assessment of sarcopenia may allow monitoring the patient over time. The results of our study shows that TPI could be an effective index for the assessment of muscle depletion in cirrhotic patients but, although the specificity is high, the sensitivity is rather low. Further study on cirrhotic patient would be necessary to detect better cut-off, especially more specific by gender.

Interest of echocardiography in the management of acute kidney injury in cirrhotic patients with ascites. Results of the prospective pilot cirren study

Brahmia Sanaa[1], Wallon Grégoire[2], Dr Guichon Céline[2], Clothilde Miaglia[1], Domitille Poinsot[1], Pauline Devauchelle[2], Marianne Maynard[1], Mathieu Gazon[2], Serge Duperret[2], Frédéric Aubrun[2], Fabien Zoulim[1], Fanny Lebossé[1]. [1]*Hospices Civils of Lyon, Hepatology, Lyon, France;* [2]*Hospices Civils of Lyon, Anaesthesiology, Lyon, France*
Email: fanny.lebosse@inserm.fr

Background and Aims: Acute kidney injury (AKI) is a severe complication of decompensated cirrhosis. Haemodynamic changes as the presence of left ventricular diastolic dysfunction may predict the risk of hepatorenal syndrome (HRS) and mortality for patients with ascites. Haemodynamic characteristics of cirrhotic patients with concomitant AKI have not been reported yet. We aimed to describe haemodynamic changes in a cohort of cirrhotic patients with non-organic AKI.
Method: We prospectively recruited 26 cirrhotic patients with ascites and non-organic AKI (as defined by the International Club of Ascites). Echocardiography was performed at the time of diagnosis before plasma volume expansion. Diagnosis of renal injury (HRS or

functional AKI) was retrospectively determined according to response to plasma volume expansion. A control cohort of 25 non-AKI cirrhotic patients with ascites was used to compare haemodynamic changes in non-organic AKI.

Results: AKI and control cohorts were similar regarding CHILD-PUGH score, bilirubin, albumin and INR levels. The AKI patients displayed a median creatinine level of 134 µmol/L and showed significantly lower serum sodium levels (median 132 vs 136 mmol/L for AKI and controls, respectively; $p = 0.01$). Left ventricular ejection fraction (LVEF) was significantly decreased in AKI patients compared to controls (60% vs 68%; $p = 0.006$). The median lateral e' velocity and e/e' ratio were 9.5 cm/s versus 11 cm/s and 6.9 vs 7.5 respectively in AKI and control groups ($p > 0.05$). No difference of septal e' velocity, e/a ratio, tricuspid velocity or left atrial surface was found between groups. Although no patients exhibited clinical signs of left heart failure, increased left ventricular filling pressure (LVFP) before plasma volume expansion was found for 1 AKI patient. In the AKI group, serum sodium level was lower at inclusion for 9 HRS patients compared to others (130 vs 133 mmol/L respectively; $p = 0.03$). No difference according to creatinine levels or echocardiography characteristics was reported between HRS and other AKI patients.

Conclusion: Serum sodium level and LVEF were significantly altered in AKI cohort compared to control cirrhotic patients. Echocardiography may reveal patients with high LVFP despite normal examination, and may be of interest to manage plasma volume expansion. Further studies are needed to explore the relevance of echocardiography and serum sodium levels for the management of AKI in cirrhotic patients.

Head to head comparison of liver stiffness measurement using transient elastography, 2D-shear wave elastography and magnetic resonance elastography for non-invasive evaluation of clinical significant portal hypertension

Filipe Andrade[1], Philippe Garteiser[2,3], Maxime Ronot[2,3,4], Laure Elkrief[1,3], Riccardo Sartoris[2], Marco Dioguardi Burgio[2], Magaly Zappa[2], Olivier Roux[1], Payance Audrey[1], Clement Lejealle[1], Didier Lebrec[1], Mohamed Bouattour[1], Olivier Soubrane[5], Dominique Valla[1,3,4], François Durand[1,3,4], Valérie Vilgrain[2,3,4], Castera Laurent[1,3,4], Bernard Van Beers[2,3,4], Pierre-Emmanuel Rautou[1,3,4]. *[1]Hospital Beaujon AP-HP, Service d'Hépatologie, DHU Unity, DMU Digest, Clichy, France; [2]Hospital Beaujon AP-HP, Department of Radiology, Clichy, France; [3]Centre de Référence des Maladies Vasculaires du Foie, French Network for Rare Liver Diseases (FILFOIE), European Reference Network on Hepatological Diseases (ERN RARE-LIVER); [4]Université de Paris, Centre de recherche sur l'inflammation, Inserm, U1149, CNRS, ERL8252, F-75018, Paris, France; [5]Hospital Beaujon AP-HP, Department of Hepatobiliary Surgery and Liver Transplant, Clichy, France*
Email: filipeteixeiraandrade@gmail.com

Background and Aims: Portal hypertension contributes to the main complications of cirrhosis and to patients' mortality. Several liver elastography-based approaches, namely transient elastography (TE), 2-dimensional shear wave elastography (2DSWE-SSI) and magnetic resonance elastography (MRE), have been proposed for the non-invasive assessment of portal hypertension. However, the ability of these approaches to estimate clinically significant portal hypertension (CSPH - hepatic venous pressure gradient (HVPG) ≥10 mm Hg) has never been compared head to head. The aim of this work was to compare technical success rate and diagnostic performance of TE, 2DSWE-SSI and MRE for detection of CSPH in patients with compensated cirrhosis.

Method: This monocentric prospective study included patients with biopsy-proven cirrhosis, without any history of liver decompensation, who underwent liver TE, 2DSWE-SSI, MRE and HVPG measurements within less than 30 days. Technical success rate was defined for TE according to EASL guidelines, for 2DSWE-SSI as temporal stability of the selected area for ≥3 seconds, homogenous color in the region of interest and measurement region of ≥10 mm, and for MRE as any value obtained. Ability of estimating HVPG and identifying patients with HVPG ≥10 mm Hg was compared between TE, 2DSWE-SSI and MRE using area under ROC curve (AUROCs).

Results: We included 44 patients: 32 men; median age 58 years; median BMI 26 kg/m^2; median MELD 9; cirrhosis related to alcohol (n = 12), HCV (n = 19), HBV (n = 7), NASH (n = 3), other (n = 3); 35 with hepatocellular carcinoma; 26 with CSPH. Technical success rate was

Techniques	AUROC	Cut-off values obtained using Youden index*	Se (%)	Sp (%)	PPV (%)	NPV (%)	Diagnostic accuracy (%)
LS using TE (kPa)	0.813	20.3	81	73	81	73	78
LS using 2DSWE-SSI (kPa)	0.810	17.1	76	80	80	69	75
Gd (kPa)	0.797	5.3	67	93	93	67	77
Gl (kPa)	0.778	2.7	67	93	93	67	77
Gabs (kPa)	0.794	6.0	71	87	88	68	77

Abbreviations: LS, liver stiffness; kPa, kilopascals; Se, sensitivity; Sp, specificity; PPV, positive predictive value; NPV, negative predictive value. Gd, storage modulus; Gl, loss modulus, Gabs, shear modulus

Figure: (abstract: SAT126): Diagnostic performance of TE, 2DSWE-SSI, and MRE for detecting CSPH in 36 patients with technical success.

higher with liver MRE (100%), than with liver TE (89%; p = 0.024) or liver 2DSWE-SSI (93%; p = 0.075). HVPG correlated with liver TE (r = 0.692; p < 0.0001), 2DSWE-SSI (r = 0.623; p < 0.0001), and liver MRE parameters [storage modulus (Gd), r = 0.522, p = 0.001; loss modulus (Gl) r = 0.540, p = 0.0007; shear modulus (Gabs) r = 0.529, p = 0.0009)]. As compared with patients with HVPG <10 mm Hg, patients with CSPH had higher liver stiffness by TE (17 vs. 32 kPa; p = 0.01), 2DSWE-SSI (14 vs. 20 kPa; p = 0.008) or MRE (Gd 3.8 vs. 5.9 kPa, p = 0.01; Gl 1.9 vs. 3.2 kPa, p = 0.005; Gabs 4.5 vs. 7.0 kPa; p = 0.008). AUROCs of TE, 2DSWE-SSI, and liver MRE parameters ranged from 0.81 to 0.78 and did not significantly differ between the 3 methods, when including patients in whom the three methods were successfully performed (Table).

Conclusion: In patients without any history of cirrhosis decompensation, liver TE, 2DSWE-SSI and MRE correlated well with HVPG and had similar performance for detecting CSPH.

Email: annabaiges1@gmail.com

Background and Aims: Patients with cirrhosis (CH) are at increased risk of developing portal vein thrombosis (PVT). Liver disease is associated with changes in the pro- and anti- coagulant factors conferring an instable homeostatic rebalance that is thought to enhance thrombotic risk although studies specifically addressing the impact of the hemostatic status on PVT development are lacking. Other factors such us severity of portal hypertension (esophageal varices, portal blood velocity (PBV) <15 cm/s), severity of liver disease, etiology of liver disease, obesity and use of non-selective BB have been suggested to facilitate PVT.

The aim of the current study is to evaluate the role of the hemostatic status on peripheral blood on PVT development.

Method: Consecutive patients with CH submitted to US-Doppler HCC screening every 6 months were included and prospectively followed-up (Dec 2010–April 2013). Only patients without PVT, HCC and not taking anticoagulants were included. Baseline clinical, laboratory data and PBV were collected. Additionally, baseline peripheral blood samples were used for a comprehensive evaluation of plasma levels of hemostatic proteins, markers of inflammation, neutrophil extracellular traps, functional tests of coagulation, clot stability and fibrinolysis.

Results: Patients were followed-up every 6 months by US to identify PVT development until Feb 2019 or until liver transplantation, death, TIPS placement or initiation of anticoagulation for any reason. 310 patients with CH were included. 59% were male, mean age was 59 ± 11 years. The main causes of cirrhosis were HCV (55.8%) and alcohol (28%); 20% of patients were obese; 72% of patients were Child-Pugh A, 22% B and 6% Child-Pugh C. Medium/large varices were present in 41% patients, 17% had previous variceal hemorrhage and 42% had ascites. 23 patients (7.9%) developed PVT (21 partial, 2 complete) during a mean follow-up of 48 ± 27months.

PVT was more common in patients with severe liver failure, taking NSBB, with EV, low PBV and alterations in hemostatic parameters. However, when Cox regression adjusted for variables assessing the severity of cirrhosis, of portal hypertension, different alteration in hemostatic parameters and use of NSBB was performed, the only variables independently associated with PVT were a baseline PBV <15 cm/sec, low albumin and low Factor X levels.

Conclusion: Based on our results, hypercoagulability does not play a major role in PVT development. Liver failure and reduction of PBV are major risk factors for PVT development.

SAT128

Comparison of the diagnostic quality of aspiration and core biopsy needles for transjugular liver biopsy

Georg Semmler[1,2], Judith Stift[3], Katharina Wöran[3], Benedikt Simbrunner[1,2], Bernhard Scheiner[1,2], Philipp Schwabl[1,2], Rafael Paternostro[1,2], Matthias Pinter[1,2], Albert Stättermayer[1,2], Tobias Meischl[1,2], Andrea Beer[3], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Laboratory; [3]Medical University of Vienna, Department of Pathology*
Email: georg.semmler@meduniwien.ac.at

Background and Aims: Liver biopsy remains essential for the diagnostic work-up of patients with liver disease. Here we comprehensively evaluated aspiration vs. core biopsy needles for transjugular liver biopsy (TJLB) in patients undergoing hepatic venous pressure gradient (HVPG) measurements.
Method: All patients undergoing TJLB between 01/2017 and 12/2018 were included. Liver biopsy were performed according to a standardized procedure and specimens were systematically evaluated for quantitative and qualitative criteria such as number of portal tracts (PT), sample length and fragmentation. Quality parameters of liver biopsy specimens obtained by aspiration needle vs. core biopsy needle were compared.

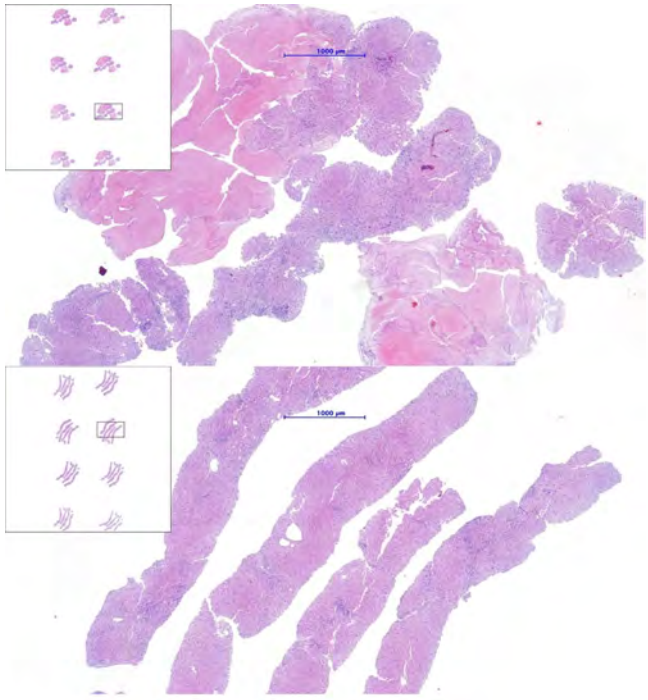

Figure: Representative liver biopsy specimens with an aspiration needle (above) and core biopsy needle (below).

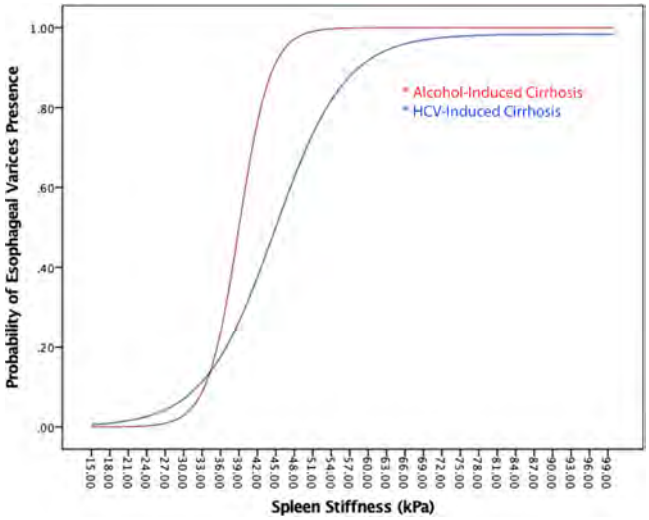
Results: 84 patients with a median MELD of 14 (IQR: 9–21) and a median HVPG of 12 (IQR: 5–19)mmHg were included. 56 patients (66.7%) had decompensated liver disease and 68 patients (81.0%) advanced fibrosis/cirrhosis (F3/4) on histology. In direct comparison of paired TJLB specimens, core biopsy samples were significantly longer (median 12 [IQR: 10–17] vs. 9 [IQR: 6–15]mm, p = 0.012), tended to contain more PT (median 8 [IQR: 5–18] vs. 6 [IQR: 2–11], p = 0.064) and were less fragmented (p < 0.001), which resulted in better confidence for liver fibrosis assessment (p = 0.035). However, a superior quality in terms of less fragmentation of core biopsy specimens (p < 0.05) was only confirmed in patients with HVPG ≥10 mmHg or LSM >40 kPa. In contrast, the aspiration needle provided significantly longer samples in patients with HVPG <10 mmHg (median 21 [IQR: 13–30] vs. 12 [IQR: 9–16]mm, p = 0.007) or with LSM <20 kPa (median 21 [IQR: 13–34] vs. 11 [IQR: 9–20]mm, p = 0.025). No major biopsy-related complications occurred.
Conclusion: In patients with HVPG ≥10 mmHg or LSM >40 kPa TJLB should be performed by using core biopsy needles, while the aspiration needle provides high quality liver biopsy specimens in patients with HVPG <10 mmHg or LSM <20 kPa.

SAT129

Spleen stiffness-based models can predict presence of esophageal varices in patients with compensated liver cirrhosis stratified by liver disease etiology

Mauro Giuffrè[1], Matteo Rossano Buonocore[1], Michele Campigotto[1], Anna Colombo[1], Alessia Visintin[1], Alessandro Aversano[1], Martina Budel[1], Sofia Fouraki[1], Fabio Tinè[2], Cristiana Abazia[2], Flora Masutti[2], Saveria Lory Crocé[1,2,3]. *[1]Dipartimento Universitario Clinico di Scienze Mediche, Chirurgiche e della Salute, Università degli Studi di Trieste; [2]Clinica Patologie del Fegato, Azienda Sanitaria Universitaria Integrata di Trieste; [3]Fondazione Italiana Fegato*
Email: gff.mauro@gmail.com

Background and Aims: Recent findings showed that even small-size esophageal varices (EVs) have to be considered as a disease stage more prone to hepatic decompensation. We want to evaluate the predictive capability of spleen stiffness (SS) as a non-invasive surrogate to appropriate EVs screening.
Method: We measured spleen stiffness (SS) using point-Shear Wave Elastography with Philips Affiniti 70 system in 219 patients with compensated liver cirrhosis, whose etiology was HCV in 96 patients and alcohol abuse in 123 patients. In total, 97 patients had EVs at screening endoscopy. The association between varices (discrete; 0 = no, 1 = yes) and LS and SS was evaluated using logistic regression. According to statistical results we created a SS-based models in which the linear predictor (LP) was employed to calculate the probability of EVs using the following formula: {1-[1/(1+e^(LP))]}.



Results: Patients with HCV-induced cirrhosis had a LP of −6.813 + 0.164*SS. The model had the following discriminative and calibration metrics: AIC = 142, BIC = 147, AUROC = 0.92, Pseudo-R2 (Nagelkerke) = 0.6, Hosmer-Lemeshow (p-value) = 0.085. Instead, the LP in patients with alcohol-induced cirrhosis was equivalent to −15.208 + 0.39*SS. This model showed AIC = 163.5, BIC = 166, AUROC = 0.97,

Pseudo-R2 (Nagelkerke) = 0.804, Hosmer-Lemeshow (p-value) = 0.509. The two probability curves (figure) showed a different behavior, with a more rapid increase of the slope of the alcoholic's curve if compared to patients with viral hepatitis.
Conclusion: It was possible to create a probability model according to SS-values that could decide to spare endoscopic screening in low-risk patients (for any grade of EVs). Having a given probability instead of a single number to rule-in or rule-out a specific event is indeed more helpful and could support the clinician in the decision of performing an invasive test if the probability is high. Cut-off values, even if they are chosen to be the most sensitive or specific, are always subjects to false-positives and false negatives; and, sometimes, even with low LS and SS, the clinical presentation may require more invasive tests, making cut-offs pointless. In conclusion, the results of this study further emphasize the potential clinical relevance of SS measurement by pSWE elastography in the clinical workup of cirrhotic patients.

SAT130
Ammonia is an independent biomarker of poor outcomes in patients with advanced cirrhosis
Gonçalo Alexandrino[1,2], Thomas Tranah[1], Tiago Dias Domingues[3], William Bernal[4], Debbie Shawcross[1]. [1]*Liver Sciences, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, London, United Kingdom;* [2]*Hospital Prof. Doutor Fernando Fonseca, Gastroenterology and Hepatology, Amadora, Portugal;* [3]*Centro de Estatística e Aplicações da Universidade de Lisboa, Lisbon, Portugal;* [4]*Liver Intensive Therapy Unit, King's College Hospital, London, United Kingdom*
Email: goncaloalexandrino@gmail.com

Background and Aims: The role of ammonia as a prognostic biomarker in patients with cirrhosis remains unclear. The aim of this study was to determine whether ammonia levels in patients with advanced cirrhosis awaiting liver transplantation influence major waiting list outcomes.
Method: Retrospective observational study of sequential cirrhotic adult patients listed for liver transplantation between January 2015 and December 2018. All patients had an arterial ammonia measured at the time of assessment for transplant. All patients were closely followed up until death or transplantation. The main outcomes were hospital admissions, infection, organ failures and mortality. Multiple logistic regression was performed using independent variables that were significantly associated with wait-list outcomes on univariate analysis.
Results: 300 patients were included (mean age: 54 ± 10 years). Mean follow-up time was 723 days. 266 (88.7%) patients were transplanted, 15 (5.0%) were de-listed for being too sick for transplant or following clinical improvement, 14 (4.7%) died on the list and 5 (1.6%) were still active on list. 97 patients (32.3%) had at least one hospitalization while on the waiting list. On multiple logistic regression arterial ammonia was independently associated with hospitalization, infection and ACLF. Ammonia level was associated with mortality ($p = 0.001$) in patients listed for liver transplantation and the development of post-transplant complications ($p < 0.001$) (Table 1). Arterial ammonia was superior to standard organ severity scores at predicting outcomes of infection (AUC 0.79), hospitalization (AUC 0.81), ACLF (AUC 0.80) and mortality (AUC 0.73) in patients listed for liver transplantation.
Conclusion: Arterial ammonia at the time of listing for liver transplantation was an independent predictor of hospitalization, ACLF, infection and mortality. These data suggest that blood ammonia may be an important determinant of wait-list survival.

SAT131
Survival outcomes of SBP, BA and CNNA in a large Scottish cohort
Malgorzata Grzelka[1], Rachael Swann[1], Ewan Forrest[2]. [1]*Queen Elizabeth University Hospital, Glasgow, United Kingdom;* [2]*Glasgow Royal Infirmary, Glasgow, United Kingdom*
Email: grzelka.m@doctors.org.uk

Background and Aims: Spontaneous bacterial peritonitis (SBP) has significant mortality rate even if treated. Diagnosis is based on the white cell (WCC) or neutrophil count and a positive culture of pathogens in the ascitic sample. The greatest sensitivity for the diagnosis is reached with a cut-off neutrophil count of 250/mm^3; where a differential is not available a WCC of 500 cells/mm^3 is used. When the sample doesn't meet the criteria, two other conditions are described: bacteriascites (BA) – the presence of a cultured pathogen without the WCC elevation, and culture negative neutrophilic ascites (CNNA) – the lack of a pathogen culture with the WCC elevation. Prognosis and guidelines for treatment of these conditions are less clear. The aim of this study was to characterise a large cohort of patients with these conditions and analyse any differences in their survival.
Method: Microbiology laboratory databases within Greater Glasgow Health Board were searched for all ascitic fluid samples from January 2014 to December 2017. Samples from non-cirrhotic ascites were excluded. Episodes were allocated a diagnosis of SBP, BA, CNNA at a WCC cut-off of 250 and 500, and survival (days from the ascitic tap to death) was analysed. A small sample of negative cases were included for comparison.
Results: A total of 2050 episodes were identified. 180 episodes were analysed (including negative). When a cut-off value of 500 WCC was used, there were 40 episodes of SBP, 42 of BA, 52 of CNNA and 46 negatives. When the 250 WCC cut-off was applied, the numbers were: SBP = 47, BA = 35, CNNA = 82, negatives = 16.
78 died during admission (43%) and 105 died within 90 days of the tap (58%). The average time to death was 125 days (median = 20).

Dependent Variable	Significant independent variables	Exp(B); OR (95% CI)	p value	AUC
Infection	Ammonia	1.03 (1.02-1.03)	p < 0.001	0.79
	INR	2.48 (1.54-4.92)	p = 0.001	0.68
Hospitalization	Ammonia	1.04 (1.03-1.06)	p < 0.001	0.81
	UKELD	1.09 (1.00-1.19)	p = 0.040	0.64
ACLF	Ammonia	1.03 (1.02-1.05)	p < 0.001	0.79
	MELD	1.14 (1.07-1.22)	p < 0.001	0.70
Post-operative complications	Ammonia	1.01 (1.01-1.02)	p = 0.002	0.69
	Albumin	0.92 (0.89-0.96)	p < 0.001	0.66
Mortality	Ammonia	1.02 (1.01-1.03)	p = 0.001	0.73
	MELD	1.13 (1.05-1.22)	p = 0.001	0.70

Figure: (abstract: SAT130)

There was a significant difference in survival at the 500 WCC cut-off (except BA vs CNNA). Survival difference in the 250 WCC cut-off groups did not uniformly reach statistical significance. In particular, the difference in BA and SBP was not significant.

		SBP	BA	CNNA	NEG
median survival (days)	cut-off 500	15	89*	547⁺	726⁺
	cut-off 250	15	90	53.5⁺	726.5⁺

*p<0.05 or ⁺p<0.01 when compared with SBP.

Conclusion: SBP is a devastating diagnosis with high mortality and short prognosis. The non-significant survival difference between SBP and BA at the 250 cut-off suggests that BA has equally poor outcomes and warrants as robust investigations and treatment as SBP. Stronger significance values were reached with the 500 cut-off. Accurate diagnosis of SBP, BA and CNNA provides the clinician and the patient with an idea of prognosis.

SAT132

Risk stratification and the effects of early tips among patients with Child-Pugh B cirrhosis and acute variceal bleeding

Email: hangh@fmmu.edu.cn

Background and Aims: Whether early transjugular intrahepatic portosystemic shunt (TIPS) should be used in patients with Child-

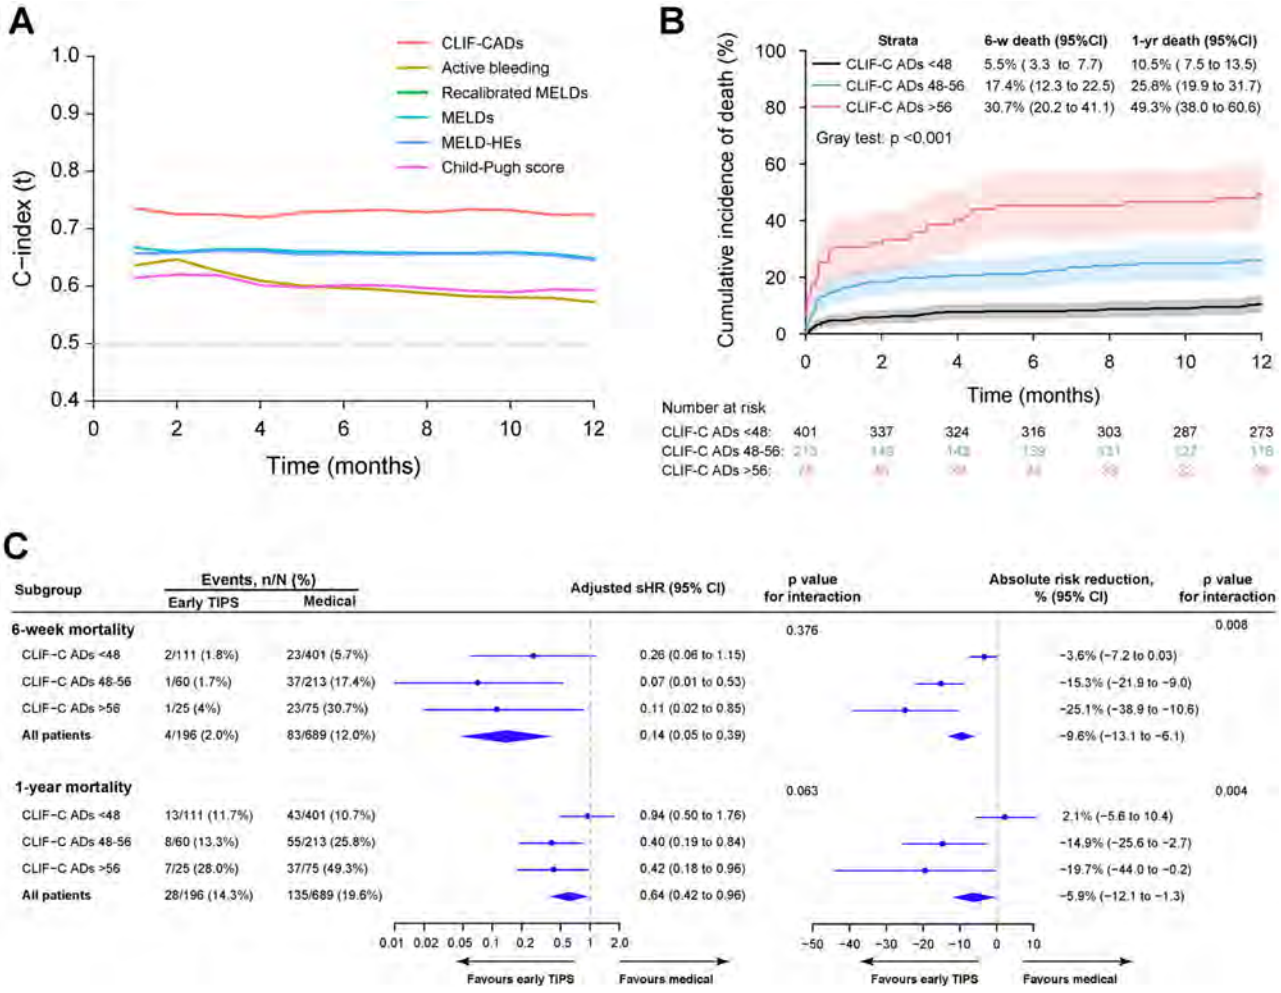

Figure: (abstract: SAT132)

Pugh B cirrhosis and acute variceal bleeding (AVB) remains an open issue. This study aimed to test the hypothesis that risk stratification using CLIF Consortium Acute Decompensation score (CLIF-C ADs) may be useful to identify a subgroup at high risk of mortality who have the greatest benefit from early TIPS in patients with Child-Pugh B cirrhosis and AVB. This study also aimed to assess the prognostic value of active bleeding and whether it modifies the effect of early TIPS.

Method: We analysed the pooled individual data from two published studies of 885 patients with Child-Pugh B cirrhosis and AVB who received early TIPS (early TIPS group, n = 196) or standard treatment (medial group, n = 689) between 2010 and 2017 in China. We compared the performance (discrimination and calibration) of CLIF-C ADs with active bleeding and other prognostic models. The Fine and Gray competing risk regression model was used to compare the outcomes between groups that were stratified based on CLIF-C ADs or active bleeding after adjusting for liver disease severity and other potential confounders.

Results: Early TIPS group had lower mortality than medial group (13.8%% vs 19.4% at 1 year, adjust sHR: 0.64, 95%CI 0.43 to 0.97). When applied to patients receiving standard treatment, the CLIF-C ADs showed satisfactory calibration (Hosmer-Lemeshow test, p = 0.268). The C-index of CLIF-C ADs for 6-week and 1-year death (0.708, and 0.707) were significantly better than those corresponding to active bleeding at endoscopy (0.645 [p < 0.001] and 0.570 [p < 0.001]) and other prognostic models (Figure A). With X-tile software to identify the optimal cutoff value, patients in medical group were categorized as low-risk (CLIF-C ADs <48, n = 401), intermediate-risk (CLIF-C ADs 48–56, n = 213) and high-risk (CLIF-C ADs >56, n = 75), with a 5.5%, 17.4% and 30.7% risk of 6-week death and a 10.5%, 25.8% and 49.3% risk of 1-year death, respectively (Figure B). The absolute mortality reductions with early TIPS were more pronounced in high-risk categories (Figure C). Furthermore, after adjusting for liver disease severity and other potential confounders, a survival benefit was observed in intermediate-risk and high-risk but not in low-risk patients (Figure C). Active bleeding at endoscopy was associated with increased risk of death (sHR 1.84, 95%CI: 1.28 to 2.55; p < 0.001) in medical group. A survival benefit associated with early TIPS was observed in those with active bleeding but not those without active bleeding.

Conclusion: In patients with Child-Pugh B cirrhosis and AVB, risk stratification using the CLIF-C AD score identifies an intermediate-risk and high-risk subset that derive greatest benefit from early TIPS. Active bleeding at endoscopy had prognostic value and could modify the effect of early TIPS.

SAT133

Risk factors for sarcopenia and its impacts on clinical outcome in patients with liver cirrhosis

Huijuan Xiao[1], Qing Ye[2], Tao Han[2]. [1]*The Third Centre Clinical College, Tianjin Medical University, Department of Nutrition, Tianjin, China;* [2]*The Third Central Hospital of Tianjin, Department of Gastroenterology and Hepatology, Tianjin, China*
Email: hantaomd@126.com

Background and Aims: Patients with chronic liver disease are at high risk for sarcopenia, which had been reported to affect up to 70% of patients with advanced liver disease. Our research is aimed to study the incidence of sarcopenia in patients with liver cirrhosis, and explore its risk factors and impact on the clinical outcomes.

Method: A total of 199 inpatients with liver cirrhosis were included in the study. Nutritional risk was assessed by NRS-2002, anthropometric and laboratory parameters were measured. Appendicular skeletal muscle mass index (ASMI) was calculated according the results of body composition analysis. The patients were divided into sarcopenia and non-sarcopenia groups according to the cutoff value of ASMI 7.0 kg/m^2 for male and 7.0 kg/m^2 for female to find the risk factors for sarcopenia. Then the survival and complications of the two groups were compared after following up for 48 years. According to different data, statistical analysis was done using *t*-test, *Chi-square* test and binary logistic regression.

Results: The incidence of sarcopenia was 36.7% in patients with cirrhosis. It was higher in patients with hepatic coma, which was 62.5%, followed by the patients with abdominal/pleural effusion 37.6%. The incidence of sarcopenia in those with nutritional risk was significantly higher than that in those without nutritional risk ($P < 0.05$). However, even in those without nutritional risk, 14.8% of the patients had sarcopenia. BMI, AMC and BCM in the sarcopenia group were lower than those in the non-sarcopenia group ($P < 0.05$), and ECW/TBW was higher than those in the non-sarcopenia group ($P < 0.05$). Multivariate analysis showed that age, sex, BMI and hepatic coma were the main influencing factors of liver cirrhosis with sarcopenia ($P < 0.05$). The mortality rate, incidence of recurrent abdominal/pleural effusion, hepatic coma and infection in sarcopenia group was significantly higher than that in non-sarcopenia group ($P < 0.05$).

Conclusion: Sarcopenia is part of the manifestations of malnutrition in patients with liver cirrhosis, which has adverse effects on clinical outcomes including survival, development of other complications. The older patient, especially the male one, with the lower BMI and hepatic coma may have higher risk for sarcopenia.

SAT134

The burden of cirrhosis on the Canadian healthcare system: a comparison between alcoholic and non-alcoholic cirrhosis patients

Hassan Azhari[1], Mark G Swain[1], Kelly Burak[1], Abdel-Aziz Shaheen[1]. [1]*University of Calgary, Department of Medicine, Division of Gastroenterology & Hepatology, Calgary, AB, Canada*
Email: hassan.r.azhari@gmail.com

Background and Aims: Recent studies have indicated an increasing burden of cirrhosis in different health care systems. However, the burden of alcoholic vs. nonalcoholic cirrhosis varies worldwide. Therefore, we evaluated the epidemiology of cirrhosis in a Canadian province, and describe the health care utilization patterns of alcoholic vs. nonalcoholic cirrhosis patients.

Method: We used a validated coding algorithm to identify cirrhosis patients in the province of Alberta, Canada (population ~4.4 million) from 2008–2018. We classified cirrhosis patients according to etiology (alcoholic vs. nonalcoholic) using the international clinical classification (ICD), versions 9 and 10. Causes of nonalcoholic cirrhosis included viral, nonalcoholic fatty liver and autoimmune chronic liver diseases. Multiple sources of data including inpatient, ambulatory, emergency room visits, and physician billing were linked. Liver-related hospitalizations or emergency department (ED) visits were identified if the primary code was a cirrhosis-related complication including variceal bleeding, ascites, hepatic encephalopathy, hepatocellular carcinoma and spontaneous bacterial peritonitis.

Results: The overall sex and age adjusted prevalence rate of cirrhosis in Alberta was 68.8 per 10,000 person, while the adjusted incidence rate was 11.2 per 10,000 person. Adjusted incidence and prevalence rates for nonalcoholic cirrhosis were higher than those for alcoholic cirrhosis (Incidence rates 8.6 vs. 2.6 per 10,000 person; Prevalence rates 48.8 vs. 20.0 per 10,000 person). The majority of cirrhosis patients were men (56%), with a median age of 61 years (IQR: 56–64). In our cohort, 31.2% of patients (n = 8,632) had alcoholic cirrhosis. Approximately 38.6% of the cirrhosis patients were hospitalized for cirrhosis-related complications within 1 year after diagnosis, with an estimated median hospitalization cost of $14,133 CAD. The median hospitalization length of stay was 5 days (IQR: 1–19). Liver-related

hospitalizations accounted for 59.8% of all hospitalizations, while liver-related ED visits represented 33.4% of all ED visits. Overall 5-year liver-related hospitalization rates for alcoholic cirrhosis were higher than for nonalcoholic cirrhosis (68.5% vs. 42.0%, p < 0.001). Similarly, 5-year liver-related ED visits were higher among alcoholic than non-alcoholic cirrhosis patients (28.0% vs. 8.1%, p < 0.001).
Conclusion: In our large Canadian population-based study, non-alcoholic cirrhosis represented two thirds of all cirrhosis patients. However, patients with alcoholic cirrhosis were more likely to visit an ED and be hospitalized for liver-related complications. This data suggests that outpatient resources should be focused on patients with alcoholic cirrhosis to improve acute health care resource utilization.

SAT135

Developed and validated a prognostic nomogram incorporating body compositions for long-term mortality in cirrhosis: a sex-stratified analysis

Lijun Hou[1], Chao Sun[1], You Deng[1], Tianming Zhao[1], Lin Lin[2], Lihong Mao[1], Junjie Hou[1]. *[1]Tianjin Medical University General Hospital, Department of Gastroenterology and Hepatology, Tianjin, China; [2]Tianjin Medical University General Hospital Airport Hospital, Department of Gastroenterology, Tianjin, China*
Email: chaosun@tmu.edu.cn

Background and Aims: Alterations in body composition (BC) as abnormal muscle quantity/quality and adiposity are related to poor outcomes and presence of complications in cirrhosis. However, no predictive tools combining all these anthropometric parameters are applicable in the clinical setting. We aimed to clarify the potential utility of BCs and develop a nomogram incorporating any independent factor for prognosticating long-term mortality in cirrhosis.
Method: A total of 414 cirrhotic patients were randomized into primary (N = 274) and validation (N = 140) cohorts. X-tile was performed to identify optimal cutpoint for stratifying subjects with distinct outcomes. Multivariate Cox regression was performed, and nomogram model incorporating BCs were generated. The utility of developed models were evaluated by Harrell's concordance index (C-index), calibration curve and decision curve analysis.
Results: Stratifying by X-tile derived cutpoints, low SMI (myopenia), high IMAC (myosteatosis) and high VSR (adiposity) were independently associated with 3-year mortality by Cox regression analysis. A sex-stratified nomogram incorporating anthropometric indices and clinical factors resulted in moderate discriminative accuracy, with a C-index of 0.787 (95%CI: 0.736–0.838) and 0.789 (95%CI: 0.727–0.851) in male and female, respectively. The calibration curve showed predictive survival corresponding optimally with the actual outcomes. Our models were feasible in clinical settings based on decision curve analysis. Similar results were observed in the validation cohort. Additionally, participants could be classified into three distinct risk groups (low, medium and high) by the nomogram.
Conclusion: Our proposed nomogram embedding BCs rendered an individualized predictive tool for long-term mortality in cirrhosis.

Collagen type XVIII is associated with platelet count and meld score in patients with trans-jugular intrahepatic portosystemic shunt

Ida Villesen[1], Mette Juul Nielsen[1], Jennifer Lehmann[2], Tina Manon-Jensen[3], Robert Schierwagen[2], Christian Jansen[2], Michael Praktiknjo[2], Diana Leeming[4], Morten Karsdal[4], Jonel Trebika[5]. *[1]Nordic Bioscience, Liver Fibrosis, Herlev, Denmark; [2]University of Bonn, Bonn, Germany; [3]Nordic Bioscience, Gastroenterology, Herlev, Denmark; [4]Nordic Bioscience, Fibrosis, Herlev, Denmark; [5]University of Bonn, Department of Internal Medicine I, Germany*
Email: ifv@nordicbio.com

Background and Aims: Increased turnover of extracellular matrix (ECM) proteins is a hallmark of fibrosis. Changes in basement membrane (BM) remodeling during fibrosis is suggested to play a reparative role as this part of the ECM is important for cell attachment and regeneration. Collagen type XVIII (COLXVIII) is attached to the BM, where it is important for both thickness and stiffness and has been shown to be crucial for hepatocyte survival. COLXVIII is best known for the signaling fragment Endostatin, a potent anti-angiogenic and anti-fibrotic molecule. However, attention is now also directed towards the many biological functions of the tree isoforms (short, medium and long) of COLXVIII. The short and long isoforms together with Endostatin was measured serologically by the ELISA assays COL-18N, PRO-C18L and Endostatin respectively. In a healthy liver, the long isoform of COLXVIII, characterized by a prolonged N-terminal, has been found to be the most abundant isoform whereas the abundance of the short isoform increases in the liver with fibrosis. Here the short isoform of COLXVIII (COL18-N) is investigated as a biomarker of disease in patients with trans-jugular intrahepatic portosystemic shunt (TIPS).
Method: Plasma samples of 110 patients with decompensated liver cirrhosis were taken from portal and hepatic veins at time of TIPS insertion and two weeks later at an invasive TIPS control. Circulating levels of COL18-N before and after TIPS was assessed in plasma using specific monoclonal ELISA and analyzed by Mann-Whitney t-test. Correlation to MELD score and platelet count were investigated by Spearman correlation.
Results: Levels of COL18-N in both the portal and hepatic veins were significantly increased after TIPS insertion ($p > 0.01$ and $p > 0.05$, respectively). MELD score was in addition found to share a negative correlation with COL18-N ($r = -0.23$), while the platelet count and COL18-N were positively correlated ($r = 0.26$).
Conclusion: We show that BM turnover is increased after TIPS and that patients, thus initiating a reparative process after TIPS. In addition, the negative correlation to MELD indicates that patients with high COL18-N levels may have better prognosis compared to patients with low COL18-N. This study shows the potential of COL18-N in assessing fibrosis status in patients after TIPS. Profiling of COLXVIII isoforms may improve non-invasive monitoring of liver fibrosis.

SAT137

Terlipressin vs noradrenaline for the treatment of hepatorenal syndrome in patients with acute-on-chronic liver failure: a 5-year retrospective analysis

Ilaria Giovo[1], Martina Rizzo[1], Paola Ponzo[1], Daniela Campion[1], Michele Roma[1], Felice Rizzi[1], Alessandra Risso[1], Gian Paolo Caviglia[2], Federico Balzola[1], Silvia Martini[1], Maria Torrani Cerenzia[1], Giorgio Maria Saracco[1], Carlo Alessandria[1]. *[1]Città della Salute e della Scienza di Torino, Gastroenterology and Hepatology, Turin, Italy; [2]University of Turin, Department of Medical Sciences*
Email: carloalessandria@libero.it

Background and Aims: Hepatorenal syndrome (HRS) is a type of acute kidney injury (AKI) that develops in cirrhotic patients. Most patients with HRS-AKI have acute on chronic liver failure (ACLF). Response to vasopressor treatment and predictive factors of mortality in HRS-AKI patients with ACLF are still unclear.
Method: A retrospective analysis of cirrhotic patients admitted in our intensive care unit from January 2014 to July 2019 was performed. Patients with ACLF and HRS-AKI were treated with albumin plus terlipressin (T) or plus noradrenalin (NA). Patients were censored at the time of death, liver transplantation or end of follow-up.
Results: Among 128 consecutive ACLF patients, 37 were diagnosed as HRS-AKI. No significant differences were observed in demographic, clinical and laboratory parameters. Response to treatment was observed in 19/37 (51%) patients, 16/24 (67%) in group T vs 3/13 (23%) in group NA ($p = 0.019$). Response was achieved in 15/24 (63%) patients with grade 1, 4/9 (44%) with grade 2, 0/4 with grade 3 ACLF ($p = 0.02$). Non responders had higher MELD-Na than responders (34 ± 5.2 vs 30 ± 5.4; $p = 0.03$). The type of vasoconstrictor [OR 5.88 (1.09–31.64); $p = 0.03$] was the only independent predictive factor of response to treatment. With respect to 28-day mortality, 18/19 (95%) responders to treatment were alive vs 7/18 (39%) of non-responders ($p < 0.01$). Leukocytes ($p = 0.01$), MELD-Na ($p < 0.01$) and ACLF grade 3 ($p < 0.01$) were also associated with 28-day mortality. Non response to treatment with vasoconstrictor and albumin was, together with MELD-Na [HR 1.17 (1.04–1.33; $p = 0.01$), the only independent predictive factor of 28-day mortality [HR 11.15 (1.35–92.12; $p = 0.025$)].
Conclusion: Terlipressin was far superior to noradrenaline in treating HRS-AKI in patients with ACLF and non response to treatment was the strongest independent predictor of 28-day mortality.

SAT138

Sarcopenia predicts mortality after transjugular intrahepatic portosystemic shunt creation in patients with refractory ascites

Ioannis Petridis[1], Roberto Miraglia[2], Luigi Maruzzelli[2], Tao Wan[3], Annalisa Berzigotti[3], Jaime Bosch[3], Riccardo Volpes[1]. *[1]Mediterranean Institute for Transplantation and Advanced Specialized Therapies (IRCCS-ISMETT), Hepatology and Gastroenterology Unit, Palermo, Italy; [2]Mediterranean Institute for Transplantation and Advanced Specialized Therapies (IRCCS-ISMETT), Diagnostic and Therapeutic Services, Radiology Unit, Palermo, Italy; [3]UVCM, DBMR, Inselspital, University of Bern, Hepatology, Bern, Switzerland*
Email: ipetridis@ismett.edu.

Background and Aims: Loss of skeletal muscle mass is a common feature of patients with cirrhosis and predicts poor outcomes in candidates to liver transplantation. However, its association with mortality has not been fully studied in patients with cirrhosis and refractory ascites requiring transjugular intrahepatic portosystemic shunt (TIPS). Muscle area quantification at the level of third lumbar vertebra using abdominal computed tomography (CT) images is a novel technique for the evaluation of sarcopenia. Our study is aimed at evaluating whether CT-based assessment of skeletal muscle mass are associated with mortality after TIPS placement in contemporary patients with cirrhosis, severe portal hypertension and refractory ascites.
Method: We retrospectively reviewed the clinical information and pre-TIPS CT-images (within 3 months before TIPS creation) of all patients with cirrhosis and refractory ascites who underwent TIPS creation by using ePTFE covered stent at a single academic center in the period between January 2015 and November 2018. Evaluation of skeletal muscle mass was made by measuring the psoas muscle (PMA) and total abdominal muscles areas (TAMA), in a semi-automated way by using a specific software (Sliceomatic, Tomovision).
Results: 115 pts (78 male; 37 female, mean age 61 ± 9years) were included. Most frequent causes of cirrhosis were alcohol and non alcoholic steatohepatitis. Mean pre-TIPS MELD score was 12 ± 4 points. The average time between CT and TIPS creation was 56 days. Technical success of TIPS was 100%, and mean porto-caval gradient pre-TIPS and post-TIPS were 15.9 ± 4.4 mmHg and 6.5 ± 2.6 mmHg

Figure: (abstract: SAT138)

respectively. 16 patients died within 6 months of TIPS placement. Univariate analysis demonstrated that skeletal muscle mass (PMA and TAMA), as well as hemoglobin level, white blood cell count, serum albumin, serum bilirubin and MELD score pre-TIPS were strongly associated with 6-months mortality after TIPS. PMA had an area under the ROC curve of 0.702 for 6 months mortality and a PMA cutoff of 16 mm² (sarcopenia) was correlated with mortality. At multivariate Cox regression analysis sarcopenia, leucopenia, MELD score and PPG were independent predictors of post-TIPS 6-months mortality.

Conclusion: Sarcopenia, assessed on standard CT images of PMA, should be considered a risk factor for 6 months mortality in patients with cirrhosis who undergo TIPS placement for refractory ascites.

SAT139

Safety, tolerability, pharmacokinetics and pharmacodynamic activity of terlipressin delivered by continuous intravenous infusion in patients with cirrhosis and refractory ascites: a phase 2a open-label trial

Jasmohan Bajaj[1], Patrick Yeramian[2], Edith Gavis[1], Andrew Fagan[1], James Fischer[3], Guadalupe Garcia-Tsao[4], Paolo Angeli[5], Denise Smith[2], Jonathan Adams[2], Penelope Markham[6]. *[1]Hunter Holmes McGuire VA Center, Richmond, United States; [2]BioVie Inc., Los Angeles, United States; [3]University of Illinois at Chicago, College of Pharmacy, Chicago, United States; [4]Yale School of Medicine, New Haven, United States; [5]University of Padova, Medicine, Padova, Italy; [6]BioVie Inc., Los Angeles, United States*
Email: pmarkham@biovieinc.com

Background and Aims: Patients with cirrhosis and refractory ascites lack long-term pharmacological outpatient treatment options. The vasoconstrictor terlipressin, which is not yet available to US physicians, may reduce the accumulation of ascites but its approved uses, administered as bolus doses, are limited to the hospital setting and do not include the treatment of ascites. The pharmacokinetics of terlipressin administered as a continuous infusion is unknown and will be required to define the continuous infusion parameters.

Method: Six adult male patients with decompensated cirrhosis and ascites, requiring at least 3 large volume paracenteses (LVP) in the previous 60 days, and serum creatinine (SCr) <2.0 mg/dL were enrolled. Within 3 days after a LVP, patients started treatment with continuous infusion terlipressin administered via a PICC line by an ambulatory infusion pump with step-wise dose escalation (2 to 3 and then 4 mg/day over 5 days based on hemodynamic response and clinical safety). Following a 7 day in-house stay, patients continued treatment as outpatients with the highest tolerated dose of terlipressin for a total of 28 days. Serial plasma samples were collected through treatment and assayed for terlipressin and its more active metabolite, 8-lysine vasopressin, by LC-MS/MS.

Results: The mean **s**teady state plasma concentrations of terlipressin and 8-lysine vasopressin, 3.78 and 0.086 ng/mL, respectively, were lower than both peak and average plasma concentrations reported from previous studies following IV bolus administration. Consistent with low drug exposure, hemodynamic and cardiac tolerance was good during terlipressin infusion treatment and there were no adverse signs of tissue ischemia or clinically significant changes in daily ECGs. Three of the six patients completed 28-day infusion of terlipressin and three discontinued terlipressin infusion early for the following severe AEs: recurrence of Grade II hepatic encephalopathy, leak from a pre-existing umbilical hernia and progressive asymptomatic hyponatremia. Four of 6 patients experienced ≥50% increase in the interval between LVPs after the start of treatment with terlipressin, two of which experienced extended control of ascites beyond the 28 days of infusion for a total of 72 and 63 days, respectively. The volume of ascites removed by paracentesis in the 28 days prior to treatment versus the 28-day of the treatment period was reduced on average by 66%. Four patients experienced a rapid reduction in SCr levels during treatment.

Conclusion: The data supports the feasibility of long-term continuous IV infusion with terlipressin in the ambulatory setting given that it appears to be safe and well-tolerated at doses from 2 mg to 3 mg per day. Early pharmacodynamic and efficacy data are consistent with terlipressin infusion improving the underlying mechanisms resulting in ascites formation.

Salivary and stool microbiota differences are related to differences in 90-day hospitalizations in Mexican compared to American patients with cirrhosis

Jasmohan S Bajaj[1], Andrew Fagan[1], Edith Gavis[1], Masoumeh Sikaroodi[2], Mayra Rojas Lara[3], Ivvone Escalona Nandez[3], Omar De Leon Osorio[3], Michael Fuchs[1], Patrick Gillevet[2], Chathur Acharya[1], Aldo Torre[3]. *[1]Virginia Commonwealth University and McGuire VA Medical Center, Richmond, United States; [2]George Mason University, Manassas, United States; [3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: Stool and salivary microbiota are affected by diet, ethnicity and cirrhosis stage, which vary between countries and can affect 90-day hospitalization risk. Aim: Define effect of dietary and ethnic differences in salivary and stool microbiota across cohorts from USA and Mexico (MX).
Method: Age-matched controls and cirrhotic pts from US & Mexico underwent dietary recall, stool and salivary microbiota (16srRNA) analysis and were followed for 90 days for non-elective admissions. Comparisons between/within cohorts were performed. 90-day admissions predictors using microbiota, demographics, cirrhosis details/medications, and diet were performed separately for stool & salivary samples.
Results: 275 subjects (133 US & 143 MX) were enrolled from tertiary care centers in US & MX. Age, PPI use, MELD, ascites/HE were similar but there were fewer men in MX cohort.
Admissions: Higher in MX vs US (p = 0.03), most were liver-related (>70%) in both cohorts.
Diet: Lower protein and higher carbohydrate-rich diet in MX vs US. Similar vegetables, beef, rice but US subjects had higher coffee, tea, pork, milk, eggs, cheese and yogurt, with lower bread and fish in their diets compared to MX.
Microbiota: *Stool*: Significant differences with lower potentially beneficial taxa (Lachnospiraceae, Ruminococaeae) in MX with higher Prevotellaceae. *Saliva*: Prevotellaceae were higher in MX with lower Streptococcaceae & Lachnospiraceae. Porphyro/Veillo were similar between groups. *Diversity*: Stool and salivary diversity was lower in MX and reduced in both groups with advancing disease.
Regression: *Stool microbiota*: MELD (OR 1.2, p = 0.008) and Ascites (5.8, p = 0.01) were positively while vegetable intake (0.31, p = 0.03), and microbial families (Prevotellaceae 0.1, p = 0.008, Lachnospiraceae 0.1,p = 0.001, Veillonellaceae 0.1, p = 0.02, Ruminococcaceae 0.1, p = 0.05) were negatively linked with admissions. *Salivary microbiota*: MELD (OR 1.1, p = 0.04) and ascites(3.9, p = 0.06) were positively and Prevotellaceae (0.1, p = 0.01), Streptococcaceae (0.1, p = 0.002) and albumin (0.3, p = 0.02) were negatively linked with admissions.
Conclusion: Despite similar cirrhosis severity, Mexican cirrhotic patients had higher 90-day hospitalizations compared to Americans, which was related to significant differences in salivary and stool microbiota. Key microbial taxa such as Prevotellaceae and Lachnospiraceae were independently associated with this risk and could be modulated by dietary differences inherent between the cohorts.

SAT141

Validation of encephalapp stroop for minimal hepatic encephalopathy diagnosis in elderly patients with cirrhosis: a multi-center study

Jasmohan S Bajaj[1], Jesse Xie[2], Andres Duarte-Rojo[2], Chathur Acharya[1], Megan Kelly[3], James Wade[1], Andrew Fagan[1], Edith Gavis[1], Mauricio Garcia[2], Vy Nguyen[3], Melanie White[1], Leroy Thacker[1], Christopher Flud[2], Hugo E. Vargas[3]. *[1]Virginia Commonwealth University and McGuire VA Medical Center, Richmond, United States; [2]University of Arkansas, United States; [3]Mayo Clinic, Phoenix, United States*
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: With the increasing age of patients with cirrhosis, current norms for minimal hepatic encephalopathy (MHE) testing, which usually are for younger patients, need to be recalibrated. **Aim**: Determine norms for EncephalApp Stroop & psychometric hepatic encephalopathy score (PHES) in elderly (>65 years) subjects with derivation & validation cohorts for MHE diagnosis.
Method: Subjects between 65 and 95 yrs were enrolled from 4 US centers. Healthy controls were those without chronic diseases. All pts

Figure: (abstract: SAT141)

had stable compensated disease. All subjects had MMSE>25 & could consent. Cirrhotic pts were enrolled in 2 cohorts; derivation: Enrolled between Mar'17–Sep'18 & validation: Oct'18–Oct'19. All subjects underwent PHES (5 tests, lower score = poor) &Stroop (OffTime +OnTime, higher time = poor). PHES/Stroop scores were compared between controls & derivation cohort pts and adjusted for on age, gender and education differences based on the controls enrolled. Cut-offs generated were used to diagnose MHE. Agreement between PHES & Stroop was studied & logistic regression was performed to assess the predictive power of Stroop on MHE on PHES (MHE-PHES). Regression equations from derivation were used for MHE diagnosis on the validation cohort.

Results: 99 controls (30 VCU 21 VA 25 Mayo 23 AR) and 96 pts (33 VCU 28 VA 10 Mayo 25 AR) were in the derivation cohort & 77 in the validation cohort (30 VCU 22 VA 20 Mayo 5 AR) (Table). Controls were younger, more educated & less likely to be men than both cirrhosis groups. Therefore, PHES & Stroop values were adjusted for age, gender & education. Apart from more men in validation, remaining demographics were similar to derivation cohort.

Cognitive performance on PHES and Stroop was worse in both cirrhosis groups compared to the controls. Validation & derivation cohorts had similar cognitive results.

MHE due to PHES & Stroop using adjusted cut-offs: For PHES, 6% of derivation cohort & 8% of the validation cohort had MHE. For Stroop, 53% of derivation & 49% of validation cohort had MHE.

Stroop vs PHES: If we considered PHES as gold standard, Stroop sensitivity in derivation cohort was 1.00, CI (0.93,1.00) with specificity 0.50, CI (0.92,1.00) while for the validation cohort sensitivity was 1.00, CI (0.61–1.00) & specificity 0.55, CI (0.43,0.66).

Logistic regression model predicting MHE-PHES by Stroop, the AUC for derivation cohort was 0.97, CI (0.89–0.99) with that of the validation cohort being 0.94, CI (0.86, 0.98).

Conclusion: Using derivation and validation cohorts of elderly cirrhotic patients in a multi-center study, age, education, and gender adjusted methods resulted in detection of MHE by Stroop in almost half the tested patients while MHE-PHES was significantly lower in prevalence. Age-specific norms are needed for accurate MHE diagnosis in the increasingly elderly population with cirrhosis.

SAT142

Lactulose withdrawal can potentiate breakthrough overt hepatic encephalopathy in patients controlled with rifaximin plus lactulose therapy: a post hoc analysis of a randomized controlled trial

Jasmohan S Bajaj[1], Vinay Sundaram[2], Catherine Frenette[3], Zeev Heimanson[4], Robert J. Israel[4], Arun Sanyal[5]. *[1]Virginia Commonwealth University and McGuire VA Medical Center, Richmond, United States; [2]Cedars-Sinai Medical Center, Division of Gastroenterology and Comprehensive Transplant Center, Los Angeles, United States; [3]Scripps Green Hospital, San Diego, United States; [4]Salix Pharmaceuticals, Bridgewater, United States; [5]Virginia Commonwealth University, Richmond, United States*

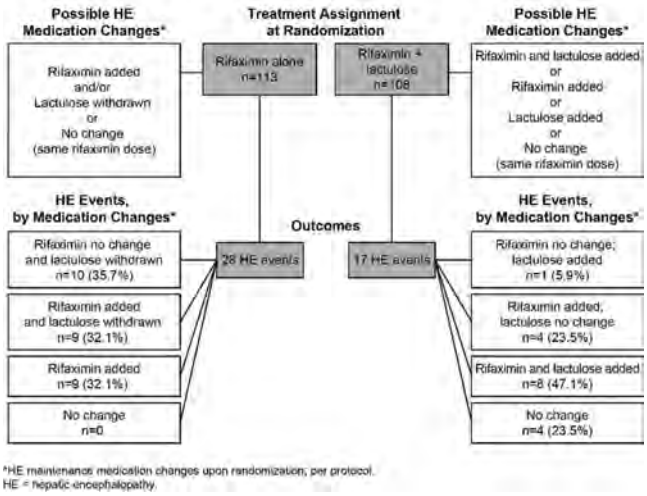
Email: jasmohan.bajaj@vcuhealth.org

Background and Aims: Hepatic encephalopathy (HE) is a recurrent complication of cirrhosis. A post hoc analysis of a phase 4 trial of rifaximin alone vs rifaximin + lactulose explored the impact of HE medication changes necessitated by the trial on HE recurrence over 6 months (Clinicaltrials.gov identifier: NCT01842581).

Method: Eligibility criteria included adults with cirrhosis with a history of ≥1 overt HE episodes during the previous 6 months, currently in HE remission. HE maintenance medications were withdrawn from patients 1 day prior to random assignment to open-label rifaximin 550 mg twice daily (BID) or rifaximin 550 mg BID + lactulose (titrated to 2–3 soft stools/d) for 24 wks. The protocol-defined primary efficacy endpoint was time to first breakthrough HE episode. HE events were captured up to time of last patient contact. HE recurrences were analyzed post hoc based on HE medication withdrawal at randomization.

Results: 113 patients were in the rifaximin alone group, and 108 were in the rifaximin + lactulose group (Figure). At randomization, a greater percentage of patients assigned to rifaximin + lactulose group had rifaximin and/or lactulose added; conversely, a greater percentage of patients assigned to rifaximin alone group had lactulose withdrawn. In rifaximin alone group, 76 (67.3%) patients had lactulose withdrawn vs 0 in rifaximin + lactulose group. Rifaximin was added at randomization for 73 (64.6%) patients in rifaximin alone group and 81 (75.0%) patients in rifaximin + lactulose group; 39 (36.1%) patients in rifaximin + lactulose group had lactulose added. Breakthrough HE events in rifaximin alone group occurred most frequently in those who had lactulose withdrawn at randomization (19/28 [67.9%]), and the HE rate was higher than that observed for patients in rifaximin + lactulose group who continued lactulose (8/17 [47.1%]; Figure). None of the 9 patients in rifaximin alone group who were taking rifaximin prior to randomization (ie, no treatment change) had an HE event. Time to first HE breakthrough event data showed that rifaximin alone group had >2 times more HE events vs rifaximin + lactulose group (17 [15.0%] vs 7 [6.5%]) during the first 56 days postrandomization. In the rifaximin + lactulose group, the greatest percentage of patients with HE events were those with a history of HE who were not receiving lactulose or rifaximin HE prophylaxis at study entry; lactulose and rifaximin are recommended as prophylaxis for prevention of HE recurrence in AASLD/EASL practice guidelines.

Figure. HE Events Subgrouped by Medication Changes at Randomization*



*HE maintenance medication changes upon randomization, per protocol.
HE = hepatic encephalopathy.

Conclusion: Lactulose and rifaximin may play a synergistic role in prevention of HE recurrence. Withdrawal of lactulose at randomization, in conflict with guideline recommendations, was associated with a higher risk of HE recurrence in patients tolerating combination therapy in this study and may have affected study outcomes in rifaximin alone group.

SAT143

Microbiome metabolic therapies reduce microbiota-associated ammonia in ex vivo fecal samples from healthy subjects and patients with minimal hepatic encephalopathy and demonstrate improved tolerability over lactulose in a clinical study

Jasmohan S Bajaj[1], Kelsey Miller[2], Jie Tan[2], Jonathan Lawrence[2], Norma Palma[2], Robert S Mittleman[2], Brian Meehan[2]. *[1]Virginia Commonwealth University and Mcguire VAMC, Division of Gastroenterology and Hepatology; [2]Kaleido Biosciences, Lexington, United States*

Email: norma.alonzo-palma@kaleido.com

Background and Aims: Microbiome Metabolic Therapies (MMT™) are novel synthetic glycans that have the potential to reverse dysbiosis associated with hepatic encephalopathy (HE) and reduce the gut contribution to blood ammonia levels, leading to improved clinical outcomes. We sought to identify an MMT that would reduce net ammonia and compared its tolerability to lactulose in Healthy Subjects (HS).
Method: Fecal samples from a HS were used to evaluate >200 MMTs in high-throughput *ex vivo* screens to assess their impact on bacteria-associated ammonia after 45 hrs of anaerobic growth. Further testing was done with fecal samples from a set of 28 HS and 25 pts with mHE (confirmed using either the Psychometric Hepatic Encephalopathy Score or Encephalapp Stroop in pts not on lactulose or rifaximin) incubated with MMTs selected from earlier testing.
We also conducted a clinical trial in HS comparing MMTs (MMT1, MMT2) titrated up to 90 g to lactulose (up to 40 ml tid) for short-term (~21 days) administration.
Results: MMTs were shown to lower both ammonia production and MDR pathogens in *ex vivo* screens. Subsequent testing of one of these MMTs showed significantly greater decreases in net ammonia than lactulose in samples from HS as well as those from patients with mHE (HS; 55% vs 41% reduction compared to control, $p < 0.001$; mHE: 37% vs 25% reduction $p < 0.001$).
In the clinical safety and tolerability study, 36 HS (12/grp) were randomized. There were no serious adverse events (SAEs). Three of twelve subjects receiving lactulose had temporary interruption of treatment due to gastrointestinal (GI) intolerance vs none receiving MMTs. All (12/12) subjects receiving lactulose had AEs (all GI, including diarrhea, abdominal distension) vs 7/12 in each group receiving MMTs (mainly GI, including abnormal GI sounds, headache). Seven subjects in the lactulose group had de-escalation of dose during the study vs one subject in each of the MMT1 and MMT2 groups. Daily stool frequency increased more from lactulose administration (from 1.2 to 2.4 stools/day) than from MMT1 (from 1.0 to 1.3) or MMT2 (from 1.1 to 0.8).
Conclusion: MMTs reduced microbiota-associated ammonia more than lactulose in fecal samples from HS and patients with mHE in an *ex-vivo* study. In a clinical study, fewer AEs and de-escalations of dosing were seen with MMTs versus lactulose. These results are promising and support further development of MMTs in HE.

SAT144

KB174 reduces relative abundance of multidrug resistance (MDR) enterobacteriaceae in fecal samples from patients with cirrhosis in an ex vivo test system

Jasmohan S Bajaj[1,2], Kelsey Miller[3], Jonathan Lawrence[3], Jie Tan[3], Norma Palma[3], Gabrielle LeBlanc[3], Tanya Yatsunenko[3]. *[1]Virginia Commonwealth University Health, Richmond, United States; [2]McGuire Veterans Hospital, Richmond, United States; [3]Kaleido Biosciences, Lexington, United States*
Email: norma.alonzo-palma@kaleido.com

Background and Aims: Patients with cirrhosis are at risk of infections, bacterial overgrowth and hospitalizations, in part due to a higher carriage of MDR organisms. These infections, such as spontaneous bacterial peritonitis (SBP), are often caused by gut-colonizing pathobionts belonging to the family *Enterobacteriaceae* translocating to ascitic fluid. With increasingly indiscriminate antibiotic use, the burden of infection from MDR organisms is mounting, resulting in a growing need for non-antibiotic strategies. Microbiome Metabolic Therapies (MMT™) are novel synthetic glycans that modulate the metabolic output of the gut through selectively enhancing growth of certain commensals. MMTs may reverse dysbiosis and could potentially be used for reduction of pathobionts that drive complications of infection in cirrhosis.
Method: Fecal samples from a healthy subject were incubated anaerobically for 45 hours with >200 MMTs in high-throughput ex vivo screens to assess their impact on bacteria-associated ammonia and the relative abundance of MDR pathogens. These pathogens were spiked in and included two carbapenem-resistant *Enterobacteriaceae* (CRE) strains of *E. coli* (CDC AR Bank #0001) and *K. pneumoniae* (CDC AR Bank #0003), and a vancomycin-resistant *Enterococci* (VRE) strain, *E. faecium* (ATCC 700221). Several MMTs demonstrated significant reductions in relative abundance of these pathogens. One MMT, KB174, was further tested for reduction of CRE *E. coli* which was spiked into fecal samples from 25 patients with cirrhosis who were not on lactulose or rifaximin and 19 healthy controls.
Results: KB174 was identified as a leading MMT that lowered both ammonia and MDR pathogens in *ex vivo* screens. Despite significant differences in community composition between healthy and cirrhotic fecal communities, incubation with KB174 led to significant decreases in the relative abundance of MDR *Enterobacteriaceae* (mean percent decrease, 43% ($p < 0.001$) and 50% ($p < 0.001$), respectively) compensated largely by significant increases of *Bacteroides* and *Parabacteroides* in both populations.
Conclusion: KB174 reduces the relative abundance of pathobionts in fecal samples from patients with cirrhosis. Based on these results, KB174 was investigated in a clinical study in cirrhotic patients (NCT03855956).

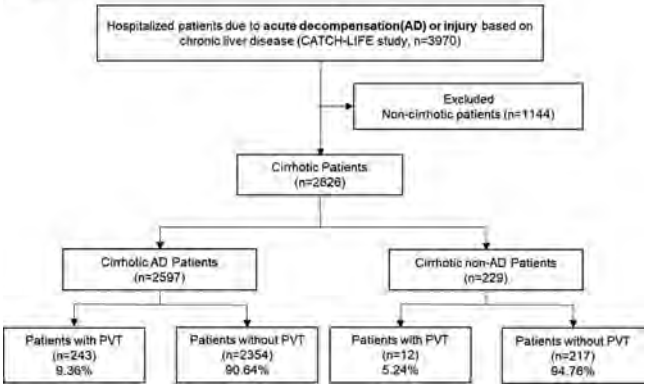
Email: haili_17@126.com

Background and Aims: Portal vein thrombosis (PVT) is a common and serious complication in cirrhotic patients. However, little is known about PVT in cirrhotic patients with acute decompensation (AD). We investigated the prevalence and clinical significance of PVT in nonmalignant cirrhotic patients with AD.

Method: Patients came from two prospective multicenter cohorts of patients with acute exacerbation of chronic liver disease, named CATCH-LIFE (NCT02457637 and NCT03641872), established by the Chinese Chronic Liver Failure Consortium from January 2015 to December 2016 and July 2018 to January 2019. The prevalence, clinical manifestations and risk factors of PVT in cirrhotic patients with AD were analyzed.

Results: The prevalence of PVT in cirrhotic patients with AD was 9.36%, significantly higher than those without AD (5.24%) ($p = 0.04$). Compared to cirrhotic AD patients without PVT, patients with PVT had a significantly higher incidence of variceal bleeding (47.33% vs 19.63%, $p < 0.001$) and a higher serum level of D-dimer ($p < 0.001$). Splenectomy, invasive procedures were independent risk factors for PVT in cirrhotic AD patients. The short- and long-term mortality rates of cirrhotic AD patients were significantly higher than those without AD ($p < 0.001$). But among cirrhotic AD patients, the short- and long-term mortality rates were similar between patients with PVT and without PVT.

Figure 1.



Conclusion: Cirrhotic patients with AD had a significant elevated prevalence of PVT. The occurrence of PVT promoted portal hypertension and variceal bleeding, thus would increase the risk for mortality as a result of the development of AD. It would be beneficial to improve portal hypertension through regular screening and preventing PVT in cirrhotic patients.

SAT146

Pre-emptive (early) transjugular intrahepatic porto-systemic shunt in the treatment of high-risk acute variceal bleeding. An individual patient data meta-analysis

Email: jcgarcia@clinic.cat

Background and Aims: Pre - emptive transjugular intrahepatic porto - systemic shunt (p - TIPS) within 72 h from acute variceal bleeding (AVB) reduced failure to control bleeding and rebleeding and showed better control of ascites without increasing hepatic encephalopathy in comparison to the use of endoscopic treatment plus drug therapy (E + P), in high-risk cirrhotic patients (defined as those with an HVPG ≥20 mmHg or with Child Pugh C less than 14 points (CP - C) or Child Pugh B with active bleeding during diagnostic endoscopy (CP - B + AB) despite vasoactive drug use). However, the survival benefit, although also consistently seen in CP - C patients, is less clear in CP - B + AB patients.
We aimed to investigate individual patient data from previous studies in order to re - evaluate the efficacy of p -TIPS versus standard - of - care, in terms of survival and post - treatment outcome in CP - C and CP - B + AB.
Method: The meta-analysis includes data from five previous studies: two randomized clinical trials and three observational studies. The analysis considers events that occurred in the first year after the index AVB, defined according to Baveno V Consensus. Adjusted models for risk evaluation were built using propensity score for baseline covariates. Multivariate Cox regression models were used to assess the predictive factors for survival.
Results: 1230 patients were included among whom 255 underwent p - TIPS and 975 E + P. Compared to E + P, p - TIPS reduced mortality in overall population (HR = 0.44; CI 95% [0.31–0.61], p < 0.000). This effect was powerfully demonstrated in CP-C patients (HR = 0.34; CI 95% [0.24–0.54], p < 0.000) and a strong trend was also observed in the overall CP - B + AB population (HR = 0.58; CI 95% [0.33–1.01], p = 0.056). In the CP - B + AB patients not receiving p - TIPS (n = 449), there was a significantly higher mortality in those patients with CP - B + AB >7 (n = 286) vs CP - B + AB = 7 (n = 163) (p < 0.000). In the subgroup of CP - B + AB >7 points, p - TIPS significantly improved survival (HR = 0.39; CI 95% [0.23–0.54], p < 0.000). p - TIPS also significantly decreased failure to control bleeding and rebleeding (HR = 0.34; CI 95% [0.25–0.45], p < 0.000) and "de novo" or worsening of previous ascites (HR = 0.23 CI 95% [0.18–0.41], p < 0.000). These effects were observed in both CP - C and in CP - B + AB patients. Compared with E + P, p - TIPS did not increase significantly the development of hepatic encephalopathy (HR = 1.15 CI 95% [0.89–1.50], p = 0.286). At multivariate analysis, adjusted by bilirubin, Child-Pugh class or MELD Score confirms that p - TIPS was an independent predictor of survival (p < 0.000).
Conclusion: In the setting of cirrhosis and AVB, in patients with CP - C < 14 points and in CP - B + AB >7 points, p - TIPS strongly improves survival and reduces rebleeding, failure to control bleeding and ascites without increasing the risk of hepatic encephalopathy and thus it represents the treatment of choice.

Email: jennifer.flemming2@kingstonhsc.ca

Background and Aims: The number of reproductive-aged women with cirrhosis is rising. Details on perinatal complications related to cirrhosis are largely lacking. The aim of this study was to estimate the risk of obstetrical and neonatal complications in a contemporary cohort of women with cirrhosis compared to the general population.
Method: Retrospective population-based matched cohort study using routinely collected healthcare data in Ontario, Canada from 2000–2016. Pregnant women with cirrhosis who carried to at least 20 weeks gestation were identified using a validated cirrhosis case definition and routine mother-infant linkage. Women with cirrhosis were matched on age and socioeconomic status in a 1:5 ratio to pregnant women in the general population. Risk ratios between cirrhosis and perinatal complications were estimated using multivariate log-binomial regression adjusting for baseline diabetes, hypertension, obesity, dyslipidemia and co-morbidity with the Elixhauser Index.
Results: 2,098 pregnant women with cirrhosis were matched to 10,490 pregnant women in the general population; the median age was 31 years (IQR 27–34). Cirrhosis etiology was 70% NAFLD, 18% viral, 6% alcohol-related and 76 women (4%) had previous decompensation. Women with cirrhosis were more likely to have diabetes (11.6% vs. 8.2%, p < 0.001), hypertension (7.0% vs. 3.0%, p < 0.001), obesity (17.5% vs. 10.6% p < 0.001) and dyslipidemia (13.5% vs. 8.2%, p < 0.001) compared to those without cirrhosis. In adjusted models, cirrhosis was independently associated with large for gestational age infants, pre-term delivery, puerperal infections, and intrahepatic cholestasis of pregnancy (p < 0.05 for all, Table). Although the absolute difference in risk was low, compared to infants born to women without cirrhosis, infants born to women with cirrhosis were more likely to be stillborn (0.5% vs. 0.2%, p = 0.02) or die within 1 year of delivery (0.7% vs. 0.3%, p = .004).

Table: Risk of perinatal complications in pregnant women with cirrhosis compared to age and SES matched women without cirrhosis. Each outcome adjusted for baseline diabetes, hypertension, obesity, dyslipidemia and co-morbidity

Outcome	Risk Ratio	95% CI	P value
Large for gestational age (>90th percentile)	1.22	1.03–1.43	0.018
Pre-term delivery (<37 weeks gestation)	1.53	1.31–1.80	<0.001
Puerperal infections	1.38	1.08–1.76	0.010
Intrahepatic cholestasis of pregnancy	10.91	7.73–15.40	<0.001

SES: socioeconomic status.

Conclusion: Women with cirrhosis have higher risks perinatal complications compared to women in the general population even after adjusting for pre-existing co-morbid illness and metabolic risk

factors. These results support the involvement of multidisciplinary high-risk obstetric teams to manage pregnant women with cirrhosis and their infants post-partum.

SAT148

Does the wedge hepatic vein pressure estimates the portal pressure in patients with NASH cirrhosis?

José Ferrusquía-Acosta[1], Octavi Bassegoda[2], Laura Turco[3], Enric Reverter[2], Juan Carlos Garcia Pagan[1], Isabel Graupera[2], Filippo Schepis[3], Marco Senzolo[4], Virginia Hernandez-Gea[1]. *[1]Hospital Clínic de Barcelona, Hepatic Hemodynamic Laboratory, Liver Unit, Barcelona, Spain; [2]Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain; [3]Azienda Ospedaliero-Universitaria di Modena, Division of Gastroenterology, Modena, Italy; [4]Azienda Ospedaliera di Padova, Multivisceral Transplant Unit, Gastroenterology, Padova, Italy*
Email: jferrusquia@hotmail.com

Background and Aims: The wedge hepatic vein pressure (WHVP) estimates the portal pressure (PP) in patients with cirrhosis. However, available evidence comes from studies performed in patients with hepatitis C virus (HCV) and alcohol-related cirrhosis. Therefore, it is unknown whether this correlation also exists in patients with cirrhosis due to non-alcoholic steatohepatitis (NASH-C). The aim of the study is to evaluate the correlation between PP and WHVP (PP-WHVP) in patients with NASH-C.

Method: Observational and retrospective study conducted in 3 European centers. We included patients with NASH-C treated with TIPS. Each patient was matched with two controls with HCV and alcohol-related cirrhosis (HCV/OH-C) who were treated with TIPS contemporaneously, adjusted for severity of liver disease. Patients with complete portal vein thrombosis or vein-to-vein communications that prevented a reliable measurement of WHVP were excluded. The PP–WHVP correlation was evaluated using the Spearman correlation (Rho) and the intraclass correlation coefficient (ICC). A PP–WHVP discrepancy ≥5 mmHg was considered significant. We compared between both groups the proportion of patients with significant PP–WHVP discrepancy and the proportion of patients in whom the hepatic venous pressure gradient (HVPG) failed to detect those with a portosystemic pressure gradient (PPG) ≥16 mmHg, a cutoff previously associated with high risk of death.

Results: So far, 93 patients have been included, 34 with NASH-C and 59 controls (34 OH, 25 HCV). The average age was 57 years and 75% were male. Reason for TIPS were variceal bleeding in 49% and refractory ascites in 43% of the cases. The PP–WHVP correlation was very good in the entire cohort (Rho: 0.818, CCI: 0.894), very poor in the NASH-C group (Rho: 0.617, CCI: 0.714) and excellent in the HCV/OH-C group (Rho: 0.906, CCI 0.957). The proportion of patients with significant PP–WHVP discrepancy was higher in the NASH-C group than in the HCV/OH-C group (15% vs. 3%, p: 0.095), being the PP underestimated by WHVP in the majority of the cases. The proportion of patients in whom HVPG failed to identify those with a PPG ≥16 mmHg was also higher in the group with NASH-C than in the group with HCV/OH-C (21% vs. 8%, p: 0.093).

Conclusion: In patients with NASH-C, the WHVP does not correlate with the PP as accurately as in other etiologies. The WHVP tends to underestimate the PP and may fail to truthfully assess prognosis in patients with NASH-C.

SAT150

Prediction of variceal eradication in decompensated liver cirrhosis: a novel model

Xing Wang[1,2], Jinni Luo[1], Hongli Shang[3], Shaoyan Guo[1], Siwei Tan[1,2], Wurina Bai[1], Haijiao Li[1], Bin Wu[1,2]. *[1]Third Affiliated Hospital of Sun Yat-sen University, Department of Gastroenterology, Guangzhou, China; [2]Guangdong Provincial Key Laboratory of Liver Disease Research, Guangzhou, China; [3]Third Affiliated Hospital of Sun Yat-sen University, Department of Nephrology, Guangzhou, China*
Email: jimmywangxing@hotmail.com

Background and Aims: High risk esophagogastric varices (EGV) is common in decompensated liver cirrhosis and ties up with short-term variceal bleeding. Variceal eradication (VE) through endoscopic therapy has be recommended as the therapeutic goal of EGV treatment. However, factors associated with VE are not clear. In this study, we aimed to identify factors associated with VE as well as to develop a predictive model for better predication of VE.
Method: We carried out the case-control study based on an established prospective cohort conducted at The Third Affiliated Hospital of Sun Yat-sen University and patients with high-risk varices proved by endoscopy were screened. The primary endpoint was VE and patients achieved VE were classified as eradication group whereas patients transferred to other non-endoscopic therapies or did not achieve VE were classified as non-eradication group. Relevant medical and endoscopic data were collected. Comparisons between eradication and non-eradication group were performed by univariate and multivariate logistic regression to identify independent risk factors associated with failure in VE. Predictive model was developed and area under receiver operating characteristic (ROC) curve was calculated.
Results: A total of 468 patients were screened and 335 of them were included for the final analysis, with the mean age of 49 years. Two hundred and 89 cases (86.3%) successfully achieved VE through sequential endoscopic therapies combing band ligation, tissue glue injection and sclerotherapy, and median time to achieve VE was 5 months. In univariate analysis, non-eradication group had higher spleen size (cm) [P < 0.001], more ascites (P = 0.023), more portal vein thrombosis (PVT) (P = 0.020) and lower platelet count (P = 0.003). No statistical significant association was observed for liver function measured by Child-Pugh score or MELD score (P = 0.862 and 0.371, respectively), nor for the endoscopic findings including severity, extended length and red wale sign of EGV. In multivariate analysis, increased spleen size [hazard ratio (HR):1.20, P = 0.001] and PVT (HR:3.13, P = 0.016) were identified as the independent risk factors for the failure of VE, whereas ascites showed non-significant increased risk (HR:1.80, P = 0.081). A predictive model composed of the above three factors was established and the area under the ROC curve was 0.730 (95%CI: 0.653–0.807, P < 0.001).
Conclusion: Splenomegaly and PVT are highly associated with VE. Although the derived model will require external validation, it provides a useful new tool for clinicians to predict the probability of VE in cirrhotic patients and may help optimizing patient selection for endoscopic therapies.

SAT151

A comparison of non-invasive methods for the screening of gastroesophageal varices in patients with compensated cirrhosis

Jonathan Ng[1], Bryan Tan[1], Walid Abu Shawish[1], Marcus Robertson[1,2]. *[1]Monash Health, Department of Gastroenterology and Hepatology, Melbourne, VIC, Australia; [2]Monash University, Department of Medicine, School of Clinical Sciences, Clayton, VIC, Australia*
Email: jnychiang@gmail.com

Background and Aims: Baveno VI and American Association for the Study of Liver Diseases guidelines recommend that in compensated cirrhosis, screening for gastroesophageal varices (GOV) may be avoided in patients with a transient elastography (TE) score <20kPA and a platelet count (PLT) >150 × 10^9/L. Many centres however do not have access to TE. Recently, the RESIST-HCV criteria proposed that a serum albumin >3.6 g/dL and PLT >120 × 10^9/L predicted patients at low risk of varices needing treatment (VNT). We compared methods of non-invasive variceal screening to assess efficacy.
Method: Patients presenting to Monash Health (Victoria, Australia) for TE from 2011–2018 were prospectively recorded. Patients were included if they had compensated (Child-Pugh A) cirrhosis (TE >12 kPa). Exclusion criteria included: hepatocellular carcinoma, previous decompensation (GOV bleeding, ascites, hepatic encephalopathy), portal vein thrombosis or treatment with a non-selective beta-blocker. Patients were stratified according to Baveno VI, modified Baveno VI, expanded Baveno VI and RESIST-HCV criteria. Primary outcome was the absence of VNT defined as diameter >5 mm, grade ≥2 GOV, high-risk stigmata, or need for endoscopic treatment.
Results: 154 patients were included (41% Hepatitis C, 35% non-alcoholic fatty liver disease, 13% alcohol). The median age was 57 and median Child-Pugh score was 5. The median TE and PLT scores were 21 kPa and 160 × 10^9/L respectively. VNT were detected in 13 (8%)

Table 1: (abstract: SAT151) Performance of non-invasive screening methods

Criteria	Number in low-risk group	Number of VNT	Specificity	Sensitivity	Negative Predictive Value	P-value
Baveno VI **(TE <20 kPa, PLT >150)**	46 (30%)	1 (2.2%)	0.32	0.92	0.98	0.11
Modified Baveno VI **(TE<21 kPa, PLT >125)**	61 (40%)	1 (1.6%)	0.43	0.92	0.98	<0.05
Expanded Baveno VI **(TE<25 kPa, PLT >100)**	84 (55%)	1 (1.2%)	0.59	0.92	0.99	<0.001
RESIST-HCV **(Albumin >3.6, PLT >120)**	75 (49%)	3 (4%)	0.51	0.77	0.96	0.08

patients. The performance of non-invasive risk scores are detailed in Table 1.
Conclusion: Non-invasive methods can accurately risk stratify patients with compensated cirrhosis and 30%–55% patients may safely avoid screening endoscopy depending on the criteria utilised. Patients meeting the RESIST-HCV criteria have a <5% chance of having high-risk varices, comparable to the Baveno VI criteria. Thus, in facilities without access to TE, serum albumin and platelet count can accurately identify patients with a low-risk of varices who may safely avoid endoscopic screening.

SAT152

Pre-procedural blood product transfusion and bleeding predictors in patients with chronic liver disease undergoing elective invasive procedures at a tertiary liver unit

Jonathan Durbin[1], Homoyon Mehrzad[1], James Ferguson[1], Debashis Haldar[1]. [1]*Queen Elizabeth Hospital Birmingham, United Kingdom*
Email: debashishaldar1983@gmail.com

Background and Aims: International guidelines recommend empirical blood product transfusions (BPT) prior to intervention in patients with chronic liver disease (CLD) based on standard coagulation tests. Our primary aim was to audit BPTs in patients with CLD undergoing invasive interventional procedures (IP). Our secondary aim was to identify factors that associate with bleeding complications.
Method: We undertook a retrospective audit of the electronic records of CLD patients who underwent any elective IPs between January and June 2019 at the Birmingham Liver Unit – a tertiary liver transplant unit in the UK. We evaluated BPTs against the international consensus guidelines available at the time (issued by the Society of Interventional Radiology and endorsed by the Cardiovascular and Interventional Radiological Society of Europe (SIR/CIRSE) in 2012), bleeding complications (BC), mortality and other complications.
Results: 154 procedures were performed [89 low- (LRP), 48 moderate- and 17 high-risk (HRP) by SIR/CIRSE stratification]. Demographics and aetiology were reflective of the chronic liver disease cohort in a developed country with: a mean age of 55, male predominance (70.1%) and dominated by alcohol related liver disease and non-alcoholic steatohepatitis (77.3%). 17/154 (11%) cases had abnormal clotting parameters that required correction; 7 (41.2%) (5 LRP) did not receive recommended correction. 2/137 (1.5%) patients with satisfactory parameters received unwarranted products. Overall non-adherence to SIR/CIRSE guidelines was 5.8%. 5 cases (2 LRP, 3 HRP) suffered a BC (3.2%). Neither platelets ($p = 0.346$), INR ($p = 0.287$) or adherence to guidelines ($p = 0.999$) correlated to bleeding on univariable regression ; however, bilirubin (OR 1.012, $p = 0.041$) and HRPs (OR 10.04, $p = 0.016$) did.
Conclusion: Current practice likely reflects growing acceptance of the inadequacy of standard clotting parameters to echo bleeding risk in CLD and mirrors subsequent SIR/CIRSE and AGA guidelines released in June and July 2019. Future use and study of other haemostasis measures (e.g. fibrinogen and thromboelastography) may advance clinical safety, reduce blood product use and provide cost savings.

SAT153

Urinary liver fatty-acid binding protein (UL-FABP) predicts acute-on-chronic liver failure (ACLF) and mortality in patients with decompensated cirrhosis

Adria Juanola[1,2], Isabel Graupera[1,2,3], Salvatore Piano[1], Chiara Elia[1], Cristina Solé[1,2,3], Octavi Bassegoda[1,2], Marta Carol[2,3], Núria Fabrellas[3,4], Marta Cervera[2,3], Martina Perez[1,2], Laura Napoleone[1,2], Elisa Pose[1,2,3], Ferran Torres[2], Elsa Solà[1,2,3,5], Pere Ginès[1,2,3,5]. [1]*Hospital Clínic de Barcelona, Liver Unit, Barcelona, Spain;* [2]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain;* [3]*Centro de Investigación Biomédica en Red Enfermedades Hepáticas y Digestivas, Barcelona, Spain;* [4]*School of Nursing, University of Barcelona, Barcelona;* [5]*Universitat de Barcelona - Facultat de Medicina, Barcelona, Spain*
Email: pgines@clinic.cat

Background and Aims: ACLF is characterized by acute decompensation of cirrhosis and organ failure(s) (OF). Considering its dismal prognosis, predicting the development of ACLF is essential. Currently there is no biomarker to predict the development of ACLF. L-FABP is a small protein that is highly expressed in the liver after tissue injury but is also expressed in other organs such as the kidney. We hypothesized that uL-FABP could be a biomarker to predict the development of ACLF in patients with decompensated cirrhosis. Our aim was to investigate the usefulness of uL-FABP as biomarker to predict ACLF and prognosis in patients with cirrhosis.
Method: Urinary L-FABP was measured at the time of admission in a prospective cohort of consecutive patients with cirrhosis admitted to hospital for complications of the disease. Clinical outcomes and survival were assessed over a 3-month period.
Results: A total of 305 patients were included (median MELDNa 21). 112 (37%) patients had ACLF at admission. uL-FABP was significantly higher in patients with ACLF compared to those without ACLF [median (IQR) 45 (18–89) vs 25 (14–60)μg/gr creat; $p = 0.005$]. Patients with liver, coagulation and circulatory failure showed significantly higher uL-FABP levels compared to those of patients without OF [liver: 80 (36–136) vs 25 (13–60), $p < 0.001$; coagulation: 65 (25–136) vs 28 (15–65), $p = 0.003$; circulatory: 81 (39–149) vs 25 (14–60); $p < 0.001$]. There were no significant differences in uL-FABP levels according to the presence or absence of respiratory, brain or renal failure. Nineteen (10%) out of the 194 patients without ACLF at admission developed it within 3 months. uL-FABP was independently associated with development of ACLF, together with MELDNa. The combination of uL-FABP and MELDNa were able to predict the development of ACLF with high accuracy (AUC 0.878). Interestingly, uL-FABP modulates the accuracy of MELDNa: patients with high uL-FABP had significantly higher probability of developing ACLF compared to those with low uL-FABP (40% if MELDNa ≥21 & uL-FABP>30 vs 10% if MELDNa ≥21 & uL-FABP<30; $p < 0.001$). Patients who died had significantly higher levels of uL-FABP compared to those who survived. In multivariate analysis, uL-FABP and MELDNa were independently associated with 3-month mortality.
Conclusion: Urinary L-FABP is a good biomarker to predict ACLF and mortality in hospitalized patients with cirrhosis. Our findings suggest that uL-FABP reflects liver and circulatory failure as main factors involved in ACLF development.

SAT154

Sarcopenia and liver cirrhosis: comparison of the European working group on sarcopenia criteria 2010 and 2019

Julia Traub[1], Ina Bergheim[2], Martin Eibisberger[3], Vanessa Stadlbauer[4]. [1]*Department of Clinical Medical Nutrition, University Hospital Graz, Graz, Austria;* [2]*Department of Nutritional Sciences, RF Molecular Nutritional Science, University Vienna, Vienna, Austria;* [3]*Department of Neuroradiology, Vascular and Interventional Radiology, Medical University of Graz, Graz, Austria;* [4]*Departement of Gastroenterology and Hepatology, Medical University of Graz, Graz, Austria*
Email: Julia.Traub@klinikum-graz.at

Background and Aims: Sarcopenia is prevalent in 30–70% of cirrhotic patients with a higher prevalence in men (61.6%) than in woman (36%). However, criteria for the diagnosis of sarcopenia are not universally accepted and several different definitions coexist. In 2010, The European Working Group on Sarcopenia in Older People (EWGSOP) provided consensus criteria for the diagnosis of sarcopenia using muscle mass, muscle strength and muscle performance as a practical clinical definition. In 2019, a revised definition was published based on the current evidence. It is yet unclear how these modified criteria influence the rate of diagnosis in high risk populations, such as liver cirrhosis.

Method: We therefore assessed if the new diagnostic criteria for sarcopenia impact on sarcopenia prevalence in liver cirrhosis. Within 2 years 114 cirrhotic patients were prospectively enrolled in the study. Sarcopenia was determined by muscle strength (handgrip strength), muscle mass (lumbal muscle index) and muscle performance (gait speed). We assessed the absence of sarcopenia (no sarcopenia group) or the presence of pre-sarcopenia or sarcopenia/severe sarcopenia using both 2010 and 2019 definitions.
Results: Based on the 2010 definition, 38/114 (33.3%) patients had no sarcopenia, 35/114 (30.7%) suffered from pre-sarcopenia and 41/114 (36%) from sarcopenia. With the 2019 definition, significantly more patients (91/114, 79.8%) were diagnosed as non-sarcopenic, whereas only 4/114 (3.5%) were diagnosed as pre-sarcopenia and 19/114 (16.7%) as sarcopenic ($p < 0.0001$). Indeed, when applying the 2010 definition, significantly more men were diagnosed as pre-sarcopenic ($p = 0.006$). Using the 2019 definition, the rate of pre-sarcopenia was significantly lower (30.7% versus 3.5%) due to the different starting points (2010 muscle strength, 2019 muscle mass) and cut-off values (muscle strength). Differences between regarding prevalences of sarcopenia when using the different diagnostic definition are summarized in a Sankey diagram also visualizing and quantifying the flow between groups (Figure 1).

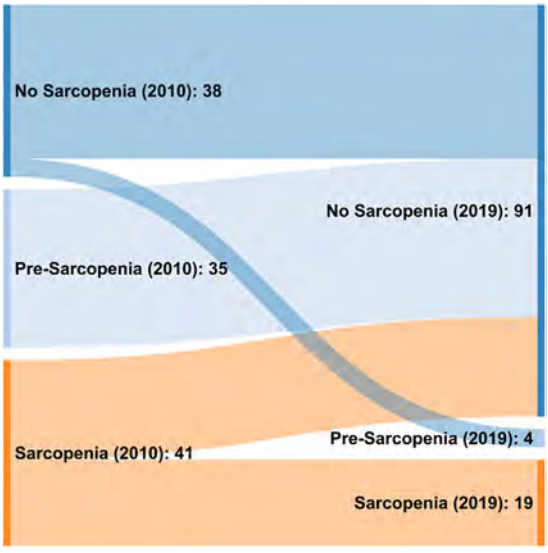

Figure: Sankey diagram to visualize and quantify the changes in sarcopenia diagnosis using the EWGSOP 2010 and 2019 criteria.

Conclusion: The change in diagnostic criteria for sarcopenia drastically influences the rate of pre-sarcopenia diagnosed cirrhotics. To evaluate, which diagnostic criteria should be chosen to diagnose sarcopenia in liver cirrhosis patients, prospective studies are needed.

SAT155

Validation of diagnostic usefulness of the spot urine Na/K ratio for replacement of 24-hour urine NA excretion in cirrhotic patients with ascites

Jinwook Lee[1], Jae-Seok Hwang[1], Woo Jin Chung[1], Heonju Lee[2], Jung Gil Park[2], Changhyeong Lee[3], Byung Seok Kim[3], Jung Eun Song[3], Young Oh Kweon[4], Won Young Tak[4], Soo Young Park[4], Se Young Jang[4], Jeong Ill Suh[5], Byoung Kuk Jang[1]. *[1]Keimyung University school of Medicine, Department of Internal Medicine, Daegu, Korea, Rep. of South; [2]Yeungnam University College of Medicine, Department of Internal Medicine, Daegu, Korea, Rep. of South; [3]Catholic University of Daegu School of Medicine, Department of Internal Medicine, Daegu, Korea, Rep. of South; [4]Kyungpook National University College of Medicine, Department of Internal Medicine, Daegu, Korea, Rep. of South; [5]Dongguk University College of Medicine, Department of Internal Medicine, Gyeongju, Korea, Rep. of South*
Email: jangha106@dsmc.or.kr

Background and Aims: The low salt diet is important for controlling ascites in patients with cirrhosis. 24-hour urine Na excretion test is standard method to determine the low-salt diet compliance. Measuring 24-hour urine Na excretion is a cumbersome method, so it is known that spot urine Na/K ratio can be measured instead. However, it is not fully validated that the spot urine Na/K ratio can replace 24-hour urine Na excretion. The purpose of this study was to validate whether the spot urine Na/K ratio could replace 24-hour urine Na excretion.
Method: A total 192 patients with liver cirrhosis and ascites were screened from multi-center. 175 patients were enrolled according to the inclusion criteria and prospectively studied. 24-hour urine collection was done and 5 mL of random urine was collected in the morning. 24-hour urine Na, creatinine, spot urine Na and K were checked. We confirmed the completeness of urine collection on the basis of 24-hour creatinine excretion over 15 mg/kg/day for men and 10 mg/kg/day for women. ROC curve analysis was performed to evaluate the feasibility of urine Na/K ratio for differentiating 24-hour urine sodium greater than 78 mmol/day.
Results: Only 57 patients were valid for urine creatinine excretion. Urine collections of 118 patients were invalid. There was no significant difference of age, sex, etiology of liver cirrhosis, Child-Pugh class, MELD score and psoas muscle thickness in two groups. In valid group, the area under ROC curve (AUROC) for random urine Na/K ratio in the prediction of 24 hr urine Na>78 mmol/day was 0.874 ± 0.051 ($P < 0.001$). In the invalid group AUROC was 0.832 ± 0.039 ($P < 0.001$). Both groups showed similar AUROC value. In valid group, the classical cut-off value over 1.0 of urine Na/K ratio showed 90.9% sensitivity, 56.0% specificity, 73.2% positive predictive value (PPV) and

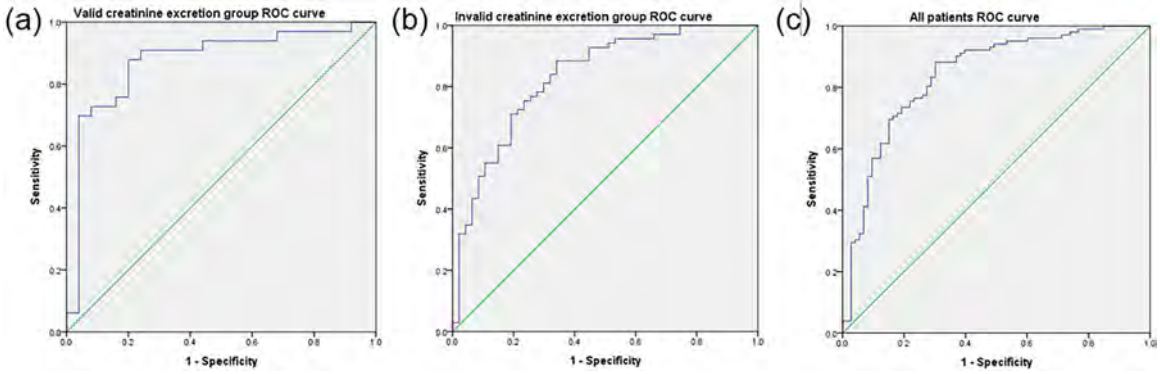

Figure: (abstract: SAT155): ROC curve of Na/K ratio in predicting 24 hour urine sodium excretion greater than 78mmol/day. (a) Valid group, (b) Invalid group, (c) All patients.

82.4% negative predictive value (NPV). The best cut-off point for Na/K ratio was 1.5, with 87.9% sensitivity and 80.0% specificity. In all patients, AUROC was 0.841 ± 0.031 (P < 0.001) and 94.1% sensitivity, 47.9% specificity, 71.6% PPV and 85.4% NPV on Na/K ratio 1.0 cut-off point. 131 patients collected urine during hospitalization. Valid urine collection did not differ between 34.4% in inpatients, and 29.5% in outpatients (p = 0.348).
Conclusion: The spot urine Na/K ratio reflects 24-hour urine Na, but ROC value in this study is lower than previous study. It is difficult to draw conclusions because the large number of incomplete urine collection. Even in hospitalized patients, there are many invalid collections, making it difficult to accurately check urine Na for 24 hours. Therefore, there is a need for a method to more easily identify low salt diet compliance in cirrhosis patients with ascites in the future.

SAT156
Proton pump inhibitor use is associated with an increased risk of hepatic encephalopathy in a large cohort of patients with cirrhosis
Koos de Wit[1], Thijs Kuipers[1], Bert Baak[2], Ulrich Beuers[1], Bart Takkenberg[1]. *[1]Amsterdam UMC, Location AMC, Gastroenterology and Hepatology, Amsterdam, Netherlands; [2]OLVG, Location East, Gastroenterology and Hepatology, Amsterdam, Netherlands*
Email: k.dewit@amc.uva.nl

Background and Aims: The incidence, etiology, clinical characteristics and survival of patients with liver cirrhosis in The Netherlands are yet poorly studied. Recent data suggested that use of proton pump inhibitors (PPIs) was associated with increased risk of hepatic encephalopathy (HE), whereas use of lipophilic statins could be associated with a decreased risk and better transplant-free survival (TFS). This study was performed to get insight in the incidence, etiology and course of the disease of patients with liver cirrhosis in The Netherlands and to detect factors, which could predict TFS and decompensation.
Method: Data of patients with liver cirrhosis from two large hospitals in Amsterdam were collected and analyzed for this study. Patients with confirmed cirrhosis, a follow-up time of >1 year and at least 2 visits at the outpatient clinic were included. Clinical parameters, use of medication, episodes of decompensation and other complications were extracted from the medical records.
Results: A total of 347 patients were included (67% males: median age 57 years (±12 years)) and median follow-up was 64 months (±60 months). Main etiology was alcohol use (29%) followed by chronic hepatitis C (18%). The median TFS was 159 months. At diagnosis, 31% of the patients had decompensated liver cirrhosis (Child-Pugh B 8 or more). Patients in the decompensated group were significantly older compared to patients in the compensated group (59 versus 56 years; p = 0.01). In 197 patients (57%) an episode of decompensation occurred during follow-up. Median TFS in the initially compensated group was 189 months compared to 99 months in the decompensated group (p = 0.01). Multivariate analysis showed that use of PPI was predictive for HE (HR 2.31 (1.23–4.34); p < 0.01). Statin use was not associated with decompensation or TFS. Sixty patients (17%) developed an hepatocellular carcinoma (HCC) during follow-up. These patients had a median survival of 25 months (±24 months) at time of HCC diagnosis. Patients with HCC screened adequately (52% of the patients) had a median TFS of 55 months compared to 24 months in the patients not screened adequately (p = 0.09).
Conclusion: Transplant-free survival of patients with decompensated and compensated cirrhosis was superior to that reported in the literature. Only half of the patients with HCC had participated in screening programs. PPI use was independently associated with development of HE.

SAT157
Quality improvement campaign led to higher surveillance rate for hepatocellular carcinoma in primary care clinic
Kanit Bunnag[1], Amarat Kongsompong[1], Wit Jeamwijitkul[1], Worayon Chuerboonchai[1], Chutatip Charoenthanawut[1], Pongpan Boonmeeseeprasert[1], Nattawit Seetalarom[2], Amnart Chaiprasert[3], Sakkarin Chirapongsathorn[4]. *[1]Phramongkutklao Hospital, Department of Internal Medicine, Bangkok, Thailand; [2]Phramongkutklao Hospital, Computer center, Bangkok, Thailand; [3]Phramongkutklao Hospital, Division of Nephrology, Department of Internal Medicine, Bangkok, Thailand; [4]Phramongkutklao Hospital, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Bangkok, Thailand*
Email: kanit.bunnag@gmail.com

Background and Aims: The European Association for the Study of the Liver (EASL) recommends surveillance for HCC in cirrhotic patient by abdominal ultrasound every six months. However, various studies suggest that the surveillance rates in actual practice are quite low. The aim of this study was to evaluate the effectiveness of implementing quality improvement (QI) campaign in increasing the rate of HCC surveillance among patients with cirrhosis in primary care clinic.
Method: Patients with cirrhosis were prospectively enrolled into QI campaign. We engaged a network of clinic-based organizations and professionals in a 12-month campaign at primary care clinic to promote the adherence to EASL evidence-based practice guideline for cirrhosis, known to reduce the risk of cirrhotic complications. By using class room education program, social network communication and implemented standardized order sets for cirrhosis among providers at primary care clinic compare with control group at gastroenterology specialist clinic. Patients enrolled in this campaign between September 2018 and August 2019 were compared to cohort in February 2017 to January 2018. The primary endpoint was the receipt of at least one abdominal imaging study every 6 months, performed for the purposes of HCC surveillance during the study period.
Results: Of the 821 cirrhotic patients enrolled, 365 (44.4%) had imaging performed for HCC surveillance. In the campaign group, there was statistically significant increase in adherence to the HCC surveillance every 6 months (25.1% vs 41.2%, p <0.001). Compared to the non-campaign group, there was no significant increase in adherence to HCC surveillance every 6 months (45.4% vs 48.1%, p = 0.45). Direct health care costs were significantly increase in primary care clinic.
Conclusion: Implementation of QI campaign incorporating reminders of surveillance status for providers can significantly increase the rate of HCC surveillance among cirrhotic patients in primary care clinic.

SAT158
Calf circumference as an easy surrogate marker for the screening of Japanese patients with chronic liver disease
Kei Endo[1], Takuro Sato[1], Takuya Okamoto[1], Yasuhiro Takikawa[1]. *[1]Iwate Medical University School of Medicine, Hepatology, Yahaba, Japan*
Email: keiendo@iwate-med.ac.jp

Background and Aims: Chronic liver disease (CLD) is a typical disorder of secondary sarcopenia. Several sarcopenia guidelines recommend diagnostic imaging methods for assessing muscle volume. However, these are unsuitable for large-scale screening tests. Therefore, a simple screening method for sarcopenia is required. We analysed the usefulness of sarcopenia screening tests using calf and arm circumferences (CC and AC, respectively) in patients with CLD.
Method: This study was a single centre cross-sectional study. We analysed patients with CLD between April and October 2019. All patients underwent abdominal CT within 6 months. The skeletal muscle index (SMI) was calculated by dividing the cross-sectional area of the skeletal muscles (cm^2) at the third lumbar vertebra using

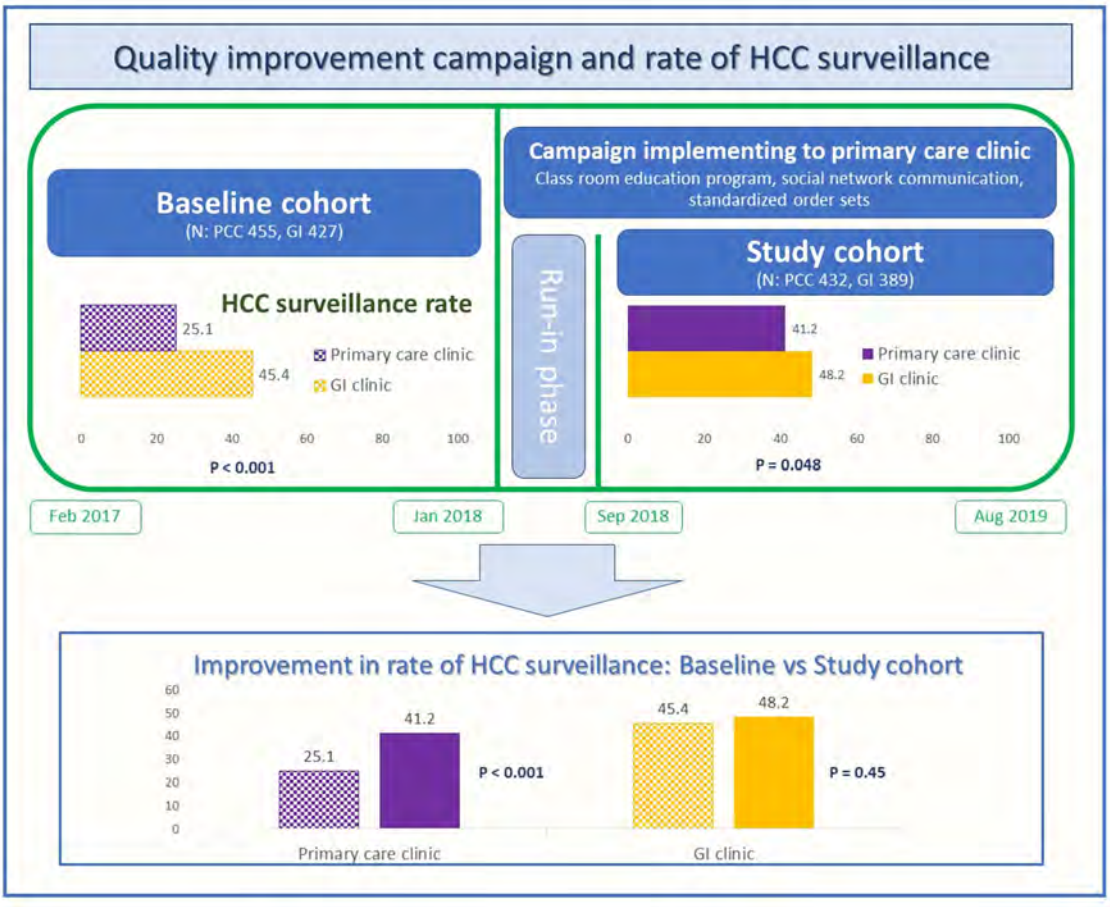

Figure: (abstract: SAT157)

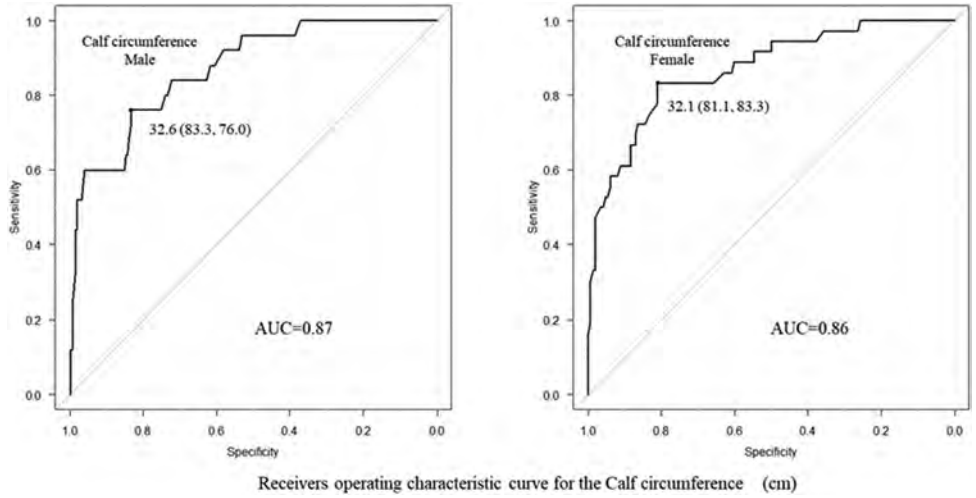
CT by the square of the height (cm^2/m^2). Sarcopenia was defined according to the Japan Society of Hepatology (JSH) guidelines for sarcopenia using a liver disease algorithm, which includes both low muscle mass and strength. Low muscle mass was defined as an SMI <42 cm^2/m^2 and <38 cm^2/m^2 in men and women, respectively. Low muscle strength was defined as a grip strength <26 kg and <18 kg in men and women, respectively.

Results: Two hundred and thirteen patients were enrolled. The median age was 71 years, and 129 (60.5%) patients were male. In addition, 119 (55.9%) patients were diagnosed with liver cirrhosis. Low muscle mass and low muscle strength were found in 76 (35.7%) and 56 (26.3%) patients, respectively. Finally, 30 (14.1%) patients were diagnosed with sarcopenia. The sarcopenia group was significantly older (69 vs 77 years, P < 0.01) and had a higher cirrhosis ratio (80% vs



Receivers operating characteristic curve for the Calf circumference (cm)

Figure: (abstract: SAT158)

52%, P < 0.01) and lower serum albumin level (3.7 vs 4.1 mg/dL, P = 0.02) than the non-sarcopenia group. The sarcopenia group had significantly lower body mass index (21.3 vs 24.2 kg/m^2, P < 0.01), CC (29.5 vs 34.8 cm, P < 0.01), and AC (22.4 vs 26.3 cm, P < 0.01) than the non-sarcopenia group. SMI was positively correlated with AC (males, r = 0.68; females, r = 0.55) and CC (males, r = 0.68; females, r = 0.62). ROC analysis was performed to confirm the validity of AC and CC for sarcopenia, and the results identified areas under the curve of 0.87 and 0.86 for males and 0.87 and 0.80 for females, respectively. From ROC analysis, the optimal cut-off values of AC and CC were 24.4 cm and 32.6 cm for males (sensitivity, 84% and 76%; specificity, 78% and 83%) and 23.5 and 32.1 cm for females (sensitivity, 67% and 83%; specificity, 82% and 81%), respectively. In females, the CC was significantly more useful in distinguishing sarcopenia than the AC (P = 0.04). When the CC was 35.1 cm and 34.6 cm for men and women, respectively, the sensitivity and specificity were 96% and 53% and 94% and 50%, respectively.

Conclusion: CC was positively correlated with CT-measured SMI and could be used as an easy surrogate marker for the screening of sarcopenia in Japanese patients with CLD.

SAT159

A novel method: can stapedial acoustic reflex have a role in the diagnosis of minimally hepatic encephalopathy?

Abdullah Emre Yıldırım[1], Alper Yazıcı[2], Bugra Tolga Konduk[3], Sezgin Barutcu[1]. [1]*University of Gaziantep, Gastroenterology;* [2]*University of Gaziantep, Otorhinolaryngology;* [3]*University of Gaziantep, Gastroenterology*
Email: draemreyildirim@gmail.com

Background and Aims: Stapedial acoustic reflex is an easily accessible and applicable test which is also valuable for the clinical conditions which affect the various locations of the central nervous system. Searching the diagnostic value of stapedial acoustic reflex at minimal hepatic encephalopathy is the aim of this research.

Method: Diagnosis of minimal hepatic encephalopathy was conducted by mini-mental state test and critical flickered frequency tests. Minimal hepatic encephalopathy diagnosed patients were established in the first group. Cirrhosis (without minimal hepatic encephalopathy or overt hepatic encephalopathy) diagnosed patients were created the control group. The stapedial acoustic reflex test was applied for minimal hepatic encephalopathy and the control group by audiologists in a soundproof room.

Results: In total 221 patients were screened and 97 patients meet the inclusion criterions. 52 patients out of 97 were the minimal hepatic encephalopathy patients and the remaining patients were created the control group. Acoustic reflex tests battery includes the evaluation of two pathways called ipsilateral and contralateral. Ipsilateral way test results were found positive in all minimal hepatic encephalopathy patients and 95% positive in the control group. Contralateral acoustic reflex test results were found 36% positive in minimal hepatic encephalopathy patients and 95% positive in the control group, respectively. Comparison of two group ipsilateral and contralateral acoustic reflex test results were displayed a statistical significance.

Conclusion: Stapedial acoustic reflex test results of cirrhosis patients may cover additional parameters for the diagnosis of minimal hepatic encephalopathy.

SAT160

Real-world treatment patterns and outcomes in hepatorenal syndrome: results from a retrospective chart review study in the United Kingdom

Kevin Moore[1], Khurram Jamil[2], Katharina Verleger[3], Linlin Luo[4], Nehemiah Kebede[4], Marieke Heisen[5], Shelby Corman[4], Rachel Bakker[5], Christine Mai[6], Nisreen Shamseddine[2], Xingyue Huang[2]. [1]*Royal Free Hospital, University College London, London, United Kingdom;* [2]*Mallinckrodt Pharmaceuticals, Global Medical, Bedminster, NJ, United States;* [3]*Pharmerit International, Berlin, Germany;* [4]*Pharmerit International, Bethesda, MD, United States;* [5]*Pharmerit International, Rotterdam, Netherlands;* [6]*AplusA, Lyon, France*
Email: scorman@pharmerit.com

Background and Aims: Hepatorenal syndrome (HRS) is a disease of impaired renal function in patients with advanced cirrhosis. The prognosis in patients with HRS is poor, with 50% patients surviving one month after diagnosis. European clinical practice guidelines recommend terlipressin in combination with albumin as the first-line

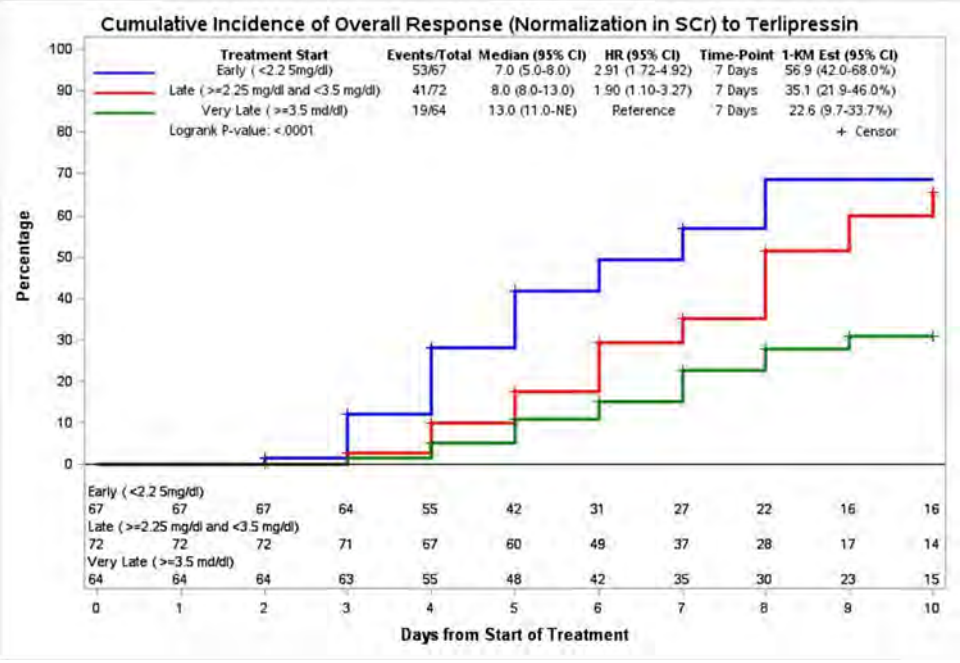


Figure: (abstract: SAT160)

treatment (tx) for HRS. However, quality real-world evidence on terlipressin use and its effectiveness are lacking. We conducted a retrospective, multi-centre medical chart study to assess tx and outcomes of terlipressin and other vasopressors (OVPs) for hospitalized HRS patients in the UK.

Method: Web-based case report forms were used to extract data of HRS patients treated with terlipressin or OVPs between Jan 1, 2013 and Dec 31, 2017. Collected data included patient characteristics, tx history, clinical outcomes and resource use. Changes in serum creatinine (SCr) from baseline post tx were used to assess clinical response (complete response [CR] if SCr ≤1.5 mg/dL; partial response [PR] if SCr reduction ≥20% but SCr >1.5 mg/dL). Descriptive analyses and Kaplan-Meier time-to-event analyses were conducted. Clinical response by tx initiation (SCr within 24 hours of admission, early SCr <2.25; late 2.25≤SCr<3.5; very late SCr ≥3.5) was also evaluated. The study complies with all EU data protection and privacy regulations.

Results: Data of 250 HRS patients was collected from 9 centres. 67% of patients were male and 72% were born before 1970. The majority of patients (80%) were treated with terlipressin monotherapy (72% in combination with albumin) on day 1 of admission with an average tx duration of 6 days. Overall response (CR and PR combined) was 73% for terlipressin monotherapy (n = 203) 59% for OVP monotherapy (n = 22), and 41% for vasopressor combinations (n = 25); CR rates were 50%, 23%, and 0%, respectively. Patients treated with terlipressin early had better cumulative overall response vs. late or very late (Figure 1). Patients with CR or PR were hospitalized for a shorter duration (median: 21.5 days) than patients with no response (median: 27.0 days). Terlipressin patients experienced the following precipitating events for HRS: diarrhoea (9%), gastrointestinal bleeding (28%), large-volume paracentesis (21%), spontaneous bacterial peritonitis (15%) and tx with diuretics (39%). Almost 79% of terlipressin patients had ascites. Common tx-attributable adverse events were fluid overload or pulmonary oedema (16% in TLP; 32% in OVPs) and multi-organ failure (9% in terlipressin; 9% in other OVPs).

Conclusion: This is the first real world study of patients with HRS in the UK. Terlipressin was the predominant tx for HRS in the UK. Clinical outcome results demonstrate that tx with terlipressin – especially early treatment – has a significant positive impact on patient outcome in the real world.

SAT161

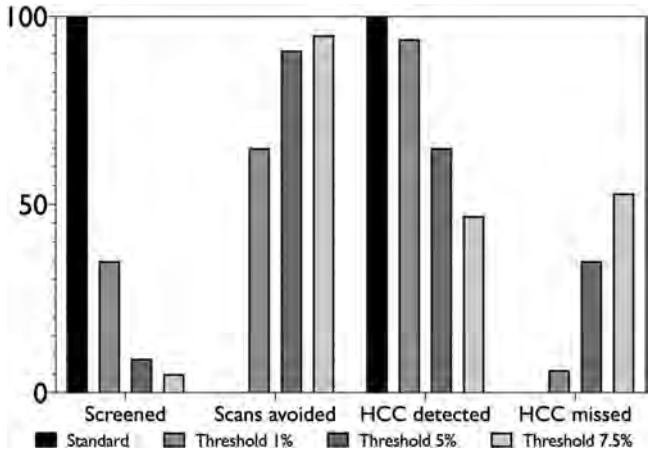
Validation of HCC risk calculator in a UK centre and implications of thresholds for screening

Laura Atkins[1], Victoria Printz[1], Jessica Shearer[1], Rebecca L Jones[1], Ian Rowe[1], Richard Parker[1]. [1]*St James's University Hospital, Hepatology, United Kingdom*
Email: laura.atkins4@nhs.net

Background and Aims: hepatocellular carcinoma (HCC) is a complication of chronic liver disease. At present guidelines suggest that six monthly surveillance screening is offered to patients with cirrhosis to detect HCC although this is not based on trial evidence. A score to evaluate the risk of HCC was recently described in a US cohort (Ioannu et al J. Hep 2019 doi: doi.org/10.1016/j.jhep.2018.07.024.) We aimed to evaluate the accuracy of this score in our cohort of patients and to assess the implications of using thresholds or risk to guide surveillance.

Method: all patients in the stable cirrhosis clinic at Leeds Liver Unit with alcohol related liver disease (ArLD) or non-alcoholic fatty liver disease (NAFLD) had their HCC risk score calculated using the online calculator (hccrisk.com) at the time of the earliest available AST:ALT result. Patients were followed up with six monthly ultrasounds until the time of data collection or diagnosis of HCC. The proportion of patients who would have been screened at five-year risk thresholds of 7.5%, 5% and 1% were calculated along with the numbers of HCC that would have been detected or missed at each threshold. The accuracy of the HCC risk score was assessed by receiver-operator curve analysis.

Results: Two hundred and ninety two patients were scored: 105 had ArLD (36%) and 187 had NAFLD (64%). The average age was 63 years, 64% were male. The average 3-year risk was 1.25%, average 5-year risk was 2.12. Average follow-up was 3.12 years. In this time 17 patients developed HCC. The HCC risk score performed well with AUROC of 0.833 at three years and 0.844 at five years. In our cohort, using HCC risk thresholds of 1, 1.5, 5 or 7.5% would avoid 61, 34, 91 or 95% of scans respectively, at the cost of potentially missing 6, 6, 35 or 53% of cancers.



Conclusion: the HCC risk score performs well in our cohort. The risk of HCC in a dedicated compensated cirrhosis clinic is low in the majority of patients who fall below the conventional threshold for cost-effective surveillance (1.5%). Instituting this threshold would reduce the number of scans by 34% at the cost of 6% missed cancers.

SAT162

Liver stiffness by transient elastography to detect porto-sinusoidal vascular liver disease in patients with portal hypertension

Email: laure_elkrief@yahoo.fr

Background and Aims: Porto-sinusoidal vascular liver disease (PSVD) is a rare cause of intrahepatic portal hypertension. PSVD is still often misdiagnosed as cirrhosis, emphasizing the need to improve PSVD diagnosis strategies. The aims of this study were to evaluate the accuracy: (i) of liver stiffness measurement (LSM) using transient elastography (TE) to discriminate PVSD from cirrhosis in

patients with portal hypertension, and (ii) of Baveno VI criteria to rule-out varices needing treatment in patients with PVSD.
Method: We retrospectively included patients with PSVD, diagnosed according to the VALDIG criteria, from 2 University hospitals. We compared them with patients with histologically-proven compensated cirrhosis, related to alcohol or hepatitis C virus (HCV) infection, selected among the prospective French INCa CIRRAL and ANRS CirVir cohorts. All patients with PSVD and cirrhosis had clinical signs of portal hypertension and had reliable (according to EASL guidelines) LSM performed within a median (IQR) interval of 0 (0–3) months before or after diagnostic liver biopsy.
Results: Eighty-eight patients with PSVD (male gender 52%, median age 56 years, medium/large varices 37%, history of portal hypertensive bleeding 22%) were included. They were compared to 117 patients with alcohol-related cirrhosis (male gender 71%, median age 57 years, medium/large varices 13%) and to 110 patients with RNA positive HCV-related cirrhosis (male gender 61%, median age 53 years, medium/large varices 11%).
In patients with PSVD, LSM value [8.2 (6.2–12.7) kilopascals (kPa)] was significantly lower than in patients with alcohol-related cirrhosis [33.8 (21.3–62.7); $p < 0.001$], and than in patients with HCV-related cirrhosis [18.2 (13.9–26.7); $p < 0.001$]. LSM <10 kPa was able to diagnose PSVD when compared to alcohol-related cirrhosis or HCV-related cirrhosis with a specificity of 97% and 95%, respectively. LS>20 kPa was able to rule-out PSVD when compared to either alcohol-related cirrhosis or HCV-related cirrhosis with a specificity of 93% and 93%, respectively (Figure).

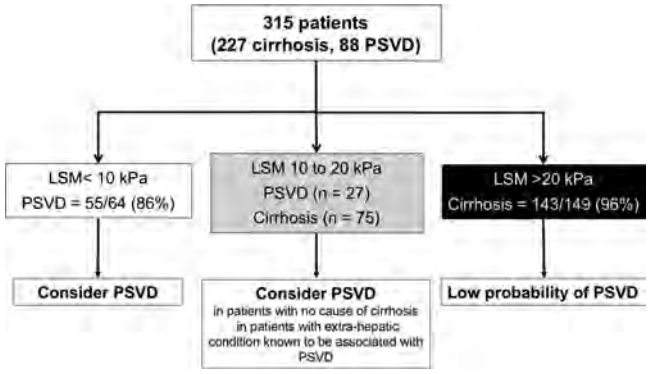

Figure: Probability of PSVD according to LSM values.

In patients with PSVD, Baveno VI criteria would potentially spare 36% endoscopies, but with an unacceptable risk of missing varices needing treatment of 29%.

Conclusion: In patients with signs of portal hypertension, LS <10 kPa strongly suggests PSVD as the cause of portal hypertension, particularly in the absence of cause for cirrhosis. Baveno VI criteria should not be applied to patients with PSVD.

SAT163
The utilisation of palliative care in patients with end-stage liver disease

Lauren Andersson[1], Derek Eng[2], Nick Kontorinis[1], Wendy Cheng[1], Adam Doyle[1], Jee Kong[1], Tim Mitchell[1]. [1]*Royal Perth Hospital, Gastroenterology and Hepatology Department, Perth, Australia;* [2]*Royal Perth Hospital, Palliative Care Department, Perth, Australia*
Email: Lauren.Andersson@health.wa.gov.au

Background and Aims: End stage liver disease (ESLD) carries high morbidity and mortality. The only offer of cure is liver transplantation. The clinical trajectory of ESLD is often tumultuous with a high symptomatic burden that rivals advanced malignancy. Palliative care involvement in ESLD significantly improves subjective symptom scores and overall quality of life. Although the end of life care needs parallel those of acute renal failure and dementia, palliative care is largely underutilised in this population with referrals often occurring late and without documented goals of care. This study aims to identify the patterns of referral to palliative care for patients with ESLD in a tertiary hospital.
Method: Patients with ESLD who died from their disease and were referred to palliative care between 01/01/2018–31/12/2018, were identified retrospectively. Clinical information including cirrhosis aetiology, number of hospital admissions, decompensation events, MELD-Na and Child Pugh scores, symptom scores and timing of palliative care referral were obtained.
Results: 38 patients were included (81% male, 18.5% female). Alcohol was the most common cause of cirrhosis (31.6%) and 50% had hepatocellular carcinoma (HCC). At the time of referral to palliative care, 88.2% had performance scores translating to significant bed rest and care requirements. The predominant symptoms at referral were loss of appetite (52.9%), fatigue (50%) and pain (47.2%). 18% of patients were admitted to ICU in the same admission as the palliative care referral. There was no significant difference in the number of admissions pre-referral to palliative care between patients without or with HCC (3.5 vs 2.8, $p = 0.429$). Patients without HCC had significantly higher Child-Pugh (10.6 v 8.5, $p = 0.005$) and MELD-Na scores (23.1 v 18.5, $p = 0.049$) at the time of referral to palliative care. Patients without HCC had a significantly shorter survival following referral (17 days v 53 days, $p = 0.009$) and were predominantly referred for end of life care. The predominant trigger for palliative care referral in the HCC group was symptom control.
Conclusion: This study highlights that patients with ESLD are referred to palliative care at a lower level of baseline functioning and with high symptom burden. Referral patterns between HCC and non-HCC groups differed with non-HCC patients referred at a later stage and predominantly for end of life care, with shorter rates of survival. Palliative care is underutilised in patients with ESLD without a coexistent cancer diagnosis, leading to missed opportunities to improve symptom control and quality of life.

Email: chjj@smu.edu.cn

Background and Aims: Current guidelines on the management of bacterascites are limited because there are few studies on this topic. This multicentre, retrospective study investigated the clinical features and outcomes of cirrhosis patients with bacterascites.
Method: Two series of cirrhosis patients were evaluated. The first included 418 patients with ascites-positive cultures at 11 hospitals

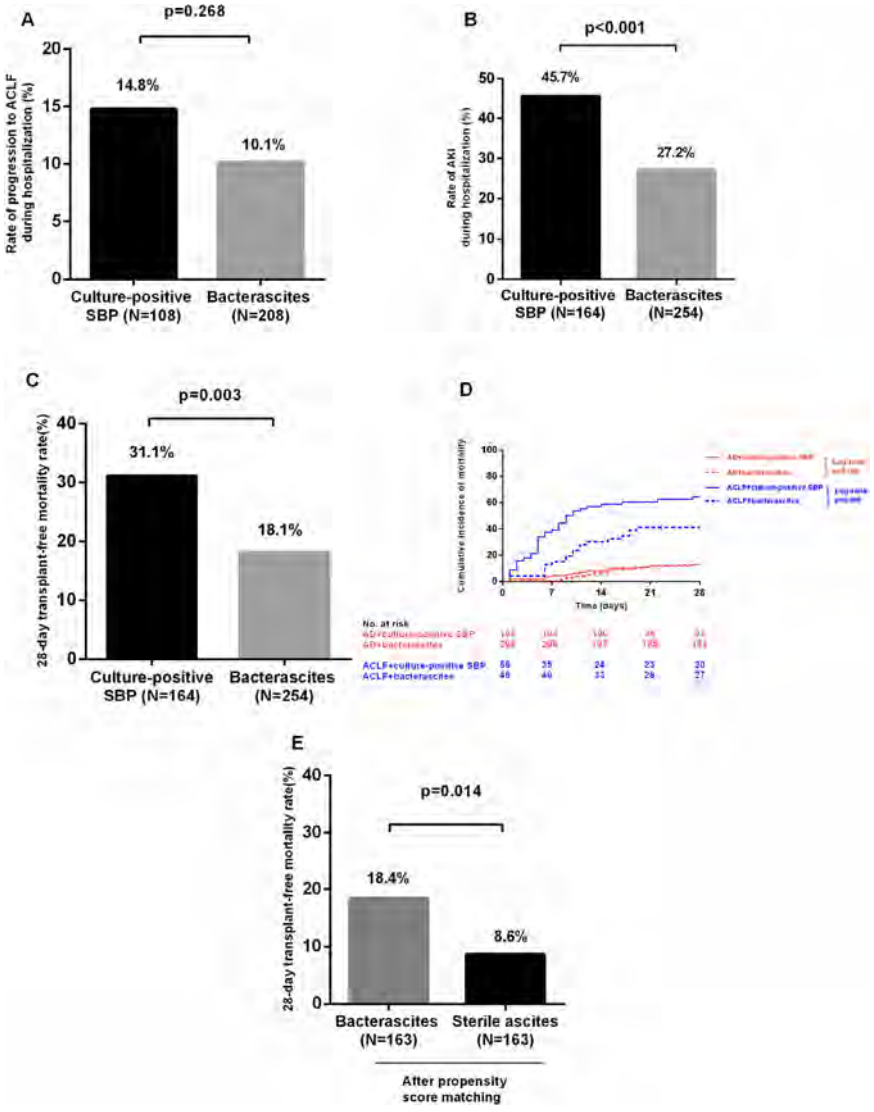

Figure: (abstract: SAT164)

during 2012–2018. Clinical characteristics and outcomes were recorded. The second series included 208 patients with sterile ascites from a prospective cohort (NCT02457637). Clinical features and outcomes of cirrhotic patients with or without bacterascites were investigated.

Results: In the first series, bacterascites was diagnosed in 254/418 (60.8%) patients, and culture-positive spontaneous bacterial peritonitis (SBP) was diagnosed in 164/418 (39.2%) patients. A total of 425 strains were isolated. Gram-positive bacteria were more prevalent in bacterascites patients than in culture-positive SBP patients (59.1% vs. 22.0%; $p < 0.001$). In this cohort, 33 patients had blood culture and the proportion of positive blood culture in bacterascites group was comparable with culture-positive SBP group (57.1% vs. 84.2%; $p = 0.084$). A higher prevalence of acute-on-chronic liver failure (ACLF) at the time of paracentesis was found in culture-positive SBP than in bacterascites patients (34.1% vs.18.1%; $p < 0.001$). For patients without ACLF, the probability of progression to ACLF within 28-day (10.1% vs 14.8%; $p = 0.268$) was comparable between bacterascites ($n = 208$) and culture-positive SBP patients ($n = 108$) (Figure A). The prevalence of in-hospital acute kidney injury (AKI) for bacterascites patients was 27.2%, which was lower than that of culture-positive SBP patients (45.7%; $p < 0.001$) (Figure B). The 28-day mortality rate was lower for bacterascites patients than for culture-positive SBP patients (18.1% vs 31.1%; $p = 0.003$) (Figure C and D), but it was much higher than that of patients with sterile ascites after propensity score matching (18.4% vs.8.6%; $p = 0.014$) (Figure E).

Conclusion: Bacterascites patients had non-negligible poor clinical outcomes, including in-hospital AKI, progression to ACLF, and 28-day mortality. Future studies are warranted to expedite the diagnosis of bacterascites and optimize antibiotic treatment.

SAT165

Continuous infusion of terlipressin for hepatorenal syndrome therapy: evaluation of efficacy and safety in real-life setting

Fernanda S. Linhares[1], Julia G. F. Costa[2], Marlone Cunha-Silva[2], Tiago Pereira[2], Alberto Queiroz Farias[1], Flair Jose Carrilho[1], Daniel Mazo[1,2]. [1]*Division of Clinical Gastroenterology and Hepatology, Department of Gastroenterology, University of São Paulo School of Medicine (FMUSP), Sao Paulo, Brazil;* [2]*Division of Gastroenterology (Gastrocentro), Department of Internal Medicine, School of Medical Sciences, University of Campinas (UNICAMP), Campinas, Brazil*
Email: danielmazo@yahoo.com.br

Background and Aims: Hepatorenal syndrome (HRS) is the most severe form of acute kidney injury (AKI) in patients with cirrhosis,

with high morbidity and mortality. Recent studies have shown that the terlipressin administration in continuous intravenous infusion appears to be as effective as its bolus use for HRS therapy, and with better tolerability. However, there is paucity of data with this strategy of administration for the treatment of patients with decompensated cirrhosis and HRS in real life setting.
Method: Prospective/retrospective cohort study in patients with decompensated cirrhosis non-electively admitted in two tertiary university hospitals from June 2018 to August 2019 who received continuous infusion of terlipressin in addition to albumin for the treatment of HRS. Clinical and laboratory characteristics of the patients, AKI stage, CHILD and MELD score, responses to treatment, adverse events, progression for liver transplantation and mortality were evaluated.
Results: A total of 25 HRS treatments in 18 patients were included in the study. Five patients (27.8%) had one or more recurrence of HRS after treatment withdrawal, in the same hospitalization on in subsequent ones, and all treatments were evaluated. Most patients were males (66.7%), with mean age of 57.5 ± 8.9 years. Alcohol (38.9%), followed by cryptogenic (22.2%), non-alcoholic steatohepatitis (16.7%) and chronic hepatitis C (16.7%) were the main etiologies of cirrhosis. Half of the patients had Child-Pugh score C, and MELD score ranged from 11 to 42. At HRS treatment initiation, ACLF grade was I in 83.4% of patients, and grade II in 11.1%, and AKI stage (S) was 1 in 44.4%, S2 in 27.8%, and S3 in 27.8%. Regarding all treatments, the mean terlipressin dose was 4.3 ± 2.5 mg, the treatment duration was 8.4 ± 4.7 days and the rate of complete response was 64%. Partial response was observed in 8% treatments, and no response in 28%. Of the latter, seven patients underwent renal replacement therapy. 38.9% of patients experienced adverse events while on therapy: 3 diarrhea, 1 abdominal pain, 2 bradycardia and 1 testicular ischemia (this one leading to treatment discontinuation). In-hospital mortality was 33.4%, and 5.5% were submitted to liver transplantation.
Conclusion: The administration of terlipressin in continuous infusion for HRS treatment seems to be a feasible and interesting option, with response to treatment and adverse events rates in line with previous reports in this scenario.

SAT166

Frailty assessed by the liver frailty index (LFI) predicts poor health-related quality of life (QOL) in patients hospitalised with liver cirrhosis

Lubomir Skladany[1], Tomáš Koller[2], Janka Vnencakova[1], Beata Skvarkova[1]. *[1]F.D.Roosevelt Univ. Hospital, HEGITO - Hepatology, Gastroenterology, and Liver Transplantation, Banská Bystrica, Slovakia; [2]University Hospital Bratislava - Ružinov, Internal Medicine V - Div. Hepatology and Gastroenterology, Bratislava, Slovakia*
Email: lubomir.skladany@gmail.com

Background and Aims: Cirrhosis has a detrimental effect on all domains of patient-reported outcomes (PROs) and QOL (Tapper 2018; Marchesini 2001). On the other hand, QOL is a good predictor of outcome and important target for intervention (Kanwal 2009; Tanikella 2010). Less is known about the determinants of QOL. Frailty is a global disorder impacting PROs beyond physical function (Lai 2014; Tapper 2019), is common in pts with cirrhosis, and is associated or correlates with poor QOL (Derck 2015; Carrey 2010). Association of the LFI (Lai 2017) – instrument from the newly recommended toolkit (Lai 2019) with QOL has not been studied yet. We aimed to determine the association of frailty with QOL and to identify predictors of poor QOL among pts admitted to hospital with liver cirrhosis.
Method: We prospectively enrolled hospitalized adults with cirrhosis from the HEGITO Registry. We recorded characteristics of pts demographics, liver disease etiology, complications, and disease stage; frailty and QOL were assessed at admission by LFI, and EQ-5D-5L™, respectively. Frailty was defined as LFI>4.5, QOL was expressed as a cumulative score of five dimensions (mobility, self-care, usual activities, pain/discomfort, anxiety/depression) with each assigned value from 1 (excellent) to 5 (poor). Poor QOL was defined as score worse (higher) than the 80th percentile.
Results: We enrolled 180 patients with all required parameters, with median age 57.7 years, 31.7% females, median MELD 17, and alcoholic etiology in 67.1%. Median LFI was 4.3 and 77 (42.8%) patients were designated as frail. Median QOL score was 8, QOL positively correlated with the LFI (r = 0.679, 95%CI 0.592–0.751, p < 0.001, Figure 1). Frail patients had a higher QOL score than non-frail patients (median 12 (25–75%, 11–14) vs. 5 (6–7). Patients with poor QOL had QOL score>14 and had significantly higher LFI, MELD, Child-Turcotte-Pugh score, C-reactive protein, lower mid-arm circumference, and were more likely to have refractory ascites and overt hepatic encephalopathy. In a multivariate logistic model, frailty (OR = 29.7, 95%CI 6.5–136.1) and refractory ascites (OR = 4.4, 1.64–12.0) were independent predictors of low QOL.

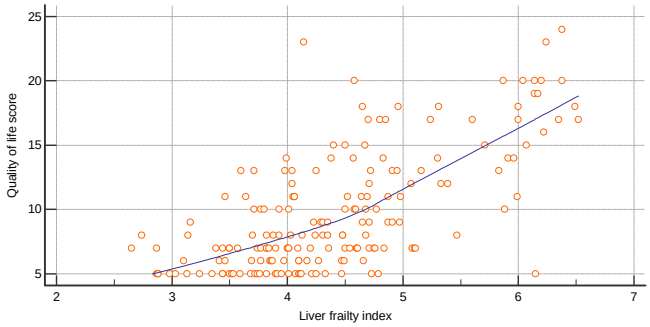

Figure 1. Correlation between liver frailty index and quality of life score (r = 0.679, 95%CI 0.592–0.751, p < 0.0001).

Conclusion: Low QOL among patients hospitalized for cirrhosis appears to be driven by frailty status and refractory ascites. Frailty is easily assessable by the LFI.

SAT167

A novel score to predict mortality after transjugular intrahepatic portosystemic shunt in patients with renal insufficiency

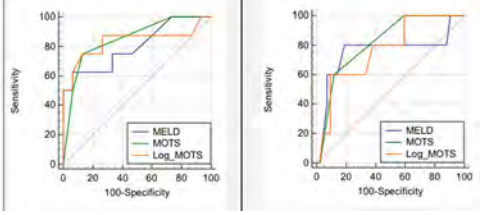
Luisa Fuerschuß[1], Florian Rainer[2], Maria Effenberger[3], Markus Niederreiter[3], Rupert Horst Portugaller[2], Peter Fickert[1], Vanessa Stadlbauer[1]. *[1]Medical University of Graz, Department of Gastroenterology and Hepatology, Graz, Austria; [2]Medical University of Graz, Department of Radiology, Graz, Austria; [3]Medizinische Universität Innsbruck, Innsbruck, Austria*
Email: vanessa.stadlbauer@medunigraz.at

Background and Aims: The model for end-stage liver disease (MELD) is the best validated mortality predicting tool for patients undergoing transjugular intrahepatic portosystemic shunt (TIPS). However, with creatinine being one of three parameters, MELD may have limited validity in patients with renal insufficiency, inter alia, because renal function improves after TIPS. We aimed to develop a modified TIPS score (MOTS), based on MELD, but easier to calculate and of higher accuracy in patients with renal insufficiency.
Method: We retrospectively analyzed 113 cases of TIPS-placement at the University Hospital Graz. Creatinine was one of 11 parameters associated with 90-day mortality in univariate analysis. In multivariate analysis, only urea and INR were significant independent predictors. Thus, a score integrating urea, INR and bilirubin was developed. Cut-off-values were defined using Youden-Index of ROC coordinates. MOTS ranged from 0 to 3 points: INR >1.6, urea >70 mg/dl and bilirubin >2.2 mg/dl imply plus one point each. Additionally, inspired by the MELD score, a LogMOTS score was developed using continuous variables, to see whether it outlined the simple MOTS. Prognostic capability of the scoring models was assessed using Area Under Receiver Operating Characteristic (AUROC) statistics. The

scores were validated in an external cohort from the University Hospital Innsbruck (n = 188).
Results: In the total training cohort as well as the validation cohort, all three models significantly predicted 90-day mortality. AUROC values were MELD: 0.84 (95% CI:0.74–0.96), MOTS: 0.85 (0.74–0.96), LogMOTS: 0.79 (0.65–0.93) in the training cohort and MELD: 0.77 (0.62–0.93), MOTS: 0.80 (0.67–0.94), LogMOTS: 0.87 (0.79–0.96) in the validation cohort. 37 patients in our training cohort and 61 in the validation cohort had renal insufficiency defined as Estimated Glomerular Filtration Rate (eGFR) <60. In the training cohort, all three scores predicted 90-day mortality in patients with eGFR <60, whereas MOTS had the highest AUROC value. In the validation cohort, MOTS was the only model significantly predicting 90-day mortality in patients with eGFR <60 (Fig. 1).

Figure 1: 90-day mortality in TIPS patients with baseline GFR <60
statistical significance: [1]p= <0.05, [2]p= <0.01, [0] not significant

AUROC 90-day mortality	Training cohort (a)	Validation cohort (b)
MELD	0.77[1] (95%CI 0.57-0.97)	0.76[0] (95%CI 0.46-1.00)
MOTS	**0.85**[2] (95%CI 0.68-1.00)	**0.81**[1] (95%CI 0.64-0.98)
LogMOTS	0.83[2] (95%CI 0.62-1.00)	0.76[0] (95%CI 0.56-0.97)



Conclusion: With the simple MOTS, we developed a valuable tool to predict post-TIPS mortality, with higher accuracy than MELD in patients with eGFR <60. A continuous score with the same parameters had no beneficial prognostic value. To optimize future patient selection, prospective validation of MOTS is crucial.

SAT168

Differential activation of humoral compensatory mechanisms in distinct stages of portal hypertension

Lukas Hartl[1,2], Mathias Jachs[1,2], Christopher Desbalmes[1,2], Dunja Schaufler[1,2], Ernst Eigenbauer[3], Rodrig Marculescu[4], Thomas Szekeres[4], Rafael Paternostro[1,2], Philipp Schwabl[1,2], Theresa Bucsics[1,2], David JM Bauer[1,2], Benedikt Simbrunner[1,2], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2].

Email: thomas.reiberger@meduniwien.ac.at

Background and Aims: The arginine-vasopressin (AVP), brain-type natriuretic peptide (BNP), and renin/aldosterone systems represent critical regulators of hemodynamic homeostasis.
Method: We assessed plasma levels of copeptin (AVP biomarker), proBNP and renin/aldosterone in patients with advanced chronic liver disease (ACLD) stratified by portal hypertension (PH) severity, i. e. hepatic venous pressure gradient (HVPG) of 6–9 mmHg (n = 149, 19.1%), 10–15 mmHg (n = 211; 27.1%), and ≥16 mmHg (n = 419, 53.8%).

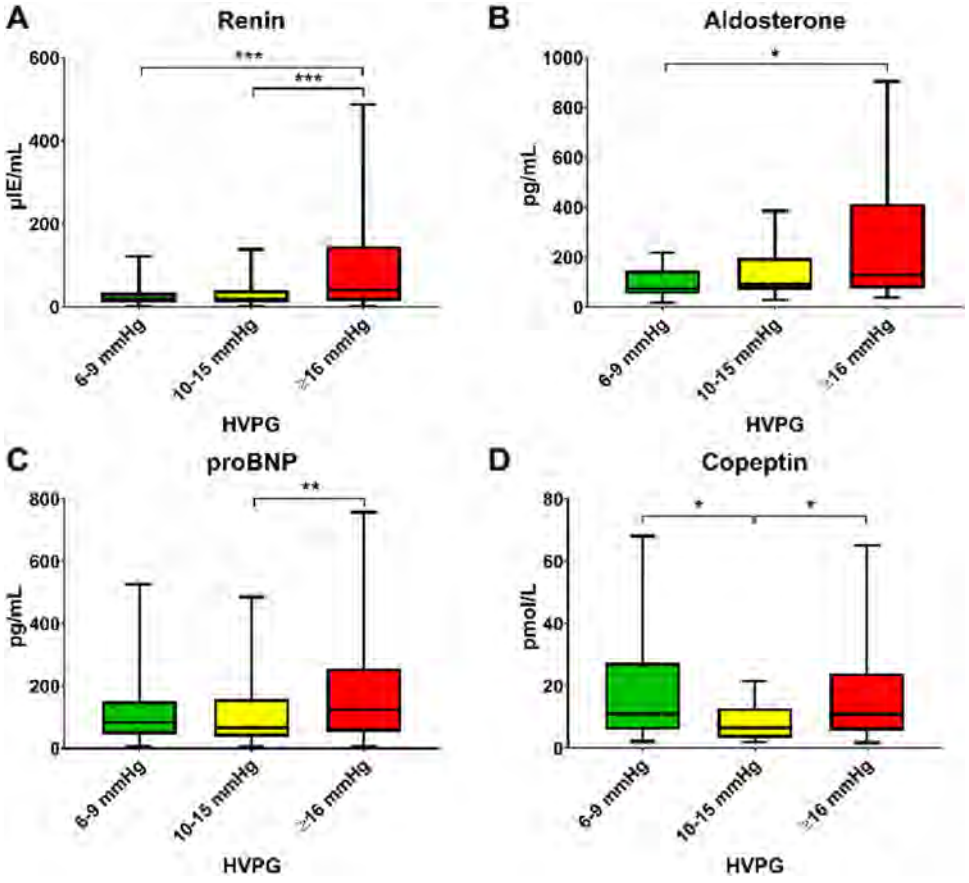

Figure: (abstract: SAT168)

Results: A total of 779 patients (age: median 56.9 years; Child-A: 58.3%, B: 29.7% and C: 12.0%) without intake of non-selective beta-blockers were included. With increasing severity of PH, higher heart rate ($p < 0.001$) as well as lower mean arterial pressure (MAP) ($p = 0.031$) and serum sodium ($p < 0.001$) indicated a hyperdynamic state. Hepatic dysfunction impacted on proBNP (Child-A: median 69.2 [IQR 88.3] vs. B: 149.7 [263.7] vs. C: 235.6 [424.0] pg/mL; $p < 0.001$), renin (Child-A: 15.6 [20.1] vs. B: 24.9 [173.2] vs. C: 136.5 [224.9] µIE/mL; $p < 0.001$) and aldosterone (A: 85.0 [84.0] vs. B: 167.0 [260.0] vs. C: 445.0 [867.7] pg/mL; $p = 0.004$).
When stratifying patients by HVPG (6–9, 10–15 and ≥16 mmHg), proBNP levels increased with PH severity (84.5 [106.6] vs. 65.9 [120.6] vs. 124.3 [203.5] pg/mL; $p = 0.004$). Moreover, both renin (18.0 [24.1] vs. 20.0 [30.4] vs. 39.9 [132] µIE/mL; $p < 0.001$) and aldosterone (74.0 [93.8] vs. 91.0 [126.0] vs. 127.5 [338.0] pg/mL; $p = 0.027$) gradually increased with HVPG.
AVP biomarker copeptin increased from Child-A: 7.2 [7.0], to B: 13.3 [21.1] and to C: 20.1 [44.3] pmol/L ($p < 0.001$), but showed no clear association with PH severity (HVPG 6–9: 11.0 [21.6] vs. HVPG 10–15: 6.5 [9.6] vs. HVPG ≥16 mmHg: 11.0 [18.4] pmol/L; $p = 0.012$).
Hyponatremia (<130 mmol/L) was associated with significantly increased levels of copeptin ($p < 0.001$), renin ($p < 0.001$) and aldosterone ($p = 0.003$), while proBNP ($p = 0.002$) and renin ($p < 0.001$) were significantly elevated in patients with severe hypotension (MAP <82 mmHg).
Conclusion: Severity of PH impacts on humoral compensatory pathways of systemic hemodynamic homeostasis as evident by proBNP secretion and renin/aldosterone activation, while the AVP axis is mainly influenced by hepatic dysfunction. In ACLD patients, arterial hypotension is linked to renin and proBNP release, whereas hyponatremia is linked to compensatory AVP and renin/aldosterone activation.

SAT169

Prospective study of magnetic resonance spectroscopy identifies specific metabolic changes in covert hepatic encephalopathy

Nway Tun[1], Joga Chaganti[2], Georgia Zeng[1], Ian Lockart[1,3], Sara Montagnese[4], Bruce Brew[1,5], Mark Danta[1,3]. *[1]UNSW Sydney, St Vincent's Clinical School, Faculty of Medicine, Sydney, Australia; [2]St Vincent's Hospital Sydney, Medical Imaging, Darlinghurst, Australia; [3]St Vincent's Hospital Sydney, Gastroenterology and Hepatology, Darlinghurst, Australia; [4]University of Padua, Department of Medicine DIMED, Padova, Italy; [5]St Vincent's Hospital Sydney, Neurology, Darlinghurst, Australia*
Email: m.danta@unsw.edu.au

Background and Aims: Hepatic encephalopathy (HE) is a complex and significant neuropsychiatric complication of liver disease. An objective imaging technique would be valuable in the diagnosis, assessment and monitoring of HE. Recent meta-analysis data of Magnetic Resonance Spectroscopy (MRS) in HE suggests brain metabolite changes, particularly in the parietal region, could provide such a technique. This study aimed to prospectively describe the parietal MRS metabolite changes in cirrhotic patients with and without covert HE.
Method: This was a single-centre prospective cohort study initiated in 2018. Covert HE was defined using neuropsychological assessment: psychometric hepatic encephalopathy score (PHES) and continuous reaction time (CRT). The participants were stratified into three groups; cirrhosis with covert HE (CHE) (PHES<–4 +/– CRT-index<1.9); cirrhosis without HE (NHE) (PHES ≥-4 +/– CRT-index>1.9); and healthy controls (HC). Participants underwent: single voxel MRS was performed in the parietal region on Philip 3.0T MRI scanner and metabolite parameters were obtained using LC-model software (v5.3-1M); electroencephalography (EEG); assessment of liver function; serum ammonia, metabolomic and cytokine ananlysis; and chronic liver disease questionnaire (CLDQ). Statistical analysis was performed using IBM SPSS (v25).
Results: A total of 35 patients (mean age 62 years; male 71%) were recruited: CHE (n = 14); NHE (n = 12); and HC (n = 9). The parietal glutamine/creatine (Gln/Cr) ratio was significantly higher in both MHE 1.19 vs HC 0.28 ($p < 0.001$); and NHE 0.49 vs HC 0.28 ($p = 0.02$). PHES scores were found to be negatively correlated with glutamine/creatine (Gln/Cr) ($r = –0.6$, $p < 0.001$) (see Figure 1) and positively correlated with myoinositol/creatine (Ins/Cr) ($r = 0.6$, $p < 0.001$) and choline/creatine (Cho/Cr) ($r = 0.47$, $p = 0.004$). NHE was also associated with a similar attenuated pattern of metabolite change. This MRS metabolite pattern was associated with higher MELD scores, higher ammonia levels and lower CLDQ scores.

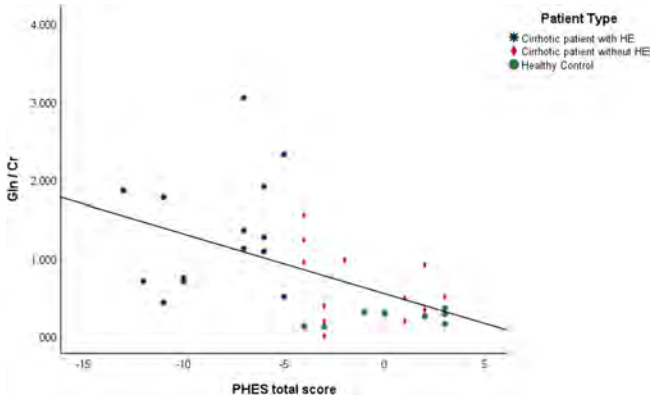

Figure: Correlation of PHES with glutamine/creatine (Gln/Cr).

Conclusion: MRS identified a specific parietal region metabolite signature with increased glutamine, reduced myo-inositol and choline, which correlated with the severity of HE. Significantly, NHE also had these identifiable changes. This MRS signature could provide an objective tool in the assessment and management of HE.

SAT170

Bacterial infections correlate with poor prognosis in cirrhosis independently from liver disease severity

Maria Corina Plaz Torres[1,2], Serena Russo[3], Davide Roccarina[2], Emmanuel Wey[4,5], Emmanuel Tsochatzis[2]. *[1]University of Genoa, Gastroenterology Unit, Department of Internal Medicine, Genova, Italy; [2]Royal Free Hospital, UCL Institute for Liver and Digestive Health and Sheila Sherlock Liver Unit, London, United Kingdom; [3]Università degli Studi di Roma Tor Vergata, Facoltà di Medicina e Chirurgia, Roma, Italy; [4]Royal Free London NHS Foundation Trust, Department of Microbiology, London, United Kingdom; [5]University College London, Centre for Clinical Microbiology, London, United Kingdom*
Email: e.tsochatzis@ucl.ac.uk

Background and Aims: Patients with cirrhosis are at increased risk of bacterial infections, which are among the most common reasons for decompensation, hospitalization and death. In recent years, evidence is growing on the dismal prognosis following an episode of infection in such patients. However, most of the studies have a retrospective design and include heterogeneous cohorts of patients. The aim of this study was to assess the prognostic significance of infections on long-term survival in a prospective cohort of patients with cirrhosis requiring hospitalization.
Method: We prospectively included consecutive cirrhotic patients admitted for at least 48 hours to a tertiary referral center over a 31 months period. Patients with hepatocellular carcinoma outside Milan criteria, extra-hepatic conditions with limited life expectancy, HIV infection, myeloproliferative diseases or previous organ transplantation were excluded. Infections were diagnosed on the base of positive cultures or strict clinical criteria. We used Cox-regression analysis for the identification of the most important predictors of long-term outcome.

Results: 254 patients (66% male, 56% alcoholic cirrhosis, mean Model for End-Stage Liver Disease (MELD) score = 15) underwent 392 admissions over the study period. Manifest hepatic decompensation (35.4%) (hepatic encephalopathy (12.4%), jaundice (5.8%) or ascites (17.2%)) and variceal bleeding (19%) were the main reasons for admission, followed by infections (18.5%). Considering the number of admissions, the prevalence of bacterial infections was 50.3% (52.3% community-acquired, 11.2% health-care associated, 36.5% nosocomial). Urinary tract infections were the most frequent infections (25.4%), followed by spontaneous bacterial peritonitis (22.3%), pneumonia (17.3%), sepsis (16.7%) and soft tissue and skin infections (7.6%). Overall, survival was independently associated with MELD score (hazard ratio (HR) 1.05; 95% confidence interval (CI) 1.02–1.08; p = 0.001) and bacterial infection (HR 1.63; 95%CI 1.02–2.59; p = 0.039). When excluding early deaths (30 days), patients with infections still showed a lower survival (p = 0.048) and a tendency to a higher mortality risk (HR 1.53; 95%CI 0.94–2.51, p = 0.086). MELD score remained significantly and independently associated with survival (HR 1.04; 95%CI 1.00–1.07, p = 0.02). Bacterial infection remained an independent predictor of poorer outcome across all stages of liver disease and mortality risk in patients with MELD score<15 and infection was comparable to that of patients with MELD score equal or higher than 15 who did not have infections.

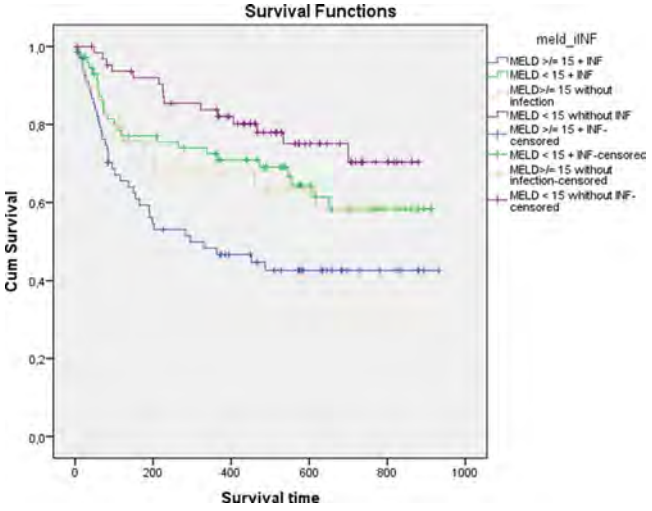

Figure: Kaplan Meier survival curves according to MELD score and the presence of infection (p = 0.001).

Conclusion: Bacterial infections represent a risk factor for increased long-term mortality in patients with cirrhosis independently from the stage of liver disease.

SAT171

Long-term albumin administration is not futile in patients with cirrhosis and uncomplicated ascites not normalizing serum albumin concentration with treatment

Email: paolo.caraceni@unibo.it

Background and Aims: The benefits of long-term human albumin (HA) administration to patients with cirrhosis and ascites seen in the ANSWER trial[1] were associated to a significant increase of serum albumin concentration (SA). A subsequent post-hoc analysis[2] showed that survival probability increases in parallel with the on-treatment SA at month 1 and optimal results follow the attainment of normal SA.

This study aimed to determine whether patients randomized to the standard medical treatment plus HA arm (SMT + HA) in the ANSWER trial who failed to normalize on-treatment SA (≥3.5 g/dl) at month 1 have any advantage as compared to those receiving SMT alone.

Method: Patients not normalizing on-treatment SA at month 1 were matched with those enrolled in the SMT arm alive at 1 month by using a propensity score technique. The baseline variables independently associated to mortality according to a multivariable logistic regression (SA, MELD and Child-Pugh scores) were used to match the two groups. Survival analysis was performed with Kaplan-Meier method and Cox regression. The incidence rates of complications were computed by the exact method based on the Poisson distribution.

Results: In SMT+HA arm, 40 patients (21%) failed to reach the lower normal limit of SA at month 1, and were compared with 40 patients receiving SMT alone selected by the propensity score. Ten patients died in SMT+HA and 17 in the SMT arm, so that the 40 patients who received HA had a significantly higher 18-month overall survival (K-M estimates: 61.3% SMT + HA vs 36.7% SMT; p = 0.0315), corresponding to a 57% reduction in mortality HR (0.43 [95%CI 0.19–0.95], p = 0.036). These patients also showed a significant reduction in the incidence rate ratio of paracentesis (0.62 [95%CI 0.47–0.82], p < 0.001) and some complications of cirrhosis, namely spontaneous bacterial peritonitis (0.33 [95%CI 0.14–0.64], p < 0.001), hepatic encephalopathy grade III/IV (0.41 [95%CI 0.22–0.73], p = 0.001), and hyponatremia (0.43 [95%CI 0.25–0.72], p < 0.001).

Conclusion: Patients who failed to normalize SA during long-term HA administration had a clear benefit in terms of survival and occurrence of complications as compared to those only receiving SMT. Thus, HA treatment cannot be considered futile in this patient subset. Rather, this observation suggests that an increase in the HA dosage can be considered in order to reach on-treatment SA associated with better outcomes.

Subtle changes of serum creatinine and C-reactive protein during the index hospitalization predict early readmission in patients with decompensated cirrhosis

Manuel Tufoni[1], Giacomo Zaccherini[1], Michele Bartoletti[1], Maurizio Baldassarre[2], Agnese Antognoli[1], Simona Leoni[3], Sonia Berardi[3], Mariarosa Tamé[4], Lorenzo Marconi[1], Elisa Basigli[1], Giulia Iannone[1], Dario Pratelli[1], Marco Domenicali[1], Pierluigi Viale[1], Franco Trevisani[1], Paolo Caraceni[1,2]. Email: manuel.tufoni2@unibo.it

Background and Aims: Patients with decompensated cirrhosis had a high risk of early re-hospitalization, thus carrying a heavy socio-economic burden. The present study aims at identifying new predictive factors and the prognostic impact of readmission within 30 days (early readmission) after discharge from an index hospitalization for acute decompensation (AD).
Method: Three hundred twenty-nine patients discharged after hospitalization due to AD were included in this prospective observational study. Laboratory and clinical data at admission, during hospital stay and at discharge of the index hospitalization were collected. Readmissions and its causes and mortality were recorded up to 1 year.
Results: Cumulative incidence of readmission was 18% at 30 days (early readmission), 39% at 90 days and 63% at 1 year. Early readmission was associated with a higher 1-year mortality (54% vs 33%, p = 0.001). The most frequent causes of early readmission were bacterial infection (21%), hepatic encephalopathy (19%) and ascites (19%). Data collected both at admission (Child-Pugh score, MELD-Na score, diabetes), during hospital stay (development of acute-on-chronic liver failure) and at discharge (MELD-Na score, platelet count, days spent in hospital) were significantly associated with early readmission.
We then investigated if subtle changes of routine laboratory parameters assessing liver and renal function and inflammatory response between admission and discharge were associated with early readmission. Multivariable competing risk regression analysis showed that increases as small as 0.2 mg/dl of serum creatinine and C-reactive protein (CRP) were associated with an increased hazard ratio (HR) of early readmission (serum creatinine: HR = 1.9 [95%CI 1.1–3.2], p = 0.034; CRP: HR = 1.8 [95%CI 1.1–3.2], p = 0.031). Such increase in serum creatinine was also associated with a higher 1-year probability of death (59% vs 31%, p < 0.001).
Conclusion: Almost one patient out of five is readmitted within 30 days after a hospitalization due to AD of cirrhosis. Besides already established parameters related to the severity of disease, even subtle increases in serum creatinine and CRP (0.2 mg/dl) between admission and discharge emerged as new risk factors for early readmission and worse prognosis, thus identifying patients who need for closer surveillance after discharge.

SAT173

Value of Hitachi shear wave elastography (SWE) for exclusion of esophageal varices in patients with compensated advanced liver disease

Marcel Razpotnik[1], Simona Bota[1], Christian Urak[1], Florian Hucke[1], Markus Peck-Radosavljevic[1]. [1]*Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology and Emergency Medicine (ZAE) with Centralized Endoscopy Service, Klagenfurt am Wörthersee, Austria*
Email: marcel.razpotnik@gmail.com

Background and Aims: Liver stiffness (LS) assessed by Transient Elastography (TE) in combination with platelet count was introduced in the Baveno VI consensus in order to guide the need for gastroscopy for esophageal varices screening in patients with compensated advanced liver disease (cALD). According to the Baveno VI consensus, screening gastroscopy is not necessary if LS <20 kPa and platelet count is >150000 cell/mm^3. However, TE has a rate of failed measurements of approx. 10% and cut-off values obtained with M and XL probe vary substantially.
Method: Liver stiffness (LS) was measured with Hitachi SWE (Arietta V70) and Transient Elastography (TE) (FibroScan®, Echosens, France). According to Ferraoli et al (J Gastrointestin Liver Dis 2017; 2: 139–143) a SWE LS cut-off value >9.15 kPa rule-in the presence of liver cirrhosis, while a cut-off value <8.4 kPa rule-out the cirrhosis. Reliable LS measurements with both methods were defined as median value of ten valid measurements with an IQR/Med <30% and expressed in kilopascals (kPa). Recent gastroscopy (not older than six months) had been conducted in all patients. The performance of the Baveno VI criteria and the performance of LS, assessed by Hitachi SWE in combination with platelet count, for ruling out esophageal varices were analyzed.
Results: Our cohort included 91 patients with cALD with a mean age of 58.7 ± 12.5 year, 67% men. 54.9% had an alcoholic etiology. Esophageal varices were diagnosed in 46.1% of the patients. The rate of reliable measurements was 98.9% for Hitachi SWE and 93.4% for TE. None of the patients with esophageal varices had LS assessed by TE <20 kPa and platelet count >150000 count/mm^3, showing a very good performance of the Baveno VI criteria. LS assessed by Hitachi SWE was significantly higher in the cohort of cALD patients with esophageal varices as compared with those without varices: 14.1 ± 4.3 kPa vs. 11.3 ± 3.8 kPa, p = 0.001. A combination of LS as assessed by Hitachi SWE (values <10.6 kPa) and platelet count >150000/mm^3, could non-invasively successfully rule-out the presence of esophageal varices in 90/91 patients (98.9%).
Conclusion: LS assessed by Hitachi SWE in combination with platelet count seems to be a good method to rule-out the presence of the esophageal varices in patients with cALD.

SAT174

Factors associated with the presence of cirrhotic cardiomyopathy defined according to the new multidisciplinary diagnostic criteria

Marcel Razpotnik[1], Simona Bota[1], Philipp Wimmer[2], Michael Hackl[2], Gerald Lesnik[3], Hannes Alber[2], Markus Peck-Radosavljevic[1]. [1]*Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Gastroenterology (IMuG), Hepatology, Endocrinology, Rheumatology and Nephrology and Emergency Medicine (ZAE) with Centralized Endoscopy Service, Klagenfurt am Wörthersee, Austria;* [2]*Klinikum Klagenfurt am Wörthersee, Department of Internal Medicine and Cardiology (IMuK), Klagenfurt, Austria;* [3]*Klinikum Klagenfurt am Wörthersee, Institut for diagnostic and interventional Radiology, Klagenfurt am Wörthersee, Austria*
Email: marcel.razpotnik@gmail.com

Background and Aims: The prevalence and associated factors of cardiomyopathy in cirrhotics remain unknown. Recently published new criteria of cirrhotic cardiomyopathy from a multidisciplinary consortium (Izzy et al. Hepatology 2019 Nov 11. doi: 10.1002/hep.31034) define systolic dysfunction of the left ventricle as ejection fraction (EF) ≤50% and/or global longitudinal strain (GLS) <−18 or > −22%, while the diastolic dysfunction is diagnosed when three of the following conditions are present: average E/e' >14, peak tricuspid regurgitation velocity >2.8 m/s, septal e'<7 cm/s, left atrial volume index >34 ml/m^2.
Our aim was to assess the factors associated with the presence of cirrhotic cardiomyopathy defined according the new diagnostic criteria.
Method: Consecutive patients with liver cirrhosis without structural heart disease, HCC outside Milan criteria, presence of TIPS and with

optimal acoustic echocardiography window were included. Conventional and speckle-tracking echocardiography (Vendor GE, EchoPAC PC software) were performed by a single investigator (EACVI TTE certified). Liver stiffness (LS) was assessed by transient elastography (TE, Fibroscan®, Echosens) and share wave elastography (SWE; Hitachi Arietta V70). Reliable results were defined as median value of 10 valid measurements with an IQR/Med <30% and expressed in kPa. Control attenuation parameter (CAP) assessed by TE was used to quantify liver steatosis.

Results: 100 patients were evaluated, but 10 did not fulfilled the inclusion criteria. The final analysis included.

90 patients, with mean age of 56.6 ± 11.1 years (67.7% males), 70% with alcoholic etiology and 57.8% with compensated cirrhosis. LS could be evaluated in 83.3% of cases by TE and in 97.7% of patients by Hitachi SWE. According to the new criteria cirrhotic cardiomyopathy was diagnosed in 55/90 (61.1%) of patients: systolic dysfunction in 57.7% (reduced EF <50% in 3.3%) and diastolic dysfunction in 6.7% of cases.

The presence of systolic dysfunction with reduced contractility (EF≤50% and/or GLS<−18%) seems to correlate with LS as assessed by Hitachi SWE and liver steatosis (Figure).

Conclusion: According to the new criteria >60% of the cirrhotic patients were diagnosed with cirrhotic cardiomyopathy. LS assessed by Hitachi SWE and liver steatosis seems to correlate with reduced systolic contractility.

SAT175

Prevalence of cirrhotic cardiomyopathy according to the old and new diagnostic criteria

	Old criteria	New criteria	Both old and new criteria	p value (old vs new criteria)
Systolic dysfunction	n=14 (15.5%)	n=52 (57.7%)	n=7 (7.7%)	<0.0001
Diastolic dysfunction	n=45 (50%)	n=6 (6.6%)	n=5 (5.5%)	<0.0001

Figure: (abstract: SAT175)

diastolic dysfunction is diagnosed when three of following conditions are present: average E/e'>14, peak tricuspid regurgitation velocity>2.8 m/s, septal e < 7cm/s, left atrial volume index >34 ml/m^2. According to the old criteria (first presented in 2005 during the World Congress of Gastroenterology) systolic dysfunction was defined as presence of EF<55% and/or blunted response on stress testing, while diastolic dysfunction was diagnosed when at least one of the following conditions was present: E/A < 1, isovolumetric relaxation time >80 ms and deceleration time >200 ms. Response to myocardial stress testing was not used in clinical practice because of widespread use of beta-blockers and reduced general condition of many patients. Our aim was to assess the prevalence of cirrhotic cardiomyopathy according to the old and new diagnostic criteria.

Method: Consecutive patients with liver cirrhosis without structural heart disease, HCC outside Milan criteria, presence of TIPS and with optimal acoustic echocardiography window were included. Conventional and speckle-tracking echocardiography (Vendor GE, EchoPAC PC software) were performed by a single investigator (EACVI TTE certified).

Results: We evaluated 100 patients, but 10 did not fulfilled the inclusion criteria. The final analysis included 90 patients with a mean age of 56.6 ± 11.1 years (67.7% males), 70% with alcoholic etiology, and 57.8% with compensated cirrhosis. According to the old criteria (without stress testing) cirrhotic cardiomyopathy was diagnosed in 55.5% of patients: systolic-15.5%;diastolic-50% of cases. According to the new criteria cirrhotic cardiomyopathy was diagnosed in 61.1% of patients: systolic dysfunction- 57.7%;diastolic dysfunction-6.6% (Figure). EF ≤50% was present in 3.3%, GLS <−18% in 13.3% and GLS >−22% in 43.3% of patients.

Conclusion: Prevalence of diastolic dysfunction is significantly lower according to the new criteria, while the prevalence of systolic dysfunction was higher. Further follow-up of patients with increased contractility and GLS>-22% is needed (pathological value only in cirrhotic patients).

SAT176

Diagnostic and prognostic role of presepsin in patients with cirrhosis and bacterial infection

Alberto Ferrarese[1], Anna Chiara Frigo[2], Francesco Paolo Russo[1], Giacomo Germani[1], Martina Gambato[1], Monica Mion[3], Mario Plebani[3], Umberto Cillo[4], Patrizia Burra[1], Marco Senzolo[1].
[1]Padua University Hospital, Multivisceral Transplant Unit, Padua, Italy; [2]Padua University Hospital, Cardiac-Thoracic-Vascular Sciences and Public Health, Padua, Italy; [3]Padua University Hospital, Department of Laboratory Medicine; [4]Padua University Hospital, Hepatobiliary Surgery and Liver Transplant Centre
Email: marcosenzolo@hotmail.com

Background and Aims: Diagnosis of bacterial infection (BI) in cirrhosis is often difficult due to the low accuracy of the available biomarkers, which poorly correlate with prognosis. Presepsin (PSP), a 13 kDa molecule produced by monocytes phagocytic activity, has been recently introduced as a potential biomarker for early diagnosis of BI. The study aimed to prospectively evaluate PSP levels in cirrhotics with and without BI, its accuracy for the early diagnosis of BI in comparison with other commonly used biomarkers (C-reactive protein (CRP), procalcitonin) and its prognostic role in terms of 28-d mortality.

Method: All adults with cirrhosis admitted at Multivisceral Transplant Unit - Padua University Hospital between 03.2016-06.2019 were consecutively evaluated. For each patient, demographic features, clinical condition and occurrence of BI at hospitalization were evaluated. PSP was measured by Pathfast technique (Chemiluminescent enzyme immune-assay); its accuracy for the early diagnosis of BI was tested creating a ROC curve and comparing it with that of CRP and procalcitonin. Patients' outcome was assessed using competing risk analysis, and a multivariable analysis was performed to evaluate predictors of 28-d mortality.

Results: 278 cirrhotic patients (M/F 179/99, mean age 56 ± 11 years) for a total of 448 hospitalizations were evaluated. Mean ± SD PSP value in the whole cohort was 1620 ± 3014 pg/mL, with a correlation with severity of liver disease according to Child-Pugh score. PSP value was significantly higher in patients with BI (28.3%) than in patients without (2486 ± 4068 vs. 1277 ± 2399 pg/mL; p = 0.001). Sensitivity and specificity of PSP for diagnosis of BI was 0.66 (95%CI 0.57–0.74) and 0.63 (95%CI 0.57–0.68), respectively. The accuracy of PSP in diagnosing BI was lower than CRP (AUC-ROC 0.68 vs. 0.77; p = 0.002) but similar to procalcitonin (p = ns). Considering the whole cohort, age, ACLF, PSP (HR 2.37; 95%CI 1.29–4.34), but not CRP nor BI, were independent predictors of 28-d mortality.

Conclusion: PSP showed a suboptimal accuracy for the early diagnosis of BI in hospitalized cirrhotic patients but it was an independent predictor of short-term mortality, likely reflecting the importance of pro-inflammatory state as prognostic marker in cirrhosis.

SAT177

Reduced efficacy of norfloxacin prophylaxis to prevent spontaneous bacterial peritonitis over time: a systematic review and meta-analysis

Marcus Mücke[1], Victoria Therese Mücke[1], Christiana Graf[1], Katharina Maria Schwarzkopf[1], Philip Ferstl[1], Javier Fernandez[2], Stefan Zeuzem[1], Jonel Trebicka[1], Christian Lange[3], Eva Herrmann[1].
[1]University Hospital Frankfurt, Frankfurt am Main, Germany; [2]Hospital Clinic Barcelona, Barcelona, Spain; [3]University Hospital Essen, Essen, Germany
Email: marcus.m.muecke@gmail.com

Background and Aims: Due to an increasing prevalence of multi-drug-resistant organisms (MDRO) in patients with liver cirrhosis, the efficacy of antibiotic prophylaxis to prevent spontaneous bacterial peritonitis (SBP) has been debated. Aim of this study was to assess changes in effectiveness of SBP prophylaxis over time.

Method: We searched PubMed, Embase and the Cochrane Central Register of Controlled Trials from database inception to May 2019 to identify randomized controlled trials of patients with liver cirrhosis that assessed SBP occurrence/recurrence during antibiotic prophylaxis with the common antibiotic agents. Network meta-analysis was performed pooling data with regard to incidence rate ratios (IRRs) of SBP, death or extra-peritoneal infections.

Results: Overall, 1626 patients in 12 RCTs were included. During primary prophylaxis, incidence rate of SBP and death in the norfloxacin treated patients was 0.117 and 0.438 per patient year, respectively, and IRRs of placebo vs. norfloxacin were significantly higher (IRR 5.35, 95% CI 1.99–14.38, p = 0.0009 for SBP and IRR 2.04, 95% CI 1.20–3.44, p = 0.008 for death). However, we observed a noticeably reduced efficacy of norfloxacin to prevent SBP over time

(p = 0.019). The reduction of efficacy was even more pronounced when analysing IRR of SBP for all quinolones (class-effect, p = 0.017). In secondary prophylaxis, the applied models showed trends, yet no overall significant differences between treatment designs due to the limited number of available studies.

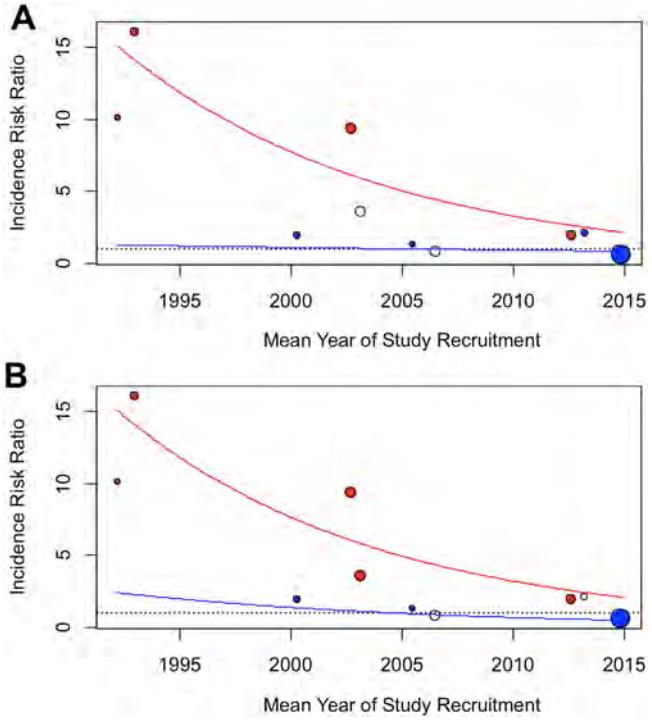

Figure: Meta-Regression plot of incidence rate ratios (IRRs) for spontaneous bacterial peritonitis. Panel A shows the results for norfloxacin, Panel B for fluoroquinolones in general. Red lines show the trend in decreasing IRRs for placebo vs. norfloxacin from direct and indirect comparisons and the blue line show the missing trend in other active treatments vs. norfloxacin from direct and indirect comparisons in a network meta regression model.

Conclusion: We observed a noticeably reduced efficacy of norfloxacin/quinolone for primary prophylaxis over time. Further studies to understand this phenomenon, e.g. the impact of colonization/infection with MDROs on prophylaxis, are urgently needed.

SAT178

Risk assessment of clinically significant portal hypertension by means of hepatosplenic volumetry in compensated cirrhosis

Mario Romero Cristóbal[1], Ana Clemente[1], Enrique Ramon Botella[2], Olga Ortega[1], Elena Velilla[1], Ana M Matilla[1,3], Laura Marquez[1], Maria Magdalena Salcedo[1,3,4], Sonia Alonso[1], Maria Vega Catalina[1], Ainhoa Fernandez[1], Fernando Diaz Fontela[1], Luis Ibañez[1], Diego Rincón[1,3], Rafael Bañares[1,3,4]. *[1]Hospital Gregorio Marañón, Hepatology, Madrid, Spain; [2]Hospital Gregorio Marañon, Radiology, Madrid, Spain; [3]Ciberehd; [4]Universidad Complutense, Madrid*
Email: rbanares@ucm.es

Background and Aims: The presence of clinically significant portal hypertension (CSPH) defines the natural history of compensated cirrhosis (CC) and determines the treatment of patients with hepatocellular carcinoma (HCC). A recent study describes how different hepatic venous pressure gradient (HVPG) thresholds are associated with a progressive surgical risk. On the other hand, it has been suggested that visceral volumetry by computed tomography (CT) could estimate the degree of portal hypertension. **Aims:** 1) to compare the accuracy of CT-volumetry to predict CSPH with other non invasive methods (NIM): liver stiffness, platelets count, PSR (platelet-spleen ratio) and LSPS (liver stiffness to spleen/platelet score), 2) to evaluate the accuracy of CT-volumetry to predict CSPH in compensated patients with HCC.
Method: we included 223 patients with CC, CT and recent HVPG. The total liver volume (LV), the left to right volume ratio (LL/RL) and the spleen volume (SV) were calculated with Philips Intellispace® software. We used logistic regression techniques to build the predictive models and to assess de risk.
Results: 81.2% of the cases were men, 80.7% had HCC and in 70.1% the aetiology was viral (87.3% hepatitis C). The mean HVPG was 10.8 (5.1) mmHg and 52.7% presented HPCS. The mean liver stiffness was 20.1 (13.8) Kpa. The median time between CT and catheterization and elastography was 1.0 (IQR 0.5–2.2) and 1.1 (IQR 0.5–4.0) months, respectively. Both LL/RL and SV were independently related to CSPH (OR 7.1, p = 0.018 and OR 1.1, p = 0.000). The different AUCs to predict CSPH were 0.77 (95%CI 0.71–0.82) for LV, 0.71 (95%CI 0.64–0.77) for LL/RL and 0.81 (95%CI 0.75–0.86) for the multiplication LL/RLxSV. There were no differences in the AUCs to predict CSPH for LL/RLxSV and other NIM (LL/RLxSV 0.85 vs elastography 0.82, ns; LL/RLxSV 0.85 vs elastography and platelets 0.88, ns; LL/RLxSV 0.81 vs PSR 0.81, ns; and LL/RLxSV 0.85 vs LSPS 0.89, ns). In the subgroup of patients with HCC (n = 172), the AUC for LL/RLxSV reached 0.83 (95%CI 0.77–089). If we combine the cut-off points LL/RLxSV <79 cc (S 97.7%, E 31.4%) to discard CSPH and >359 cc (S 36.1%, E 97.7%) to confirm HPCS, up to 36.0% of the sample cases could be classified (2.3% false negatives and false positives).
Conclusion: CT-volumetry is a useful and accessible tool to predict CSPH, with a similar accuracy to other NIM. In compensated patients with HCC, a single CT scan would confirmed the diagnosis of HCC, determine the tumour stage and assess the risk of CSPH to select the patients that require catheterization.

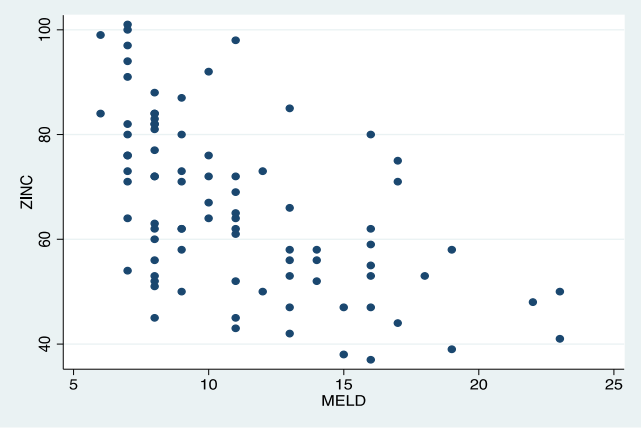
SAT179

Zinc deficiency in cirrhosis predicts hepatic decompensation and mortality

Marta Hernández Conde[1], Elba Llop[1], Beatriz Tormo[1], Christie Perelló[1], Marta López-Gómez[1], Javier Abad Guerra[1], Luis Rodríguez[1], José Luis Martínez Porras[1], Natalia Fernández Puga[1], Maria Trapero[1], Carlos Ferre[1], Enrique Fraga[1], José Luis Calleja Panero[1]. *[1]Hospital Puerta de Hierro-Majadahonda, Majadahonda, Spain*
Email: marta.hernandez.conde@gmail.com

Background and Aims: Zinc is an important micronutrient that has been most evaluated and that has been associated with higher severity and worse prognosis in patients with liver cirrhosis.
Method: Prospective study in which all outpatients attending the cirrhosis care clinic were consecutively included. At the time of inclusion, it was performed: blood test, anthropometric measurements and bioimpedanciometry. The diagnosis of cirrhosis was based on the combination of clinical features, radiological images, presence of portal hypertension, compatible biochemical parameters and/or compatible biopsy findings. The exclusion criteria were: history of chronic respiratory or cardiovascular disease, chronic renal failure or hemodialysis, HIV coinfection, previous renal or hepatic transplantation, history of neoplasia requiring chemotherapy or radiotherapy, hepatocellular carcinoma outside of Milan criteria, intestinal resection, TIPs and lack of will to participate in the study.
Results: From 2016 through 2019, 329 patients were evaluated, of which 254 met all the inclusion criteria and none of the exclusion criteria. 56 patients (22.1%) presented zinc deficiency. In the multivariate analysis the factors that were independently associated with the presence of zinc deficiency were: alcoholic liver cirrhosis (OR 3.2, 95% CI 1.4–7.4; p = 0.007), higher Child -Pugh score (OR 1.3, 95% CI 1.1–1.5; p < 0.001) and lower phase angle (PA) by bioimpedanciometry (OR 0.3, 95% CI 0.2–0.5; p < 0.001). In our study we show a moderate correlation between zinc levels and the severity of liver disease measured by MELD score (r = –0.47; p < 0.001) (Figure). Regarding the prognostic implications, patients with zinc deficiency had a higher risk of liver decompensation (41.5 vs. 11.3%; p < 0.001),

including hepatic encephalopathy (18.9 vs. 2.6%; p < 0.001). They also presented a higher risk of mortality during follow-up (21.2 vs. 3.6%; p < 0.001).



Conclusion: Zinc deficiency is more frequent in patients with alcoholic liver cirrhosis, higher severity of liver disease and lower PA. In addition, the deficit of this micronutrient has prognostic implications, both in terms of liver decompensation and mortality. Furthermore, its correction with oral zinc supplementation is simple.

SAT180

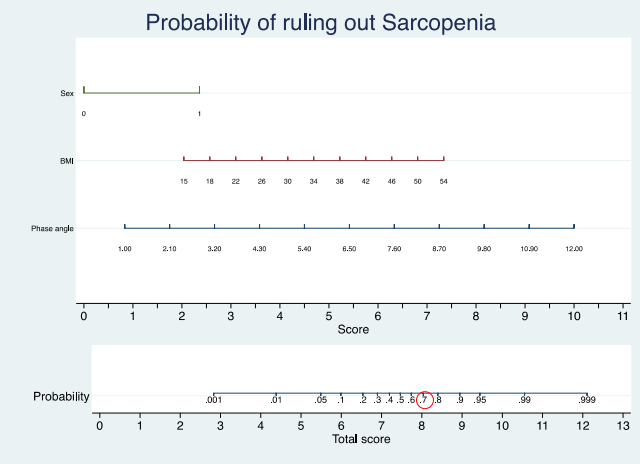
A nomogram as an indirect method to identify sarcopenia in patients with liver cirrhosis

Marta Hernández Conde[1], Elba Llop[1], Carlos Fernández-Carrillo[1], Christie Perelló[1], Marta López-Gómez[1], Javier Abad Guerra[1], Luis Rodríguez[1], José Luis Martínez Porras[1], Natalia Fernández Puga[1], Maria Trapero[1], Carlos Ferre Aracil[1], Enrique Fraga[1], José Luis Calleja Panero[1]. [1]*Hospital Puerta de Hierro-Majadahonda, Majadahonda, Spain*
Email: marta.hernandez.conde@gmail.com

Background and Aims: Sarcopenia (loss of muscle mass) in liver cirrhosis has been associated with worse prognosis. Although CT scan is the gold standard for diagnosis of sarcopenia, it is necessary to find indirect methods to identify it.

Method: We performed a prospective study in which all outpatients with liver cirrhosis and recent CT scan evaluated at the cirrhosis care clinic were consecutively included. At the time of inclusion, it was performed: blood test, anthropometric measurements and bioelectrical impedance analysis. The diagnosis of cirrhosis was based on the combination of clinical features, radiological images, presence of portal hypertension, compatible biochemical parameters and/or compatible biopsy findings. The exclusion criteria were: carrying a cardiac pacemaker or metal implants, amputated limbs, chronic renal failure or hemodialysis, HIV coinfection, previous renal or liver transplantation, a history of neoplasia requiring chemotherapy or radiotherapy, hepatocellular carcinoma outside of Milan criteria and TIPs.

Results: 174 patients met all the inclusion criteria and none of the exclusion criteria. 71 patients (40.8%) had sarcopenia on CT scan. In the multivariate analysis, the factors that were independently associated with the presence of sarcopenia on CT scan were: male sex (OR 33.6 95% CI 8.8–128.3; p < 0.001), lower body mass index (BMI) (OR 1, 2 95% CI 1.1–1.4; p < 0.001) and lower phase angle (PA) by bioelectrical impedance analysis (OR 3.5 95% CI 2.0–5.9; p < 0.001). With the variables resulting from the multivariate study, we developed a nomogram (Figure) that would allow us to rule out the presence of sarcopenia. Our model rules out sarcopenia with an area under the receiver operating characteristic curve (AUROC) value of 0.88. The cut-off point of the probability to rule out sarcopenia was 0.70 (sensitivity 76%, specificity 84% and Youden index 0.60).



Conclusion: Sarcopenia is one of the most common complications of cirrhosis, associated with an increased risk of morbidity and mortality. Therefore, it is necessary to perform a properly nutritional evaluation in these patients. But since the CT scan has radiation exposure and limited availability, we propose using this nomogram as an indirect method to rule out sarcopenia in those patients in whom there is no clinical indication for CT scan.

SAT181

Impact of beta blocker therapy on systemic inflammation stratified by hepatic venous pressure gradient response

Mathias Jachs[1,2], Lukas Hartl[1,2], Dunja Schaufler[1,2], Christopher Desbalmes[1,2], Ernst Eigenbauer[3], Thomas Szekeres[4], Rodrig Marculescu[4], Rafael Paternostro[1,2], Benedikt Simbrunner[1,2], Philipp Schwabl[1,2], Theresa Bucsics[1,2], David JM Bauer[1,2], Michael Trauner[1], Mattias Mandorfer[1,2], Thomas Reiberger[1,2]. [1]*Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Internal Medicine III, Vienna, Austria;* [2]*Medical University of Vienna, Hepatic Hemodynamic Lab, Vienna, Austria;* [3]*Medical University of Vienna, IT-Systems and Communications, Vienna, Austria;* [4]*Medical University of Vienna, Department of Laboratory Medicine, Vienna, Austria*
Email: thomas.reiberger@meduniwien.ac.at

Background and Aims: Non-selective beta-blockers (NSBB) decrease portal pressure, i.e. hepatic venous pressure gradient (HVPG) in patients with clinically significant portal hypertension. Interestingly, NSBB may also exert anti-inflammatory activity.

Method: We assessed markers of systemic inflammation (WBC, CRP, IL-6, PCT) and endothelial dysfunction (VWF) at sequential HVPG measurements, i.e. without NSBB at baseline (BL) and with NSBB at follow-up (FU). The impact of NSBB on these biomarkers was assessed by paired analyses stratified by Child-Turcotte-Pugh stage (CTP), type of NSBB, and HVPG-response (≥20% relative decrease/decrease to <12 mmHg).

Results: 332 patients were included: median age: 56 years; CTP-A = 94 (28.3%), B = 174 (52.4%), C = 64 (19.3%). Carvedilol and propranolol were used in 206 (62.0%) and 126 (38.0%) patients, respectively. HVPG-response was achieved in 111 patients (33.4%).

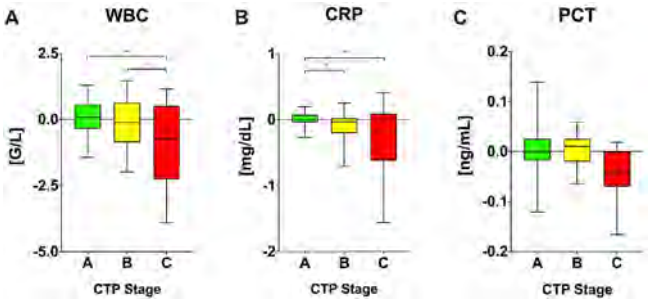
NSBB therapy was associated with a significant decrease of WBC (median: −1.8%; median 4.71 [IQR 3.12] to 4.60 [2.91] G/L; p = 0.021), and of CRP levels (−12.59%; 0.41 [0.81] to 0.33 [0.59] mg/dL; p < 0.001), while no significant effects were seen on IL-6 (10.79 [21.25] to 12.60 [14.39] pg/mL; p = 0.544) and PCT (0.12 [0.14] to 0.12 [0.10] ng/mL; p = 0.348). Moreover, VWF significantly decreased under NSBB therapy from 342 (163) to 306 (157)% (p < 0.001).

CTP-C patients showed most pronounced reductions in WBC (−14.58%; 5.74 [4.1] to 5.19 [2.74] G/L; p = 0.001), CRP (-24.88%; 1.15 [1.44] to 0.75 [1.19] mg/L; p = 0.003), and PCT levels (−16.67%; 0.20 [0.08] to 0.15 [0.07] ng/mL; p = 0.022); and their absolute changes in HVPG correlated significantly with changes in WBC (R = 0.306; p = 0.014).

Achieving an HVPG-response was associated with more significant decreases of WBC (−7.56%; 4.97 [3.2] to 4.62 [3.26] G/L vs. +0.71%; 4.45 [2.96] to 4.58 [2.84] G/L; p = 0.001) but similar decreases of CRP (−14.29%; 0.32 [1.18] to 0.28 [0.73] mg/dL vs. −12.68%; 0.42 [0.68] to 0.34 [0.46] mg/dL; p = 0.698) as compared to HVPG non-responders.

In contrast to propranolol, carvedilol led to pronounced decreases in WBC (−3.85%; 4.75 [2.96] to 4.39 [3.16] G/L vs. +2.92%; 4.67 [3.33] to 4.93 [2.76] G/L; p = 0.02), however, decreases of CRP were found with both treatments (−15.25%; 0.35 [0.69] to 0.28 [0.54] mg/dL vs. −3.45%; 0.5 [0.98] to 0.47 [0.71] mg/dL; p = 0.722).

Importantly, a NSBB-induced decrease of WBC by ≥15% was also associated with amelioration of systemic IL-6 (−24.51%; mean 23.89 ± 26.22 to 14.05 ± 11.52 pg/mL; p = 0.059) and PCT (−18.33%; 0.14 [0.13] to 0.12 [0.12] ng/mL; p = 0.017) levels.



Conclusion: NSBB therapy exerts systemic anti-inflammatory activity as suggested by decreases in WBC and CRP levels. This effect seems most pronounced in CTP-C, HVPG-responders and with carvedilol treatment. Moreover, NSBB treatment may ameliorate endothelial dysfunction.

SAT182

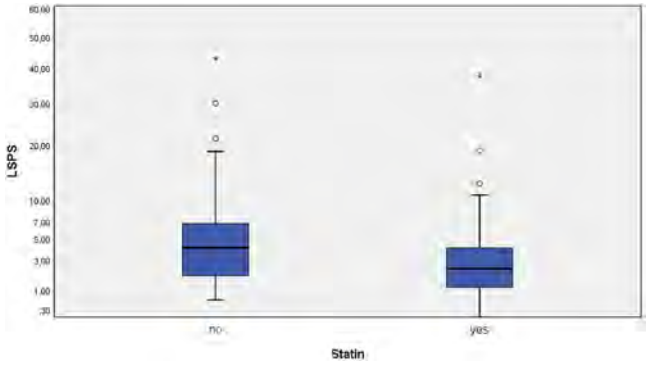
Protective effects of statin therapy in liver cirrhosis are limited by the common SLCO1B1 variant

Melissa Merkel[1], Liebe Roman[1], Christina Schneider[1], Robin Greinert[2], Alexander Zipprich[2], Cristina Ripoll[2], Frank Lammert[1], Matthias Reichert[1]. *[1]Saarland University Hospital, Department of Medicine II, Homburg, Germany; [2]Universitätsklinikum Halle (Saale), Department of Medicine I, Halle (Saale), Germany*
Email: melissa-merkel@outlook.com

Background and Aims: Complications of liver cirrhosis and portal hypertension (PH) might be reduced by statin therapy. We aimed to assess whether this effect is reflected in the liver-stiffness to platelet score (LSPS), an important non-invasive marker of PH. The common loss-of-function variant p.A174 V in the transporter SLCO1B1 mediating the hepatic uptake of statins, results in decreased transporter function. The specific aim of this study was to assess the impact of statin therapy and to control confounders by propensity score matching (PSM) in a cohort of patients with cirrhosis, stratified for the genotypes of the *SLCO1B1* variant.

Method: In total, we identified 1,088 patients with liver cirrhosis in two German academic medical centers in Homburg and Halle. After exclusion and PSM, we included 154 patients on statins and 154 matched controls who never used statins. Complications of liver cirrhosis were retrospectively assessed applying EASL consensus criteria. The patients were genotyped for the common variant of *SLCO1B1* p.A174 V (rs4149056) using allelic discrimination assays.

Results: After PSM, standard deviation of all matching-parameters was reduced and the distribution of characteristics was equalized; genotype distribution was consistent with Hardy-Weinberg equilibrium. Concerning signs of PH, patients on statins presented less frequently with varices (OR 0.39; 95% CI 0.23–0.66; p < 0.001) and lower LSPS (4.8 ± 11.5 vs. 5.6 ± 6.4; p = 0.021). Decompensation events were significantly reduced in patients on statins (OR 0.54; 95% CI 0.32–0.90; p = 0.018). Ascites (OR 0.61; 95% CI 0.38–0.97; p = 0.038) and variceal bleeding (VB) (OR 0.35; 95% CI 0.15–0.83; p = 0.017) occurred less, whereas hepatorenal syndrome (HRS), jaundice and hepatic encephalopathy (HE) were distributed equally among the groups. Patients carrying at least one risk allele presented significantly more often varices (OR 2.68; 95% CI 1.24–5.81; p = 0.011) and HRS (OR 11.07; 95% CI 1.11–110, p = 0.011). In addition, bacterial infections (OR 2.5, 95% CI 1.14–5.47; p = 0.02), in particular spontaneous bacterial peritonitis (OR 3.47; 95% CI 1.16–10.38; p = 0.02), were more frequent in these patients.



Conclusion: In this PSM cohort, complications and signs of PH were markedly reduced in patients with liver cirrhosis treated with statins, as reflected by LSPS. This effect was diminished by the common mutation of the statin transporter *SLCO1B1*. Further prospective studies in independent cohorts are warranted to confirm these genotype-restricted observations.

SAT183

Shifting the focus of liver cirrhosis to prevention with the help of the SEAL program

Nagel Michael[1], Anita Arslanow[1,2], Marc Nguyen-Tat[1,3], Marcus-Alexander Woerns[1], Matthias Reichert[2], Franz Josef Heil[4], Dagmar Mainz[4], Gudula Zimper[5], Burkhard Zwerenz[4], Johannes Jäger[6], Harald Binder[7], Erik Farin-Glattacker[7], Bogatyreva Lioudmila[7], Fichtner Urs[7], Graf Erika[7], Stelzer Dominikus[7], Reyn van Ewijk[8], Dr. Julia Ortne[9], Louis Velthuis[9], Frank Lammert[2], Prof. Dr. Galle Peter R.[1]. *[1]University Medical Center of the Johannes Gutenberg-University Mainz, Department of Internal Medicine I, Mainz, Germany; [2]Saarland University Medical Center, Department of Medicine II, Homburg, Germany; [3]Hospital Osnabrück, Department of Internal Medicine II, Osnabrück, Germany; [4]German Gastroenterology Association (bng), Berlin, Germany; [5]General Practitioners' Association Saarland, Kirkel - Altstadt, Germany; [6]Saarland University, Center for General Medicine, Homburg, Germany; [7]Faculty of Medicine and Medical Center - University of Freiburg, Institute of Medical Biometry and Statistics, Freiburg im Breisgau, Germany; [8]Johannes Gutenberg University Mainz, Department of Economics, Mainz, Germany; [9]Johannes Gutenberg University Mainz, Chair of Management Accounting, Mainz, Germany*
Email: michael.nagel@unimedizin-mainz.de

Background and Aims: Most patients with liver cirrhosis are detected at late stage of their disease. In approximately 75% of

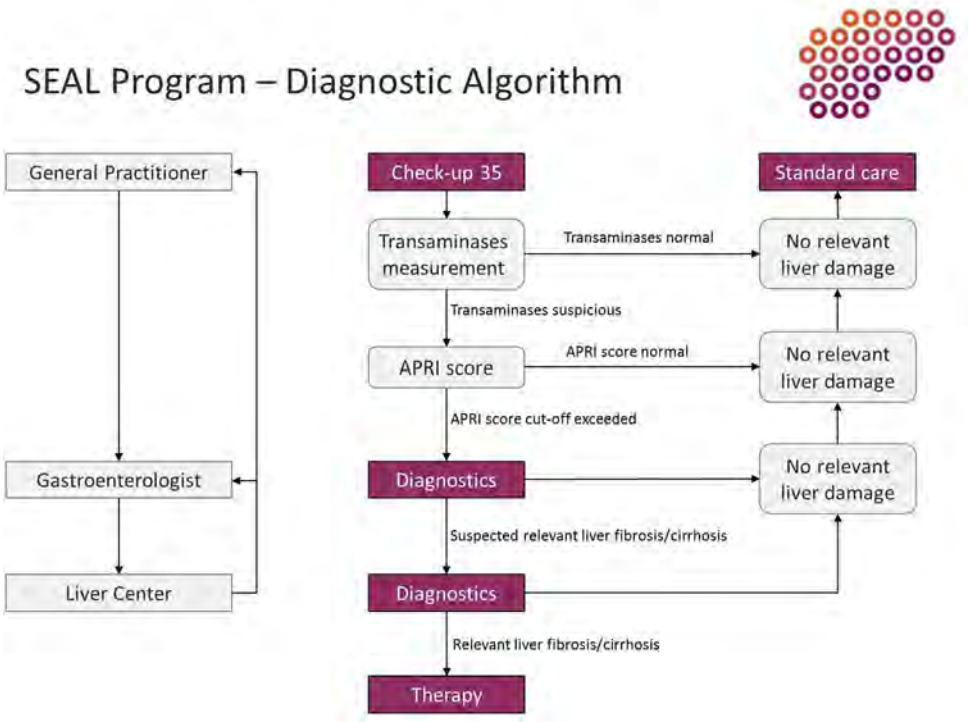


Figure: (abstract: SAT183)

these patients, diagnosis is based on the development of complications such as ascites or variceal bleeding. At this stage, causative treatment interventions are less successful or even impossible. Screening for liver health and disease is not included in standard medical check-up programs in Europe. The SEAL algorithm investigates the feasibility, effectiveness and cost-benefit assessment of a general screening strategy for liver fibrosis and cirrhosis in Germany.
Patients and Methods: As part of the SEAL program funded by the Federal Joint Committee (G-BA), 16,000 individuals are offered additional testing of liver enzymes by general practitioners as part of a nationwide primary care program (Check-up 35) in two federal states (Rhineland-Palatinate and Saarland). In case of elevated serum aminotransferase activities, the APRI score as liver fibrosis risk score is calculated. If the APRI score is suggestive for liver disease, patients are referred to a gastroenterologist for further differential diagnostic assessment. Patients with suspected liver fibrosis are referred to a tertiary liver center for full hepatologic work-up. Endpoints are cost-effectiveness of early diagnosis as well as data on the epidemiology of elevated liver enzymes and liver fibrosis in the general population.
Results: To date, 7.100 patients have been recruited. Of the examined patients, 11% and 6% presented with increased ALT and AST activities. Notwithstanding that in 499 patients a known liver disease was already present at inclusion, 11% of patients without known liver disease presented with elevated aminotransferases. Overall, 307 patients (4.3%) showed elevated ALT or AST and a conspicuous APRI score ≥0.5, 76% of whom were not known to suffer from chronic liver disease. Up to now, referral for further diagnostics was indicated in 245 patients.
Conclusions: To date, strategies to establish the diagnosis of chronic liver diseases as early as possible has been controversially discussed by physicians and health care providers. Our screening data indicate that a relevant group of the population is not aware of their increased aminotransferases or chronic liver diseases. The SEAL program provides novel data on the cost-effectiveness and utility of screening for liver diseases in Germany in particular and segmented health care systems in general.

Algorithm to predict development of sarcopenia after transjugular intrahepatic portosystemic shunt in decompensated cirrhosis

Michael Praktiknjo[1], Römer Julia[1], Chang Johannes[1], Clees Caroline[1], Abu-Omar Jasmin[1], Luetkens Julian[2], Christian Strassburg[1], Carsten Meyer[2], Jonel Trebicka[3,4]. *[1]University of Bonn, Department of Internal Medicine I, Bonn, Germany; [2]University of Bonn, Department of Radiology, Bonn, Germany; [3]University of Frankfurt, Department of Internal Medicine 1, Frankfurt, Germany; [4]European Foundation for the Study of Chronic Liver Failure, Barcelona, Spain*
Email: jonel.trebicka@kgu.de

Background and Aims: Meticulous patient selection for treatment of portalhypertensive complications with transjugular intrahepatic portosystemic shunt (TIPS) is important for beneficial effects and sarcopenia has been reported as a risk factor for post-TIPS hepatic encephalopathy (HE) and mortality. This study evaluates the prognostic role and a predictive algorithm of post-TIPS sarcopenia.
Method: This study included patients with decompensated liver cirrhosis undergoing TIPS procedure from the prospective NEPTUN cohort. In a training cohort, CT scans before and after TIPS were analyzed to obtain transversal psoas muscle thickness (TPMT). In a validation cohort, CT scans after TIPS were analyzed for TPMT. Primary endpoint was mortality. Secondary endpoints were acute decompensations and acute-on-chronic liver failure (ACLF). A sequential muscle prediction (MP)-algorithm was developed.
Results: In the training cohort, 43 patients (23 female) were included. 13 patients were sarcopenic before TIPS. After TIPS 6 sarcopenic patients improved their muscle mass classified as non-sarcopenic, while 3 non-sarcopenic patients developed sarcopenia. Pre-TIPS sarcopenia was associated with post-TIPS HE. Post-TIPS sarcopenia was an independent predictor of 1-year mortality. Post-TIPS muscle loss was a predictor of development of ACLF and associated with higher mortality. Low pre-TIPS aspartate aminotransferase (AST) level and high CLIF-C AD score were associated with development of post-TIPS sarcopenia. MP-Algorithm predicted post-TIPS sarcopenia

in training and validation (n = 105) cohort with an accuracy of 91% and 80%.
Conclusion: This study demonstrates that post-TIPS muscle loss predicts ACLF and death in decompensated cirrhotic patients receiving TIPS and offers an easy-to-obtain MP-algorithm to predict development of post-TIPS sarcopenia.

SAT185
In-hospital falls and fall-related injury in patients with liver-cirrhosis - malnutrition matters
Nada Abedin[1], Christoph Welsch[1], Stefan Zeuzem[1], Jörg Bojunga[1], Georg Dultz[1]. [1]*Department for Internal Medicine I, University Hospital Frankfurt, Goethe University, Frankfurt am Main, Germany*
Email: nada.abedin@kgu.de

Background and Aims: Patients with liver cirrhosis are prone to develop complications such as complicated infections and renal failure. Particularly malnutrition in patients with cirrhosis is associated with higher rates of mortality and morbidity. Here, we aimed at assessing the actual risk of falling and defining risk factors that can help prevent and create awareness towards falls of hospitalized patients with liver cirrhosis.
Method: In a retrospective analysis, hospitalized patients with liver cirrhosis from 2014 to 2019 at University Hospital Frankfurt were characterized and patients with documented falls further assessed for risk factors. Falls were documented in a standardized clinic-wide form in the patient's electronic file, from which clinical data was collected.
Results: In total, 5830 hospitalizations of 2553 patients with liver cirrhosis were included in the study. Patients were predominantly male 67.6% (3941/5830). Median age was 60 years. A total of 251 (4.3%) falls by 206 patients (3.5%) were documented in this cohort in the analyzed time frame; median age in this group was 64 years.
Out of 206 patients with described falls, 127 (61%) had alcoholic liver cirrhosis, 54 (26.1%) viral cause (HBV 24; HCV 30). Most common cause for admission in patients who fell were hydropic decompensation (91/206) and hepatic encephalopathy (62/206). Falls were mostly described as a slip to the ground (93/251), 47 (18%) patients fell on their way to the bathroom. Major injuries (fractures, bleedings, associated death) were observed after 14 (5.6%) falls, minor injuries (hematoma, pain or scratches) were seen in 96 (38.25%) falls, while 147 (58.57%) falls were not followed by any injury. Malnutrition was assessed via the nutritional risk screening (NRS). According to the NRS 60 of 168 cases (35.7%) had a risk score >1, indicating a moderate to severe impaired nutritional status. A NRS score >1 was significantly correlated with fall related injury ($p = 0.015$); Both, male gender ($p = 0.005$; OR 2.837) and malnutrition ($p = 0.01$, OR 2.579) were independently associated with fall related injury in the multivariate model.
Conclusion: Falling patients with cirrhosis are at high risk for moderate to severe injuries. Malnutrition proved to be an independent risk factor in the fall assessment of patients with liver cirrhosis, thus, warranting its assessment and counteraction.

SAT186
Body composition parameters predict outcomes of acute kidney injury in patients with cirrhosis
Naomi Lange[1,2], Jean-Francois Dufour[1], Annalisa Berzigotti[1], Susana G. Rodrigues[1]. [1]*Swiss Liver Center, UVCM, Inselspital, Bern University Hospital, Department of Biomedical Research, University of Bern, Bern, Switzerland, Bern, Switzerland;* [2]*Inselspital, Bern University Hospital, University of Bern, Department of General Internal Medicine, Bern, Switzerland*
Email: susana.gomesrodrigues@insel.ch

Background and Aims: Sarcopenia and adipopenia influence prognosis in cirrhosis. We examined whether body composition markers of adipose and muscle tissue associated with renal function and clinical outcomes in cirrhotic in-patients after a first episode of acute kidney injury (AKI).
Method: In a single-center retrospective cohort study, we identified 73 cirrhotic patients with a first episode of AKI and computed tomography (CT) within 12 weeks of AKI followed for 6 months or until death/transplantation. CT images collected at the level of third lumbar (L3) vertebra were used to assess body composition parameters, including adipose tissue indices normalized to height in cm^2/m^2 (subcutaneous - SATI, visceral - VATI, intramuscular - IMATI, total - TATI), the L3 skeletal muscle index (SMI), and mean tissue densities in HU. Sarcopenia was defined according to guidelines as an SMI < 50 cm^2/m^2 in men and < 39 cm^2/m^2 in women.
Results: Forty-three (59%) patients were male; mean age was 60.0 ± 10.3 years. The prevalence of sarcopenia in men and women was 70% and 73%, respectively ($p = 0.80$). Mean follow-up was 21.2 ± 20.5 months. Absence of sarcopenia was associated with resolution of AKI at day seven (D7) (OR 5.56, $p = 0.004$). SMI correlated with estimations of renal function at D7 as calculated by MDRD6-eGFR ($r = 0.31$, $p = 0.01$), CKDEPI-eGFR ($r = 0.31$, $p = 0.01$) and RFH-eGFR ($r = 0.27$, $p = 0.02$), but not with creatinine ($r = -0.05$, $p = 0.66$). Among adipose tissue parameters, SATI was associated with AKI resolution at D7 (OR 1.02, $p = 0.02$). High IMATI was associated with 90-day mortality/transplantation (OR 1.32, $p = 0.025$). Higher mean density of SAT and VAT (OR 1.05, $p = 0.009$, and OR 1.1, $p = 0.007$) were associated with 90-day mortality and transplantation. In univariate analysis, high SAT density was associated with progression of AKI at D7 (OR 1.05, $p = 0.038$).
Conclusion: Higher SMI and SATI – reflecting more preserved muscle and adipose tissue mass - were associated with favorable evolution of renal function in cirrhotic patients following an AKI episode. High IMATI was associated with 90-day mortality/survival. High SAT density - possibly indicating subcutaneous adipose tissue edema or inflammation - was associated with progression of renal failure as well as mortality and transplantation.

SAT187
Usefulness of handgrip as a non-invasive tool to predict the outcome of patients with cirrhosis. A prospective study
Nesrine Amari[1], Antonella Putignano[1], Amandine Szalai[2], Trépo Eric[1], Lukas Otero-Sanchez[1], Antonia Lepida[1], Pierre Deltenre[1], Nathalie Boon[1], Thomas Serste[1], Thierry Gustot[1], Degré Delphine[1], Christophe Moreno[1]. [1]*Hospital Erasme, Gastroenterology, Hepato-Pancreatology and Digestive Oncology, Bruxelles, Belgium;* [2]*Hospital Erasme, Dietology and Nutrition, Bruxelles, Belgium*
Email: putignano.anto@gmail.com

Background and Aims: Malnutrition is an independent predictive factor of mortality and morbidity in patients with cirrhosis. Recently, handgrip (HG) emerged, in cirrhotic male patients only, as a better predictor of mortality compared to other invasive techniques (1). We aimed to confirm the effectiveness of HG as a mortality predictor in patients with cirrhosis and to compare it to other non-invasive indicators of malnutrition.
Method: Observational, prospective study including all cirrhotic patients admitted to a tertiary Belgian center from January 2017 to August 2018. Non-invasive malnutrition evaluation was based on HG (2), Mid Arm Circumference (MAC) and Subjective Global Assessment (SGA, 3). HG <20 Kg in female and <30 kg in male were used to identify patients at risk of malnutrition ("Risk HG" group). Chi Square or Fisher Test were used to compare outcomes and variables, Kaplan Meier (Log Rank test) to estimate the cumulative survival and Cox Regression to model predictors of overall and 90-day mortality ($p < 0.05$). Transplanted patients were censored for the survival analysis.
Results: Eighty-nine cirrhotic patients were included: male 62 (69.7%), age 59.8 (±10.4), MELD 15 (IQR 9). Among them, 63 patients (70.8%) had alcohol related cirrhosis, 47 were admitted for an acute decompensation (52.8%), 19 presented HCC (21.3%) and 33 underwent liver transplantation (37.1%). The median follow-up was 161

days (IQR 258), and, during the observation period, 15 patients (16.9%) died, 11 within the 90th day. The estimated overall and 90-day survival rates were inferior for patients belonging to the "Risk HG" group (64.4% vs 83.4%, p = 0.033 and 93.0% vs 75.0%, p = 0.028, respectively, Fig. 1). On the other hand, increased mortality was not detected according to SGA and MAC. Predictors of overall and 90-day mortality at the univariate analysis were BMI (OR 1.12, p = 0.029 and HR 1.19, p = 0.007 respectively), MELD score ≥17 (OR 2.96, p = 0.040 and HR 3.33, p = 0.055 respectively), "Risk HG" (OR 3.1, p = 0.043 and HR 4.07, p = 0.042 respectively) and albumin (OR 0.92, p = 0.040 and HR 0.87, p = 0.04 respectively). The multivariate analysis confirmed, for both overall and 90-day outcome, the "Risk HG" (OR 3.1, p = 0.042 and HR 4.3, p = 0.035) as the only predictor of poor survival.
Conclusion: This study confirms, in a heterogeneous population of cirrhotic patients, that low HG is associated with worst survival, while other non-invasive methods of malnutrition assessment failed. These results should be validated in larger cohorts in order to support the integration of HG to MELD score as a tool for predicting mortality in cirrhotic patients.

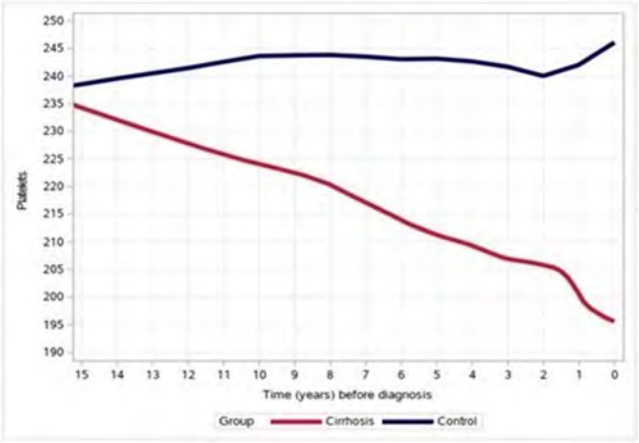
SAT188

Longitudinal assessment of progressive decrease in platelet counts as a surrogate marker of liver fibrosis and portal hypertension

Neta Gotlieb[1,2], Naama Schwartz[3], Shira Zelber-Sagi[1,3], Gabriel Chodik[4], Varda Shalev[4], Oren Shibolet[1,2]. *[1]Tel Aviv Medical Center, Gastroenterology and Hepatology, Tel Aviv, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel; [3]University of Haifa, School of Public Health, Haifa, Israel; [4]Maccabi Health Services, Institute for Research and Innovation, Tel Aviv, Israel*
Email: orensh@tlvmc.gov.il

Background and Aims: Most non-invasive scores predicting hepatic fibrosis incorporate platelets as a strong risk factor which is incorporated in the formula as a single point measurement. However, little is known about the association between longitudinal changes in platelets count (PTC), when still within the normal range, and the risk of cirrhosis. Our aim was to explore whether PTC trajectories over time can predict the diagnosis of liver disease across the different aetiologies and complications of cirrhosis and portal hypertension, assessing their gradual effect on various fibrosis scores respectively.
Method: A nested case-control study utilizing a computerized database of a national payer-provider insurer. Cirrhosis cases (n = 5258) from 2001 to 2018 were compared to controls (n = 15,744) matched for age, sex at a ratio of 3:1. All participants had multiple laboratory measurements prior to enrolment and trends throughout the preceding 20 years were calculated. The association between PTC, cirrhosis complications and fibrosis scores prior to cirrhosis diagnosis was investigated, compared to healthy controls. Liver enzymes and synthetic liver tests were evaluated correspondingly.
Results: The leading aetiologies were viral infection, alcoholic liver disease and NAFLD. The mean PTC decreased from 235,000/μL to 190,000/μL up to 15 years prior to cirrhosis diagnosis compared to controls whose PTC remained stable. This trend was consistent regardless of sex, cirrhosis etiology and was pronounced in patients who developed complications of portal hypertension mainly varices and ascites. AST and ALT increased from 40 to 75 U/l, bilirubin increased gradually from 0.6–1.2 mg/dL and albumin decreased mildly from 4.5–3.8 mg/dL compared to controls. In concordance to the gradual PTC decrease and AST and ALT increase, FIB-4 increased gradually ranging from 1.3 to 3 prior to cirrhosis diagnosis. In multivariable regression analysis, a decrease of 50 units in PTC was associated with 1.3 times odds of cirrhosis (95%CI 1.25–1.35).



Conclusion: In the preceding years before the diagnosis of cirrhosis, there is a progressive decline in average PTC occurs, within the normal limits, matched to a gradual increase in fibrosis scores. This should alert the treating physicians of an early liver disease and may serve as a non-invasive tool for early diagnosis.

SAT189

Factor VIII/protein C and not ADAMTS13/VWF:Ag ratio is a prognostic risk factor for patients with cirrhosis and low MELD score

Niccolò Bitto[1], Giulia Tosetti[2], Armando Tripodi[1], Ilaria Mancini[1], Luciano Baronciani[1], Carla Valsecchi[1], Pietro Lampertico[2], Flora Peyvandi[1], Massimo Primignani[2], Vincenzo La Mura[1,2].

Medicina Generale Emostasi e Trombosi, Università degli studi di Milano, Milan, Italy; [2]Fondazione IRCC Ca' Granda, Ospedale Maggiore Policlinico, C.R.C. "A.M. e A. Migliavacca" per lo Studio e la Cura delle Malattie del Fegato, Università degli studi di Milano, Milan, Italy
Email: niccolo.bitto@unimi.it

Background and Aims: The pro-hemostatic imbalance of cirrhosis has been postulated as one of the mechanisms explaining liver damage. Low ADAMTS13/Von Willebrand Factor antigen (VWF:Ag) and high factor VIII/protein C ratio (FVIII/PC) represent biochemical markers of platelet hyperaggregation (primary hemostasis) and hypercoagulation (secondary hemostasis), respectively. This study describes the association of such hemostatic parameters with the severity of the liver disease measured by Child-Pugh, MELD, MELD-Na and their prognostic role on the clinical outcome.
Method: We investigated 123 patients (78% male, age 62 ± 12, 58% in-hospital) with cirrhosis Child-Pugh:8.2 ± 2.2, MELD:15.6 ± 7.7, MELD-Na:16.3 ± 6.6. The main etiologies were virus (40%), alcohol (30%), virus + alcohol (15%). The hemostatic parameters included: VWF:Ag, ADAMTS13 activity, the pro-(FVIII, FII)and anti-coagulant factors (antithrombin, PC). Their correlations with indexes of severity were tested by the Pearson coefficient. Patients were followed up to 12 months. Decompensation (requiring hospitalization), death or transplantation were retrospectively collected and presented as cumulative risk. The prognostic role of the hemostatic parameters was tested by logistic regression and finally expressed as risk of adverse outcome predicted by the model.
Results: Patients presented a pro-hemostatic imbalance resumed by ADAMTS13/VWF:Ag of 0.21+/−0.14 and FVIII/PC of 6.0 ± 6.5. All the hemostatic parameters correlated with all the markers of cirrhosis severity (p < 0.05). Adverse outcomes occurred in 74 patients: 35

(28%)decompensations, 23 (19%)deaths, 16 (13%) transplantations. MELD-Na had the highest prognostic accuracy (AUC = 0.809) in comparison with MELD (AUC = 0.774) and Child-Pugh (AUC = 0.771). Among all the hemostatic parameters, FVIII/PC was the only variable associated with the composite clinical end-point at logistic regression analysis (OR:1.215;95%-CI:1.05–1.38; p = 0.006). A prognostic model which included MELD-Na and FVIII/PC led to a slight increase of the AUC vs MELD-Na alone (AUC 0.815 vs 0.809) in the whole series. A FVIII/PC≥2.78 (i.e. the lowest tertile in our series) identified patients at higher risk of adverse outcome and was more evident in MELD-Na<15 (45% vs 27%) than in those with MELD-Na≥15 (83% vs 75%).
Conclusion: Markers of primary and secondary hemostasis correlate with common indexes of liver disease severity. FVIII/PC ratio has a relevant prognostic role in patients with MELD-Na<15.

SAT190

Baveno VI criteria as a prognosis index for clinical complications in patients with cirrhosis

Nicolas Asesio[1], Priscila Pollo-Flores[1], Mona Munteanu[1], Yen Ngo[2], An Ngo[2], Thierry Poynard[2], Dominique Thabut[1], Marika Rudler[1].
[1]Pitié-Salpêtrière Hospital, Hepatology, Paris, France; [2]Biopredictive, Paris, France
Email: marika.rudler@aphp.fr

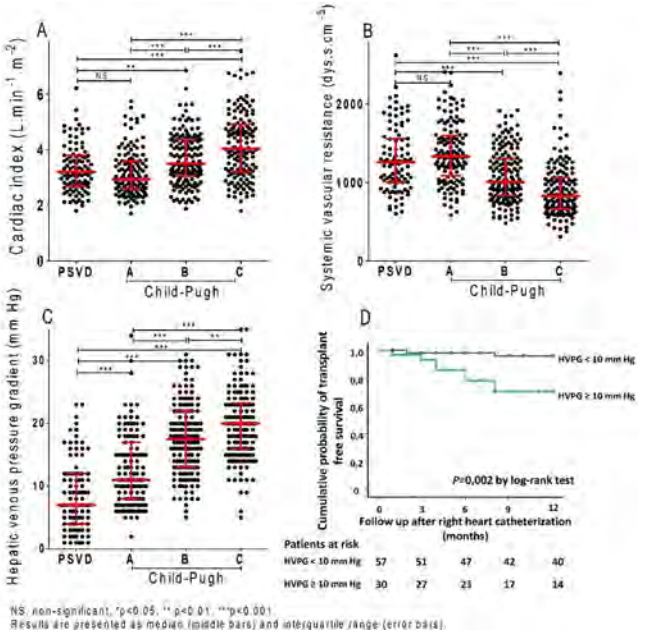
Background and Aims: The Baveno VI recommendations stated that the combination of liver stiffness measurement (LSM) and blood platelets could safely rule out varices needing treatment (VNT) in patients (pts) with compensated advanced chronic liver disease (cACLD). Upper endoscopy is not necessary in low-risk pts defined by a LSM <20 kPa and a platelet count >150 G/L. Few data are available regarding prognosis and liver-related complications in low-risk patients. We aimed to evaluate 4-year liver-related complications and survival in these patients.
Method: a retrospective analysis of prospectively collected data in a tertiary centre of Hepatology. All consecutive pts evaluated between 2012 and 2015 were analysed. Inclusion criteria were: 1) Cirrhosis (LSM≥12.5 kPa); 2) Absence of previous complication (i.e. ascites, hepatic encephalopathy (HE), variceal bleeding (VB), portal vein thrombosis or hepatocellular carcinoma (HCC)). Pts were divided into 2 groups: pts at low risk according to Baveno VI criteria (LSM <20 kPa and platelet count>150 G/L (Baveno VI favourable status)) and pts at high-risk (LSM ≥20 kPa or platelet count ≤150 G/L (Baveno VI unfavourable status)).
Results: 454 pts with cACLD were analysed (mean age 57 ± 11 yrs, male gender 72%, cause of cirrhosis hepatitis C/NASH/alcohol/hepatitis B/other in 42/25/17/10/6% of cases, Child-Pugh score A 100%, LSM 21,5 ± 11 kPa, platelet count 173 ± 74 G/L, VNT 19.6%). Two hundred and one patients had a favourable Baveno VI status, 1.35% with VNT. Mean follow-up was 3.6 ± 1.3 years. The 4-year probability of being free of developing ascites (96.2 vs 90.5%, p = 0.03), HE (99.4 vs 95.7%, p = 0.03), VB (99.4 vs 96.3, p = 0.05) or any hepatic decompensation (96 ± 1,5% vs. 89% ± 2,3%, p = 0.01) was higher in patients with Baveno VI favourable status. Overall, 28 pts developed hepatic decompensation. Baveno VI status was evaluated in 26 pts at the time of decompensation: all of them had an unfavourable status. The probability of developing HCC was significantly lower in pts with Baveno VI favourable status (3.9% vs 10.2%, p = 0.04). Liver-related mortality was no different between the 2 groups (p = 0.31). In Multivariate analysis, the independent factors associated with further development of hepatic decompensation were albumin (p < 0.001), bilirubin (p = 0.003), prothrombin time (p = 0.01) and LSM (p = 0.01).
Conclusion: In our series of pts with cirrhosis with Baveno VI favourable status, the 4-year probability of developing portal hypertension-related complication or HCC was significantly lower, compared to pts with unfavourable status. The Baveno VI criteria could predict clinical outcome in cACLD. As previously described, HCC has to be screened in this population.

SAT191

Systemic and splanchnic hemodynamic features of patients with porto-sinusoidal disease as compared with cirrhosis

Nicolas Drilhon[1,2], Valérie Paradis[2,3], Shantha Valainathan[1,2], Lazareth Marie[1], Olivier Roux[1,4], Clement Lejealle[1], Payance Audrey[1,4], Marion Jager[1], Hortense Davy[1], François Durand[1,2,4], Didier Lebrec[1], Aurélie Plessier[1,2,4], Dominique Valla[1,2,4], Pierre-Emmanuel Rautou[1,2,4]. *[1]Hopital Beaujon, AP-HP, Service d'Hépatologie, DHU Unity, DMU Digest, Clichy, France; [2]Université de Paris, Centre de recherche sur l'inflammation, Inserm, U1149, CNRS, ERL8252, Paris, France; [3]Hopital Beaujon, AP-HP, Service d'Anatomie Pathologique, Clichy, France; [4]Hopital Beaujon AP-HP, Centre de Référence des Maladies Vasculaires du Foie, French Network for Rare Liver Diseases (FILFOIE), European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Clichy, France*
Email: nicolas.drilhon@gmail.com

Background and Aims: Data on hemodynamic features of patients with porto-sinusoidal vascular disease (PSVD) are limited. We aimed at comparing systemic and splanchnic hemodynamic features of patients with PSVD with those of patients with cirrhosis.
Method: This retrospective study included all patients with signs of portal hypertension, who underwent liver and right heart catheterization at our center between 2011 and 2018 and had either of the 2 following conditions: (a) PSVD according to VALDIG criteria; (b) histologically proven cirrhosis related to alcohol consumption, chronic viral hepatitis, autoimmune hepatitis and/or metabolic syndrome. Non-inclusion criteria included infection or alcoholic hepatitis within 2 weeks before hemodynamic study. Biopsies were reviewed by an expert pathologist and histological elementary lesions were classified according to pre-specified criteria.



Results: We included 428 patients with cirrhosis (73% male, median age 57 years, 73% esophageal varices, 51% ascites) and 96 patients with PSVD (57% male, median age 59 years, 58% esophageal varices, 25% ascites). 77 (81%) patients with PSVD had at least one extra-hepatic condition known to be associated with PSVD. Cardiac index and systemic vascular resistance of patients with PSVD were similar to those of patients with Child-Pugh A cirrhosis, but patients with PSVD had lower cardiac index and higher systemic vascular resistance

than Child-Pugh B or C cirrhosis (Fig. A and B). Patients with PSVD had lower hepatic venous pressure gradient (HVPG) than patients with cirrhosis, whatever Child-Pugh score (Fig. C). Analyses restricted to patients without ascites or without betablockers gave similar results. Prevalence of portopulmonary hypertension was similar in PSVD (3%) and cirrhosis (2%) ($p = 0.401$). Ascites was more common among PSVD patients with HVPG ≥10 mm Hg than in those with HVPG <10 mm Hg (41% vs. 15% respectively, $p = 0.01$). Histological features associated with HVPG ≥10 mm Hg included portal vein narrowing ($p = 0.002$) and nodular regenerative hyperplasia ($p < 0.001$). After a median follow-up of 13 months, patients with PSVD and HVPG ≥10 mm Hg had lower transplant free survival than those with a lower HVPG (Fig. D).

Conclusion: Patients with PSVD had systemic hemodynamic features similar to those of patients with Child-Pugh A cirrhosis, but lower HVPG. Prevalence of portopulmonary hypertension was low and similar in PSVD and cirrhosis. HVPG ≥10 mm Hg was associated with a lower transplant free survival in patients with PSVD.

SAT192

Circulating microfibrillar-associated protein 4 is an independent predictor of transplant-free survival in compensated and decompensated cirrhosis

Nikolaj Torp[1,2], Mads Israelsen[1,2], Ditlev Nytoft Rasmussen[1,2], Bjørn Stæhr Madsen[1,2], Maria Kjærgaard[1,2], Philipp Lutz[3], Christian Strassburg[3], Christian Mortensen[4], Anne Wilkens Knudsen[4], Grith Sorensen[5], Uffe Holmskov[5], Anders Schlosser[5], Maja Thiele[1,2], Jonel Trebicka[2,6,7], Aleksander Krag[1,2]. *[1]Odense University Hospital, Department of Gastroenterology and Hepatology, Odense, Denmark; [2]University of Southern Denmark, Institute of Clinical Research, Odense, Denmark; [3]University of Bonn, Department of Internal Medicine I, Bonn, Germany; [4]Copenhagen University Hospital, Hvidovre, Gastro Unit Medical Division, Hvidovre, Denmark; [5]University of Southern Denmark, Institute for Molecular Medicine, Odense, Denmark; [6]University Hospital Frankfurt, Department of Internal Medicine I, Frankfurt am Main, Germany; [7]European Foundation for the Study of Chronic Liver Failure (EF-CLIF), Barcelona, Spain*
Email: nikolaj.christian.torp@rsyd.dk

Background and Aims: Circulating microfibrillar-associated protein 4 (cMFAP4) has been associated with advanced fibrosis in early stage liver disease related to alcohol and viral hepatitis C. We aimed to investigate cMFAP4 as a prognostic marker of transplant-free survival in patients with compensated and decompensated cirrhosis.

Method: We prospectively enrolled patients with compensated and decompensated cirrhosis from two Danish and one German hospital. Compensated patients were enrolled in relation to liver biopsy and only patients with verified cirrhosis were enrolled. Decompensated patients were enrolled in relation to therapeutic paracentesis. Patients were followed for up to 12 months, death or liver transplantation (LTx). cMFAP4 was compared to established prognostic models including Model for End-stage Liver Disease-sodium (MELD-Na), Child-Pugh Score (CPS) and CLIF Consortium Acute Decompensation score (CLIF-C AD). We used the median cMFAP4 (81.9 U/l) to divide the cohort into low-cMFAP4 and high-cMFAP4.

Results: We included 104 patients of which 45 were compensated and 59 were decompensated. Median age was 59 ± 8.2 years, 73% were male and 96 had alcohol-related cirrhosis. The median level of cMFAP4 was 123.6 U/l (95.3–162.6) in high-cMFAP4 and 49.1 U/l (31.1–69.2) in low-cMFAP4.

The distribution of Child-Pugh class (A/B/C) was 31/47/16 with more severe stages of disease in the group of low-cMFAP4 ($p < 0.01$). The median MELD-Na score was 16 (11–20), CLIF-C AD 52 (46–56) both significantly higher in the low-cMFAP4 group (OR = 0.88, $p < 0.01$; OR = 0.94, $p = 0.02$ respectively). During 12 months follow-up we observed 13 deaths (12.5%) and two LTx (1.9%). Transplant-free survival was significantly decreased in low-cMFAP4 compared to high-cMFAP4 ($p < 0.01$) (see Figure). In multivariate Cox regression with age, sex and MELD-Na as control variables high-cMFAP4 was independently associated with transplant-free survival (HR = 0.22, $p = 0.02$). An AUROC model comparing cMFAP4, MELD-Na, CPS, CLIF-C AD showed similar prognostic performance between the models. However, the highest AUROC was obtained in a combined model of CPS and cMFAP4 (AUROC = 0.65).

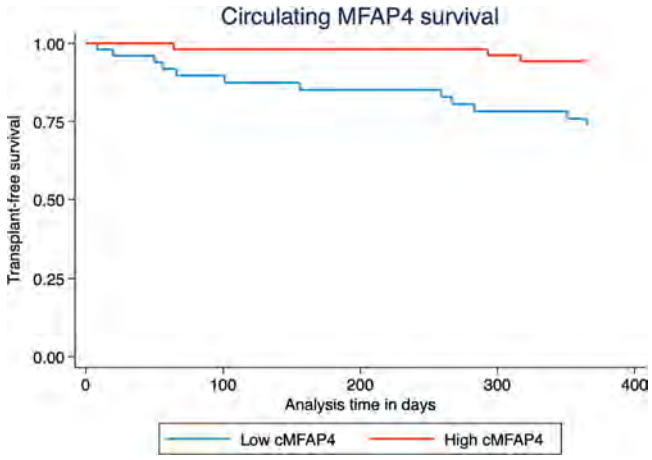


Figure: Kaplan-Meier curve of transplant-free survival.

Conclusion: Transplant-free survival was significantly lower in patients with lower levels of cMFAP4 independent of established prognostic biomarkers of mortality in cirrhosis. cMFAP4 is a strong independent predictor of transplant-free survival and adding this marker can be used to increase prognostic performance.

SAT193

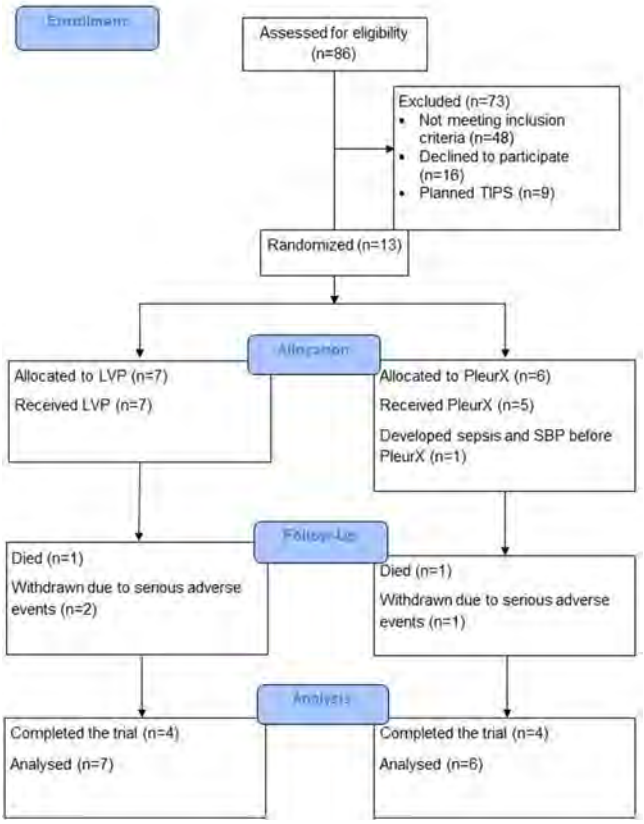
Tunnelated peritoneal catheter versus large volume paracentesis for refractory ascites in cirrhosis: a randomized controlled trial

Nina Kimer[1,2], Agnete Riedel[2], Lise Hobolth[2], Christian Mortensen[2], Mette Lehmann Andersen[3], Frank Vinholt Schiødt[4], Lone Madsen[5], Søren Møller[6], Lise Lotte Gluud[2]. *[1]The University of Copenhagen, Faculty of Health and Medical Sciences, Center for Basic Metabolic Research, København, Denmark; [2]University Hospital Hvidovre, Gastro Unit, Medical Division, Hvidovre, Denmark; [3]University Hospital Herlev, Department of Gastroenterology, Herlev, Denmark; [4]University Hospital Bispebjerg, Abdominal Center, København N, Denmark; [5]Zealand University Hospital Køge, Department of Medicine, Køge, Denmark; [6]University Hospital Hvidovre, Center of Functional and Diagnostic Imaging and Research, Department of Clinical and Nuclear Medicine, Hvidovre, Denmark*
Email: nina.kimer@regionh.dk

Background and Aims: Refractory ascites is associated with a median survival of six months. Repeated large volume paracentesis (LVP) and albumin infusion is standard treatment, but complications are common and involve hyponatriemia, bacterial peritonitis and renal impairment. The PleurX catheter is a tunnelated catheter with a cuff that allows entrenchment in the subcutaneous fat. Ascetic fluid is drained intermittently at the patient's home using vacuum containers. In a randomized controlled trial, we aimed to evaluate the beneficial and harmful effects of the PleurX catheter versus LVP and albumin infusion in patients with cirrhosis and non-malignant ascites.

Method: The trial was approved by relevant authorities (EudraCT: CIV-16-10-017324, H-16040179) and registered at clinicaltrials.gov (NCT03017635). Random allocation was computer-generated, and allocation was concealed using sealed opaque envelopes. Patients were included from January 2017 to December 2018. Inclusion criteria were I) adults with cirrhosis and recurrent ascites, II) expected survival of >3 months. Exclusion criteria were I) eligible

for TIPS insertion, II) hepatic encephalopathy or variceal bleeding within two weeks, III) ongoing infection, III) intraabdominal surgery within four months, IV) increased risk of complications as judged by the primary healthcare provider. Patients were monitored for infections and all culture positive samples were repeated after 14 days for verification.



Results: The study aimed to enrol 32 participants, but due to slow recruitment and implementation of the procedure at hospital departments, the trial was terminated prematurely after 13 patients allocated to PleurX (n = 6) versus LVP (n = 7). Seven were female, age range 51 to 80 years. No procedure related complications were observed. Two patients died within the first month. One died due to variceal bleeding (PleurX group). One died due to septicaemia of unknown origin and hepatorenal syndrome (HRS) (LVP group). One patient in the PleurX group was withdrawn before insertion of the catheter due to sepsis and HRS. One patient in the PleurX group was withdrawn after one month due to hyponatremia. In the LVP group, two patients were withdrawn due to SBP and HRS (n = 1) or infection of unknown origin (n = 1). In the PleurX group, all patients developed colonisation of the catheter within one to four months, but only two developed SBP. The most common bacterial colonisation was *Staphyloccous Epidermidis* (n = 4). In the LVP group, one participant developed SBP.

Conclusion: In selected patients, the PleurX catheter may be a safe alternative to LVP and efficiently mobilizes ascetic fluid, but the risk of infection should be considered in each case. The impact of colonization on the risk of infections including SBP as well as immunological dysfunction in cirrhosis needs further investigations.

SAT196

Efficacy of transjugular intrahepatic porto-systemic shunt in cirrhotic patients with hepatorenal syndrome - chronic kidney disease

Paola Ponzo[1], Martina Rizzo[1], Daniela Campion[1], Ilaria Giovo[1], Michele Roma[1], Felice Rizzi[1], Alessandra Risso[1], Gian Paolo Caviglia[2], Giorgio Maria Saracco[1], Carlo Alessandria[1]. *[1]Città della Salute e della Scienza, Gastroenterology and Hepatology, Torino, Italy; [2]University of Turin, Department of Medical Sciences*
Email: carloalessandria@libero.it.

Background and Aims: transjugular intrahepatic porto-systemic shunt (TIPS) has proved to ameliorate renal function in patients with type 2 hepatorenal syndrome (HRS). However, available evidence is based on: 1- 'old' diagnostic criteria for type 2 HRS and not on the current definition of HRS–chronic kidney disease (CKD) and 2- studies of relatively small sample size. Among patients who underwent TIPS for refractory ascites over the last 11 years, we aimed to investigate the renal function of those with HRS-CKD.
Method: 38 out of 199 patients fulfilled the current diagnostic criteria for HRS-CKD and were included in the analysis. Renal function (serum creatinine - sCr and Glomerular Filtration Rate – GFR using Modification of Diet in Renal Disease 4 – MDRD4 and Chronic Kidney Disease Epidemiology Collaboration– CKD-EPI formulas) was evaluated 1 week and 1–3–6 and 12 months after TIPS.
Results: Renal function significantly improved since 1 week after TIPS (sCr: 1.94 ± 0.56 vs 1.40 ± 0.32 mg/dl; $p < 0.001$; GFR-MDRD4: 36.29 ± 9.65 vs 53.72 ± 14.4 ml/min/1.73 m2; $p < 0.001$), and the improvement was maintained during the follow up. Considering the baseline CKD stages, the amelioration in renal function was observed in stage G3a (GFR-MDRD4 49.81 ± 3.65 vs 59.31 ± 11.0 ml/min/1.73 m2; $p = 0.025$) as well as in stage G3b (GFR-MDRD4 38.29 ± 4.97 vs 53.75 ± 16.83 ml/min/1.73 m2; $p < 0.001$) and stages G4-G5 (GFR-MDRD4 25.25 ± 3.15 vs 50.43 ± 11.67 ml/min/1.73 m2; $p < 0.001$). Since one week after TIPS and during the whole follow up, sCr and GFR became comparable between stages G3a vs G3b vs G4-G5 ($p = ns$), whilst significantly different ($p < 0.05$) at baseline.
Conclusion: TIPS led to an early and persistent improvement in renal function in patients with HRS-CKD, irrespective of the baseline CKD stage. After TIPS, renal function parameters became rapidly comparable between patients with slightly reduced GFR and patients with severe HRS-CKD.

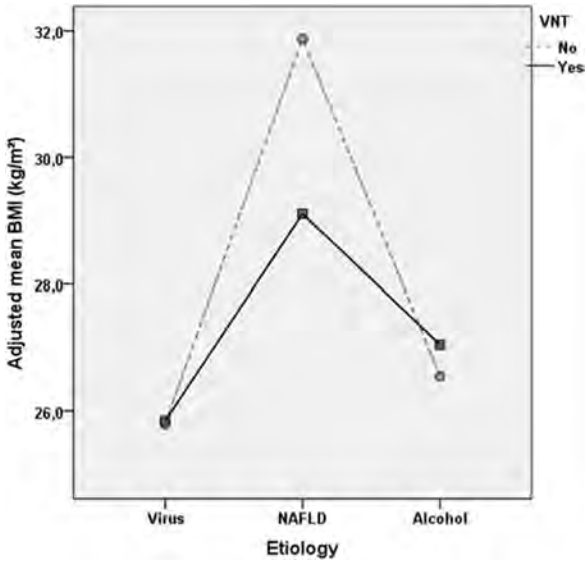
SAT197

The prevalence of esophageal varices needing treatment depends on gender, etiology and BMI

Arthur Berger[1], Federico Ravaioli[2], Oana Nicoara-Farcau[3], Davide Festi[2], Horia Stefanescu[3], Pierre Nahon[4], Christophe Bureau[5], Nathalie Ganne-Carrié[4], Annalisa Berzigotti[6], Victor de Lédinghen[7], Salvatore Petta[8], Paul Cales[1]. *[1]University Hospital, Hepato-Gastroenterology, Angers, France; [2]University of Bologna, Gastroenterology and Hepatology Unit, Department of Medical and Surgical Sciences, Bologna, Italy; [3]Regional Institute of Gastroenterology and Hepatology, Liver Unit, Cluj-Napoca, Romania; [4]Paris Seine-Saint-Denis University Hospitals, Hepato-Gastroenterology, Bondy, France; [5]Purpan University Hospital, Hepato-Gastroenterology, Toulouse, France; [6]Swiss Liver Center, Visceral Surgery and Medicine Clinic, Hepatology, Bern, Switzerland; [7]Haut-Lévêque Hospital, Hepatology, Bordeaux, France; [8]University of Palermo, Gastroenterology and Hepatology, Palermo, Italy*
Email: paul.cales@univ-angers.fr.

Background and Aims: The epidemiology of esophageal varices has so far been evaluated under conditions restricted by the size and etiology of the population. It is essential to know the epidemiological predictors to improve predictive scores. The main objective was to evaluate the epidemiology of varices needing treatment (VNT) in a vast population of multiple etiologies.

Method: 2,290 patients with chronic liver disease were included in 8 countries in a retro-prospective study. Their characteristics were, age: 59 ± 11 years, men: 63.5%, etiologies: virus: 50.0%, NAFLD: 29.5%, alcohol: 20.5%, BMI: 28.4 ± 5.8 kg/m², MELD score: 9.5 ± 3.0, liver stiffness ≥10 kPa: 93%. The VNT prevalence was 14.9%.
Results: The main significant differences between patients with VNT vs no VNT were: increased prevalence in men, high MELD, alcohol etiology and decreased in NAFLD vs virus etiology, lower BMI and creatinine. Thus, the odds ratio of VNT for men was 1.55 (1.19–2.03) after adjusting for covariates.
In multivariate analysis, the independent predictors of VNT were: etiology, sex, platelets, prothrombin index, liver stiffness, albumin and ALT without role for age, BMI, AST, creatinine, and MELD score. This model provided a first score of usual tests (SCOUT 1). A second model taking into account the multiple interactions called SCOUT 2 made it possible to increase the AUROC for VNT to 0.819 vs 0.806 for SCOUT 1 (p = 0.019). SCOUT scores were compared to published VNT scores ANTICIPATE and PLER (ratio platelets/liver stiffness). SCOUT 2 was very well calibrated according to gender, etiology and MELD unlike other scores. The sensitivity ≥95% for VNTs (condition of Baveno VI criteria for missed VNT ≤ 5%) was for VNT scores or tests: Baveno VI: 24.1% (of patients), PLR: 29.2%, ANTICIPATE: 31.5%, SCOUT 1: 34.8%, SCOUT 2: 37.8% (p < 0.001 between each test). This analysis also showed a significant interaction between BMI and etiology or prothrombin index. Thus, BMI of VNTs adjusted on covariates (by ANCOVA) was significantly decreased in NAFLD (p = 0.002) but significantly increased in alcohol (p = 0.009) vs no VNT (Figure).



Conclusion: The prevalence of VNTs varies according to etiology, liver function and fibrosis, and sex. The role of BMI is unmasked owing to a real interaction with etiology: negative influence in NAFLD and positive in alcoholic etiology. These new findings allow improving the performance and calibration of predictive scores for VNT and finally tests to rule out VNT.

SAT198
Direct acting oral anticoagulant use in cirrhosis patients: real-world bleeding and discontinuation rates

Joseph Mort[1], Jessica Davis[1], Giselle Mahoro[1], Matthew Stotts[1], Nicolas Intagliata[1], Patrick Northup[1]. [1]*University of Virginia, Charlottesville, United States*
Email: pgn5qs@virginia.edu.

Background and Aims: Previously published studies on the use of direct acting oral anticoagulants (DOACs) in patients with cirrhosis are limited by small sample size, short follow up, and inadequately validated cirrhosis diagnoses. In this study we systematically determine the characteristics, indications, and outcomes of verified cirrhosis patients of all severity classes taking DOACs.
Method: Patients from a large liver transplant center with documented cirrhosis were retrospectively evaluated for clinical characteristics, indications for DOAC use, and clinical outcomes. Standardized and validated definitions (ISTH) for all bleeding complications were used.
Results: 138 confirmed cirrhosis patients received DOACs. See table. The patients were exposed to 58,240 person-days (mean 422 days per patient) of DOAC treatment. 93 patients (68%) were CP B or C. 29 patients (21%) stopped therapy due to bleeding. The most common bleeding events were non-variceal upper and lower GI bleeding. No pretreatment laboratory parameters were predictive of bleeding on treatment including platelet count (p = 0.50), INR (p = 0.34), creatinine (p = 0.27), and MELD score (p = 0.22). Related bleeding rates were not different between CP class (p = 0.81), DOAC indication (p = 0.60), or DOAC dosage (p = 0.10). Patients with active malignancy (p = 0.01) were more likely to have major bleeding on therapy. Major bleeding was numerically more common in CP C patients due to a larger hemoglobin drop when bleeding was identified.

Characteristic	n (138)	(% of population)
Bleeding Complications		
Related Bleeding Events	45	33%
Major bleeding	11	8%
Clinically relevant non-major bleeding (CRNMB)	22	16%
Minor bleeding	12	9%
Stopped DOAC due to bleeding event	29	21%
Child Pugh Class (CP)		
A	45	33%
B	70	51%
C	23	17%
Indication for DOAC		
DVT/PE	47	34%
AF	44	32%
PVT	39	28%
Type of DOAC		
Apixaban	94	68%
Rivaroxaban	32	23%
Dabigatran	12	9%

Conclusion: Patients with cirrhosis have higher bleeding rates when taking long term DOACs than previously described. Pretreatment laboratory parameters, DOAC dose, and CP class were not predictive of bleeding although CP C and active malignancy are associated with major bleeding.

SAT199
Fluency is associated with hepatic encephalopathy using a common and easy language task

Patricia Bloom[1], Ashwini Arvind[1], Michael Daidone[1], Anoopum Gupta[2], Raymond Chung[1]. [1]*Massachusetts General Hospital, Gastroenterology, Boston, United States;* [2]*Boston, Neurology, Boston, United States*
Email: ppbloom@partners.org

Background and Aims: Current tools for neurocognitive evaluation in hepatic encephalopathy (HE) are limited, typically requiring a trained practitioner in an office setting and over 10 minutes to perform. We evaluated easy-to-obtain aspects of language as novel biomarkers for HE.
Method: We enrolled adult cirrhotic patients with fluency in English. Patients performed the psychometric HE score (PHES), a validated neurocognitive test in HE, and were audio recorded while describing

the Cookie Theft Scene from the Boston Diagnostic Aphasia Examination. The following variables were measured: words per minute (fluency), empty phrases (lacking obvious meaning), stutters, fillers ("um" or "uh"), pauses ≥2 seconds and tangential thoughts (irrelevant to image). Prior history of overt HE (OHE) was identified. A t-test compared language variables in those with and without minimal HE (MHE), defined as a PHES score≤−4.

Results: 40 cirrhotic patients (58% men) with mean MELD 16.5 (SD 7.8), aged 59.8 years (range 27–79) and with years of education 16.0 (SD 2.8) were audio recorded. Cirrhosis etiology was alcohol in 40%, NASH in 18% and viral in 23%. 23 (58%) patients had a history of OHE (OHE), while 17 (42%) did not. 13 (33%) patients met the PHES threshold for MHE at the time of study visit, while 27 (67%) did not. More patients with current MHE had a history of OHE than patients without MHE (92% vs. 41%, $p < 0.01$; Table 1). In the entire cohort, number of empty phrases ($r = -0.34$, $p < 0.05$) and number of words per minute ($r = 0.50$, $p = 0.001$) correlated with PHES score. Patients with MHE used fewer words per minute than those without (121 words/min vs. 141 words/min; $p = 0.02$). Number of empty phrases ($p = 0.27$), filler words ($p = 0.43$), stutters ($p = 0.45$), pauses ($p = 0.24$) and tangential thoughts ($p = 0.17$) did not correlate with the presence of MHE. Amongst the 23 patients with a history of OHE, number of words per minute correlated with PHES score ($r = 0.45$, $p < 0.05$). Amongst the 17 patients without a history of OHE, number of words per minute did not correlate with PHES score ($r = 0.03$, $p = 0.90$).

Table 1: Language Variables by Minimal Hepatic Encephalopathy Status.

	MHE§ (n=13)	No MHE (n=27)	P value
History of OHE*	92%	41%	<0.01
Words/minute	121	141	0.02
Empty phrases	0.42	0.18	0.27
Filler words	3.39	2.71	0.43
Stutters	0.39	0.71	0.45
Pauses	1.11	0.76	0.24
Tangential thoughts	0.17	0.04	0.17

Conclusion: Number of words per minute, or fluency, is associated with MHE. Modern technology permits straightforward and timely assessment of fluency. Future research should explore using fluency to predict future OHE and to evaluate treatment response.

SAT200

A smartphone app is feasible for outpatient ascites management

Patricia Bloom[1], Madeline Marx[1], Thomas Wang[2], Ashwini Arvind[1], Jasmine Ha[1], Bradley Green[1], Michelle Tagerman[1], James Richter[1].
[1]Massachusetts General Hospital, Gastroenterology, Boston, United States; [2]Massachusetts General Hospital, Medicine, Boston, United States
Email: ppbloom@partners.org

Background and Aims: Ascites is a frequent, painful and dangerous complication of cirrhosis. Body weight is a reliable proxy for ascites volume. Therefore, daily weight monitoring is recommended to optimize ascites management. This pilot study evaluates the feasibility of a Smartphone app in facilitating outpatient ascites management.

Method: In this feasibility study, cirrhotic patients with ascites requiring active management were enrolled in the inpatient or outpatient setting. Patients were subsequently discharged with a Bluetooth-connected scale, which transmitted weight data to the PGHD Connect Smartphone App, and then via the cloud to the electronic medical record (EMR). Weights were monitored every weekday. In the event of a weight change ≥5lbs in 1 week, patients were called and administered a short symptom questionnaire, and providers received an email alert. The primary outcomes of this study were percentage of enrolled days during which weight data was successfully transmitted to the EMR, and the percentage of weight alerts which prompted a response by the provider.

Results: 78 cirrhotic patients were identified as potential candidates: 8 did not own a Smartphone, 23 were encephalopathic and were excluded. 1 declined to participate and 3 withdrew prior to discharge due to severe illness. 25 patients were enrolled: 12 (48%) were male and mean age was 57.6 years (range 35–81 years). 17 (68%) were enrolled as inpatients. Cirrhosis aetiology was non-alcoholic steatohepatitis in 44%, alcohol in 40% and viral in 12%. 15 patients opted to extend their participation beyond the initial 28-day study period. Weight data was successfully transmitted to the EMR during 71% of study enrolment days, with technology issues reported on 16% of days. Of a total 80 weight alerts to date, 39 (49%) were triggered by weight loss and 41 (51%) by weight gain. Providers acknowledged 71 (89%) weight alerts, and intervened in response to 38 (48%), for example by contacting the patient, scheduling clinic or paracentesis appointments, modifying the diuretic dose or requesting laboratory workup. 17 readmissions occurred during the study period.

Conclusion: We demonstrate feasibility of a Smartphone app in facilitating the management of ascites. We report excellent rates of patient and provider engagement. This innovation could enable early therapeutic intervention, decreasing the burden of morbidity and mortality among cirrhotic patients.

SAT201

Comparative study between spontaneous fungal peritonitis and spontaneous bacterial peritonitis in patients with end stage liver disease

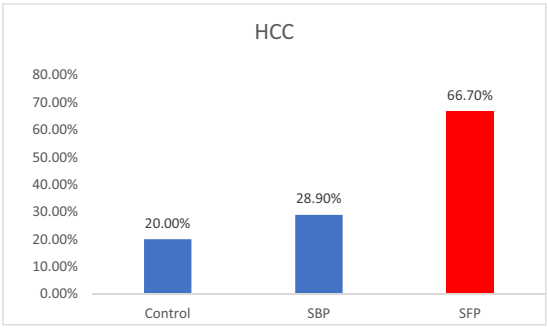
Mohamed Elnadry[1], Abdalla Hendawy Elshahat[2], Mohamed Abu Ghabsha Abughabsha[3]. *[1]Al-Azhar University, Hepatogastroenterology, Cairo, Egypt; [2]Al-Azhar University, Hepatogastroenterology, Cairo, Egypt; [3]Al-Azhar University, Clinical Pathology, Cairo, Egypt*
Email: prof_nadry@yahoo.com

Background and Aims: Bacterial infections in end stage liver disease (ESLD) are common and associated with increased mortality. The aim of this study was to evaluate clinical and laboratory characters, risk factors, and outcome of fungal and bacterial peritonitis in cirrhotic patients with ESLD.

Method: This prospective cohort study enrolled 50 patients with liver cirrhosis and ascitic culture-positive spontaneous peritonitis, including 12 with SFP, and 38 culture-positive SBP, and 10 patients without clinical or laboratory evidence of peritonitis as a control group, during the study period, between 1st February 2018 and 30th May 2019. We compared the clinical, laboratory findings, Child–Pugh scores, MELD score, risk factors and mortality rates between patients with spontaneous peritonitis associated with fungal culture-positive ascites, and those with spontaneous peritonitis associated with bacterial culture-positive ascites.

Results: The mean duration of ESLD in the studied patients was 4.75 ± 1.8 year, 57 patients (95.0%) were Child score C and 3 patients (5%) were Child score B. The mean MELD score was 23.32 ± 5.49. All patients with evidence of peritonitis were Child C and mean MELD scores was 22 ± 5.7and 26.1 ± 4.5 in SBP and SFP groups respectively. Jaundice, GI bleeding and hepatic encephalopathy were highly significant clinical presentation and also highly significant predictors of mortality in SFP group compared to SBP and control group ($p < 0.001$). Lower level of Hg, S. albumin and platelets count and increased level of TLC, INR, and bilirubin was significantly higher in SFP group compared to SBP and control group.

Duration of ESLD and hospital admission was highly significant in SFP compared to SBP and control group. HCC was evident in SFP group 8/12 patients (66.7%) that was highly significant in comparison to SBP 11/38 (28.9%) and control group 2/10 (20%) ($p = 0.041$). Overall mortality rate among the studied groups was 27/60 (45%), the mortality rate was significantly increased in SFP group 9/12 (75%) compared to SBP16/38 (42.1%) and control group2/10 (20%) ($p = 0.03$). The mean MELD score was significantly increased in non-survival group 27.6 ± 4.0 compared to 19.2 ± 3.3 in survival group ($p = <0.001$). The duration of ESLD was significantly increased in non-survival group 5.7 ± 2.0 year compared to 4.1 ± 1.5 year in survival group p = (0.004)



Conclusion: Prolonged and severe underlying liver disease with a high Child- Pugh or MELD score, renal impairment, HCC, and onset of severe sepsis have reported as a risk factors in increased mortality in patients with SFP than in SBP. In SFP, mortality is associated not only with the severity of the underlying liver disease but also with delay in diagnosis and initiation of antifungal therapy. Further studies are needed to clarify the features of SFP and determine the effects of antifungal therapy on patient's outcome.

SAT202

Association between proton pump inhibitor use in hospitalized cirrhotics and development of hepatic encephalopathy and spontaneous bacterial peritonitis

Pearl Tan[1], Marissa Ukos[2], Caragh Miller[2], Julia Lombardi[2], Erin Kelly[1]. [1]*University of Ottawa, Division of Gastroenterology;* [2]*University of Ottawa*
Email: ekelly@toh.ca

Background and Aims: Proton pump inhibitors (PPI) are commonly prescribed medications which are indicated in various different gastrointestinal (GI) diseases, including peptic ulcer disease, gastro-esophageal reflux disorder and upper GI bleeding. There is some evidence to suggest that PPI use in cirrhosis may predispose to the development of hepatic encephalopathy (HE) and spontaneous bacterial peritonitis (SBP), albeit with some controversy. We aim to conduct a retrospective epidemiological analysis of the association between PPI use in hospitalized patients with cirrhosis, and prevalence of HE and SBP.

Method: This was a retrospective cohort study of 600 adult patients (mean age 61.4 (SD = 12.2)) admitted the Ottawa Hospital between January 1, 2011 and December 31, 2015 with cirrhosis. A chart review was conducted and relevant information extracted.

Results: Average MELD-Na on admission was 16.2 (SD = 6.7). 14.8% of patients had a history of HE, 5.0% SBP, 7.8% with history of hepatocellular carcinoma and 1.0% with history of hepatorenal syndrome. 28.5% of patients had a history of varices, of which 11.0% had previous variceal bleeding. 69.3% of patients were on a PPI during their hospitalization. Not surprisingly, patients admitted with variceal bleeding were more likely to be exposed to PPI in hospital (97.2% vs 63.2%, $p < 0.01$) Patients with a diagnosis of cirrhosis prior to index admission were more likely to be on a PPI in hospital ($p = 0.001$) and on discharge ($p = 0.001$). Patients with ascites were less likely to be on a PPI than those without ascites (64.1% vs 77.6%, $p < 0.01$). There was no significant correlation between in hospital PPI use and MELD score ($p = 0.42$). Amongst patients on PPI in hospital, 85.9% remained on a PPI at discharge. Although numerically greater, no statistically significant differences were observed in terms of prevalence of HE (21.3% in patients on PPI vs 8.3% in those not on PPI ($p = 0.37$)), nor SBP (5.7% on PPI vs. 3.7% in those not on PPI ($p = 0.29$)).

Conclusion: We did not observe a significant difference in HE and SBP among this cohort of cirrhotic patients by in-hospital PPI use. We did however note significantly higher PPI use in patients with previous diagnosis of cirrhosis as compared to those who were newly diagnosed, as well as those whose admissions were related to bleeding. Patients with ascites had lower prevalence of PPI use. Prescribing patterns for PPIs in patients with cirrhosis warrant further attention, including clinical utility and longer-term risks and benefits of this therapy.

SAT203

Sarcopenia increases the risk of post transjuglar intrahepatic portosystemic shunt hepatic encephalopathy

Puja Bhatia Kapoor[1], Harshita Tripathi[1], Jaya Benjamin[1], Rakhi Maiwall[2], Yashwant Patidar[3], Shalini Thapar[4], Dr. Puneet Puri[5], Guresh Kumar[6], Yogendrakumar Joshi[1], Shiv Kumar Sarin[2]. [1]*Institute of Liver and Biliary Sciences, Department of Clinical Nutrition, New Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Department of Hepatology, New Delhi, India;* [3]*Institute of Liver and Biliary Sciences, Department of Intervention Radiology, New Delhi, India;* [4]*Institute of Liver and Biliary Sciences, Department of Radiology, New Delhi, India;* [5]*Virginia Commonwealth University, Department of Internal Medicine, Richmond, United States;* [6]*Institute of Liver and Biliary Sciences, Department of Biostatistics, New Delhi, India*
Email: pujabhatia27@hotmail.com

Background and Aims: Hepatic Encephalopathy (HE) is a potentially lethal complication and sarcopenia an undesirable consequence of chronic liver disease. Transjuglar intrahepatic portosystemic shunt (TIPS) procedure increases the risk of HE. We investigated the effects of sarcopenia on the incidence and outcome of HE after a TIPS procedure.

Method: Clinical, biochemical and follow-up data of patients who underwent TIPS procedure between 2010 and 2018 at the Institute of Liver and Biliary Sciences (ILBS), New Delhi, were extracted from the hospital information system (HIS). Single slice computed tomography (CT) images at L3 level of scans performed within 3 months prior to TIPS were analyzed using Slice-o-matic software to assess the skeletal muscle index (SMI)- expressed as skeletal muscle area (cm^2)/height (m^2). Sarcopenia was defined if SMI was <50 in males and <42 in females and overt HE as per West-Haven criteria.

Results: Of the 210 patients who underwent TIPS, complete information was available in 79 patients [Male: 68(86%); age: 50.5 ± 11.2 years; CTP: 9.29 ± 1.6; MELD: 15.7 ± 6.3; etiology - Alcohol: 44 (56%), NASH: 16(20%), others: 19(24%); TIPS indication - Ascites: 56 (71%); bleed: 23(29%)]. Overt HE developed in 29(37%) patients within a period of 1–9 months post-TIPS. Both the prevalence of sarcopenia (69% vs 44%; $p = 0.03$) and serum ammonia (177.6 ± 82.5 vs 115.5 ± 40.5 mmol/L; $p = 0.008$) were higher in patients who developed HE compared to those who did not develop HE. Patients with sarcopenia had 2.8 times higher risk of HE [OR (95% CI): 2.8 (1.08–7.4), $p = 0.02$]. The risk of multiple episodes of HE was 8.2 times higher in sarcopenics 31% (n = 13) than non-sarcopenics 5.4% (n = 2); [OR (95%CI): 8.2(1.68–40.5), $p = 0.009$].

Conclusion: Nearly one in 3 cirrhotic undergoing TIPS is sarcopenic. Sarcopenia reduces ammonia detoxification capacity and increases the risk of post-TIPS hepatic encephalopathy in patients with cirrhosis. Early and effective nutritional habilitation and physical training programs are vital for better outcome of TIPS in sarcopenic patients.

SAT204

Distinct features of the portalhypertensive syndrome in patients with advanced chronic liver disease due to non-alcoholic steatohepatitis

Rafael Paternostro[1], Wilhelmus Kwanten[2], Jeannette Becker[1], Benedikt Hofer[1], Vera Panagl[1], Helena Schiffke[1], Luisa Vonghia[2], Thomas Vanwolleghem[2], Ali Bagdadi[2], Benedikt Simbrunner[1], Georg Semmler[1], Philipp Schwabl[1], Bernhard Scheiner[1], Theresa Bucsics[1], David JM Bauer[1,3], Ernst Eigenbauer[4], Michael Trauner[1], Mattias Mandorfer[1], Sven Francque[2], Thomas Reiberger[1]. Figure: (abstract: SAT204)

Hemodynamic Lab, Vienna, Austria; [4]Medical University of Vienna, IT Systems and Communications
Email: thomas.reiberger@meduniwien.ac.at

Background and Aims: Due to the global epidemic of obesity, non-alcoholic steatohepatitis (NASH) has become a leading cause of cirrhosis. Clinically significant portal hypertension (CSPH) is a major driver of decompensation and mortality; however, features of CSPH have not been systematically assessed in patients with advanced NASH.

Method: NASH patients with hepatic venous pressure gradient (HVPG) ≥6 mmHg were included. Clinical characteristics including data on gastroesophageal varices, splenomegaly, ascites and Child-Pugh score (CPS) were recorded. CSPH features were described in NASH patients stratified by CPS and compared to a cohort of HCV patients. Patients on non-selective beta-blocker therapy or with HCC were excluded.

Results: 162 patients with NASH (n = 43, 26.5%, subclinical portal hypertension [scPH: HVPG 6–9]; n = 119, 73.5% with CSPH [HVPG≥10 mmHg]) and 280 with HCV (scPH: 26.1%; CSPH: 73.9%) were included. CPS stage distribution were in NASH vs. HCV: CPS-A n = 75(53%) vs. n = 128 (61%), CPS-B: n = 38(44%) vs. n = 67(32%), CPS-C: n = 19(13%) vs. n = 15(7%).

Median HVPG in CPS-A was 12 (8–17) mmHg in NASH vs. 12 (8–15) mmHg in HCV (p = 0.723) in CPS-B: NASH:18 (13–21) mmHg vs. HCV: 17 (15–20) mmHg (p = 0.831); and in CPS-C NASH: 17 (12–21) mmHg vs. HCV: 22 (16–27) mmHg (p = 0.051). CSPH was detected in CPS-A NASH: 65.3% vs. HCV: 64.8% (p = 0.944); in CPS-B NASH: 91.7% vs. HCV: 92.5% (p = 0.864); and in CPS-C: NASH: 78.9% vs. HCV: 100% (p = 0.059), respectively. In compensated patients the prevalence of splenomegaly (NASH: 64.5% vs. HCV: 75.6%, p = 0.234) and gastro-esophageal varices (56.3% vs. 54.4%, p = 0.795) was similar in NASH and HCV, while thrombocytopenia was less common in NASH (58.8% vs. 77.9%, p = 0.002). In NASH-CSPH patients, the prevalence of severe/grade-III ascites was 11% vs. 5.3% in HCV-CSPH patients (p < 0.001). The median HVPG in patients with severe ascites was 19 (16–23) mmHg in NASH and 22 (15–28) mmHg in HCV (p = 0.285), respectively.

Conclusion: Two thirds of compensated NASH patients may suffer from CSPH. When stratified by hepatic dysfunction, HVPG values were similar in NASH and HCV cirrhosis. However, NASH-CSPH patients showed less thrombocytopenia while severe ascites was more prevalent despite similar HVPG values as compared to HCV patients.

SAT205

A novel, smartphone-based scleral image capture technique accurately determines serum bilirubin level and can be used for home-based monitoring of patients discharged from hospital, after an episode of acute decompensation

Rahul Kumar[1,2], Miranda Nixon[3], Eman Ibrahim Alabsawy[2], Ahmed Adel Amin[2], Felix Outlaw[3], T leung[3], Raj Mookerjee[2]. *[1]Changi General Hospital, Gastroenterology and Hepatology, Singapore; [2]Institute of Liver and Digestive Health, University College of London, London; [3]University College of London, Medical Physics and Biomedical Engineering, London, United Kingdom*
Email: rahul.kumar@singhealth.com.sg

Background and Aims: Acute decompensation (AD) of cirrhosis, including progression to acute-on-chronic liver failure (ACLF) is characterized by high 28-day mortality and hospital re-admission. Current non-invasive tools to predict new decompensation are limited, and costs of frequent outpatient visits are prohibitive. Given the importance of bilirubin levels in determining outcome, this study explores whether simple smart-phone based scleral image capture can accurately predict total serum bilirubin (TSB) levels, thereby serving as a home-based clinical monitoring tool.

Method: Consecutive patients admitted to Royal Free London with AD or ACLF over a year till August 2019 were screened based on predefined inclusion and exclusion criteria for an ongoing biomarker study, approved by institutional research ethics; 39 patients consented to participate. The scleral images were captured using the rear-facing camera of a dedicated Samsung® S8® phone. Images were then processed in MATLAB® (Mathworks®, r2018a), resulting in a numeric scleral colour value (SCV).

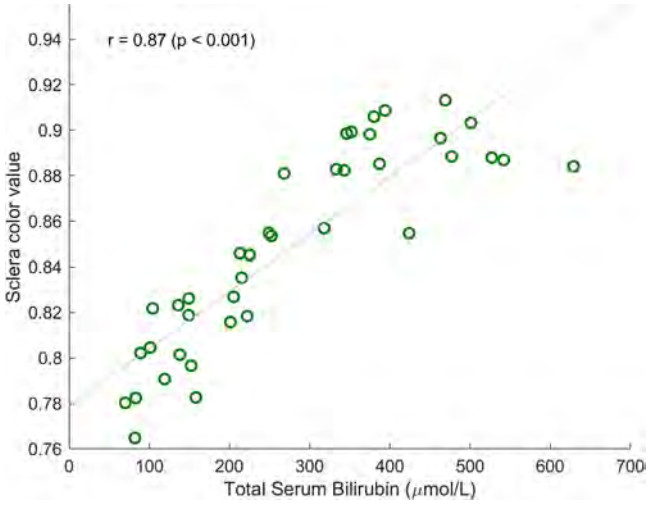

Figure 1: Correlation Between Sclera Colour Value and Total Serum Bilirubin.

Results: The mean patient age was 46.97 ± 8.6 years; 92% male. The mean creatinine and TSB were 96.3 ± 58.0 mmol/dl and 277.5 ± 150.9 mmol/dl, respectively. The most common cirrhosis aetiologies were alcohol (82%), NASH (12%) and viral hepatitis (2.5%), whilst a common cause of decompensation was alcoholic hepatitis in 41%. Around 92% patients had detectable ascites (U/S or clinical), and 48% patient had some grade of hepatic encephalopathy. The median MELD, MELD-Na and UKELD scores were 24.9 ± 4.7, 27.2 ± 4.7 and 47.1 ± 4.1, respectively. Figure 1, represents the scatter plot

between TSB and SCV. The mean SCV was 0.849 ± 0.04. The Pearson correlation coefficient was 0.87; 2-tailed significance of $p < 0.001$. This significant correlation between TSB and SCV was independent of aetiology of liver cirrhosis (alcohol vs. non-alcoholic $p < 0.001$), liver disease severity (Child B: $p = 0.002$; Child C: $p < 0.001$) and precipitant of decompensation (alcoholic hepatitis vs other precipitant ($p < 0.001$).

Conclusion: This novel smart phone based technique of scleral image capture can accurately predict serum bilirubin levels in patients with acute cirrhosis decompensation. Our results suggest this technology has the potential for home based TSB measurement for patients at risk of decompensation and need for early intervention.

SAT206

Degree of portal and systemic hemodynamic alterations predict repeated episodes of acute kidney injury and chronic kidney disease in patients with cirrhosis

Rakhi Maiwall[1], Samba Siva Rao Pasupuleti[2], Shiv Kumar Sarin[1].
[1]*Institute of Liver and Biliary Sciences, Hepatology, South West Delhi, India;* [2]*Institute of Liver and Biliary Sciences, Biostatistics, South West Delhi, India*
Email: shivsarin@gmail.com

Background and Aims: Cirrhotics are predisposed to develop frequent episodes of acute kidney injury (AKI) which in about one-third of patients leads to chronic kidney disease (CKD). There is limited data on systemic and portal hemodynamic alterations and development of CKD in cirrhotics.

Method: Consecutive patients with cirrhosis and without AKI, with a complete record of baseline hemodynamics, were followed for identifying risk factors for the development of AKI episodes and CKD. Negative binomial regression and competing risk survival analysis were performed to identify risk factors for AKI episodes and CKD respectively.

Results: Cirrhotics [n = 2013, aged 50.1 ± 11.8 years, 80% males, mean hepatic venous pressure gradient (HVPG) 16.2 ± 5.8 mm Hg, systemic vascular resistance index (SVRI) 2292.5 ± 810.6 dynes.s/cm5/m2 and cardiac index (CI) of 3.71 ± 1.35 L/min/m2 were enrolled. Of these, 893 (44.3%) received beta-blockers (BB) (carvedilol- 78%, propranolol-22%; second HVPG in 495 patients) of which 219 (44.2%) were responders (R+). On follow-up, median 379 (IQR 68–869) days, AKI developed at an incidence rate of 0.37 episodes per person-year, 26% patients developed CKD and 8% died. A lower incidence of AKI [HR 0.18, 95% CI 0.10–0.34] and lower mean number of AKI episodes [0.05 ± 0.25 vs. 0.42 ± 0.868; $p < 0.001$] were observed in R+. The incidence of CKD [subdistribution hazard ratio (SHR) 0.74, 0.54–1.02] and mortality [HR 0.21,0.06–0.73] were also lower in HVPG R+. Lower CTP class, use of BB and higher SVRI were independent predictors of hemodynamic response. Higher HVPG [ratio of means (RM); 1.79, 1.32–2.41], lower SVRI [0.15, 0.11–0.20], higher CI [1.87, 1.36–2.57] alongside presence of diabetes [1.81, 1.34–3.39], higher MELDNa score[1.07, 1.04–1.10] and use of BB[0.63, 0.48–0.83] were independent predictors of cumulative AKI episodes on negative binomial regression analysis. The cumulative episodes of AKI (1.60. 1.07–1.26), diabetes (2.6,2.1–3.1), higher MELDNa (1.05,1.03–1.06), higher age (1.03, 1.02–1.04) and lower SVRI (0.74, 0.61–0.90) were independent predictors of CKD.

Conclusion: High portal pressure and hyperdynamic circulation predispose cirrhotics to repeated AKI episodes which is a risk factor for CKD. Response to beta-blockers reduced the risk of AKI and CKD and lowered mortality. The severity of vasodilatation was associated with lower hemodynamic response to BB and higher incidence of CKD. Routine monitoring and therapies targetting the vasodilatory state could improve the hemodynamic response to BB, prevent frequent AKI and reduce the risk of CKD development in cirrhotics.

SAT207

Long-term 20% albumin administration normalizes the plasma albumin binding capacity in patients with decompensated cirrhosis

Raquel Horrillo[1], Anna Mestre[1], Ana Maria Ortiz[1], Alba Pérez[1], Aida Raventós[1], Mireia Torres[1], Antonio Páez[1], Vicente Arroyo[2], Javier Fernandez[2,3], Joan Clària[2,3], Todd Willis[1], Montserrat Costa[1].
[1]*Grifols, Bioscience Research Group, Sant Cugat del Vallès, Spain;* [2]*EF Clif, EASL-CLIF Consortium and Grifols Chair, Barcelona, Spain;* [3]*Hospital Clinic, IDIBAPS, CIBERehd, Barcelona, Spain*
Email: montse.costa@grifols.com

Background and Aims: Long-term albumin administration may be effective for treatment of cirrhotic patients. The PRECIOSA phase III trial (NCT03451292) is being conducted to assess the efficacy of one-year albumin treatment in the prevention of mortality in decompensated cirrhotic patients with ascites. The beneficial effects of albumin might be related to non-oncotic functions, particularly on its capacity to bind, transport and modulate biologically active molecules such as fatty acids, proinflammatory mediators and reactive oxygen species. In the present study we characterized the albumin binding capacity of patients with decompensated cirrhosis from the previous Pilot-PRECIOSA trial (NCT00968695) compared to healthy controls (HC), as well as the effects of i.v. albumin administration (Albutein® 20%, Grifols) on albumin binding capacity and its correlation with clinical parameters.

Method: Plasma samples from 22 patients included in the Pilot-PRECIOSA study were analyzed. This was a prospective, open-label and non-randomized clinical trial in decompensated cirrhotic patients with ascites, treated during 12 weeks with Albutein® 20% (low dose: 1 g/kg every 2 weeks; high dose: 1.5 g/kg weekly). Albumin binding capacity to Sudlow Binding Site II was determined using a specific fluorescent marker. AST and ALT were assessed by biochemical methods, and plasma renin activity (PRA) by radioimmunoassay. Results were expressed as median and IQR.

Results: Decompensated cirrhotic patients with ascites were not only hypoalbuminemic (1) but also its albumin presented a lower binding capacity respect to HC's one (n = 21) (77.5% [64.1–87.1] vs 96.3% [87.7–96.3]; $p < 0.0001$), which lead to a decrease in effective albumin for transport (18.7 mg/mL [12.9–28.7] vs 33.3 mg/mL [29.0–35.4] in HC; $p < 0.0001$). Albumin infusion increased the content of albumin with binding capacity up to HC-comparable levels ($p < 0.01$), being this increase dose-dependent. Moreover, the increased functionally-active albumin correlated with an improvement in AST and ALT levels and PRA over the course of treatment.

Conclusion: Albumin binding capacity was impaired in decompensated cirrhotic patients with ascites. Long-term albumin administration not only restored albumin concentration (1) but albumin transport capacity to normal levels, in parallel with improvement with circulatory dysfunction, estimated by PRA, and liver dysfunction. Our data suggest that an improvement of albumin transport may be a mechanism contributing to the beneficial effect of albumin treatment in cirrhosis.

Aminoglycosides and metronidazole for the treatment of hepatic encephalopathy in adults with cirrhosis

Rebecca Jayaraj[1], Sonam Vadera[1], Zhi Yang Low[1], Lise Lotte Gluud[2], Marsha Morgan[1]. [1]*UCL Institute for Liver & Digestive Health, Division of Medicine, Royal Free Campus, University College London, London, UK;* [2]*Gastrounit, Medical Division, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark*
Email: marsha.morgan@ucl.ac.uk

Background and Aims: The EASL/AASLD guidelines endorse the use of neomycin and metronidazole as second line treatment for overt

hepatic encephalopathy (HE), whereas the Italian guidelines state that these antibiotics should not used to treat HE, because of their potential for systemic toxicity. This study evaluates the utility of aminoglycosides and metronidazole for the management of HE in adults with cirrhosis.

Methods: Electronic/manual literature searches were undertaken for relevant RCTs. The results of the meta-analyses are presented as risk ratios (RR) with 95% confidence intervals (CIs). Bias control was assessed using CHBG domains and the certainty of the evidence using GRADE.

Results: Nineteen RCTs evaluated the aminoglycosides neomycin (n = 15), paromomycin (n = 3), and ribostamycin (n = 1). Treatment was given for 3 to 168 days. Comparators included: placebo (n = 3), NADs (n = 4), other antibiotics *viz.* rifaximin, erythromycin and ciproxin (n = 9), BCAAs (n = 2) and nicotinohydroxamic acid (n = 1). Only two trials had a low risk of bias; the certainty of the evidence was low or very low for all outcomes.

Nineteen trials reported mortality data, with no events in 11; 99 of 537 participants allocated to aminoglycosides died compared to 121 of 567 allocated to comparators (RR 1.06, 95% CI 0.67 to 1.69, I^2 63%, p = 0.79). Fifteen trials, with 1004 participants, reported data on HE; no differential beneficial or harmful effects were found in any of the trials (RR 0.95, 95% CI 0.71 to 1.28, I^2 38%, p = 0.75). Seventeen trials, reported on serious adverse events (SAEs), with no events in six; 139 of 507 participants allocated to aminoglycosides developed SAEs compared to 179 of the 532 allocated to comparators (RR 1.19, 95% CI 0.72 to 1.96, I^2 78%, p = 0.50) (Figure).

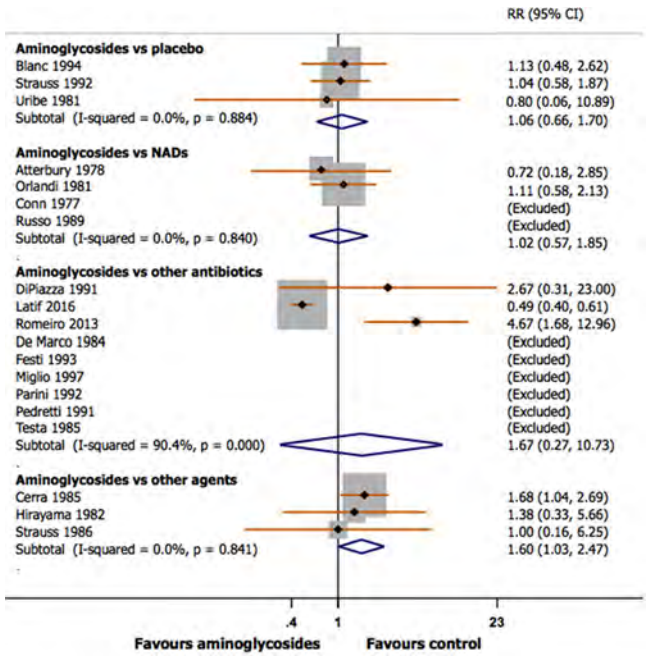

Figure: SAEs and aminoglycosides in patients with HE.

Three RCTs with 282 participants evaluated metronidazole with alternative therapies *viz.* vs. lactulose and LOLA (n = 1); vs. rifaximin and nitazoxanide (n = 1) and vs. rifaximin (n = 1). Metronidazole was associated with a higher risk of HE compared to LOLA in one trial (RR 2.25, 95% CI 1.17 to 4.33, p = 0.02) but otherwise the regimes were comparable.

Conclusion: No significant differences were observed in the utility of these antibiotics and a variety of comparators but the trials the quality of the evidence was low or very low. Recommendations can not be made on the basis of this review. Further well-conducted, RCTs are needed.

SAT209

Spleen stiffness and liver stiffness for predicting high risk varices in patients with compensated liver cirrhosis

Renata Fofiu[1], Sporea Ioan[2], Bende Felix[2], Roxana Sirli[2], Alina Popescu[2]. [1]*Department of Gastroenterology and Hepatology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania, Timișoara, Romania;* [2]*Department of Gastroenterology and Hepatology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania*

Email: renata.fofiu@yahoo.com

Background and Aims: To determinate the utility of spleen and liver stiffness (SS/LS) values measured by a 2D-SWE technique associated with spleen size (SSZ) as non-invasive markers for prediction of high risk varices (HRV) in patients with compensated liver cirrhosis.

Method: A prospective study was performed in 107 subjects with compensated liver cirrhosis, who underwent abdominal ultrasound, spleen and liver stiffness measurements (SSM, LSM) with a 2D-SWE technique from General Electric (LOGIQ E9) and upper endoscopy in the same admission. Reliable SSM and LSM were defined as the median value of 10 measurements acquired in a homogenous area and IQR/M <0.30. HRV were defined as grade II, III esophageal and gastric varices. Compensated liver cirrhosis was diagnosed based on clinical, biological and elastography criteria (liver transient elastography >12.5 kPa).

Results: We obtained reliable SSM by 2D-SWE in 103/107 subjects (96.2%) and reliable LSM in 104/107 subjects (97.1%). 101 subjects were included in the final analysis. 41/101 (40,6%) subjects had HRV. The mean SS, LS values and SSZ were significantly higher for patients with HRV as compared to those with first grade or no varices (16.78 ± 3.38 kPa vs. 12.69 ± 2.21 kPa, p < 0.0001; 14.13 ± 2.32 kPa vs. 11.4 ± 1.4 kPa, p < 0.0001; 14.54 ± 1.95 cm vs. 13.12 ± 1.66 cm, p = 0.0002). The best SS, LS and SSZ cut-off values for predicting the presence of HRV are presented in the following table:

Parameter	Cut-off	AUC	Se (%)	Sp (%)	PPV (%)	NPV (%)
Liver Stiffness	12.1 kPa	0.86	85.3	68.3	64.8	87.2
Spleen Stiffness	13.2 kPa	0.84	87.8	68.3	65.5	89.1
Spleen size	12.9 cm	0.71	85.3	48.3	53	82.9

In both univariate and multivariate analysis, SSM, LSM and SSZ were associated with the presence of HRV (all p < 0.001 for univariate analysis, respectively p = 0.0019, p = 0.0365 and p = 0.0046 in multivariate analysis). Using these factors as predictors, by multiple regression analysis we obtained the following score: 0.053* SS + 0.054* LS + 0.059* SSZ-1.84 with a cut-off value >0.31 (AUROC – 0.91; sensitivity-90%; specificity- 65%; PPV- 64%; NPV- 90%). By comparing the AUROC's our score performed better than spleen size for predicting HRV, but it's accuracy was similar to SS and LS by 2D-SWE (p = 0.0006, p = 0.1448; p = 0.2563).

Conclusion: SS, LS and SSZ are good non-invasive predictors of HRV, both separately or together.

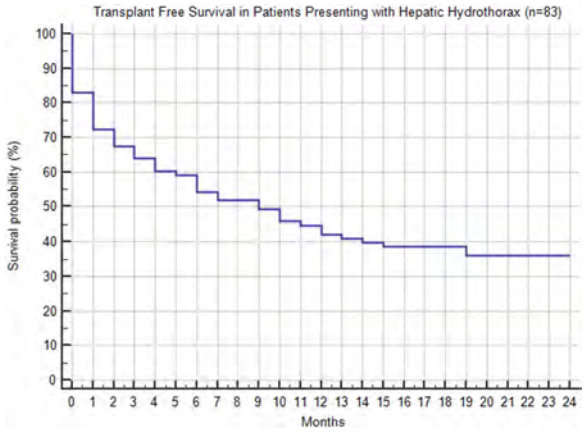
SAT210

Natural history and outcomes of patients with liver cirrhosis complicated by hepatic hydrothorax

Sarah Romero[1], Preet Singh[2], Chamani Kodikara[1], Rachel Shingaki-Wells[1], Sam Hui[1], Tess McClure[2], Marcus Robertson[1,3,4]. [1]*Monash Medical Centre, Clayton, Australia;* [2]*Austin Hospital, Heidelberg, Australia;* [3]*Monash University, Department of Medicine, Clayton, Australia;* [4]*Austin Health, Gastroenterology, Heidelberg, Australia*

Email: s.romero.md@gmail.com

Background and Aims: Hepatic hydrothorax (HH) is an uncommon and difficult-to-manage complication of cirrhosis with no established clinical guidelines. We sought to define the clinical outcomes of patients presenting with HH managed with current standards-of-care.
Method: International Classification of Diseases-10 codes identified cirrhotic patients with HH presenting to 3 tertiary centres (Melbourne, Australia) from 2010 to 2018. HH was defined as pleural effusion in the absence of cardiopulmonary disease. Medical records were reviewed to determine baseline characteristics and survival. Primary outcome was 12-month mortality. The Kaplan-Meier method was used to calculate survival probability.
Results: 83 patients were included. Median age was 59 years (IQR 54–63), 57% were male and median MELD score was 29 (IQR 25–33). Common causes of cirrhosis were viral (33%), alcohol (27%) and non-alcoholic fatty liver disease (19%); 29% had hepatocellular carcinoma. Pleural effusions were typically right-sided (83%) and 73% had concurrent ascites. There were 169 hospital admissions for HH over the study period. Median length of stay was 11 days and 22% required intensive care unit admission. 89% and 7% patients were prescribed diuretics and non-selective beta-blockers respectively at presentation. Diuretic therapy alone was commenced in 13 (8%) presentations while 120 (71%) received diuresis and pleurocentesis (median 3L drained); 17% required blood products to facilitate pleurocentesis. 23 patients received intercostal drain insertion, 1 pleurodesis and 10 proceeded to transjugular intrahepatic portosystemic shunt insertion. 31 (37%) patients underwent liver transplantation (OLT). Significant complications were observed in 45% of admissions, including: infection [n = 25], hepatic encephalopathy [n = 19] and pneumothorax [n = 11]. 86% patients required re-admission within 6-months of index admission. The 12-month mortality rate was 29% (n = 24) and probability of transplant-free survival was 42% and 36% at 12- and 24-months respectively (Figure). All patients receiving OLT survived to 12-months.



Conclusion: Patients with decompensated cirrhosis and HH are a challenging population with a poor 12-month survival despite current treatments. Transplant assessment should be considered in all cases. There is a high prevalence of in-hospital and procedure-related complications and a minority of patients experience disease control with diuretic therapy alone.

SAT211

Acute or recent portal vein thrombosis in cirrhosis predicts a hidden or upcoming diagnosis of hepatocellular carcinoma

Tawfik Khoury[1], Hosam Mahajna[1], Mohammad Masarwa[1], Yael Milgrom[1], Izhar Levi[1], David Hakimian[1], Naama Lev-Cohen[1], Itay Kalisky[1], Sameer Abu Gazala[1], Abed Khakayla[1], Rifaat Safadi[1].
[1]Hadassah University Hospital, Ein Kerem, Liver Unit, Jerusalem, Israel
Email: safadi@hadassah.org.il

Background and Aims: Portal vein thrombosis (PVT) is a common complication in cirrhosis. We assessed whether acute or recent PVT predicts hepatocellular carcinoma diagnosis.
Method: In an ICD9 retrospective study, total 560 PVT cases admitted to Hadassah Medical Organization 1982 until 2017 reviewed. Clinical and laboratory characteristics collected up the end of follow up (EoFU) to include acute or new onset PVT in cirrhotic patients, and to exclude hepatocellular carcinoma (HCC) or other active malignancy at the time of PVT diagnosis.
Results: Of 38 patients fulfilling the criteria, 12/38 diagnosed later with HCC at the post PVT follow up (31.6%). Early HCC diagnosed in 7/12 within 2 months (18.4% of the 38, mean age 60.3 ± 7.8 years, CHILD/MELD were 8.1 ± 2.9/15.4 ± 7.5, 25% alive at EoFU, group A) suggesting missed diagnosis of concomitant "PVT and HCC" at the PVT diagnosis. Late HCC diagnosed in 5/12 within 29.8 ± 36.7 months (13.2%, 59.9 ± 8 y, CHILD/MELD were 6.7 ± 0.6/12.8 ± 4.8, 40% alive at EoFU, group B). The rest 26 PVT patients did not had HCC by the end of follow up (68.5%, 56.8 ± 14.9 y, 58% alive at EoFU, CHILD/MELD were 7.7 ± 2.1/14.2 ± 5.6, group C). The most common underlying aetiology was viral (HBV/HCV) in HCC groups (early 66.7% and late 80%, respectively), while NAFLD led the non-HCC group (50%). 12% of non-HCC cases underwent transplantation, while all PVT/HCC cases were beyond transplant salvage.
Conclusion: Acute or recent PVT diagnosis in cirrhotic patients without evidence of HCC needs careful and immediate investigation for concomitant hidden HCC (by extending image modalities) followed by short-term HCC surveillance, mainly in viral aetiologies.

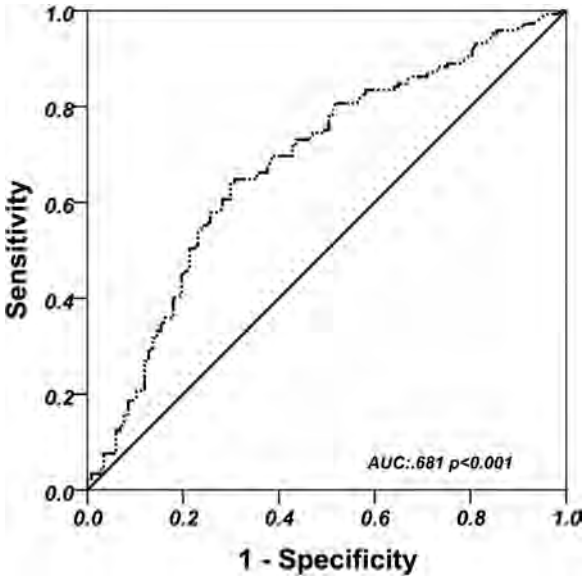
SAT212

The association of sarcopenia with myostatin, follistatin and irisin levels in cirrhotic patients: a multicenter cross-sectional study

Salih Boga[1], Abdullah Emre Yıldırım[2], Enver Ucbilek[3], Ali Riza Koksal[4], Sevil Tokdemir Sisman[5], Ibrahim Durak[6], Ilker Sen[7], Beril Dogu[8], Erdinc Serin[9], Ayse Bolat Ucbilek[10], Makbule Ozge Yildirim[11], Sukru Mehmet Erturk[12], Huseyin Alkim[7], Canan Alkim[7]. *[1]Memorial Bahçelievler Hastanesi, Department of Gastroenterology, Istanbul, Turkey; [2]Gaziantep University Medical Faculty, Department of Gastroenterology, Turkey; [3]Mersin University Faculty of Medicine, Department of Gastroenterology, Turkey; [4]Tulane University School of Medicine, Department of Medicine, Section of Gastroenterology and Hepatology, New Orleans, United States; [5]Sisli Hamidiye Etfal Education and Research Hospital, Department of Radiology, Istanbul, Turkey; [6]Sisli Hamidiye Etfal Education and Research Hospital, Department of Internal Medicine, Turkey; [7]Sisli Hamidiye Etfal Education and Research Hospital, Department of Gastroenterology, Turkey; [8]Sisli Hamidiye Etfal Education and Research Hospital, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey; [9]Sisli Hamidiye Etfal Education and Research Hospital, Department of Medical Biochemistry, Istanbul, Turkey; [10]Adana City Hospital, Department of Radiology, Adana, Turkey; [11]25 Aralık Hospital, Department of Physical Medicine and Rehabilitation, Gaziantep, Turkey; [12]Sisli Hamidiye Etfal Education and Research Hospital, Department of Radiology, Turkey*
Email: salihboga@yahoo.com

Background and Aims: Sarcopenia is independent predictor of mortality in cirrhosis. Because radiological analysis is the only current way to diagnose sarcopenia in cirrhosis, new practical diagnostic tests are needed to predict sarcopenia. We aimed to evaluate the efficacy of serum myostatin, follistatin and irisin levels as potential biomarkers for sarcopenia.
Method: A total of 262 patients followed up in 3 centers and 50 controls were included. Diagnosis of sarcopenia was confirmed when low muscle strength and low muscle mass were both detected. Muscle strength was measured by a handgrip test. Skeletal muscle mass assessed using skeletal muscle index (SMI) determined by calculating cross-sectional area of abdominal skeletal muscle at L3

level. Liver-specific subjective global assessment (SGA) was used to consider the nutritional status.
Results: Our study cohort had a median age of 58 years and included 139 (53.1%) males, whereas controls had a median age of 55 years and included 25 (50%) males. The median MELD and Child scores were 6.3 [3.5–9.95] and 6 [5–7] respectively. Muscle weakness was observed in 168 (64.1%) and decreased SMI was found in 214 (81.7%) patients. Eventually, a total of 145 (55.3%) patients were diagnosed as sarcopenia and this result was irrespective of nutritional status (SGA A, B, C) or gender. Serum myostatin levels were significantly higher in patients compared to controls 22.4 [9.2–35.8] vs. 2.2 [1.0–3.1 ng/dl $p < 0.001$) whereas serum irisin and follistatin levels showed no significant difference. While follistatin levels showed no significant difference between sarcopenia and non-sarcopenia groups, serum myostatin levels were significantly higher and serum irisin levels were significantly lower in the sarcopenia group (29.4 [14.8–41.2] vs. 14.3 [6.2–27.1] ng/dl $p < 0.001$ and 36.8 [15.8–103.7] vs. 54.8 [24.4–149.1] ng/dl $p < 0.01$). In order to detect the differentiating power of miyostatin levels for sarcopenia, we performed ROC analysis and AUC was 0.681. (Optimal cutoff value 23.3 ng/mL; sens 64%, spec of 70%). Serum myostatin showed positive moderate correlations with MELD and Child scores. ($r = 0.446, P < 0.001$; $r = 0.545, P < 0.001$). In BMI adjusted ANCOVA analysis, myostatin was independently higher in the sarcopenia group ($p < 0.001$)



Conclusion: Circulating miyostatin and irisin, but not follistatin are promising practical biomarkers that can be used in the diagnosis of sarcopenia in cirrhosis.

SAT213

A prospective evaluation of the Bristol prognostic score: poor sensitivity and specificity in a non-Bristol cohort

Sarah Bowers[1], Alana Brown-Kerr[1], Debbie Troland[1], Iain Hay[1], Fiona Finlay[2], Ewan Forrest[1], Stephen Barclay[1]. [1]*Glasgow Royal Infirmary, Department of Gastroenterology, Glasgow, United Kingdom;* [2]*Queen Elizabeth University Hospital, Department of Palliative Medicine, Glasgow, United Kingdom*
Email: sarah.bowers4@nhs.net

Background and Aims: People with end-stage liver disease often have an unpredictable trajectory throughout the course of their illness which can make anticipatory care planning difficult. The Bristol Prognostic Score (BPS, Hudson et al, *Frontline Gastroenterol.* 2017) was developed to identify patients with decompensated liver disease likely to die within one year, to allow consideration of palliative care input. We sought to prospectively evaluate the performance of the score amongst an inpatient cohort in a non-transplant Scottish gastroenterology unit.
Method: Inpatients with decompensated liver disease in our unit as of the 1st of March 2017, and those admitted up to July 2017, were prospectively recruited. Admission BPS was calculated (based on Child's C, >2 admission in last 6 months, ongoing alcohol in ArLD, exclusion from transplant, WHO performance status 3 or 4). Electronic case notes were reviewed and mortality noted. Sensitivity, specificity and positive predictive values for BPS ≥3 were calculated. Frequency of BPS scores and 1 year mortality were compared against the original Bristol cohort using chi-square.
Results: 50 patients were studied. One emigrated and was excluded thereafter. 41 of the remaining patients (83.7%) had alcohol-related liver disease and 29 were male (59%). The median age was 55 (range 31–81, IQR 16).
33 (67.3%) were BPS positive (≥3/5). 19 (38.8%) of patients were dead at one year post admission, 12 in the BPS positive group. The sensitivity, specificity and positive predictive value of a positive BPS score for one year mortality were 63.2%, 30% and 36.4% respectively. Comparisons of our cohort compared with the Bristol cohort are shown in the table below.

Table: Number of patients stratified by BPS status and 1 year mortality

	Current cohort *n* (%)	Bristol cohort *n* (%)	
BPS ≥ 3	33 (67.3)	32 (43.8)	$p < 0.02$
1 year Mortality	19 (38.8)	36 (49.3)	$p = 0.33$
Sensitivity	63%	72.2%	
Specificity	30.8%	83.8%	
Positive Predictive Value	45.5%	81.3%	

Conclusion: Our patients had a higher prevalence of a positive BPS but not significantly different 1 year mortality compared with the original Bristol cohort. 7/19 (36.8%) of deaths occurred in the BPS negative group. Overall these results demonstrated poor sensitivity, specificity and a low positive predictive value for one year mortality in patients with a BPS ≥3. Prospective validation of the BPS in individual settings should be undertaken before being considered as a tool in routine care.

SAT214

Blood and ascites pharmacokinetics of meropenem in patients with nosocomial spontaneous bacterial peritonitis and decompensated liver cirrhosis

Marie Schultalbers[1], Denis Grote-Koska[2], Thorsten Book[1], Birgit Bremer[1], Korbinian Brand[2], Michael P. Manns[1,3], Markus Cornberg[1,3], Julius J. Schmidt[4], Benjamin Maasoumy[1,3]. [1]*Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany;* [2]*Hannover Medical School, Department of Clinical Chemistry, Hannover, Germany;* [3]*Centre for Individualised Infection Medicine (CIIM), c/o CRC Hannover, Hannover, Germany;* [4]*Hannover Medical School, Department of Nephrology, Hannover, Germany*
Email: maasoumy.benjamin@mh-hannover.de

Background and Aims: Nosocomial spontaneous bacterial peritonitis (nSBP) is a severe complication in patients with decompensated liver cirrhosis. Inadequate concentrations of antibiotics may cause treatment failure and drug resistance, which has been increasing over the last years. However, there are quite limited data available on pharmacokinetics of carbapenems in patients with advanced liver disease, in particular with regard to the ascites fluid. The aim of the study was to investigate the Meropenem kinetics in blood and ascites in patients with nSBP.
Method: Seven patients with nSBP, decompensated liver cirrhosis and indication for Meropenem treatment were prospectively recruited. Plasma and ascites samples were collected at baseline as

well as 15, 30, 45, 60, 120, 240, 480, 510 and 960 minutes after the first Meropenem infusion at day 0 and at the same time points on an additional day >48 hours after start of treatment. In addition, plasma and ascites samples were obtained once on each day previous to Meropenem infusion. Overall, 100 plasma and 110 ascites samples were available for the assessment of Meropenem drug level. Minimum inhibitory concentration (MIC) was defined as 2 mg/l referring to Enterobacteriaceae (EUCAST).

Results: Three women and four men with a median age of 51 years and median MELD score of 22 were included. Median creatinine was 197 µmol/l, weight 67 kg and height 1.72 m. Median ascites drainage volume was 1600 ml/day. The median Meropenem dosage was 3 g/day. Some remarkable pharmacokinetic differences were documented when comparing Meropenem levels in plasma and ascites. The maximal concentration (Cmax) was higher in plasma than in ascites (44.7 mg/l vs. 26.0 mg/l, p = 0.001). While median time to Cmax was only 30 minutes in plasma, it took 120 minutes in ascites (Figure). However, therapeutic concentration (>4xMIC) was achieved already after 15–45 minutes in ascites and remained above this threshold for at least 44% of the time in all patients. Of note, at all times measured concentrations in blood plasma and ascites were higher than the MIC in all analysed patients and did not yield toxic levels.

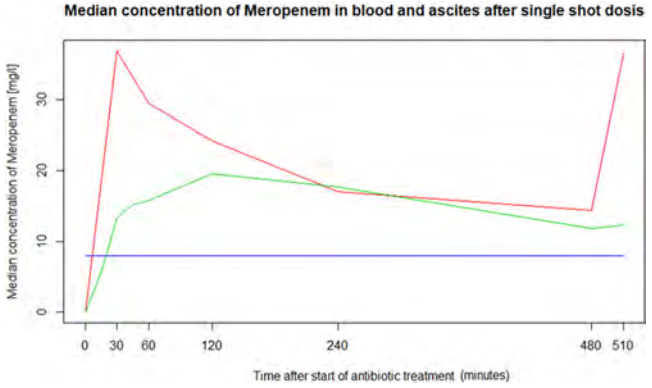


Figure: Meropenem concentration in blood (red) and ascites (green) shown. The 4xMIC is displayed in blue.

Conclusion: Although distinct differences between Meropenem pharmacokinetics in ascites and blood exist, the concentration never falls under the MIC in both compartments. Current nSBP treatment strategy with Meropenem seems to be safe and achieves sufficient drug levels in ascites.

SAT215

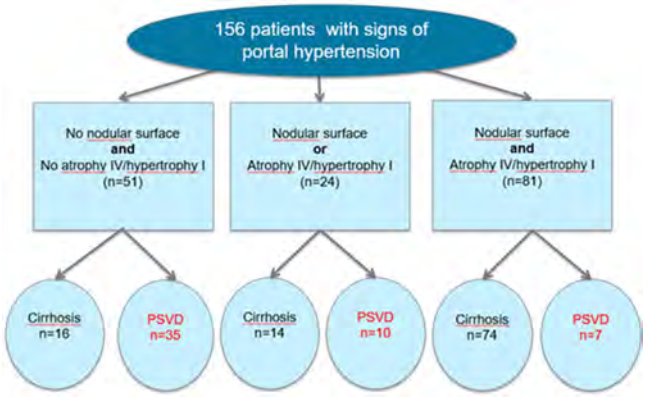
Diagnostic performance of contrast-enhanced CT for the diagnosis of portosinusoidal vascular disease: a case-control study

Shantha Valainathan[1,2], Pellegrino Silvia[3], Nivolli Arianna[3], Nicolas Drilhon[1,2], Lazareth Marie[1], Bruno Onorina[3], Aurelie Plessier[1,2,4], François Durand[1,2,4], Maxime Ronot[2,3], Dominique Valla[1,2,4], Valérie Paradis[2,5], Valerie Vilgrain[2,3], Pierre-Emmanuel Rautou[1,2,4]. *[1]Hopital Beaujon AP-HP, Service d'Hépatologie, DHU Unity, DMU Digest, Clichy, France; [2]Université de Paris, Centre de recherche sur l'inflammation, Inserm, U1149, CNRS, ERL8252, Paris, France; [3]Hôpital Beaujon AP-HP, Service d'imagerie, Clichy, France; [4]Centre de Référence des Maladies Vasculaires du Foie, French Network for Rare Liver Diseases (FILFOIE), European Reference Network on Hepatological Diseases (ERN RARE-LIVER), France; [5]Hôpital Beaujon AP-HP, Service d'Anatomie Pathologique, Clichy, France*
Email: shantha.valainathan@gmail.com

Background and Aims: Porto-sinusoidal vascular disease (PSVD) is a rare cause of portal hypertension. Imaging findings have been described as associated with PSVD, but their diagnostic value has not been established and their relationship with histological lesions is unknown. The aim of this study was to assess diagnostic performance of contrast-enhanced CT (CECT) features in patients with PSVD and signs of portal hypertension, as compared to patients with cirrhosis.

Method: This retrospective monocentric case-control study included all patients with PSVD, according to VALDIG criteria, who underwent a liver biopsy between 2011 and 2018 and performed CECT in the year before or after liver biopsy. Each patient with PSVD was matched for the severity of ascites with 2 patients with histologically proven cirrhosis without hepatocellular carcinoma outside Milan criteria. PSVD biopsies were reviewed by an expert pathologist and elementary lesions classified according to pre-specified criteria. CT images were reviewed by 2 independent radiologists, not aware of the liver disease, and classified according to pre-specified criteria.

Results: 52 patients with PSVD [23 women; 60 years (43–68); MELD 9 (7–10)] and 104 patients with cirrhosis [23 women; 62 years (52–68); MELD 11 (8–16)] were included. In patients with PSVD, as compared with patients with cirrhosis, abnormalities of intrahepatic portal branches and/or extrahepatic portal vein (p = 0.047), mesenteric and/or splenic vein thrombosis (p = 0.01), inter-hepatic vein collaterals (p = 0.005), and hepatic veins near to the capsulae (p = 0.002) were statistically more common, and spleen was larger (p = 0.011). In patients with PSVD, simultaneous atrophy of segment IV with hypertrophy of segment I (p < 0.0001), and a nodular liver surface (p < 0.0001) were less common. Using binary logistic regression, imaging features associated with PSVD were an absence of simultaneous atrophy of segment IV with hypertrophy of segment I, and an absence of nodular liver surface (OR = 4.7 (IC 95% 1.8–12.3) p = 0.002 for both) (Fig.). Combining the latter 2 criteria had a sensitivity of 67% and a specificity of 87%. Among patients with PSVD, no significant associations between pathological and imaging data were found.



Conclusion: In patients with signs of portal hypertension, absence of simultaneous atrophy of segment IV with hypertrophy of segment and absence of nodular surface of the liver should raise suspicion of PSVD.

SAT216

Broad defect in energy metabolism drives immune dysfunction in cirrhosis and cirrhosis associated sepsis

Anupam kumar[1], Dhananjay Kumar[1,2], Deepanshu Maheshwari[2], Ashini Hidam[2], Nidhi Nautiyal[2], Rakhi Maiwall[3], Shiv Kumar Sarin[1,3]. *[1]Institute of Liver and Biliary Sciences, New Delhi, India; [2]Institute of Liver and Biliary Sciences, MCM, India; [3]Institute of Liver and Biliary Sciences, Hepatology, India*
Email: shivsarin@gmail.com

Background and Aims: Immune dysfunction have been shown to be associated with increased incidences of sepsis with high mortality in cirrhosis. Underlying cause of immune paralysis in response to infection in cirrhosis is not defined. Energy metabolism has recently

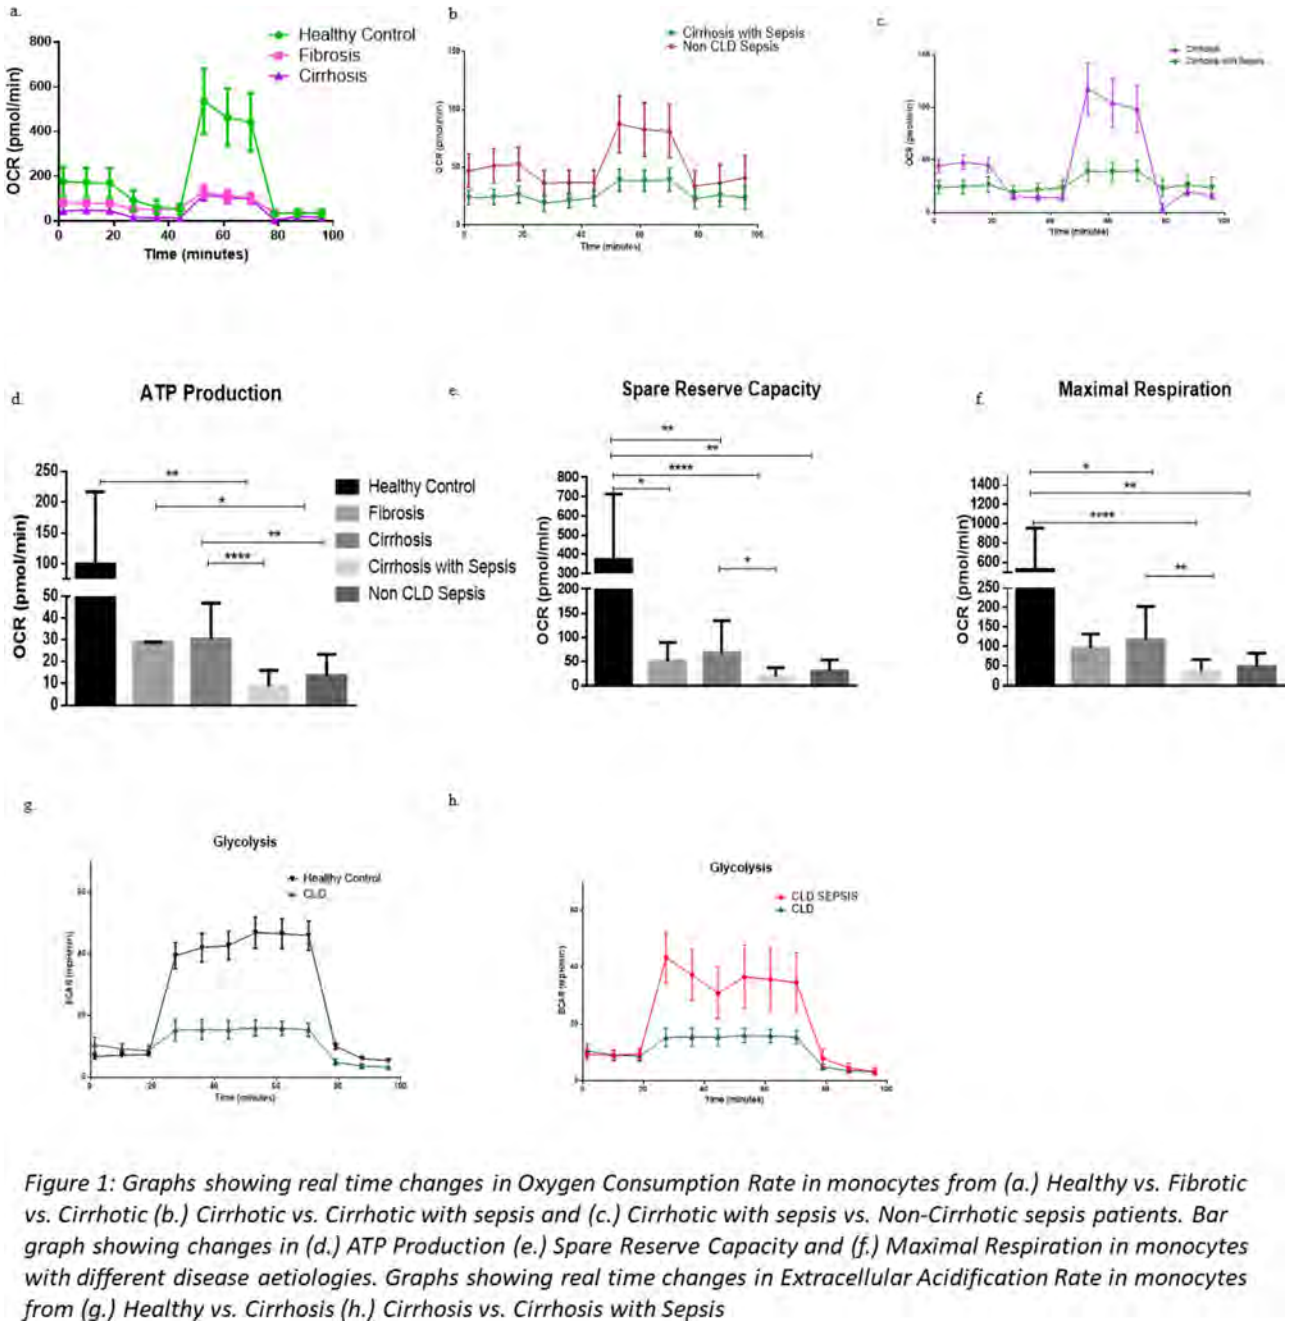


Figure 1: Graphs showing real time changes in Oxygen Consumption Rate in monocytes from (a.) Healthy vs. Fibrotic vs. Cirrhotic (b.) Cirrhotic vs. Cirrhotic with sepsis and (c.) Cirrhotic with sepsis vs. Non-Cirrhotic sepsis patients. Bar graph showing changes in (d.) ATP Production (e.) Spare Reserve Capacity and (f.) Maximal Respiration in monocytes with different disease aetiologies. Graphs showing real time changes in Extracellular Acidification Rate in monocytes from (g.) Healthy vs. Cirrhosis (h.) Cirrhosis vs. Cirrhosis with Sepsis

Figure: (abstract: SAT216)

shown to guide the inflammatory and resolving function of monocytes in response to infection. our aimed to see the effect of cirrhosis on energy metabolism of monocytes and on its function

Method: Mitochondrial respiration and glycolysis of monocytes were analysed in fibrosis (F2 F3) patients (n = 6), cirrhosis without sepsis (CLD,n = 18), cirrhosis with sepsis (S-CLD,n = 23), non-cirrhotic sepsis patients (NCS,n = 10) and healthy(HC,n = 17). Phagocytic function of monocytes was assed using Phagocytosis Kit.

Results: Monocytes from fibrotic and CLD patients showed significant loss in mitochondrial potential compared to HC (fig 1a). Sepsis with cirrhosis resulted in further decrease in mitochondrial bioenergetics (Fig 1b-c). Sepsis was associated with significant decrease in cellular ATP production ($p < 0.005$) (fig 1d). S-CLD showed decrease in spare reserve capacity and maximal respiration compared to CLD ($p < 0.05$, fig 1e-f). Inhibition of mitochondrial ATP production in healthy monocytes significantly decrease ($p < 0.005$) their phagocytosis. In comparison to healthy, cirrhotic monocytes showed decrease ($p < 0.0001$) in phagocytic activity which further dampen ($p < 0.001$) with sepsis. Together suggesting loss of mitochondrial respiration leads to defect in monocytes phagocytosis in cirrhosis. Monocytes from CLD patients showed reduced glycolysis compared to HC (fig 1g) and showed decrease production of inflammatory cytokines (TNF-alpha, IL-1beta) in response to LPS. In cirrhotic sepsis, while there is rapid increase in glycolysis on injecting glucose, this rapidly decreases with time, suggesting glucose intolerance (fig 1h). In comparison to NCS cirrhotic monocytes show t impairment in both glycolysis and mitochondrial respiration

Conclusion: Our data suggests that chronic liver injury compromises bioenergetic potential of monocytes. Infection further dampen the energy metabolism of monocytes in cirrhosis leading to their

functional exhaustion. This might be responsible for poor resolution of infection and increased mortality in septic cirrhosis. Restoring bioenergetic potential of monocytes in CLD and CLD-Sepsis may result in improved outcomes in these patients.

SAT217

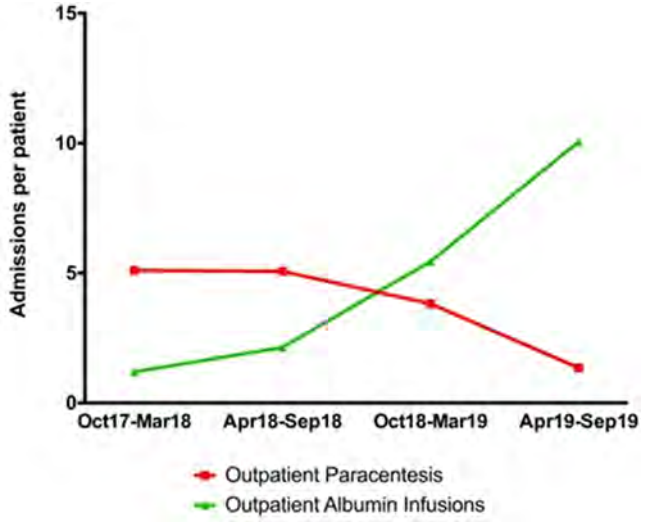
A nurse-led albumin infusion service reduces the need for therapeutic paracentesis in the outpatient day procedure setting

Kelsey Rutland[1], William Beattie[1], Siddharth Sood[1,2]. [1]*The Royal Melbourne Hospital, Department of Gastroenterology & Hepatology, Parkville, Australia;* [2]*University of Melbourne, Department of Medicine, Parkville, Australia*
Email: siddharth.sood@mh.org.au

Background and Aims: Recent evidence has suggested a significant benefit from regular albumin infusions in patients with cirrhosis. We initiated a nurse-led service for patients that gradually began arranging regular albumin infusions for patients with cirrhosis and ascites from late 2017. We aimed to observe the take-up and impact of this service on day procedure admissions for therapeutic paracentesis over the last 2 years.

Method: A nurse-led albumin infusion program was gradually introduced as patients began being referred by their treating Hepatologist at a tertiary liver centre. Inclusion criteria were patients with cirrhosis and ascites admitted under Gastroenterology to the day procedure ward for either therapeutic paracentesis of at least 1L, or intravenous albumin infusions between 01/10/2017–30/09/19. As per standard practice, 100 ml of 20% concentrated albumin was given for either every 2L of ascites drained, or 2 × 100 ml per albumin admission. Statistical analysis included linear regression, with a $p < 0.05$ considered significant. Hospital coding was reviewed to ensure there was no corresponding increase in inpatient admissions.

Results: 460 unique patient episodes were documented in 28 patients over 2 years. A median 12.5 patients (range 10–17) had admissions to the day procedure centre for either paracentesis or albumin throughout each 6 month period. The average paracentesis/pt decreased during each 6 month period from 5.10 in the first 6 months to only 1.35 in the most recent period ($r^2 = 0.84$, $p = 0.08$), whilst admissions for albumin infusions per patient significantly increased from 1.2 to 10.1 ($r^2 = 0.93$, $p = 0.04$) (figure 1). Neither the average volume of ascites drained with each paracentesis ($r^2 = 0.51$, $p = 0.29$) or overall albumin volume per patient ($r^2 = 0.81$, $p = 0.10$) have significantly changed. Inpatient admissions with ascites did not increase, with a gradual drop from 30 to 25 per 6 month period over the 2 years ($p = 0.29$).



Conclusion: We report the successful introduction of a nurse-led outpatient albumin infusion service. With increasing use of albumin, there has been a corresponding reduction in need for therapeutic paracentesis without any subsequent increase in inpatient activity.

SAT218

Increased levels of soluble mannose receptor are associated with poor outcome in cirrhosis: results from a 2-year longitudinal study

Signe Wiese[1], Jens Hove[1], Holger Jon Møller[2], Flemming Bendtsen[1], Henning Grønbæk[3], Søren Møller[1]. [1]*Copenhagen University Hospital Hvidovre;* [2]*Aarhus University Hospital, Dept Clinical Biochemistry, Denmark;* [3]*Aarhus University Hospital, Dept. Gastroenterology, Denmark*
Email: signeswiese@gmail.com

Background and Aims: Activated hepatic macrophages play a key role in inflammation and fibrosis progression in chronic inflammatory liver diseases. In cross-sectional studies the macrophage activation marker soluble mannose receptor (sMR) is a promising prognostic marker for occurrence of cirrhosis-associated complications. However, the development in sMR levels over time has never been assessed in patients with cirrhosis. We therefore aimed to investigate changes in sMR over a 2-year period and the association with poor outcome.

Method: 61 cirrhotic outpatients (Child class: A = 9, B = 44, C = 8) were included in this 2-year longitudinal study. Clinical evaluations and biomarkers including sMR were assessed at 0/6/12/18/24 months. Patients were followed-up with registration of liver transplantation (LT), and death.

Results: We found a stepwise increase in baseline sMR with increasing Child classes CP-A: 0.21 mg/L (0.13–0.35), CP-B 0.36 mg/L (0.28–0.44), CP-C 0.83 mg/L (0.53–0.94), $p < 0.001$. During a median follow-up of 30 months 4 patients underwent LT and 19 patients died. Within the initial six months 4 patients underwent LT and 4 patients died. These patients had significantly higher baseline median sMR 0.83 mg/L (IQR:0.52–0.93) and 0.87 mg/L (IQR:0.47–1.33)) than those without events 0.31 mg/L (IQR: 0.23–0.42), $p = 0.003$ and $p = 0.006$, respectively. Additionally, we found significantly increasing sMR levels over time in the 15 patients who died and had repeated measurements from baseline median sMR 0.40 mg/L (IQR:0.29–0.48) to last visit median sMR 0.46 mg/L (IQR: 0.33–0.53) whereas patients without events had a slightly decrease in sMR levels over the 2-years with a last visit median sMR 0.26 mg/L (IQR:0.20–0.35), $p = 0.02$ for the difference in delta sMR and $p = 0.002$ for the difference in last visit sMR.

Conclusion: The sMR levels increase over time in cirrhotic patients who die during follow-up. Moreover, increased sMR levels are associated with poor both short-term and long-term outcome. This further emphasize and support that macrophage activation and inflammation are key components in disease progression and poor outcome in cirrhosis. Moreover, sMR seems a promising prognostic marker and potentially also for treatment response in patients with liver cirrhosis.

SAT219

MRI-derived myocardial extracellular volume is closely associated with markers of collagen formation in cirrhosis

Signe Wiese[1], Andrei Voiosu[1,2], Jens Hove[1], Karen Danielsen[1], Henning Grønbæk[3], Holger Jon Møller[3], Federica Genovese[4], Alexander Lynge[4], Ove Andersen[1], Flemming Bendtsen[1], Søren Møller[1]. [1]*Copenhagen University Hospital Hvidovre;* [2]*Colentina Clinical Hospital, Romania;* [3]*Aarhus University Hospital;* [4]*Nordic Bioscience Biomarkers & Research A/S, Denmark*
Email: signeswiese@gmail.com

Background and Aims: Fibrotic remodeling of the extracellular matrix is a key component in the development and progression of liver cirrhosis. Contrast-enhanced MRI with quantification of the

extracellular volume (ECV) has proven to be closely related to presence of histological fibrosis in both the liver and the heart. Recently, we reported a strong interrelation between myocardial and hepatic ECV in patients with cirrhosis. We therefore hypothesized that a parallel accumulation of cardiac fibrosis is a likely contributing mechanism of cirrhotic cardiomyopathy. Our aim was to investigate the role of collagen turnover on myocardial ECV in patients with cirrhosis.

Method: We prospectively included 47 cirrhotic patients. All patients underwent contrast-enhanced MRI with T1-mapping and quantification of myocardial and hepatic ECV, and assessments of inflammatory biomarkers such as sCD163, sMR, IL-6 and IL-8, and serological biomarkers of collagen formation and degradation comprising PRO-C3, PRO-C5, PRO-C6, C4M, C5M, and LG1M.

Results: Myocardial ECV increased in relation to disease severity in cirrhosis. Myocardial ECV was closely correlated with markers of collagen formation: PRO-C3 ($r = 0.43$, $p = 0.002$), PRO-C6 ($r = 0.40$, $p = 0.004$) and markers of inflammation: sMR ($r = 0.43$, $p = 0.003$), IL6 ($r = 0.46$, $p = 0.001$). Moreover, myocardial ECV correlated with hepatic ECV ($r = 0.48$, $p = 0.001$). In a multivariate analysis, myocardial ECV was predicted by PRO-C6, IL-6 and sMR.

Conclusion: Myocardial ECV is increased in patients with advanced cirrhosis and the strong correlations with markers of collagen formation and hepatic ECV suggest that fibrogenesis is concomitantly activated in the cirrhotic liver and heart. Myocardial ECV can easily be determined by contrast-enhanced MRI and may reveal the degree of cardiac fibrosis. This method therefore represents an important tool for further insight into the role of fibrogenesis in the development of structural abnormalities in the heart leading to cirrhotic cardiomyopathy.

SAT220

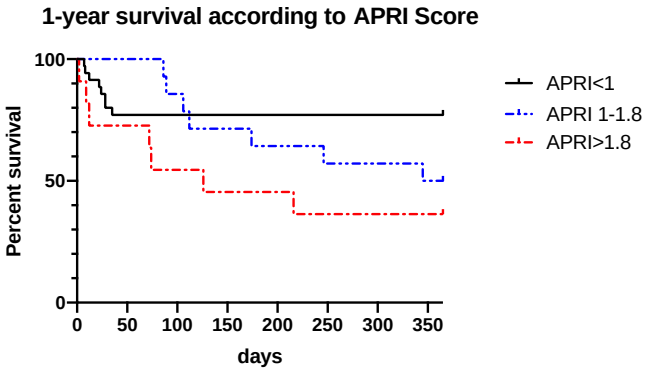
FIB-4 and APRI-scores predict survival in patients with transjugular intrahepatic portosystemic stent shunts

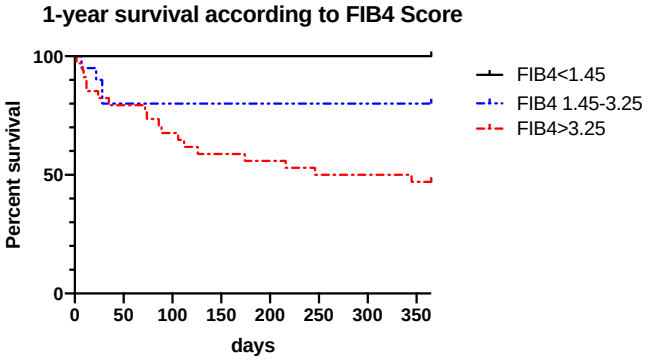
Simone Anna Keimburg[1], Jens Theysohn[2], Matthias Buechter[1], Jassin Rashidi[1], Axel Wetter[2], Christian Lange[1], Heiner Wedemeyer[1], Antoaneta Angelova Markova[1]. *[1]University Hospital Essen, Gastroenterology and Hepatology, Essen, Germany; [2]University Hospital Essen, Radiology, Essen, Germany*
Email: antoaneta.markova@uk-essen.de

Background and Aims: Transjugular intrahepatic portosystemic shunt (TIPS) is a standard therapy in patients with liver cirrhosis. Interventional techniques and type of shunts have changed during the last 15 years. It is crucial to define easy and reliable factors associated with TIPS outcome, which however, may have different values depending on the shunt type and patient cohort. We here studied a homogenous single center cohort of TIPS patients and investigated predictors of patient survival.

Method: We analyzed a total of 100 consecutive patients with liver cirrhosis evaluated for TIPS, which has been placed in 87 patients by two radiologists between January 2017 and November 2019. TIPS diameter was <8 mm in 19 patients, 8 mm in 26 patients, and >8 mm in 42 patients. Major indication for TIPS was a hydropic decompensation (82/100 patients). Patients were followed for a median of 216 days (range 2–1012).

Results: The majority of patients was male (57/87). Median age was 57 years (range 20–88), median BMI was 25,4 kg/m^2. Child Pugh A/B/C class were 25/55/7 patients. Patient survival after 3, 6 and 12 months was 82%, 75% and 70% respectively. Acute hepatic decompensation, defined as bilirubin increase >5 g/dl as well as INR decrease, occurred within 3 months after TIPS in 9 cases. In univariate analysis, neither bilirubin nor INR or liver enzymes alone were associated with 6 and 12 months post-TIPS survival. However, both FIB-4 and APRI scores were associated with overall survival. The hazard ratio for death at 1 year was 3.5 (95% Confidence intervals 1–11) for patients with a FIB-4 score of >3.25 compared to <1.45, and 4.7 (95% Confidence intervals 1–16) for an APRI score of >1.8 compared to patients with an APRI of <1.





Conclusion: A combination of markers reflecting portal hypertension and biochemical disease activity predicts long-term outcome after TIPS with most recent shunts using covered stents.

SAT221

Real-world effectiveness of piperacillin/tazobactam-based therapies for spontaneous bacterial peritonitis

Stefanie Quickert[1], Philipp Reuken[1], Aleksandra Markendudis[1], Andreas Stallmach[1], Tony Bruns[1,2]. *[1]Jena University Hospital, Dpt. of Internal Medicine IV, Jena, Germany; [2]University Hospital RWTH Aachen, Dpt. of Internal Medicine III, Aachen, Germany*
Email: tonybruns@gmail.com

Background and Aims: Current guidelines recommend empiric therapy with piperacillin/tazobactam (PTZ) for spontaneous bacterial peritonitis (SBP) at low risk for multi-drug resistant organisms (MDROs) based on in vitro antimicrobial resistance data. However, controlled trials of PTZ-based regimens for SBP are lacking and real-word data are sparse.

Method: In 2015 we implemented standard operating procedures for empiric antibiotic therapy of SBP at our department, advocating treatment with PTZ ± linezolid (LZD) for empiric therapy of SBP at low risk for Gram-negative MDROs, after using predominantly third generation cephalosporins (TGC) before. In order to assess the efficacy of PTZ-based regimens, we evaluated microbial resistance, cytologic response, treatment failure, and mortality in patients receiving TGC or PTZ-based therapies for SBP.

Results: 81 empirical treatments with PTZ-based regimen (44 PTZ, 37 PTZ + LZD) and 81 historical treatments with TGC were included. SBP was community-acquired in 48% of episodes (53% in TGC vs. 43% in PTZ-based regimens; $P = 0.27$). 71 (44%) episodes were culture-positive with a low prevalence of TGC-resistant Gram-negatives (6 ESBL-producing enterobacteriaceae) and a high prevalence of TGC-resistant Gram-positives (11 enterococci, 1 MRSA, 4 listeriae, 2 others).

Therapy failure resulting in antimicrobial therapy escalation was observed in 6 (16%) episodes treated with PTZ + LZD, 22 (50%) episodes treated with PTZ monotherapy, and 30 (37%) episodes treated with TGC monotherapy, respectively (p = 0.006). This was due to a low antimicrobial resistance rate in patients treated with PTZ + LZD (0/17 [0%]) vs. PTZ alone (5/21 [24%]) or TGC (10/33 [30%]) (p = 0.04) alongside low rates of cytological non-response (5/32 [16%] in PTZ+LZD vs. 8/33 [24%] in PTZ alone vs. 10/36 [28%] in TGC alone; p = 0.48). Therapy escalation because of clinical decision in the absence of resistance or cytological non-response was rare in patients treated with PTZ+LZD (1/37 [3%]) vs. PTZ monotherapy (11/44 [25%]) or 3GC (12/81 [15%]) treatment (p = 0.02).
The need for antimicrobial therapy escalation was associated with poor 30-days survival (60% vs. 83%; p = 0.001 log-rank). However, short-term survival did not significantly differ according to empirical treatment (79% PTZ+LZD vs. 70% PTZ vs. 75% TGC; p = 0.78).
Conclusion: These real-world data support the use of PTZ-based empirical therapies for SBP in settings of low rates of Gram-negative MDROs. PTZ+LZD combination therapy is associated with low rates of therapy failure.

SAT222

Etiology and diagnosis of ascites: contemporary cohort study in a secondary care setting

Mohsan Subhani[1], Peuish Sugathan[1], Guruprasad Aithal[1], Emilie Wilkes[1], Naaventhan Palaniyappan[1]. *[1]The Queen's Medical Centre, NIHR Nottingham Biomedical Research Centre, Nottingham, United Kingdom*
Email: subhani@doctors.org.uk

Background and Aims: Studies performed in specialist centers more than 25 years ago reported liver cirrhosis (80–85%) as main etiology of ascites and diagnostic accuracy of serum-ascites albumin gradient (SAAG) greater then 11 to identify portal hypertension as cause up to 97%. This has impact on clinical decision-making and guidelines have prioritized particular tests based on their utility in routine practice. We aimed to describe the contribution of different etiologies of ascites in a contemporary cohort of patients and to test validity of SAAG and cytology in this cohort.
Method: Using the data from a National Health Service hospital providing secondary care to a population of 700,000, patients with a primary or secondary diagnosis of ascites were identified. Adult patients above age of 18 year, from May 2013 to April 2018 with confirmed ascites on ultrasound or CT scan were included. Patient with peritoneal fluid collection as an immediate or late manifestation of acute abdomen or postoperative complication were excluded (surgical cases).
Results: Over a period of 5 years, 286 patients [F:148] presented with new onset ascites. We excluded 122 surgical cases, and included 164 medical cases. Out of 164 cases, 90 (55%) had liver cirrhosis [Alcohol related liver disease 58, non-alcoholic fatty liver disease 21, chronic viral hepatitis 4, Auto immune liver diseases 3, and cryptogenic cirrhosis 4], 29% had malignancies [gynecological: 12, Gastrointestinal: 25 and others: 11], 6% cardiac failure (CF), 3% End stage renal disease (ESRD) and 7% others etiologies. We further divided participants into high SAAG (≥11) and low SAAG (<11) groups. SAAG was done in 116 patients. In high SAAG group out of 83 (71%) patients, 65 (78%) had liver cirrhosis and 6 (7%) have cardiac failure. On applying foster 2 by 2 contingency test, high SAAG (≥11) was 78% sensitive, 52% specific and had diagnostic accuracy of 64% in identifying portal hypertension as cause of ascites in this group. In low SAAG group (<11) out of 33 (29%) patients, 13 (40%) have malignant ascites and 5 (15%) had ESRD. In study cohort 29 (18%) patients had hepatic portal pressure gradient (HPVG) measured, of these 24 patients had a HPVG of >10, in this group high SAAG (≥11) was 90%, sensitive for portal hypertension. In patients with malignant ascites 40 patients (83%) had ascitic cytology checked out of this 20 (50%) has positive cytology for malignancy.
Conclusion: In a contemporaneous medical cohort of patients with ascites, underlying etiology and validity of currently available tests (SAAG, cytology) varied substantially from what is described in the literature with liver cirrhosis only accounting for over half the cases and malignancies contributed to quarter of cases. Current information related to the etiology of ascites should inform clinical practice particularly regarding the prioritization of diagnostic tests and setting up services.

SAT223

Sarcopenia is not associated with poor outcomes after transjugular intrahepatic portosystemic shunt insertion for refractory ascites

Thomas Tranah[1], Oliver Tavabie[1], Zillah Cargill[1], Swathi Rajagopal[1], Sarah Brown[1], Pauline Kane[1], Brian J. Hogan[1], Debbie Shawcross[1]. *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom*
Email: t.tranah@nhs.net

Background and Aims: Sarcopenia is a common complication of end-stage chronic liver disease and is associated with adverse transplant waiting list and post-transplant outcomes. We undertook this study to evaluate whether sarcopenia was associated with hepatic encephalopathy (HE) or reduced transplant-free survival after transjugular intrahepatic portosystemic shunt (TIPSS) insertion.
Method: Adult cirrhotic patients undergoing TIPSS for diuretic refractory ascites or hepatic hydrothorax at King's College Hospital between 2010–2019 were retrospectively reviewed. Skeletal muscle index (SMI) was captured from CT imaging performed within 3 months of TIPSS using Sectra IDS7 image analysis software to calculate the cross-sectional area of abdominal skeletal muscle at the level of the third lumbar vertebrae and normalised to patient height (cm^2/m^2). Using pre-defined criteria, <50 cm^2/m^2 and <39 cm^2/m^2 were accepted cut-offs for the presence of sarcopenia. Demographic, biochemical, and radiological data were collected in addition to outcome data relating to episodes of early (<3 months) and late (>3 months) HE and transplant-free survival.
Results: 49 patients with diuretic refractory ascites were included in our analysis; 33 male, 16 female; mean age 56.2 +/– 19.8 years. Univariate analysis demonstrated no significant associations of biochemical data, organ severity scoring, ammonia or sarcopenia indices with the development of early or late HE. The majority (86%) of patients undergoing TIPSS for refractory ascites met radiological thresholds for sarcopenia. Late HE complicated 17/49 (35%) of TIPSS procedures. Ammonia (54.7 vs. 48.0 mmol/L, p = 0.50), MELD (11.9 vs. 11.9, p = 0.97) and baseline EEG evidence of mild HE (likelihood ratio 1.23, p = 0.64) were poor predictors of both early- and late hepatic encephalopathy; older patients were more likely to experience late hepatic encephalopathy (60.0 vs. 53.3, p = 0.023). SMI estimation showed good interobserver reliability (95%) and correlated well with estimated dry body mass index (BMI) as a marker of sarcopenia (pearson r = 0.651, p < 0.0001) but not ammonia (pearson r = 0.172, p = 0.33). Sarcopenia showed a trend towards an association with early HE (odds ratio 5.54, p = 0.167) but was not associated with late HE (odds ratio 1.18, p = 0.779) or transplant-free survival (p = 0.593).
Conclusion: Sarcopenia demonstrated a non-significant association with early HE but was not associated with either late HE or worse transplant-free survival and should not preclude consideration of TIPSS; this may reflect improvements in muscle mass and ammonia metabolism after TIPSS. Current modalities for predicting risk of HE post-TIPSS are poor and larger studies evaluating combined parameters in the assessment of advanced chronic liver disease are needed to improve prognostication in this area.

SAT224

Impact of acute decompensation on prognosis in patients with hepatocellular carcinoma

Takayuki Kondo[1], Yoshihiko Ooka[1], Keisuke Koroki[1], Susumu Maruta[1], Kengo Kanayama[1], Hiroaki Kanzaki[1], Kazufumi Kobayashi[1,2], Masato Nakamura[1], Soichiro Kiyono[1], Naoya Kanogawa[1], Tomoko Saito[1], Sadahisa Ogasawara[1,2], Eiichiro Suzuki[1], Shingo Nakamoto[1], Akinobu Tawada[1,3], Tetsuhiro Chiba[1], Makoto Arai[1,3], Tatsuo Kanda[4], Hitoshi Maruyama[5], Jun Kato[1], Naoya Kato[1]. *[1]Chiba University, Graduate School of Medicine, Department of Gastroenterology, Chiba, Japan; [2]Chiba University Hospital, Translational Research and Development Center, Chiba, Japan; [3]Chiba University, Graduate School of Medicine, Department of Medical Oncology, Chiba, Japan; [4]Nihon University School of Medicine, Department of Internal Medicine, Tokyo, Japan; [5]Juntendo University School of Medicine, Department of Gastroenterology, Tokyo, Japan*
Email: takakondonaika@yahoo.co.jp

Background and Aims: The most common hospital presentation of patients with cirrhosis is acute decompensation (AD). Among these patients, the occurrence of organ failure defines acute-on-chronic liver failure (ACLF), and it is characterized by high short-term mortality. However, little is known about the clinical features of AD during the long clinical course of hepatocellular carcinoma (HCC). The present study aimed to clarify the impact of AD on prognosis in patients with HCC.

Method: This retrospective study included data from our institutional database between 2011 and 2016. The study enrolled 617 consecutive patients initially diagnosed with HCC, and they were stratified into early, intermediate, and advanced stage groups (380, 121, and 116 patients, respectively).

Results: During a median follow-up of 35.9 months, 331 patients (early/intermediate/advanced: 177/82/72 patients) with AD were hospitalized. The AD incidence was greater in the intermediate/advanced group than in the early group (early: 7.9% at 1 y/21.2% at 3 y; intermediate: 27.8% at 1 y/54.9% at 3 y; advanced: 48.3% at 1 y/56.1% at 3 y; $p < 0.001$). AD during follow-up negatively affected long-term survival (free from AD vs. presence of AD; early: 95.8% vs. 88.9% at 1 y/89.9% vs. 67.0% at 3 y, $p < 0.01$; intermediate: 92.8% vs. 67.6% at 1 y/56.8% vs. 39.9% at 3 y, $p < 0.01$; advanced: 50.7% vs. 41.3% at 1 y/34.7% vs. 7.3% at 3 y, $p = 0.04$). Fifty-two patients (15.7%) (early/intermediate/advanced: 21 (11.8%)/19 (23.1%)/12 (16.6%) patients) with AD who presented ACLF at admission showed high 28-day mortality compared to those without ACLF (Non-ACLF) for all stages (Non-ACLF vs. ACLF; early: 16.7% vs. 52.4%, $p < 0.01$; intermediate: 20.6% vs.47.4%, $p = 0.04$; advanced: 30% vs. 66.7%, $p = 0.02$). However, there is no significance difference in 90-day mortality between Non-ACLF and ACLF patients in the intermediate (42.9% vs. 52.6%)/advanced (50% vs. 67%) group. In the intermediate/advanced stage, multivariate analysis showed that the CLIF-AD score (HR = 1.06 [95%CI: 1.01–1.12]; $p < 0.01$) and MELD score (HR = 1.10 [95%CI: 1.01–1.20]; $p < 0.01$) were independent predictors of 90-day mortality in non-ACLF patients. A prognostic model for 90-day mortality obtained by CART analysis indicated the following subpopulations with distinct prognoses: low risk (CLIF-AD score <53; 90-day mortality: 29%); intermediate risk (CLIF-AD score ≥53, MELD score <7/CLIF-AD score 53–62, MELD score ≥7; 90-day mortality: 35%–57%); and high risk (CLIF-AD score ≥63, MELD score ≥7; 90-day mortality: 76%).

Conclusion: Our findings indicate the prognostic importance of AD for mortality in patients with HCC. In patients with intermediate/advanced HCC, AD without ACLF might be associated with high 90-day mortality, and a simple CART algorithm involving the CLIF-AD score and MELD score can predict 90-day mortality.

SAT225

Serum cholinesterase is an independent predictor of hepatic encephalopathy, acute-on-chronic liver failure and mortality after transjugular intrahepatic portosystemic shunt insertion in patients with liver cirrhosis

Lena Thöle[1], Marie Schultalbers[1], Nicolas Simon[2], Jan Hinrichs[3], Svetlana Gerbel[2], Markus Cornberg[1,4], Michael P. Manns[1,4], Bernhard Meyer[3], Benjamin Maasoumy[1,4]. *[1]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Hannover Medical School, Centre for Information Management (ZIMt), Hannover, Germany; [3]Hannover Medical School, Diagnostic and Interventional Radiology, Hannover, Germany; [4]Centre for Individualised Infection Medicine (CIIM), Hannover, Germany*
Email: maasoumy.benjamin@mh-hannover.de

Background and Aims: Transjugular intrahepatic portosystemic shunt (TIPS) is an effective treatment for portal hypertension related complications. However, careful selection of patients eligible for TIPS is crucial and not indisputably established to date. Cholinesterase (CHE) has been suggested as a valuable marker for nutritional status as well as hepatic synthesis capacity. However, its potential as a predictor for the outcome after TIPS insertion has not been investigated in detail, so far. The aim of this study was to evaluate the potential value of CHE in patient selection for TIPS.

Method: All 201 consecutive cirrhotic patients providing informed consent and receiving a TIPS at Hannover Medical School between 2012 and 2018 were considered. One patient with missing CHE value was excluded. ROC curves were used to identify optimal cut-offs and log rank test to analyze survival. Role of CHE was analyzed with uni- and multivariate Cox Regression adjusting for MELD, TIPS indication (ascites or bleeding), age and portosystemic pressure gradient (PSG). Competing risk analysis was applied to evaluate hepatic encephalopathy (HE) or acute-on-chronic liver failure (ACLF) treating death as competing risk.

Results: Median age of the patients was 58 years and median MELD 11.9. TIPS indication was refractory ascites in about 75% and variceal bleeding in 25%. Overall, 34 patients (17%) died within 1 year after TIPS insertion. Those who died had a higher MELD ($p < 0.001$) and PSG ($p = 0.034$) as well as a significantly lower CHE at baseline ($p < 0.001$). Of note, other indicators of the hepatic synthesis capacity such as INR and albumin were not significantly different between both groups. A CHE of <2.49 kU/L was determined as optimal cut-off predicting 1-year mortality with a sensitivity of 85%, a specificity of 56% and a negative predictive value of 95% ($p < 0.001$, figure). Multivariate analysis revealed MELD (HR:1.18, $p < 0.001$) and CHE<2.49 kU/L (HR:5.14, $p = 0.001$) as only independent predictors for 1-year survival. A CHE<2.49 kU/L was also significantly associated with HE ($p = 0.012$) and ACLF ($p < 0.001$) development and remained statistical significant even after adjusting for MELD, TIPS indication, age and PSG in the multivariate analysis.

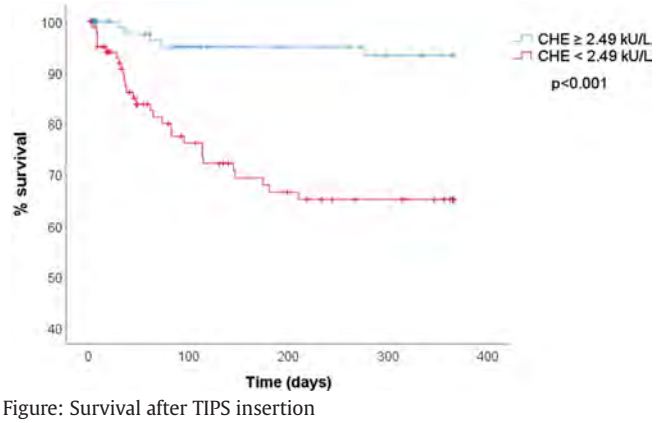


Figure: Survival after TIPS insertion

Conclusion: CHE is significantly associated with HE, ACLF and mortality after TIPS insertion. Therefore, it might be further evaluated as a novel, additional parameter when selecting patients for TIPS.

SAT226

Transjugular intrahepatic portosystemic shunt in cirrhotic elderly patients with refractory ascites - to do or not to do?

Lena Thöle[1], Marie Schultalbers[1], Tammo Lambert Tergast[1], Svetlana Gerbel[2], Jan Hinrichs[3], Nicolas Simon[2], Markus Cornberg[1,4], Michael P. Manns[1,4], Bernhard Meyer[3], Benjamin Maasoumy[1,4].
[1]Hannover Medical School, Gastroenterology, Hepatology and Endocrinology, Hannover, Germany; [2]Hannover Medical School, Centre for Information Management (ZIMt), Hannover, Germany; [3]Hannover Medical School, Diagnostic and Interventional Radiology, Hannover, Germany; [4]Centre for Individualised Infection Medicine (CIIM), Hannover, Germany
Email: maasoumy.benjamin@mh-hannover.de

Background and Aims: The management of cirrhotic patients with ascites is challenging, in particular at higher age when liver transplantation is restricted. Transjugular intrahepatic portosystemic shunt (TIPS) is an established therapeutic procedure for refractory ascites, but safety data in the older population are rare. The aim of this study was to evaluate the applicability and safety of TIPS insertion in elderly patients with decompensated liver cirrhosis and ascites.
Method: All consecutive cirrhotic patients receiving a TIPS for refractory ascites at Hannover Medical School between 2012 and 2018 were considered. Survival between patients <65 years (y) and ≥65 y was analyzed using the log-rank test. Multivariate Cox Regression was adjusted for MELD, sex and portosystemic pressure gradient. Periinterventional complications such as infections, hepatic encephalopathy (HE) and acute-on-chronic liver failure (ACLF) were compared using chi squared or Fisher's exact test. Propensity score matching was conducted to match TIPS patients ≥65 y 1:1 with those ≥65 y with refractory ascites treated with paracentesis.

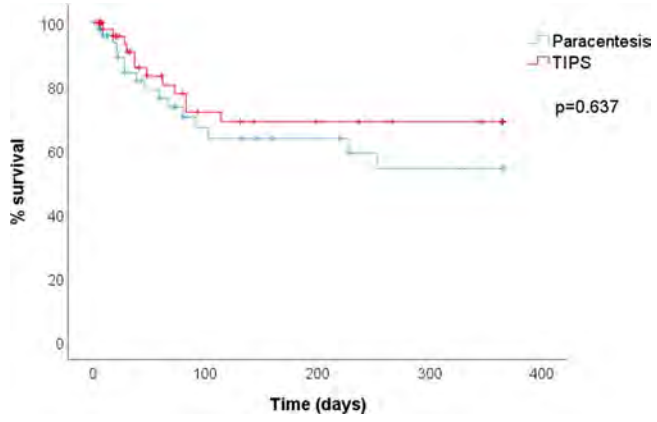

Figure: Survival of patients ≥65 y.

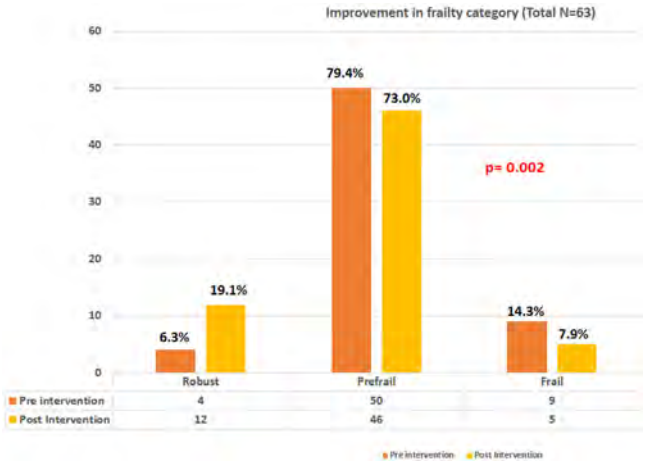
Results: Overall, 160 patients were included in the analysis with a median age of 59 y (n = 107 <65 y and n = 53 ≥65 y) and a median MELD of 12.6. Periinterventional course in those ≥65 y appeared slightly more complicated than in <65 y as reflected by a significantly longer hospital stay (p = 0.030), more ACLF episodes (21% vs. 10%; p = 0.044) and numerically more infections during hospital stay (26% vs. 17%; p = 0.153). Of note, no difference was observed in terms of HE. 28-day (d) mortality was similar between both groups (p = 0.350). In contrast, survival in the younger patients was significantly higher at 90d and numerically higher at 1 y (p = 0.029 and p = 0.171, respectively). Age ≥65 y remained an independent predictor for 90d mortality (HR:2.58; p = 0.028) in the multivariate analysis, while only MELD was associated with 1 y survival (HR:1.18; p < 0.001). Importantly, after matching for potential confounders 90d and 1 y survival was not inferior in elderly patients if treated with TIPS as compared to those managed with paracentesis (p = 0.796 and p = 0.637, respectively; figure).
Conclusion: TIPS in patients of higher age with refractory ascites appears to be slightly more complicated compared to younger individuals but well feasible and at least not inferior to paracentesis.

SAT227

Four weeks of aerobic and resistance training improves frailty in patients with liver cirrhosis-liver habilitation (Li-Hab) center outcome data

Varsha Shasthry[1], Jaya Benjamin[1], Rakesh Kumar[2], Naveen Aggarwal[2], Guresh Kumar[3], Arun Kumar Sood[4], Yogendrakumar Joshi[1], Shiv Kumar Sarin[5]. *[1]Institute of Liver and Biliary Sciences, Clinical Nutrition, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Physiotherapy, New Delhi, India; [3]Institute of Liver and Biliary Sciences, Biostatistics, New Delhi, India; [4]Institute of Liver and Biliary Sciences, Cardiology, New Delhi, India; [5]Institute of Liver and Biliary Sciences, Hepatology, New Delhi, India*
Email: varsha.bhat@gmail.com

Background and Aims: Fatigue and reduced exercising capacity in cirrhotics results in physical inactivity and frailty which are associated with morbidity and mortality. A monitored exercise prescription (aerobic and resistance exercises) along with adequate nutrition are vital for muscle strength and performance. We evaluated feasibility and effect of structured exercise and nutritional programme on liver frailty index (LFI) and physical performance in cirrhotics.
Method: After a cardiopulmonary clearance, 96 consenting cirrhosis patients were enrolled into Li-Hab programme (LHP) in past 12 months. A 4-week LHP included 8 sessions of supervised exercise [treadmill walking and resistance exercises of major muscles with or without weights based on MRC (medical research council) scale; each for 30 minutes] as 2 sessions per week supervised by a physiotherapist, including at home. A diet comprising of 20–30 Kcal/Kg/day; and 1.2–1.5 g/Kg/day of protein as 6 divided meals including a pre-exercise and late evening protein supplements was prescribed. A complete physical and functional assessment was done [hand grip strength (HGS-Kg) by dynamometer, 6 minute walk test (6MWT-meters), gait speed (GS-meters second^{-1}) and LFI (HGS, chair rise and balance test)]. Frailty was categorised as LFI<3.2-robust; 3.3–4.5-prefrail; >4.5-frail. All assessments were repeated at the end of 8 sessions at 4 weeks.



Results: Out of 96, 63 (65.6%) patients [M-71.4%; Age-55.4 ± 10.8 yrs; CTP-6.4 ± 1.5; MELD-12.3 ± 3.7; BMI- 26.7 ± 4.6 Kg/m^2; aetiology (alcohol-23.8%, NASH-55.6%, others-20.6%); Child A:B:C (65.1%:30.2%:4.8%)] were 100% compliant with the LHP hence taken for pre-post analysis. There were no adverse events of LHP and no significant changes in body weight; however LFI improved by 6% (0.3)

(4.0 ± 0.58 to 3.7 ± 0.53; p < 0.001) 6MWT by 34 m (423 ± 105 to 457 ± 99; p < 0.001), GS by 0.13 m/s (0.97 ± 0.23 to 1.1 ± 0.2; p < 0.001), protein intake by 13 gm (62.3 ± 15.4 to 75 ± 12.6; p < 0.001) in all patients. Frailty category improved in 12 (19%) patients [8 became robust from pre-frail and 4 pre-frail from frail; Fig.1]

Conclusion: A structured exercise program is acceptable and feasible in cirrhosis patients. Four weeks of monitored exercise and nutrition program improves frailty, muscle strength and physical performance in these patients and is recommended for routine intervention.

SAT228

Effect of rivaroxaban on hypercoagulopathy risk factors in liver cirrhosis patients with nonvalvular atrial fibrillation

Nataliya Virstyuk[1], Nataliya Matkovska[1], Iryna Vakalyuk[1], Oleg Virstyuk[2]. [1]*Ivano-Frankivsk National Medical University, Internal Medicine Department, Ivano-Frankivsk, Ukraine;* [2]*Ivano-Frankivsk Central Clinical Hospital, Neurological Department, Bogorodchany, Ukraine*
Email: virstyukn@gmail.com

Background and Aims: A number of studies have shown an increase in procoagulant risk in liver cirrhosis (LC) patients (ps). Long-term Direct Oral Anticoagulants (DOACs) are used for the treatment and prevention of thrombosis and thromboembolism, however, in LC, their use is limited. The aim of this study was to investigate the effect of DOACs drug Rivaroxaban on hypercoagulopathy risk factors in alcoholic (ALC) ps with nonvalvular atrial fibrillation (NVAF) and their safety profile.

Method: We analyzed 41 ALC ps with Child-Pugh class A cirrhosis and with NVAF (6 females/35 males; age, 51.3 ± 4.9 yr; body mass index (BMI), 34.7 ± 2.5 kg/m^2): 18 ps treated with Rivaroxaban 10 mg once daily in complex therapy in stroke prevention (I group), 23 ps treated with antiplatelet drugs (II group) for twelve months. ALC ps with Child-Pugh class B and C cirrhosis, with markers of hepatitis B and C viruses (HBV/HCV) were not included in the study. The results were compared with those of 20 healthy controls (group III; 4 females/16 males).

The diagnosis of LC was based on clinical, biochemical, ultrasound imaging and endoscopic findings, suggesting advanced liver disease with portal hypertension, Desmet's classification of chronic hepatitis in liver biopsy specimens (stage > 3) or liver stiffness assessed via elastography (F-score > 3). Factor VIII (FVIII), von Willebrand factor (vWF), antithrombin III (AT III), protein C, platelet-endothelial cell adhesion molecule-1, (PECAM-1), P-selectin, plasminogen activator inhibitor-1 (PAI-1), thrombin activatable fibrinolysis inhibitor (TAFI) plasma levels were measured by the immuno-assay method.

Results: Hypercoagulopathy was detected in 88.9% of ps in group I, 78.3% – of ps in II group. In ps with ALC ps with NVAF a statistically significant increase of FVIII (p = 0.008) and vWF (p = 0.001), PECAM-1 (p = 0.004), P-selectin (p = 0.002), PAI-1 (p = 0.001) and TAFI (p = 0.007) and decrease of AT III (p = 0.005), protein C (p = 0.002) plasma levels vs. group III were found.

After twelve months treatment with Rivaroxaban FVIII, vWF, PECAM-1, P-selectin, PAI-1 and TAFI plasma levels decreased in I group vs. group II (p < 0.05); AT III and protein C plasma levels in I group and group II were not significantly different (p > 0.05).

Ps in group I had no thrombotic or bleeding complications for 12 months, 1 (5.5%) patient had mild cytolytic syndrome, which was eliminated by silymarin without cancellation of rivaroxiban; 1 (4.3%) patient of group II had ischemic stroke, 1 (4.3%) – gastrointestinal bleeding.

Conclusion: Most ALC ps with Child-Pugh class A cirrhosis and with NVAF have a hypercoagulant state. Use of rivaroxaban for twelve months contributes to the reduction of hypercoagulopathy risk factors in ALC ps with Child-Pugh class A cirrhosis and with NVAF and has no serious side effects compared to antiplatelet drugs.

SAT229

Between rapid diagnosis and prediction of survival in minimal hepatic encephalopathy

Vlad Taru[1,2], Mina Ignat[3], Madalina Gabriela Indre[3], Bianca Olar[3], Tamas Racz[3], Horia Stefanescu[3,4], Daniela Matei[4,5], Zeno Sparchez[4,5], Bogdan Procopet[3,4,5]. Email: bogdanprocopet@gmail.com

Background and Aims: Minimal hepatic encephalopathy (MHE) affect up to 80% of patients with liver cirrhosis. MHE predicts the onset of overt hepatic encephalopathy, is responsible for decreased health-related quality of life, and it is associated with an increased risk of motor vehicle accidents. The standard diagnosis method is Psychometric Hepatic Encephalopathy Score (PHES) but, recently, the EncephalApp Stroop test proved to be a valid diagnostic method. This study aims to assess the performance of the EncephalApp Stroop test in diagnosis MHE and to compare PHES and Stroop in predicting survival.

Method: A total of 148 consecutive patients with liver cirrhosis (LC) were enrolled between October 2017-July 2019, in a Romania tertiary health care center hospital. None of the patients showed clinical signs of overt hepatic encephalopathy at the inclusion. Patients were screened for MHE using PHES (n = 148) and Stroop (n = 143). The diagnosis of MHE was established with PHES score using the Romanian standardized scores, with a cut-off of <–4, and the Stroop result was expressed as time in seconds, consisting of the sum of 5 Stroop-off and 5 Stroop-on runs (the cut-off value for MHE was considered 245 sec).

Results: The etiology for liver cirrhosis was alcohol in 51 (34.5%) patients, viral in 84 (56.8%), and others in 13 (8.7%). The Child-Pugh class was A in 99 (66.9%) patients, B in 38 (25.7%), and C in 11 (7.4%), while the mean MELD-Na was 12.3 ± 5.29. MHE was identified in 59 (40%) patients.

The performance of Stroop was good, AUROC = 0.82 (95%C.I.: 0.74–0.89), p < 0.001 and an accuracy of 78%. Patients were followed-up on a median of 10.5 (22.5) months, and 16 deaths (10.8%) occurred during follow-up. Based on the PHES score, there is a significant difference in survival between the patients without HME (93.3%) and those with MHE (83.1%)(log-rank test, p = 0.05). If the Stroop test is used, there is no difference in survival between the patients without MHE (89.6%) and those with MHE (89.4%)(log-rank test, p = 0.8).

Conclusion: Although the Stroop test is a valid method for diagnosing MHE, it fails to predict survival as compared to the PHES score.

SAT230

Efficacy and safety of rivaroxaban in portal vein thrombosis in patients with liver decompensated cirrhosis

Min Wang[1], Yu Wang[1], Guanhua Zhang[1], Hong Ma[1], Xin Zhang[1], Xuechun Mu[1]. [1]*Beijing Friendship Hospital, Capital Medical University, Liver Research Center, Beijing, China*
Email: wangyuliver@126.com

Background and Aims: The use of rivaroxaban for portal vein thrombosis (PVT) in decompensated cirrhosis remains unknown. Here, we aimed to evaluate the pharmacokinetic characteristics, efficacy and safety of rivaroxaban for PVT in decompensated cirrhotic patients.

Method: Serial venous blood samples were collected after single-dose and multiple-dose of rivaroxaban administration to determine the plasma concentrations. We analysed the data of rivaroxaban with initial dose of 10 mg daily for PVT in cirrhotic patients between April

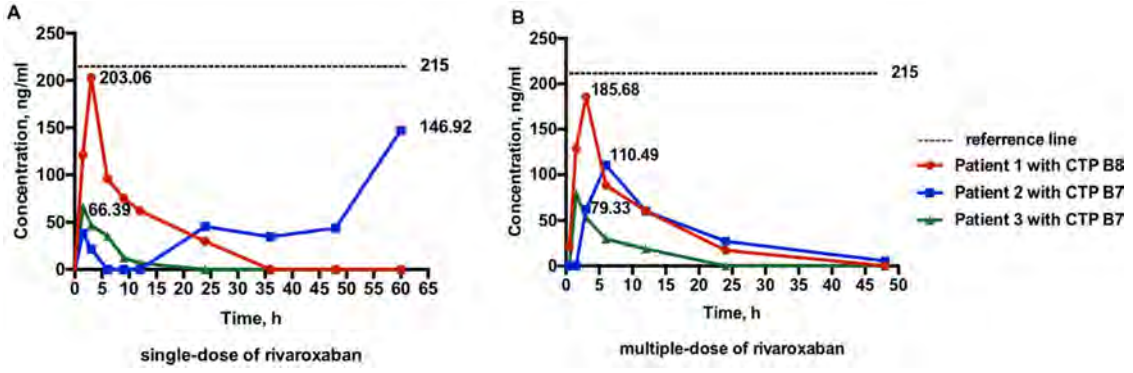

Figure: (abstract: SAT230): Single-dose (10 mg/d, A) and multiple-dose (10 mg/d, B) of rivaroxaban for PVT in three patients with decompensated cirrhosis (Child-Pugh B7-8) —reference line refers to Cmax of rivaroxaban (20 mg/d) at 2–4 h in non-cirrhotic patient.

2018 and Sep 2019 in our center. Regular imaging (abdominal CT or MRI) was performed to monitor the recanalization of PVT. Adverse events including bleeding episodes were recorded during anticoagulation treatment.

Results: 1. One patient with Chid-Pugh B8 had maximum concentrations (Cmax) with 203.06 ng/ml and 185.68 ng/ml at 3 h after single-dose and multi-dose of rivaroxaban respectively. The Cmax in single-dose and multiple-dose of two patients with Child-Pugh B7 were 146.92 ng/ml at 60 h, 66.39 ng/ml at 1.5 h and 110.49 ng/ml at 6 h, 79.33 ng/ml at 1.5 h respectively. **2.** A total of six patients with Child-Pugh B (7–9) enrolled. The median follow-up under anticoagulation therapy was 9.7 months (rang 2.8–17.9 months). Partial recanalization was achieved in 4 patients (66.7%) with a median time of 4.8 months, but two patients with lower Cmax had thrombosis progression at 12 m. **3.** Two bleeding episodes (minor gastrointestinal bleeding and gingival bleeding), two hepatic encephalopathy (Grade II or more) were observed. One patient had a significantly decreased platelet. **4.** Compared with baseline, no significant difference in Child-Pugh score, MELD score, hepatic and renal function, platelet and prothrombin time at 3 m, 6 m and 12 m during rivaroxaban treatment were observed.

Conclusion: Rivaroxaban may provide a promising benefit for PVT in decompensated cirrhotic patients, and need to be further studied.

SAT231

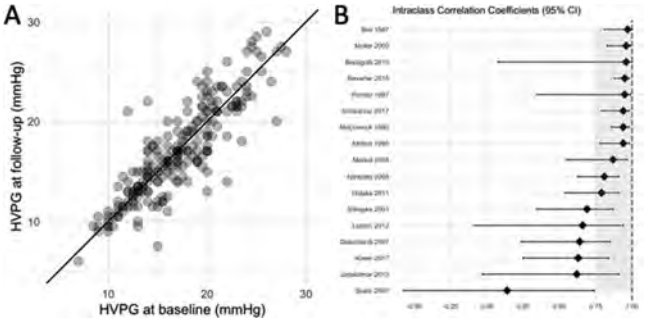
Test-retest reliability of hepatic venous pressure gradient: a study in 215 patients from the control arms of 17 randomized controlled trials

Wayne Bai[1], Mustafa Al-Karaghouli[1], Jesse Stach[1], Juan G Abraldes[1].
[1]*Division of Gastroenterology (Liver Unit), University of Alberta*
Email: juan.g.abraldes@ualberta.ca

Background and Aims: Portal hypertension (PH) is a major driver for cirrhosis complications. Portal pressure is estimated in practice by the hepatic venous pressure gradient (HVPG). The assessment of HVPG changes has been used for drug development in PH. Moreover, there is increasing interest in wider use of HVPG as a clinical outcome measure in RCTs for the treatment of cirrhosis. This requires a thorough understanding of the test-retest reliability of HVPG. This study aimed at quantifying the test-retest reliability of HVPG in the specific context of RCTs for the treatment of PH in cirrhosis.

Method: We performed a systematic search of published RCTs in patients with cirrhosis reporting individual patient-level data of HVPG at baseline and after an intervention, and that included a placebo or untreated control arm. Baseline and follow-up HVPG in the control groups were extracted after digitizing the plots. Test-retest reliability was estimated by the intraclass correlation coefficient (ICC). Pooled ICC and potential associations with study characteristics were estimated with linear mixed models (patient and study as random effects). We considered ICC > 0.75 as excellent as recommended for measures with physiological variability.

Results: Seventeen trials including a total of 215 patients in the placebo/untreated groups had plots with legible individual HVPG changes. Time range between HVPGs was 20 min to 730 days. Fig. A shows the association between baseline and follow-up HVPGs, and Fig. B the ICCs of individual studies. 18% and 8% of the patients showed a ≥10% and ≥20% response, respectively. 11/17 studies showed excellent reliability (>0.75) of repeated HVPGs, and 5 showed moderate reliability. Only one study showed poor reliability (ICC: 0.14). In that study, a wedged catheter was used for HVPG measurement (as opposed to balloon catheter in the other 16 studies). Pooled ICC was excellent (0.88). We did not find an association between reliability and proportion of patients with alcohol-related liver disease, compensated vs decompensated cirrhosis, multicentric vs single-center studies, year of publication or time between measurements.



Conclusion: We show in this study that, in the context of RCTs, test-retest reliability of HVPG is excellent. We provide quantitative information on the range of expected reliability parameters, that will be useful for sample size calculation and results' interpretation in trials with HVPG as an outcome measure.

SAT232

The survival effect of sarcopenia in patients with cirrhosis undergoing transjugular intrahepatic portosystemic shunt: a single-center review

Wei Zhang[1], Ahmed Ouni[2], Blake Thompson[2], Walid Khan[2], Andreas Zori[1], Giuseppe Morelli[1]. [1]*University of Florida College of Medicine, Division of Gastroenterology & Hepatology, Gainesville;* [2]*University of Florida College of Medicine, Department of Medicine*
Email: wei.zhang@medicine.ufl.edu

Background and Aims: Sarcopenia is common in patients with cirrhosis and is associated with increased mortality. Placement of

Variable	OR	Interval	P value	Multivariate analysis	CI	P value
Sarcopenia	2.556	1.381-4.728	0.003	1.88	1.056-3.378	0.032
BMI	0.985	0.947-1.024	0.449	0.994	0.953-1.036	0.763
MELD	1.093	1.036-1.153	0.001	1.089	1.025-1.157	0.006

Figure: (abstract: SAT232)

transjugular intrahepatic portosystemic shunt (TIPS) is frequently utilized in cirrhotic patients with hepatic decompensation. No studies have evaluated the association between the presence of sarcopenia and its effect on mortality after TIPS. The purpose of this study was to investigate the post TIPS mortality in patients with sarcopenia.

Method: We conducted a single-centre retrospective study of 305 patients with cirrhosis who underwent TIPS between 2010 and 2015. Psoas muscle index at the third lumbar vertebra (PMI) was measured by computed tomography adjusted by height. Sarcopenia was defined as a PMI less than the 25th percentile of the study population stratified by gender as previously described. We conducted univariate and multivariate analysis to identify the association between sarcopenia and post-TIPS mortality.

Results: Overall 184 (60.3%) patients received TIPS for refractory ascites, 97 (31.8%) patients received TIPS for oesophageal variceal (EV) bleeding and 24 (7.9%) for other indications. The mean age was 63.88 ± 9.86 years old. Sarcopenia was present in 67 (22%) of patients. Median MELD scores for the Sarcopenic and non-Sarcopenic groups were 13.25 ± 3.98 and 12.98 ± 5.06 ($p = 0.602$) respectively. BMI was higher for the non-Sarcopenic patients compared to those with Sarcopenia, 29.13 ± 6.27 and 25.36 ± 6.37 ($p < 0.001$), respectively. Average PMI was lower in the Sarcopenic group compared to those without Sarcopenia, 2.66 ± 0.47 vs 4.94 ± 1.28 ($p < 0.001$). Patients with sarcopenia had higher mortality rate at 1 year as compared to patients without sarcopenia (38.8% vs 25.2%, $p < 0.05$). Multivariate analysis after adjusting MELD and BMI, patients with sarcopenia had higher odds of mortality comparing to patients without sarcopenia (odds ratio [OR]: 1.88, 95%; confidence interval [CI]: 1.056–3.378). However, no statistically significant differences were found between sarcopenia and long term (3-year and 5-year) mortality.

Conclusion: In cirrhotic patients with sarcopenia who underwent TIPS, there was increased mortality at 1 year but not beyond. Future studies are needed to investigate the impact of post-TIPS nutrition optimization in this patient population.

SAT233

Comparison of MELD, MELD-Na and MELD-sarcopenia in predicting mortality in patients with cirrhosis undergoing transjugular intrahepatic portosystemic shunt

Wei Zhang[1], Ahmed Ouni[2], Walid Khan[2], Blake Thompson[2], Nabeel Moon[2], Andreas Zori[1], Giuseppe Morelli[1]. [1]*University of Florida College of Medicine, Divison of Gastroenterology & Hepatology, Gainesville, United States;* [2]*University of Florida College of Medicine, Department of Medicine, Gainesville*
Email: wei.zhang@medicine.ufl.edu

Background and Aims: The Model for End-Stage Liver Disease (MELD) score was developed to predict the mortality after transjugular intrahepatic portosystemic shunt (TIPS). Limitations to the MELD in predicating post TIPS mortality have led to subsequent derivations such as MELD-Na and MELD-Sarcopenia. However, few studies have compared these MELD modifications in predicting post TIPS mortality. The purpose of this study was to compare the various derivations of the MELD formula in patients undergoing TIPS.

Method: At our medical centre, 305 consecutive patients underwent TIPS placement from Jan 2010 to Dec 2015. MELD, MELD-Na and MELD-sarcopenia scores were calculated for each patient. MELD-Sarcopenia was calculated as MELD+10.35 × Sarcopenia as previously reported. Receiver operating characteristic (ROC) Curves were used to compare the MELD, MELD-Na and MELD- Sarcopenia scores and determine their accuracy in predicting the mortality after TIPS for various indications.

Results: Overall 184 (60.3%) patients received TIPS for refractory ascites, 97 (31.8%) patients received TIPS for oesophageal variceal (EV) bleeding and 24 (7.9%) for other indications. The mean age was 63.88 ± 9.86 years old. The mean MELD score was 13.04 ± 4.83 and mean MELD-Na score was 15.75 ± 5.64. Sarcopenia was present in 67 (22%) of patients. The mean MELD-Sarcopenia score was 23.40 ± 4.84. Mortality after TIPS was 28.20% at 1 year and 54.75% at 5 years. Based upon ROC curves, none of the MELD derivations (MELD-Na, MELD-sarcopenia) delineated themselves as being a better predictor of mortality post TIPS at 1 and 5 years as compared to the MELD score (AUC of 0.65, 0.65 vs 0.63 at 1 year and 0.60, 0.60 vs 0.61 at 5 years). Regarding indications of TIPS placement, the MELD score and its derivations showed better prediction of mortality at 1 and 5 years in patients receiving TIPS for EV bleeding compared to patients receiving TIPS for ascites ($P < 0.05$).

Conclusion: There is no difference between MELD score and its related modifications (MELD-Na and MELD-Sarcopenia) in predicting mortality in patients post TIPS. However, when evaluating the indications for TIPS, the scores may be useful. Prospective studies are needed to confirm our observations.

SAT234

Empirical carbapenem versus third-generation cephalosporin treatment for spontaneous bacterial peritonitis: a multicenter study

Sun Woong Kim[1], Jun Yong Park[2], Yong Jin Jung[3], Jeonghoon Lee[1], Jae Seung Lee[2], Jisoo Song[3], Han Ah Lee[4], Yeon Seok Seo[4], Minjong Lee[5], Dae Hee Choi[5], Moon Young Kim[6], Seong Hee Kang[6], Jin Mo Yang[7], Do Seon Song[7], Jun Sik Yoon[8], Minseok Albert Kim[1], Hyunwoo Oh[1], Heejoon Jang[1], Cheol-Hyung Lee[1], Sungwon Chung[1], Yun Bin Lee[1], Eun Ju Cho[1], Su Jong Yu[1], Yoon Jun Kim[1], Jung-Hwan Yoon[1]. [1]*Seoul National University College of Medicine, Internal Medicine and Liver Research Institutute;* [2]*Yonsei University College of Medicine, Seoul, Korea, Internal Medicine;* [3]*Seoul Metropolitan Government-Seoul National University Boramae Medical Center, Internal Medicine;* [4]*Korea University College of Medicine, Seoul, Korea, Internal Medicine;* [5]*Kangwon National University Hospital, Chuncheon, Korea, Internal Medicine;* [6]*Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Korea, Internal Medicine;* [7]*St. Vincent's Hospital, The Catholic University of Korea, Suwon, Korea, Internal Medicine;* [8]*Busan Paik Hospital, Inje University College of Medicine, Busan, Korea, Internal Medicine*
Email: pindra@empal.com

Background and Aims: Third-generation cephalosporin (TGCs) is currently recommended as the first-line empirical antibiotic for spontaneous bacterial peritonitis (SBP). However, recent studies suggest that antibiotics against multidrug-resistant organisms (e.g.,

carbapenem) may be necessary, particularly for nosocomial SBP. This study aimed to evaluate whether carbapenem is superior to TGC for SBP.

Method: This study retrospectively examined consecutive SBP patients at seven referral centers in Korea. The primary outcome was in-hospital mortality and secondary outcomes included 3-month mortality.

Results: A total of 827 patients with SBP were included; 253 (30.6%) were culture-positive. The in-hospital mortality rate was higher in culture-positive SBP patients than in culture-negative patients (31.6% vs. 23.7%, P = 0.02). Among culture-positive SBP patients, 100 (39.5%) had TGC-resistant bacterial infection. As initial empirical antibiotics, 632 patients (76.4%) received TGCs and 86 (10.4%) received carbapenem. Among the entire study cohort, there was no significant difference in in-hospital mortality between the TGC and carbapenem groups in multivariable analyses (adjusted odds ratio [aOR], 0.80; 95% confidence interval [CI], 0.46–1.42; P = 0.45). However, in patients with a high CLIF-SOFA score (≥7, n = 301), the administration of carbapenem as an empirical antibiotic was independently associated with significantly lower in-hospital mortality (aOR, 0.42; 95% CI, 0.19–0.91; P = 0.03). In contrast, in-hospital mortality was comparable between carbapenem and TGC groups in patients with a low CLIF-SOFA score (n = 417; aOR, 1.53; 95% CI, 0.64–3.67; P = 0.34).

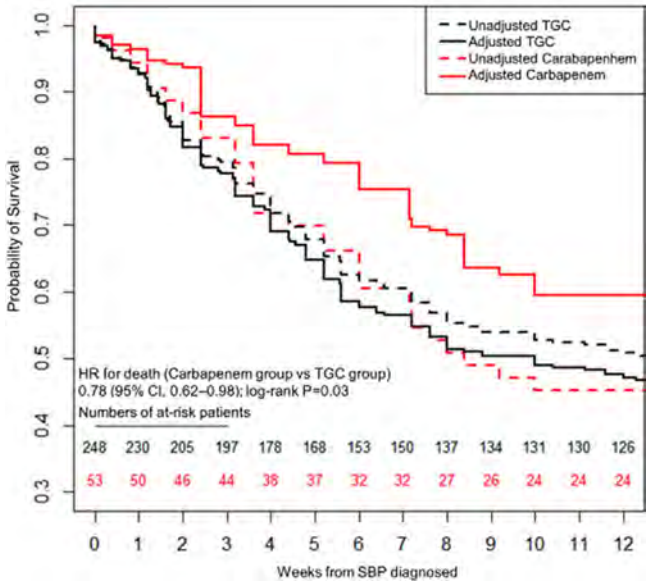


Figure: Kaplan-Meier estimates of overall survival in SBP patients with a high CLIF-SOFA score

Conclusion: In the overall SBP cohort, empirical carbapenem treatment failed to improve in-hospital mortality versus TGCs. However, among critically ill patients with a high CLIF-SOFA score, empirical carbapenem treatment was significantly associated with lower in-hospital mortality versus TGCs.

SAT235

Early albumin improves survival in cirrhotic patients on diuretic therapy who develop significant acute kidney injury: real-world evidence in the United States

W. Ray Kim[1], Karthik Raghunathan[2], Greg S. Martin[3], Elizabeth Anne Davis[4], Navreet Sindhwani[4], Santosh Telang[5], Kunal Lodaya[5]. [1]*Stanford University Medical Center, Stanford, United States;* [2]*Duke University, Durham, United States;* [3]*Emory University, Atlanta, United States;* [4]*Grifols, Research Triangle Park, United States;* [5]*Boston Strategic Partners, Inc., Boston, United States*
Email: e.anne.davis@grifols.com

Background and Aims: Acute kidney injury (AKI) is diagnosed in 20% to 50% of patients hospitalized with cirrhosis. AKI is associated with poor prognosis and high mortality among this population, especially in AKI stage 3. Albumin infusion is an essential component for the evaluation and management of renal dysfunction in cirrhotic patients. The aim of this study is to examine the impact of albumin infusion on mortality in hospitalized cirrhotic patients on diuretic therapy, who develop significant AKI during their hospital stay.

Method: We utilized a nationwide Electronic Health Record dataset (Cerner Health Facts(R)) to extract real-world data on adult patients (> = 18 years old) with cirrhosis, admitted from January 1, 2009, through April 30, 2018. Further, we only included patients with AKI stage 3 who received diuretics before (including a 30-day lookback period) or on the same day as when they developed any AKI. International Classification of Diseases (ICD-9/10) codes were used to identify cirrhosis and other diagnostic information. We reported significant AKI as stage 3 based on the Kidney Disease: Improving Global Outcomes (KDIGO) guidelines. The Model for End-stage Liver Disease Sodium (MELD-Na) score was calculated for each patient visit at baseline using laboratory data. We used multivariable logistic regression to assess the relationship between albumin infusion and mortality.

Results: We identified 23,745 unique visits for patients with cirrhosis and AKI of any stage, out of which 609 visits met the inclusion criteria. Albumin was infused within 24 hours of admission ('early albumin') in 36% and after 24 hours in 42%, while it was not administered in 22%. MELD-Na was higher at presentation in early albumin cases than late- or no-albumin cases (mean 29.5 and 23.6). Unadjusted mortality was lower in patients receiving early albumin (33.5%) than late or no albumin (38.9%). Adjusted analysis revealed that odds of mortality were lower for patients who received early albumin as compared to patients who received late or no albumin (OR 0.52, 95% CI 0.32–0.87, p = 0.013).

	Early Albumin (< = 24 hrs.) N = 218	Late (>24 hrs.)/ No Albumin N = 391	Standardized Mean Difference
	N (%)	N (%)	
Male	142 (65.1%)	224 (57.3%)	−0.162
Unadjusted Mortality	73 (33.5%)	152 (38.9%)	−0.112
	Mean (SD)	**Mean (SD)**	
Age	59.1 (12.0)	59.0 (12.8)	0.007
Baseline MELD-Na	29.5 (8.1)	23.6 (8.9)	0.688
Baseline Charlson Comorbidity Index	9.2 (4.0)	8.9 (3.8)	0.083

Conclusion: These real-world data indicate that early use of albumin has a mortality benefit in hospitalized cirrhotic patients who develop AKI stage 3. Following the established guidelines of using albumin infusion early in this patient population may lower the likelihood of death. The data also suggest that, in many cases, albumin is administered to patients late in their hospital stay, presumably when prior therapies have failed.

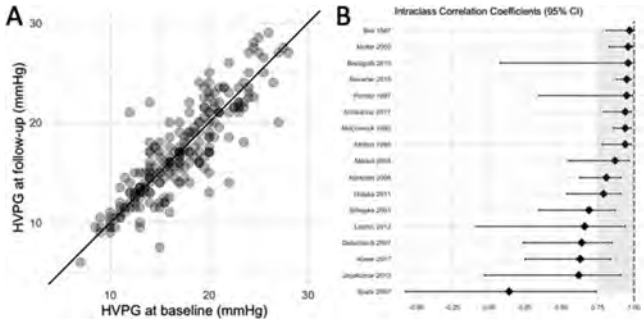
SAT236

Test-retest reliability of hepatic venous pressure gradient: a study in 215 patients from the control arms of 17 randomised controlled trials

Wayne Bai[1], Mustafa Al-Karaghouli[1], Jesse Stach[1], Juan G Abraldes[1].
[1]*University of Alberta, Division of Gastroenterology, Edmonton, Canada*
Email: wwbai@ualberta.ca

Background and Aims: Portal hypertension (PH) is a major driver for cirrhosis complications. Portal pressure is estimated in practice by the hepatic venous pressure gradient (HVPG). The assessment of HVPG changes has been used for drug development in PH. Moreover, there is increasing interest in wider use of HVPG as a clinical outcome measure in RCTs for the treatment of cirrhosis. This requires a thorough understanding of the test-retest reliability of HVPG. This

study aimed at quantifying the test-retest reliability of HVPG in the specific context of RCTs for the treatment of PH in cirrhosis.
Method: We performed a systematic search of published RCTs in patients with cirrhosis reporting individual patient-level data of HVPG at baseline and after an intervention, and that included a placebo or untreated control arm. Baseline and follow-up HVPG in the control groups were extracted after digitizing the plots. Test-retest reliability was estimated by the intraclass correlation coefficient (ICC). Pooled ICC and potential associations with study characteristics were estimated with linear mixed models (patient and study as random effects). We considered ICC>0.75 as excellent as recommended for measures with physiological variability.
Results: Seventeen trials including a total of 215 patients in the placebo/untreated groups had plots with legible individual HVPG changes. Time range between HVPGs was 20 min to 730 days. Fig. A shows the association between baseline and follow-up HVPGs, and Fig. B the ICCs of individual studies. 18% and 8% of the patients showed a ≥10% and ≥20% response, respectively. 11/17 studies showed excellent reliability (>0.75) of repeated HVPGs, and 5 showed moderate reliability. Only one study showed poor reliability (ICC: 0.14). In that study, a wedged catheter was used for HVPG measurement (as opposed to balloon catheter in the other 16 studies). Pooled ICC was excellent (0.88). We did not find an association between reliability and proportion of patients with alcohol-related liver disease, compensated vs decompensated cirrhosis, multicentric vs single-center studies, year of publication or time between measurements.



Conclusion: We show in this study that, in the context of RCTs, test-retest reliability of HVPG is excellent. We provide quantitative information on the range of expected reliability parameters, that will be useful for sample size calculation and results' interpretation in trials with HVPG as an outcome measure.

SAT237

Prognosis of alcoholic or viral B/C cirrhosis according to ABO blood group: results of abocirralvir, from CIRRAL and ANRS CO12 CirVir cohorts

Isabelle Ollivier-Hourmand[1], Pierre Nahon[2], Cendrine Chaffaut[3], Thong Dao[1], Nga Nguyen[1], Marcellin Patrick[4], Dominique Roulot[5], Victor de Lédinghen[6], Stanislas Pol[7], Dominique Guyader[8], Isabelle Mabile-Archambeaud[9], Fabien Zoulim[10], Frédéric Oberti[11], Albert Tran[12], Jean-Pierre Bronowicki[13], Louis Dalteroche[14], Denis Ouzan[15], Jean Marie Peron[16], Jean-Pierre Zarski[17], Marc Bourliere[18], Dominique Larrey[19], Alexandre Louvet[20], Paul Cales[11], Armand Abergel[21], Philippe Mathurin[20], Ariane Mallat[22], Jean-Frédéric Blanc[6], Eric Nguyen Khac[23], Ghassan Riachi[24], Laurent Alric[16], Lawrence Serfaty[25], Tereza Antonini[26], Christophe Moreno[27], Pierre Attali[28], Dominique Thabut[29], Christophe Pilette[30], Jean Didier Grange[31], Christine Silvain[32], Nicolas Carbonell[33], Brigitte Bernard Chabert[34], Odile Goria[24], Claire Wartelle-Bladou[35], Romain Moirand[8], Christos Christidis[36], Gabriel Perlemuter[37], Violaine Ozenne[38], Jean Henrion[39], Sophie Hillaire[40], Vincent Di Martino[41], Xavier Amiot[42], Angela Sutton[43], Nathalie Barget[44], Yohann Repesse[45], Sylvie Chevret[3], Nathalie Ganne-Carrié[44]. *[1]University Hospital, Hepatology, Caen, France; [2]University Hospital, Hepatology, Bondy, France; [3]University Hospital, Unité de Recherche Clinique (URC) Saint-Louis Lariboisière Fernand-Widal, Paris, France; [4]University Hospital Beaujon, Hepatology, Clichy, France; [5]University Hospital Avicenne, Hepatology, Bobigny, France; [6]University Hospital, Hepatology, Bordeaux, France; [7]University Hospital Cochin, Hepatology, Paris, France; [8]University Hospital, Hepatology, Rennes, France; [9]university Hospital, Hepatology, Nantes, France; [10]University Hospital, Hepatology, Lyon, France; [11]University Hospital, Hepatology, Angers, France; [12]University Hospital, Hepatology, Nice, France; [13]University Hospital, Hepatology, Nancy, France; [14]University Hospital, Hepatology, Tours, France; [15]Institut arnault tzanck, Hepatology, Saint-Laurent-du-Var, France; [16]University Hospital, Hepatology, Toulouse, France; [17]University Hospital, Hepatology, Grenoble, France; [18]Hôpital Saint Joseph, Hepatology, Marseille, France; [19]University Hospital, Hepatology, Montpellier, France; [20]University Hospital, Hepatology, Lille, France; [21]University Hospital, Hepatology, Clermont Ferrand, France; [22]University Hospital Henri Mondor, Hepatology, Creteil, France; [23]University Hospital, Hepatology, Amiens, France; [24]University Hospital, Hepatology, Rouen, France; [25]University Hospital, Hepatology, Strasbourg, France; [26]University Hospital, Hepatology, Villejuif, France; [27]Hôpital Erasme, Hepatology, Bruxelles, Belgium; [28]University Hospital Paul Brousse, Hepatology, Villejuif, France; [29]University Hospital La Pitié Salpétrière, Hepatology, Paris, France; [30]Centre Hospitalier Général, Hepatology, Le Mans, France; [31]University Hospital Tenon, Hepatology, Paris, France; [32]University Hospital, Hepatology, Poitiers, France; [33]University Hospital Saint Antoine, Hepatology, Paris, France; [34]University Hospital Saint Antoine, Hepatology, Reims, France; [35]Centre Hospitalier Général, Hepatology, Aix en Provence, France; [36]Institut Mutualiste Montsouris, Hepatology, Paris, France; [37]Hôpital Antoine Béclère, Hepatology, Clamart, France; [38]University Hospital Saint Antoine, Hepatology, Paris, France; [39]Centre Hospitalier Jolimont-Lobbes, Hepatology, La Louviere, Belgium; [40]Hôpital Foch, Hepatology, Suresnes, France; [41]University Hospital, Hepatology, Besancon, France; [42]Hôpital Tenon, Hepatology, Paris, France; [43]University Hospital Jean Verdier, Laboratoire de Biochimie, Bondy, France; [44]University Hospital Jean Verdier, Hepatology, Bondy, France; [45]University Hospital, Hematology Laboratory, Caen, France*
Email: yoiojo@orange.fr

Background and Aims: Non-O blood group (Non-O Gp) promotes deep vein thrombosis and venous thromboembolism recurrence in general population. Non-O Gp has also been associated with an increased risk of liver fibrosis in hepatitis C and hepatocellular carcinoma (HCC). The mechanism could be microthrombotic due to the decrease of ADAMTS 13 activity resulting in an increase of procoagulant factors VIII and Willebrand. These kinds of coagulation alterations are observed in case of cirrhosis. The aim was to evaluate the influence of Non-O Gp on the prognosis of alcoholic or viral cirrhotic patients.
Method: This is an observational study from CIRRAL et CIRVIR, 2 prospective cohorts of alcoholic and virological Child-Pugh A cirrhotic patients. The main criterion was the cumulated incidence of complications at 3 years with 2 composite criteria: « **Decompensation** » defined as at least one sign among: ascites, hydrothorax, encephalopathy, portal hypertension bleeding, bilirubin >45 umol/l, spontaneous bacterial peritonitis and « **Disease Progression** » including a « Decompensation » or « the occurrence of one or more parameters » : PT < 45%, albumin <28 g/l, Child-Pugh aggravation, hepatorenal syndrome, non tumoral portal vein thrombosis (NTPT), hepato-pulmonary syndrome, or pulmonary arterial hypertension.

Table 1: (abstract: SAT238): noninvasive criteria for ruling out high-risk varices.

	APP score <0.24				
Variable	Training cohorts (221)	Validation cohorts (113)	ALB<3.6 and PLT <120	PLT >150 or MELD = 6	p-value
EGD Spared	56.6% (125/221)	51.3% (59/113)	31.7% (70/221)	27.6% (61/221)	<0.0001
HRV miss	4.8% (6/125)	1.7% (1/59)	1.4% (1/70)	1.6% (1/61)	0.42
Low risk varices miss	(14.4%) 18/125	(11.7%) 7/59	(10.0%) 7/70	(8.2%) 5/61	0.75
NPV	95.2%	98.3%	98.6%	98.3%	0.30

Results: 1787 cirrhotic patients (pts) (519 alcoholic and 1268 viral C or B), median age 56 years, 67.7% male, have been followed during a median of 64 months (at least 3 years for 79,4% of patients), 60% were Non-O Gp and 40% Gp O. The cumulated incidence of complications at 3 years was respectively 32.1% in Non-O Gp (46.1% of pts), and 29.4% (42.5% of pts) in Gp O (p = 0.20). Among these complications, in the Non-O Gp, the cumulated incidences of NTPT and HCC were respectively 3.2% and 9.2% at 3 years. In the Gp O, theses incidences were 3.4% (p = 0.63) and 7.7% (p = 0.51). The probability of **Decompensation** or **Disease Progression** at 3 years did not differ according to blood group. At 3 years the cumulated incidence of **Decompensation was** 8.3% in the Non-O Gp (14.2% of pts) and 7.3% in the Gp O (12.2% of pts) (p = 0.28). At 3 years the cumulated incidence of **Disease Progression** was 22.1% in the Non-O Gp (33.1% of pts) and 20.7% in the Gp O (29.9% of pts) (p = 0.25). The 3 years mortality rate was similar in both groups: 183 (17.1%) patients of Non-O Gp and 124 (17.3%) patients of Gp O. Death was related to liver disease in 54.6% of cases with 25% due to HCC. At 3 years the overall survival was 92.6% in the Non-O Gp and 93.6% in the Gp O (p = 0.90). Platelets, albumin and bilirubin were prognostic factors related to most of the events.
Conclusion: Despite its thrombotic role in general population, Non-O group is related neither to the risk of non tumoral portal vein thrombosis, nor to the risk of hepatocellular carcinoma, nor to the risk of disease progression in well compensated cirrhotic patients.

SAT238
Development and validation of a risk scoring system for screening high-risk varices
Yuling Yan[1], Li Yang[1], Jinlin Yang[1]. [1]*West China Hospital, Sichuan University, Department of Gastroenterology and Hepatology, Chengdu, China*
Email: yuling.yan@scu.edu.cn

Background and Aims: to create and validate an easy-to-use risk score system based on routine laboratory and routine liver doppler ultrasonography to accurately identify high-risk varices and spare esophagogastroduodenoscopy (EGD) in patients with hepatitis B virus (HBV) related compensated advanced chronic liver disease (cACLD).
Method: this was a single-center retrospective study. The training cohorts included 221 patients and validation cohorts included 113 patients. All patients were diagnosed with HBV related cACLD, and had routine biochemical examination, liver doppler ultrasonography and esophagogastroduodenoscopy (EGD) results.
Results: in training cohorts, the prevalence of HRV was 29.5%. a large proportion of patients with Child-Turcotte-Pugh A (94.1%). Within the multivariable logistic regression analysis, ALB (OR: 0.832; 95% confidence index (CI): 0.773–0.895; p < 0.0001), PLT (OR: 0.975, 95% CI: 0.964–0.986; p < 0.0001) and PVD (OR: 1.402; 95% CI: 1.152–1.706; p = 0.001) were independent risk factors for presence of HRV. The following risk score was created: logistic (P) = 4.780 + 0.338(PVD) –0.025(PLT)–0.184(ALB), which was named as albumin-platelet-portal vein diameter varices risk score (APP score). APP score <0.24, resulted in negative predictive value (NPV) were 95.2%. Within training cohort, 125 of 221(56.6%) patients met the new criteria of APP score <0.24. In validation cohort, 59 of 113 (51.3%) patients met the APP score <0.24. Several previous reported routine biochemical based criteria also analyzed in training cohort. 70 of 211 (31.7%) patients met the criteria (ALB<3.6 g/L or PLT<120 × 109 cells/L). PLT>150 × 109 cells/L or MELD = 6 can spare 61 of 221(27.6%) EGD screenings. The number of spared EGD with APP score in training cohort and validation cohort was larger than previous reported criteria(P < 0.0001), had equivalent HRV miss rate (P = 0.42), low risk varices miss rate (P = 0.75) and NPV (P = 0.30) (Table 1).
Conclusion: APP score <0.24 is a potential model for safely screening HRV in patients with HBV related-cACLD.

SAT239
Effect of rifaximin or norfloxacin on hepatic venous pressure gradient in patients with cirrhosis: a systematic review and meta-analysis
Yuly Paulin Mendoza[1], Susana G. Rodrigues[1], Annalisa Berzigotti[1], Jaime Bosch[1]. [1]*Inselspital, Department of Biomedical Research (DBMR), University of Bern, University Clinic for Visceral Surgery and Medicine (UVCM), Bern, Switzerland*
Email: yuly.mendoza@extern.insel.ch

Background and Aims: Translocation of intestinal bacteria or of bacterial products is thought to worsen chronic liver disease and portal hypertension. The effects on hepatic venous pressure gradient (HVPG) of non- or poorly-absorbable antibiotics commonly used for intestinal decontamination in cirrhosis are debated. This systematic review analyzes the effects of rifaximin or norfloxacin on HVPG and on markers of bacterial translocation and proinflammatory cytokines.

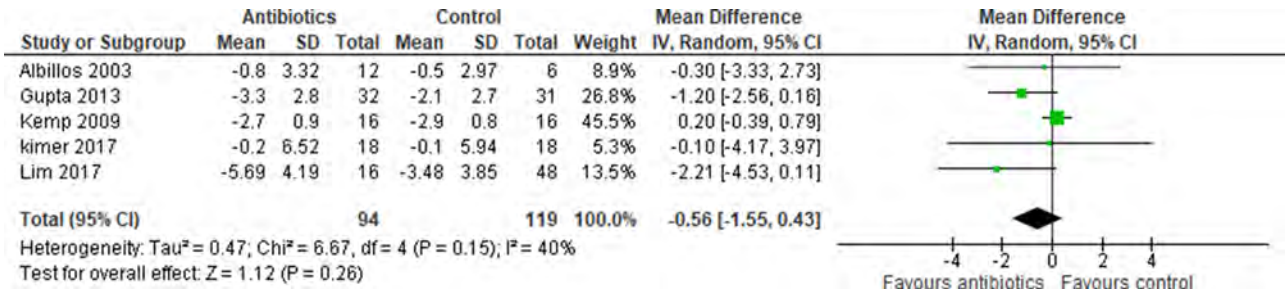


Figure: (abstract: SAT239)

Method: We performed a systematic search of the MEDLINE, EMBASE and SCOPUS databases (in English, up to December 2018). Two authors independently extracted randomized clinical trials (RCT) involving patients with cirrhosis and portal hypertension, assessing the effect of antibiotics (rifaximin or norfloxacin) vs control (placebo or no medication) on HVPG. Some studies associated non-selective beta-blocker (NSBB) in both the actively treated and the control arm. Pooled analyses were based on random-effects models, heterogeneity was assessed by Cochran's Q, I2 statistic and subgroup analyses. We used the Cochrane Collaboration's tool for risk of bias assessment.
Results: Five studies (215 patients) were included; the majority had low quality for control of bias. HVPG changes after antibiotics (norfloxacin or rifaximin) or control were similar. The summary mean absolute difference in HVPG was - 0.56 mmHg (95% CI: −1.55–0.43; p = 0.26), with moderate heterogeneity (I2 = 40%) (Figure), which disappeared after pooling RCTs with longer therapy (60–90 days). In the latter group, antibiotics were given in combination with NSBB and the observed reduction in HVPG was greater (mean difference −1.46 mmHg; 95% CI: −2.63 – −0.28; p = 0.01) than in controls (NSBB alone or plus placebo). Lipopolysaccharide-binding protein (LBP) was reported in 3 studies, and significantly decreased with antibiotics in all; levels of interleukin-6 and tumor necrosis factor alpha decreased significantly in 2/3 studies.
Conclusion: Rifaximin or norfloxacin did not significantly reduce HVPG in patients with cirrhosis and CSPH in the available studies. This conclusion is partly limited by heterogeneous population, small numbers and low quality of the studies. Studies using antibiotic plus NSBB for longer periods showed a significantly greater decrease in HVPG as compared to NSBB alone. Whether antibiotics combined to NSBB improve portal hypertension should be confirmed in an appropriately designed RCT

SAT240

Repeated versus single treatment of esophageal variceal ligation after esophageal variceal bleeding

Young Youn Cho[1], Jeonghoon Lee[2], Jung-Hwan Yoon[2], Hyung Joon Kim[1]. [1]*Chung-Ang University Hospital, Department of Internal Medicine;* [2]*Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute*
Email: yycho@hotmail.com

Background and Aims: International guidelines recommend repeated esophageal variceal ligation (EVL) for treatment of esophageal variceal bleeding. However, due to patient compliance and complications of repeated EVL procedure, many physicians perform single EVL treatment after varix bleeding. We aimed to compare the risk of variceal re-bleeding after repeated EVL versus single EVL.
Method: This retrospective study included consecutive patients who underwent initial esophageal variceal ligation (EVL) for the first esophageal variceal bleeding. Primary endpoint was the recurrence of variceal bleeding and uni-/multi-variate analyses were conducted to find independent predictors.
Results: A total of 210 patients were included: 133 in the repeated EVL group and 77 in the single EVL group. During follow-up duration (median = 46.5 months), 17 (12.8%) in the repeated EVL group and 36 (46.8%) in the single EVL group developed re-bleeding (P < 0.01 by log-rank test). However there were no difference of overall survival between the two groups (P = 0.05). Multivariate analysis showed that the single EVL group compared to the repeated group (adjusted hazard ratio [aHR] = 3.372, 95% confidence interval [CI] = 1.824–6.234, P < 0.001) was the only independent risk factor after adjustment for alcohol etiology (HR = 3.370, 95% CI = 1.717–6.618, P < 0.001), combined gastric varix (HR = 1.333, 95% CI = 1.250–9.612, P = 0.017) and high MELD score (HR = 2.379; 95% CI = 1.192–4.748; P = 0.014).
Conclusion: Repeated EVL after esophageal varix bleeding can improve re-bleeding. However, there was no difference in overall survival. Further randomized control studies are needed.

Non-invasive assessment of liver disease except NAFLD

SAT241

Serum gamma-glutamyl transpeptidase as a simple and useful indicator for predicting significant fibrosis in patients with chronic hepatitis B

Jian Wang[1], Rui Huang[1], Xiaomin Yan[1], Juan Xia[1], Bei Jia[1], Zhaoping Zhang[1], Weimao Ding[2], Chao Wu[1]. [1]*Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Infectious Diseases, Nanjing, China;* [2]*Huai'an No. 4 People's Hospital, Department of Hepatology, Huai'an, China*
Email: dr.wu@nju.edu.cn

Background and Aims: Assessing the stages of liver fibrosis is critical in guiding the treatment of chronic hepatitis B (CHB). The gamma-glutamyl transpeptidase (GGT) was reported to be associated with the severity of liver diseases. We aimed to investigate the association between GGT and the severity of liver fibrosis in CHB.
Method: Six hundred eighty-three treatment-naïve CHB patients who underwent liver biopsy were enrolled from two medical centers. Liver histology was evaluated using the Scheuer classification system. The diagnostic accuracy was evaluated by the area under the receiver operating characteristic curve (AUROC).
Results: The GGT level showed an increasing trend with fibrosis stages in CHB patients. The GGT level was positively correlated with the stages of liver fibrosis in entire CHB patients (r = 0.346, p < 0.001), HBeAg positive CHB patients (r = 0.438, p < 0.001) and HBeAg negative patients (r = 0.307, p < 0.001). GGT was an independent factor for predicting significant fibrosis (S ≥ 2) in the entire CHB patients and HBeAg positive patients, but not in HBeAg negative patients. The AUROCs of GGT for predicting significant fibrosis were 0.658 (95%CI 0.6148 to 0.7016), 0.703 (95%CI 0.6453 to 0.7603) and 0.628 (95%CI 0.5616 to 0.6938) in entire CHB patients, HBeAg positive and HBeAg negative CHB patients, which was comparable with aspartate transaminase (AST) to PLT ratio index (APRI) (p > 0.05) and fibrosis-4 score (FIB-4) (p > 0.05).
Conclusion: The GGT level was positively correlated with the severity of liver fibrosis in CHB patients. The GGT level alone showed similar diagnostic accuracy for significant fibrosis in CHB patients as compared to APRI and FIB-4.

The predictive value of MRI-based markers of liver disease on clinical outcomes in patients with cirrhosis

Christina Levick[1,2], Michael Pavlides[1,2], Emmanuel Selvaraj[1,2], Arjun Jayaswal[2], Ferenc Mozes[2], David J Breen[3], Kathryn Nash[4], Matthew Robson[2,5], Stefan Neubauer[2], Eleanor Barnes[1,6]. [1]*University of Oxford, Translational Gastroenterology Unit, Oxford, United Kingdom;* [2]*University of Oxford, Oxford Centre for Clinical Magnetic Resonance Research, Oxford, United Kingdom;* [3]*University Hospitals Southampton NHS Foundation Trust, Department of Radiology, Southampton, United Kingdom;* [4]*University Hospitals Southampton NHS Foundation Trust, Department of Hepatology, Southampton, United Kingdom;* [5]*Perspectum Diagnostics, Oxford, United Kingdom;* [6]*University of Oxford, Peter Medawar Department, Oxford, United Kingdom*
Email: christina.levick@gmail.com

Background and Aims: Non-invasive risk stratification for liver-related outcomes is important for the management of patients with cirrhosis. This prospective cohort study explores the ability of magnetic resonance imaging (MRI)-based markers of a.) liver fibrosis (liver cT1); b.) portal hypertension (spleen extracellular volume fraction (ECV)); and c.) liver function (percentage reduction in liver T1 with gadoxetic acid (%rT1)) to predict liver-related outcomes.

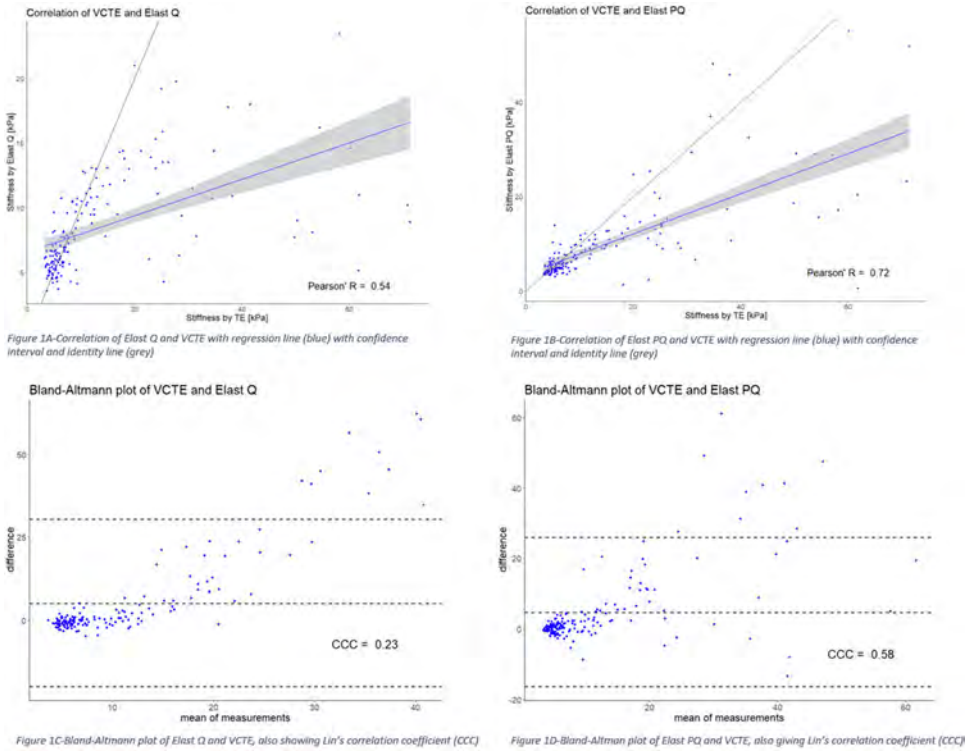

Figure 1A-Correlation of Elast Q and VCTE with regression line (blue) with confidence interval and identity line (grey)

Figure 1B-Correlation of Elast PQ and VCTE with regression line (blue) with confidence interval and identity line (grey)

Figure 1C-Bland-Altmann plot of Elast Q and VCTE, also showing Lin's correlation coefficient (CCC)

Figure 1D-Bland-Altman plot of Elast PQ and VCTE, also giving Lin's correlation coefficient (CCC)

Figure: (abstract: SAT243)

Method: One hundred and thirty-five patients with cirrhosis of mixed aetiologies were followed up by telephone consultation and medical record review for ≥1 year following MRI with gadoxetic acid administration, clinical, blood and transient elastography assessments. Time to first development of a composite endpoint comprising new variceal bleeding, ascites, spontaneous bacterial peritonitis, hepatic encephalopathy, hepatocellular cancer, liver transplantation or liver-related death was recorded. The association of MRI and other non-invasive liver disease markers with the composite endpoint was assessed by Kaplan Meier and Cox regression analyses.
Results: The cohort of median age 61 (IQR 54–8) years comprised 73% males and 74% with compensated advanced chronic liver disease (cACLD). During follow up of median 571 (IQR 432–634) days, 28 (21%) patients reached the composite endpoint. Spleen ECV >0.36 and %rT1 <55.05% were associated with reduced endpoint-free survival (both $p < 0.001$). Liver cT1 (HR 1.004, $p = 0.026$), spleen ECV (HR 1.068, $p = 0.001$) and %rT1 (HR 0.922, $p < 0.001$) were predictive of the composite endpoint in univariate analysis. Of the MRI markers, %rT1 ($p = 0.015$) remained a significant predictor of the composite endpoint in multivariable analysis, together with bilirubin ($p = 0.001$), sodium ($p = 0.014$), Child Pugh score ($p = 0.005$), MELD ($p = 0.004$) and APRI ($p = 0.001$).
Conclusion: MRI-based markers of liver fibrosis, portal hypertension and liver function are predictive of liver-related outcomes. In particular, %rT1 adds prognostic benefit to clinical and serum-based markers.

SAT243

Elast q - 2D shear wave liver elastography correlates well with vibration controlled transcient elastography in patients with different etiologies of chronic liver disease

David JM Bauer[1,2], Annalisa De Silvestri[3], Dr. Laura Maiocchi[3], Ruxandra Mare[4], Ioan Sporea[4], Theresa Bucsics[1,2], Giovanna Ferraioli[3], Thomas Reiberger[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Wien, Austria; [2]Medical University of Vienna, Vienna Hepatic Hemodynamic Lab, Wien, Austria; [3]Fondazione I.R.C.C.S. Policlinico San Matteo, University of Pavia, Pavia, Italy; [4]"Victor Babes" University of Medicine and Pharmacy Timisoara, Timișoara, Romania*
Email: david.bauer@meduniwien.ac.at

Background and Aims: Two dimensional (2D-SWE) and point shear wave (pSWE) elastography modules implemented on high-end ultrasound machines are increasingly used for screening of liver disease. As compared to vibration-controlled transient elastography (VCTE), ultrasound-based elastography quantification (ElastQ) allows fibrosis assessment in a larger region of interest.
Method: In this prospective multicenter study, we acquired paired liver stiffness measurements (LSM) by VCTE and 2D-SWE (ElastQ) and pSWE (ElastPQ) using the Philips EPIQ7 system. We applied WFUMB quality criteria (ElastQ: median of 5, VCTE and Elast PQ: median of 10 acquisitions, respectively; for all IQR/Median<30%), as well as the manufacturer recommendation of confidence >60% for ElastQ to LSM results. Correlations of LSM by VCTE to LSM by ElastQ and ElastPQ were assessed by Pearson's correlation coefficient and concordance by Lin's correlation coefficient (CCC). Optimal Youden, specific rule-in and sensitive rule out-cutoffs for significant ≥F2 and F4 fibrosis were calculated.
Results: We included 175 consented patients. Median age was 60.5 [IQR:22] years, M:98 (53%), W:86 (47%), median BMI: 24.9 [5.7] kg/m2, and ALT: 28 [30] U/L. As defined by VCTE 90 (51.4%) had F0/F1 (≤8.3 kPa), 85 (48.6%) ≥F2 (>8.4 kPa) and 58 (33.1%) F4 (>12.8 kPa) fibrosis stage. Main etiologies were HCV: 101, HBV: 23, NAFLD: 20 and ALD: 22. We found a high correlation of ElastQ ($r = 0.54$, $p < 0.001$)) and ElastPQ ($r = 0.72$ ($p < 0.001$)) with VCTE (Fig-1a/b). The concordance was 0.23 (0.12–0.34) and 0.58 (0.38–0.73), respectively (Fig-1c/d).
The optimal ElastQ cutoff for ruling out ≥F2 fibrosis was at <7.1 kPa (Sens: 0.92, Spec: 0.84) and for ruling in ≥F2 at ≥8.1 kPa (Sens: 0.85, Spec: 0.92). ElastPQ cutoffs for ≥F2 were <6.35 kPa (Sens: 0.91, Spec: 0.85) for ruling-out and ≥7.1 kPa (Sens: 0.85, Spec: 0.91) for ruling-in ≥F2, respectively.

For F4 cirrhosis, optimal ElastQ cutoffs for ruling-out were at <8.1 kPa (Sens: 0.85, Spec: 0.75) and for ruling-in at >9.7 kPa (Sens: 0.74, Spec: 0.85). For ElastPQ, the cutoff for ruling-in and -out F4 cirrhosis were at <8.0 kPa (Sens: 0.85; Spec: 0.75) and >9.7 kPa (Sens: 0.74; Spec: 0.85), respectively.
Conclusion: LSM by the ElastQ (2D-SWE) and the ElastPQ (pSWE) technology accurately reflect liver fibrosis stages in patients with different etiologies of liver disease.

SAT244

Liver function assessment by 13C-methacetin test before and after placement of a transjugular portosystemic shunt: a prospective pilot study

David Semela[1], Roman Stillhard[1], Patrizia Kuenzler[1], Sascha Müller[2], Bruno Schmied[3], Lukas Hechelhammer[4]. [1]*Kantonsspital St. Gallen, Division of Gastroenterology and Hepatology, St. Gallen, Switzerland;* [2]*Klinik Beau-Site, Visceral Surgery, Bern, Switzerland;* [3]*Kantonsspital St. Gallen, Division of Visceral Surgery, St. Gallen, Switzerland;* [4]*Kantonsspital St. Gallen, Institute of Radiology, St. Gallen, Switzerland*
Email: david.semela@kssg.ch

Background and Aims: Transjugular intrahepatic portosystemic shunt (TIPS) placement can lead to severe complications such as hepatic encephalopathy or acute-on-chronic liver failure. Risk factors for the development of such post-TIPS complications are ill-defined. A point-of-care diagnostic ^{13}C-methacetin test for the determination of maximal liver function capacity (LiMAx®) has been developed and validated by predicting adequately post-operative liver failure after liver resection (Stockmann M et al. J Hepatol 2012 & Annals of Surgery 2009). The aim of this prospective study is to evaluate the performance of LiMAx® before and after TIPS placement and to ideally correlate pre-TIPS measurements to post-TIPS outcomes.
Method: Patients undergoing TIPS for refractory ascites, secondary prevention of variceal bleeding and/or for partial portal vein thrombosis on imaging with the danger of complete thrombosis were included. Patients undergoing TIPS placement were tested before (−1 day) and after (+1, +7, +28, +72 and +180 days) the intervention for: LiMAx®, hepatic encephalopathy (HE; critical flicker frequency, Stroop & connect the numbers test), laboratory (MELD score) as well as imaging of the TIPS flow by Doppler ultrasound. Patients with TIPS indication for acute bleeding (<72 h), presence of HCC, CHILD >12, or overt HE or right heart failure were excluded.
Results: 15 patients (13 male/2 female, mean age 63 (48–71) years, range) with a mean CHILD 7.8 (5–9) and MELD 9.0 (6.4–14) were included (TIPS indications: ascites n = 9, varices n = 3, portal vein thrombosis n = 3). ^{13}C-methacetin test showed a rapid, persistent and significant decline after TIPS placement (day 0: 218 ug/kg/h (range 753–61) vs. day 7: 139 ug/kg/h (559–43), p = 0.0024). This drop was paralleled by worsening of liver function assessed by MELD score (day 0: 9.0 (6.4–14.0) vs. day 7: 11.5 (8.5–18.9), p = 0.0019). In contrast, HE testing did not correlate with decrease in of LiMAx®.
Conclusion: Our results indicate that the ^{13}C-methacetin (LiMAx) test is a sensitive method for capturing decrease in liver function after TIPS placement. LiMAx decrease is paralleled by increase in MELD score after TIPS placement. A larger study is needed to assess the value of LiMAx testing as predictor for post-TIPS complications.

SAT245

A novel diagnostic model using liver stiffness measurement and platelet count that accurately predicts the presence of portal hypertensive gastropathy in patients with cirrhosis

David Lee[1], Ahmed Al-Khazraji[2], Vilas Patwardhan[2], Gary Trey[2], Raza Malik[1]. [1]*Tufts Medical Center, Liver Center, Division of Gastroenterology, Boston, United States;* [2]*The Liver Center at BIDMC, Liver Center, Division of Gastroenterology, Boston, United States*
Email: dlee7@tuftsmedicalcenter.org

Background and Aims: Portal hypertensive gastropathy (PHG) and esophageal varices (EV) are common complications of cirrhosis and portal hypertension that require endoscopic screening for diagnosis. The objective of the study is to predict the presence of PHG and EV using noninvasive markers of chronic liver disease.
Method: This was a cross-sectional, retrospective study in patient with chronic liver disease using clinical, biochemical, endoscopic, and histological data. Multivariate analyses were performed to identify the variables associated with the presence of PHG and EV. Receiver operator characteristic (ROC) curves were constructed for single variables and combinations of variables and compared to established models of liver fibrosis. Optimal cutoffs for sensitivity/negative predictive value and specificity/positive predictive value were derived from the curves.
Results: 151 patients were included in the study, of which 54.7% had cirrhosis confirmed by liver biopsy. Additionally, 29.7% had PHG and 32.5% had EV diagnosed by endoscopy. Univariate analysis showed PHG was associated with: older age (p = 0.006), increased transient elastography (TE) (p = <0.001), cirrhosis (p = 0.001), lower platelet count (p = <0.001), increased INR (p = <0.001), increased AST (p = 0.019), increased alkaline phosphatase (p = <0.001), elevated bilirubin (p = 0.007), and lower albumin (p = <0.001). Multivariate analysis showed that lower platelet count (p = 0.023) and increased TE (p = 0.015) were the only variables associated with the presence of PHG. Using the multivariate analysis, we developed a diagnostic model incorporating TE and platelet count: TE-PLT (TE divided by the platelet count). The area under the ROC (AUROC) for TE-PLT (AUROC = 0.867) was superior to TE alone (AUROC = 0.838), FIB4 (AUROC = 0.822), APRI (AUROC = 0.803), AAR (AUROC = 0.650), and AARPRI (AUROC = 0.795). In a range of cutoffs at 0.0675 to 0.1921 for TE-PLT, the lower value had NPV/sensitivity of 90% and upper value had PPV/specificity of 90%, indicating a good test sensitivity and specificity. Similarly, ROC curves for the presence of EV showed TE-PLT (AUROC = 0.805) to be superior to TE alone (AUROC = 0.782), FIB4 (AUROC = 0.723), APRI (AUROC = 0.703), AAR (AUROC = 0.573), and AARPRI (AUROC = 0.719). In a range of cutoffs at 0.0402 to 0.2041 for TE-PLT, the lower value had NPV/sensitivity of 90% and upper value had PPV/specificity of 90%. In conjunction to the AUROC curves, PHG had a higher correlation with cirrhosis (Spearman coefficient = 0.463, p = <0.001) than EV (Spearman coefficient = 0.435, p = <0.001), suggesting PHG to be a more sensitive indicator of portal hypertension in cirrhosis.

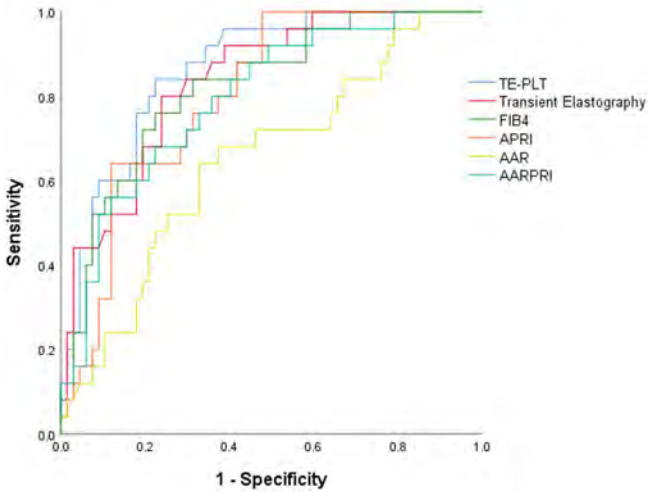

Figure: Area under the curve (AUROC) for TE-PLT compared to other non-invasive models of fibrosis in detecting the presence of PHG.

Conclusion: The novel TE-PLT index accurately predicts the presence of PHG and EV compared to other models of liver fibrosis.

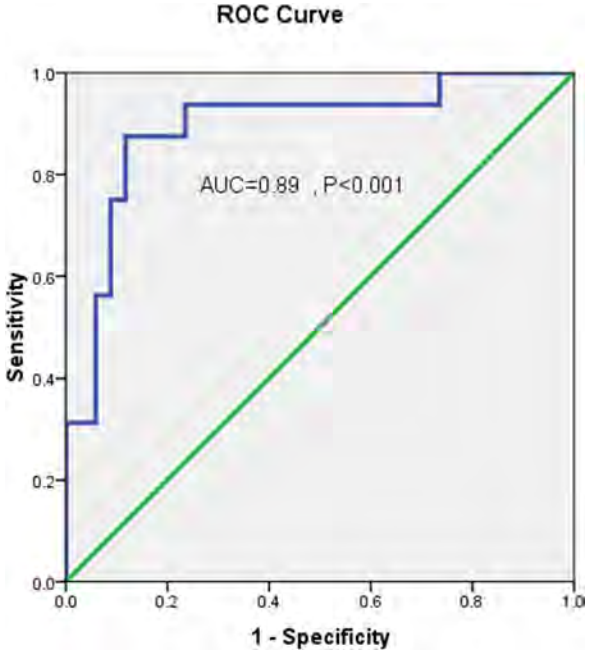
SAT246

Endothelin-1 level at first presentation of hematemesis as indicator of recurrent bleeding within 5 days

Shaker Ibrahim[1], Ahmed El-Mesery[2], Ahmed Ibrahim[2], Metwaly Mortada[3], Walid Elsherbiny[2], Hatem Elalfy[2]. [1]*Faculty of Medicine, Port Said University, Endemic Hepatology and Gastroenterology Department, Port Said, Egypt;* [2]*Faculty of Medicine, Mansoura University, Endemic Hepatology and Gastroenterology Department, Mansoura, Egypt;* [3]*Faculty of Medicine, Mansoura University, Clinical Pathology Department, Mansoura, Egypt*
Email: elalfy_hatem66@yahoo.com

Background and Aims: Acute variceal bleeding is a severe complication of portal hypertension carrying an overall 6-week mortality of 10–30% according to degree of liver dysfunction. Previous studies demonstrated that peripheral and hepatic levels of endothelin-1 (ET-1) have been correlated with the stage of portal hypertension determined invasively by hepatic venous pressure gradient (HVPG) and degree of liver insufficiency in patients with liver cirrhosis. The aim of this study is to evaluate serum level of ET-1 as a non-invasive predictor of early variceal rebleeding within 5 days after endoscopic control.

Method: Out of 66 patients presented to our endoscopy unit between March 2019 and August 2019, written informed consents were obtained from 50 patients who had been enrolled in this prospective study, presented with proved esophageal acute variceal bleeding on endoscopy as a complication of Hepatitis C virus induced liver cirrhosis and portal hypertension. All patients were subjected to routine laboratory investigations and assessment of serum level of ET-1 prior to endoscopic therapy. Patients were grouped into 2 groups on basis of early rebleeding within 5 days after endoscopic control: group A included 16 patients who developed rebleeding within 5 days and group B included 34 patients with no recurrent bleeding in the same follow up period.



Results: Stepwise multivariate logistic regression analysis showed that 2 variables were independent risk factors for early rebleeding: ET-1 level [odds ratio (OR) 1.05, 95% CI: 1.02–1.08, $p < 0.001$] and serum albumin level (OR 0.006, 95% CI: 0.001–0.83, $p = 0.04$). At the best cut-off value of ET-1 level at 65.29, the specificity of prediction of 5 days variceal rebleeding was 88.2%, the sensitivity was 87.5%, accuracy was 88% and area under the curve (AUC) was 0.89. Furthermore, ET-1 level was significantly higher in patients presenting with more advanced portal hypertensive endoscopic findings particularly the number of variceal cords ($p = 0.006$) as well as post bleeding adverse events including drop in hemoglobin level ($p = 0.002$) and degree of renal impairment ($p < 0.001$). Interestingly, ET-1 level showed significant correlation with the duration of hospital stays ($p < 0.001$).

Conclusion: Serum ET-1 level appears to be effective, convenient and non-invasive predictor of not only early variceal rebleeding but also associated comorbidities such as degree of renal impairment and duration of hospital stay.

SAT247

Spleen acoustic radiation force impulse (ARFI) elastography predicts decompensation in patients with liver cirrhosis

Elba Llop[1,2,3], Christie Perelló[1,3], Marta López-Gómez[1,3], Teresa Fontanilla[4], Marta Hernández Conde[1,3], Javier Minaya[4], Javier Abad Guerra[1,3], Natalia Fernández Puga[1,3], Maria Trapero[1,2,3], Carlos Ferre Aracil[1,3], José Luis Martínez Porras[1,2,3], Enrique Fraga[1,3], José Luis Calleja Panero[1,2,3]. Email: elballop@gmail.com

Background and Aims: Hepatic venous pressure gradient(HVPG) predicts prognosis in liver cirrhosis(LC). However, it is invasive and not available in most centers. Our aim was evaluate hepato-splenic ARFI elastography to predict prognosis in LC.

Method: Consecutive patients with LC and HVPG measurement were included prospectively and followed up until death, liver transplant or last day of follow-up. Exclusion criteria: hepatocellular carcinoma out Milan-Criteria, portal thrombosis and refuse to participate. On the same day of the HVPG measurement, laboratory test and abdominal ultrasound with hepato-splenic ARFI were performed. Data from transient hepato-splenic elastography were collected if was performed at least 6 month before.

Results: From November 2010 to November 2019, 76 patients were included.73.7% males, mean age 56(DE8). Main etiologies: HCV 43.4%,AFLD/NAFLD 42.1%. Mean MELD 10.4(DE3.8) and CHILD PUGH A/B/C 80.9%/11.8%/7.3%. 58(76.3%) were compensated. Mean follow-up 41 months (2–108). 10(13.2%) died and 5(6.6%) were transplanted during follow-up. Mean HVPG(mmHg) was 15.5(De5.7), mean ARFI hepato-splenic elastography(m/s) was 2.6(SD0.7) and 3.2(SD 0.5) respectively, hepato-splenic transient elastography (KPa) was 32.1(SD 17.6) and 66.3(SD11.8) respectively. HVPG showed a moderate correlation with splenic ARFI($r = 0.5$;$p = 0.001$) and hepatic Fibroscan®($r = 0.5$;$p < 0.001$).20 out of 58 compensated patients (34.5%) had first hepatic decompensation(HD) during follow-up. Factors related to HD were: albumin(g/dL) 3.7(SD0.6)vs4.0(SD0.4);$p = 0.03$, MELD 12.0 (SD2.9)vs8.8 (SD2); $p = 0.001$; HVPG 17.2(DE5.9) vs13.4 (DE5.1); $p = 0.01$, splenic ARFI(m/s)3.3(0.5); $p = 0.04$vs3.0 (DE0, 5) and spleen diameter(cm) 15.4(2.7)vs13.2(2.6); $p = 0.03$. In the multivariate analysis, MELD showed a HR 1.3(1.1–1.8); $p = 0.03$ and splenic ARFI a HR3.7(1.1–12.8); $p = 0.04$. The AUC of the ROC curve of splenic ARFI and MELD to predict HD was 0.8 and 0.8 respectively. A splenic ARFI cutoff≥3 m/s had high sensitivity 95% and high NPV 94%. The accumulated probability of HD at 12 and 24 months was: splenic ARFI ≥3 m/s: 29% and 43.8% and<3 m/s: 5.6% and 5.6%; $p = 0.001$. Factors related to death in the global cohort were: MELD 18.3(DE2.8) vs9.3(DE2.4);$p < 0.001$, albumin(g/dL)3.3(SD0.6) vs4.0(SD0.5), bilirubin(mg/dL)2.8(SD3.0) vs.1.4(SD1.4);$p = 0.02$ and spleen size(cm) 16(SD3.7)vs13.7(SD2.6); $p = 0.02$.

Conclusion: Splenic ARFI elastography and MELD predict HD in compensated patients with LC. Patients with splenic ARFI ≥3 m/s are at high risk of HD.

SAT248

Automatic high-risk fibrosis score prediction using computed tomography imaging

Elton Rexhepaj[1], Corinne Ramos[1], Nozha Boujemaa[1], Benoit Huet[1], Oliver Lucidarme[2]. [1]*MEDIAN Technologies, Valbonne, France;* [2]*University Hospitals Pitié Salpêtrière - Charles Foix, Paris, France*
Email: elton.rexhepaj@mediantechnologies.com

Background and Aims: Hepatic fibrosis diagnosis is important for risk stratification, prognosis evaluation and monitoring of treatment response. We have previously shown that computer tomography (CT) perfusion imaging and splenic radiomics can accurately assess and grade liver fibrosis. Using this methodology, the objective of this study is to identify patients whose tumors are at high risk of recurrence after hepatic resection.
Method: Ninety-four patients with focal liver lesions referred for liver resection underwent a pre-surgery standard triphasic contrast CT scan. The patients also had excised tissue samples graded for fibrosis by histopathology per the METAVIR scoring system (F0-F4). A logistic regression algorithm was used to model the relation between hepatosplenic radiomics and fibrosis stages. The dataset was split between a training and a validation set according to fibrosis stages. A logistic regression algorithm was used to model the relation between hepatosplenic imaging features and advanced fibrosis stages. The subsequent high-risk Fibrosis score is then correlated to the recurrence event.
Results: Receiver operator curves show the performances in the training (AUC = 0.83) and validation dataset (AUC = 0.91). Clinical prediction performances were comparable in the training (Sensitivity = 75%, Specificity = 93%, NPV = 93%, PPV = 75%) in the validation (Sensitivity = 86%, Specificity = 100%, NPV = 82%, PPV = 100%) dataset. Kaplan-Meier survival analysis was used to correlate fibrosis risk with the clinical outcome defined as recurrence free survival (RFS). Cox-regression modelling of recurrence hazard ratios showed similar results for histology scores (HR = 6.6, pval < 0,01) and non-invasive fibrosis scores (HR = 4.1, pval < 0,01). When combining the histology (invasive) and non-invasive methods we are able to stratify the low risk recurrence group as defined by histology in two sub-groups with significant differences (pval < 0.05) in recurrence free survival outcome.
Conclusion: A fully automated hepatosplenic radiomics quantification is used as a non-invasive method to identify liver high-risk fibrosis score. Prognosis of patients that underwent liver tumor resection is accurately derived from the developed advanced fibrosis score. Further validation is warranted to determine high risk fibrosis prognostic value in independent cohorts.

SAT249

The variscreen algorithm using successively platelets, liver stiffness and INR improves and secures the screening of esophageal varices needing treatment

Federico Ravaioli[1], Arthur Berger[2], Oana Farcao[3], Davide Festi[1], Horia Stefanescu[3], Francois Buisson[2], Pierre Nahon[4], Christophe Bureau[5], Nathalie Ganne-Carrié[4], Annalisa Berzigotti[6], Victor de Lédinghen[7], Salvatore Petta[8], Paul Cales[2]. [1]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy;* [2]*University Hospital Angers, Hepato-Gastroenterology Department, Angers, France;* [3]*Regional Institute of Gastroenterology and Hepatology, Liver Unit, Cluj-Napoca, Romania;* [4]*Paris Seine-Saint-Denis University Hospitals, Hepato-Gastroenterology Department, Paris, France;* [5]*Purpan University Hospital, Hepato-Gastroenterology Department, Toulouse, France;* [6]*University of Bern, Hepatology, Swiss Liver Center, Visceral Surgery and Medicine Clinic (UVCM) Inselspital, Bern, Switzerland;* [7]*Haut-Lévêque Hospital, Hepatology Department, Bordeaux, France;* [8]*University of Palermo, Department of Gastroenterology and Hepatology, Palermo, Italy*
Email: f.ravaioli@unibo.it

Background and Aims: Based on platelets and liver stiffness measurement (LSM by vibration-controlled transient elastometry), the Baveno VI criteria (B6C), the expanded B6C (EB6C) or the ANTICIPATE score can be used to rule out varices needing treatment (VNT). We aimed to evaluate and improve these tests.

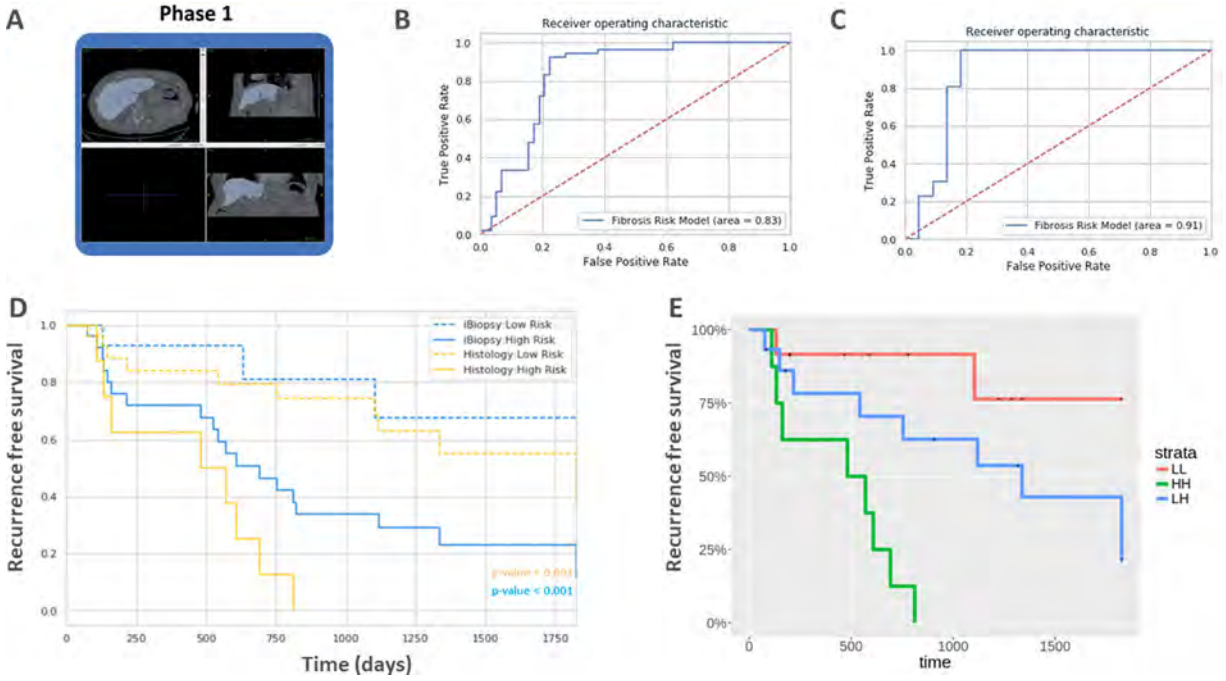

Figure: (abstract: SAT248): Fibrosis risk prediction. A) Hepatic fibrosis is analyzed both in the liver and its adjacent organs (spleen is used in this study). Receiver operator curves show the performances in the B) training and C) validation dataset. D) Kaplan-Meier survival analysis was used to correlate fibrosis risk with the clinical outcome defined as recurrence free survival (RFS). E) Stratification of histology low risk group into two sub-groups : Low-Histology & Low-iBiopsy (in red) and Low-Histology & High-iBiopsy (in blue).

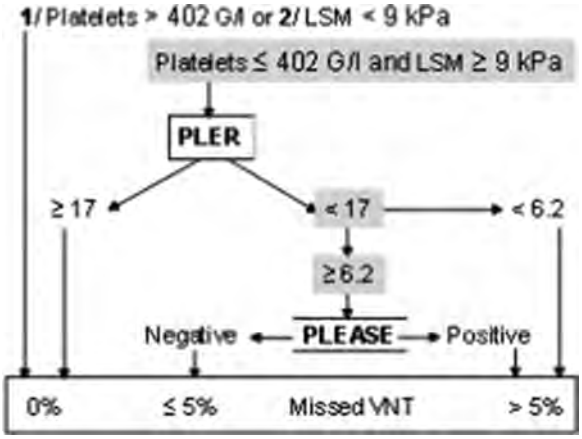
Method: 2368 patients were randomized in derivation (2/3, n = 1579) and validation (1/3, n = 789) populations with chronic liver diseases (CLD) of various etiologies and severities in a multicenter retro-prospective study. Published tests were compared to two new tests: PLER (platelets/LSM ratio) and PLEASE (PLER adjusted on etiology/sex/INR). In the derivation population, patient characteristics were: VNT: 15.1%, etiologies: viral: 50.2%, NAFLD: 28.9%, alcoholic: 20.8%, MELD score: 9.5 ± 3.0, LSM≥10 kPa: 93.0%. Patient characteristics were not significantly different in the validation population.



Results: 1/Tests to diagnose VNT. AUROC for VNT were significantly different between scores: PLER: 0.761, ANTICIPATE: 0.770, PLEASE: 0.798. PLEASE score was better calibrated than other scores (Spearman's r: 0.37, $p < 0.001$). 2/Tests to spare endoscopy. Performances for spared endoscopy rate and safety for missed VNT rates (respectively, in parentheses) were, in increasing order: B6C: 23.9% (2.9%), ANTICIPATE: 24.3% (4.6%), PLER: 26.6% (4.6%), PLEASE: 34.8% (3.3%) and EB6C: 41.9% (10.9%). Differences in spared endoscopy rates were significant between tests ($p \leq 0.001$) except for B6C vs ANTICIPATE. Differences in missed VNT rates were significant only between EB6C vs other tests ($p \leq 0.009$). PLEASE was the only safe test (missed VNT ≤ 5%) whatever the sex or etiology. A VariScreen algorithm (Figure), based successively on platelets or LSM then PLER (in 94.2% of patients) then PLEASE (in only 35% of patients), secured screening with no missed VNT in poor liver function (MELD ≥ 10). The rates of VariScreen for spared endoscopy and missed VNT were 35.7% and 2.9%, respectively. Test performance and safety were not significantly different between populations. Tests and Variscreen algorithm can be calculated at http://forge.info.univ-angers.fr/~gh/wstat/pler-please-variscreen.php

Conclusion: B6C are safe for missed VNT rate regardless of CLD etiology and severity, and regardless of sex; EB6C are unsafe and no longer recommended. To improve current VNT screening, we propose the sequential VariScreen algorithm applicable to any main-etiology CLD and secured for liver severity.

SAT250

Breath-based monitoring of liver metabolism using exogenous volatile organic compounds - towards improved detection

Giuseppe Ferrandino[1], Isabel Orf[1], Rob Smith[1], Marzia Calcagno[1], Anita Kaur Thind[1], Megan Williams[1], Olga Gandelman[1], Alexandra De Saedeleer[1], Max Allsworth[1], Billy Boyle[1], Marc P. van der Schee[1], Chris Mayhew[2], Matthew Hoare[3], Michael Allison[4], Rebecca C. Fitzgerald[5], Victoria Snowdon[4].
[1]Owlstone Medical, United Kingdom; [2]University of Birmingham, United Kingdom; [3]Cancer Research UK Cambridge Institute, United Kingdom; [4]Addenbrooke's Hospital, United Kingdom; [5]MRC Cancer Unit, Hutchison/MRC Research Centre, United Kingdom
Email: victoria.snowdon@addenbrookes.nhs.uk

Background and Aims: Targeted analysis of the subset of metabolites exhaled as volatile organic compounds (VOCs) represents an attractive non-invasive means to measure the functional capacity of the liver. Limonene, an exogenous VOC (eVOC) we are regularly exposed to through diet and the environment, is metabolised by the CYP450 enzymatic complex. In this study, we tested the hypothesis that limonene reflects changes in liver function by analysing breath limonene levels of subjects with early-stage cirrhosis (Child-Pugh class (CP) A and B) and hepatocellular carcinoma (HCC).

Method: We collected breath samples from 26 healthy controls (65 [41–81] year, f/m [15/11]), 20 patients with cirrhosis (55 [35–78] year, f/m [9/11]), and 14 patients with HCC (69.5 [48–84] year, f/m [4/10]) using the ReCIVA Breath Sampler combined with a CASPER Portable Air Supply to reduce ambient contamination. Breath samples were analysed by thermal desorption gas chromatography mass spectrometry (TD-GC-MS), using a Q-Exactive GC hybrid quadrupole

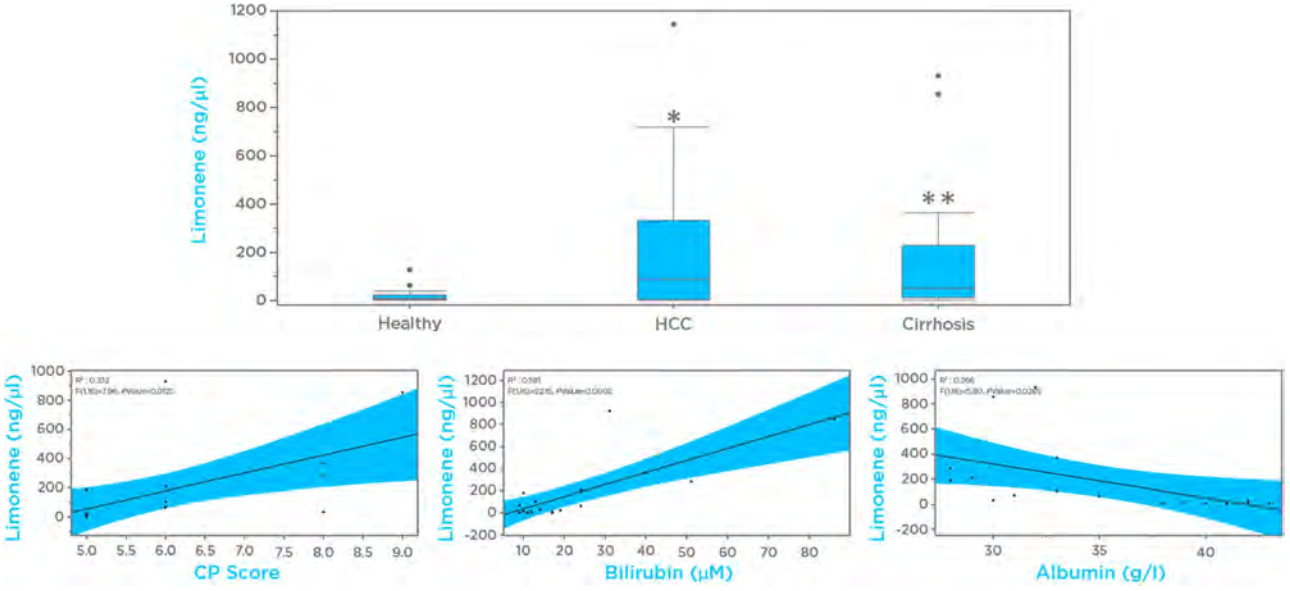


Figure: (abstract: SAT250)

Orbitrap mass spectrometer. Peak integration was performed with Chromeleon data system. Limonene standards were run to provide absolute quantitation. Limonene levels were compared groupwise by using a Mann-Whitney U-test.

Results: Limonene breath levels were significantly elevated in subjects with HCC (84.5, [0–1142] ng/µl) and cirrhosis (47.9 [0.3–928] ng/µl) compared to controls (5.9, [0–124] ng/µl), (p-value 0.03 and 0.004, respectively). A subset of subjects with HCC and cirrhosis showed near normal levels of exhaled limonene. A bivariate linear regression inference revealed that breath limonene correlates with the Child-Pugh (CP) score ($p = 0.01$, $R^2 = 0.3$), and serum bilirubin levels in patients with cirrhosis ($p = 0.0002$, $R^2 = 0.6$), but not in patients with HCC ($p = 0.53$, $R^2 = 0.04$; $p = 0.73$, $R^2 = 0.0.011$). Similarly, a negative correlation with albumin levels was found in subjects with cirrhosis ($p = 0.02$, $R^2 = 0.3$).

Conclusion: Exhaled limonene levels are significantly elevated in subjects with cirrhosis and/or HCC and reflect cirrhosis severity, detoxifying capacity, and protein synthesis, as demonstrated by correlations with CP score, bilirubin, and albumin serum levels. The observed spread of limonene levels could be related to differences in enzymatic activity, disease severity and/or limonene exposure. These data demonstrate that analysis of breath VOCs can probe specific hepatic pathways for the extraction of clinically relevant information related to liver function.

SAT251

Intelligent liver function testing in action: a one-year review

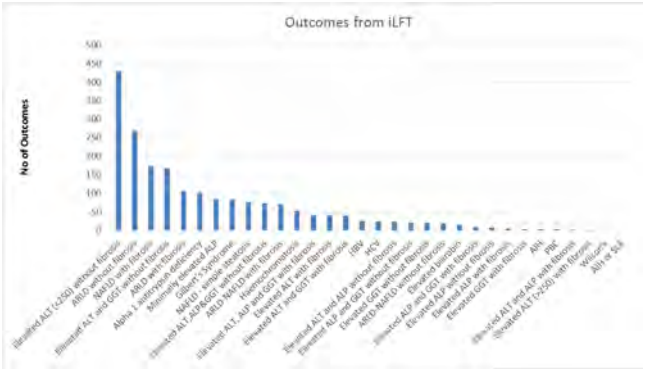
Iain Macpherson[1], Ruari Pitts[2], Emma Robinson[1], Jennifer Nobes[3], Elizabeth Furrie[4], Michael Miller[1], Ellie Dow[3], John Dillon[1]. [1]*School of Medicine, University of Dundee, United Kingdom;* [2]*University of Dundee;* [3]*Ninewells Hospital and Medical School, Department of Biochemical Medicine, Dundee, United Kingdom;* [4]*Ninewells Hospital and Medical School, Department of Blood Sciences*
Email: iain.macpherson3@nhs.net

Background and Aims: Liver Function Tests (LFTs) are abnormal in 20% of cases in primary care, and mortality from chronic liver disease continues to rise. Intelligent liver function testing (iLFT) was launched in the Tayside region of Scotland in August 2018. General Practitioners (GPs) provide data on alcohol intake, BMI and comorbidities, and those with abnormal LFTs have reflex tests without further venepuncture. GPs are then provided with management plans with a recommended outcome: secondary care referral for fibrosis assessment or complex treatment; primary care follow-up of early or simple liver disease; or when a diagnosis is unclear, staging information and referral criteria. iLFT is designed to improve diagnosis of liver disease and as a result, improve the quality of further investigations while optimising the time of referral to secondary care. This will reduce both mortality and cost to practitioners.

Method: A retrospective analysis was performed of all patients who had iLFT requested in the first year (August 2018 – August 2019) of the live system, recording the outcome(s) for each request.

Results: 2362 iLFT requests were received in the one year from launch. 160 (6.8%) were rejected. 378 (16%) had normal LFTs and thus iLFT did not cascade. There were 1824 (77.2%) requests with at least one abnormal liver enzyme, resulting in iLFT cascade and 2013 diagnostic outcomes. The most common outcome was isolated ALT elevation without fibrosis (23.5%), followed by alcohol related liver disease without fibrosis (14.7%) and non-alcoholic fatty liver disease with fibrosis (9.4%). The frequency of each outcome is shown in Figure 1. iLFT recommended patients be referred to secondary care in 509 (25.3%) outcomes (of which 393 (77.2%) were for further assessment of fibrosis only), with 1504 (74.7%) recommending primary care management.

Conclusion: iLFT safely and rapidly detects patients at risk of chronic liver disease using reflex fibrosis scores and autoimmune, virology and genetic tests. Only 25% of patients with abnormal LFTs had secondary care referral recommended, allowing 75% to be managed in primary care. GPs are currently using iLFT to investigate patients known to have abnormal LFTs, rather than a screening tool, so the number requiring referral should fall once this pool has been exhausted. iLFT is improving the diagnosis of liver disease and ensuring patients who require secondary care are seen, whilst reducing unnecessary referrals.

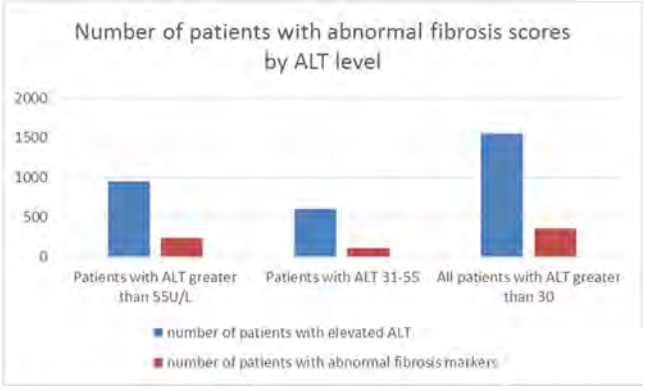


SAT252

ALT level in the diagnosis of chronic liver disease and advanced fibrosis

Iain Macpherson[1], Jennifer Nobes[2], Emma Robinson[1], Elizabeth Furrie[3], Michael Miller[1], Ellie Dow[2], John Dillon[1]. [1]*School of Medicine, University of Dundee;* [2]*Ninewells Hospital and Medical School, Department of Biochemical Medicine;* [3]*Ninewells Hospital and Medical School, Department of Blood Sciences*
Email: iain.macpherson3@nhs.net

Background and Aims: Serum level of alanine aminotransferase (ALT) is one of the most common parameters used in the assessment of liver disease. Mortality from chronic liver disease is continuing to rise, in part due to late diagnosis or recognition of signs and symptoms. Historically, our laboratory has used an upper limit of normal (ULN) of 55 U/L for ALT. However, there is significant evidence suggesting an ULN of 30 U/L or even lower should be used, dependent on sex. Intelligent Liver Function Testing (iLFT) is an automated algorithm which aims to use co-morbidities and alcohol intake to diagnose liver disease earlier and streamline patient management between primary and secondary care. We aimed to assess how many extra patients were diagnosed with abnormal fibrosis markers if an ALT ULN of 30 U/L was used rather than 55 U/L in our population.



Method: A retrospective analysis of all patients who had iLFT performed between August 2018 and 2019 was performed. Each

patient had non-invasive fibrosis markers performed (NAFLD score and FIB4 score) and the result of the iLFT algorithm for each patient was noted. This was then assessed in conjunction with their ALT.
Results: 948 patients had an ALT greater than 55U/L. Of these patients, iLFT recommended 317 (33.4%) be referred to secondary care; 243 (25.6%) of whom had abnormal fibrosis scores and required assessment for liver fibrosis. However, a further 601 patients had an ALT greater than 30 U/L but less than 55 U/L, resulting in a total of 1549 patients. iLFT recommended 148 (24.6%) patients with ALT 31–55 be referred to secondary care; 114 (18.9%) had abnormal fibrosis scores requiring further assessment, as shown in Figure 1.
Conclusion: Lowering the ULN of ALT from 55 to 30 in our population identified an additional 114 patients with abnormal fibrosis scores, increasing the detection of patients requiring further assessment for fibrosis in secondary care from 15.7% to 23.0% of all patients with ALT >30 U/L. This provides the potential to diagnose chronic liver disease in more patients, allowing the timely recommendation of lifestyle intervention and therapeutics.

SAT253

Multiparametric magnetic resonance imaging of liver and spleen is a reliable non-invasive predictor of clinically relevant hepatic venous pressure gradient thresholds and predicts failure of primary prophylaxis for variceal bleeding

Pik Eu Jason Chang[1], Arjun Jayaswal[2], Lionel Cheng[3], Mei-Fang Tay[3], Apoorva Gogna[4], Hiang Keat Tan[1], Chow Wei Too[4], Albert Low[3], Chee-Kiat Tan[1]. *[1]Singapore General Hospital, Gastroenterology & Hepatology, Singapore, Singapore; [2]University of Oxford, United Kingdom; [3]Singapore General Hospital, Diagnostic Radiology, Singapore, Singapore; [4]Singapore General Hospital, Interventional Radiology, Singapore, Singapore*
Email: jason.chang@singhealth.com.sg

Background and Aims: Multiparametric MRI (mpMRI) of the liver and spleen is a promising modality for non-invasive assessment of portal hypertension, offering a potential alternative to hepatic venous pressure gradient (HVPG) measurement, which is invasive and not widely available. Clinically relevant HVPG thresholds include (i) HVPG ≥ 10 mmHg, which defines clinically significant portal hypertension (CSPH) and predicts decompensation, (ii) HVPG > 12 mmHg, which predicts increased risk of variceal bleeding, and (iii) HVPG > 16 mmHg, which is associated with increased mortality. This study aims to evaluate the reliability of mpMRI of liver and spleen to predict clinically relevant HVPG thresholds (HVPG ≥ 10 mmHg, HVPG > 12 mmHg, HVPG > 16 mmHg) and development of variceal bleeding in a cohort of patients with chronic liver disease.
Method: Patients scheduled to undergo HVPG measurement for evaluation of portal hypertension were prospectively recruited for this IRB-approved study. All subjects underwent paired HVPG measurement and mpMRI (Liver*MultiScan*™, Perspectum Diagnostics, UK) to measure liver cT1 (assesses liver fibrosis and inflammation, corrected for iron) and spleen cT1 (assesses splenic congestion). Correlation between HVPG and mpMRI parameters (liver cT1 and spleen cT1) was evaluated using Pearson co-efficient and their performance for prediction of the various HVPG thresholds and variceal bleeding was evaluated using AUROC statistics.
Results: Forty subjects were enrolled, 50% males with median age of 64 years. Liver cirrhosis was present in 37 subjects (57% Child A). Median HVPG was 14 mmHg (IQR 12–17). 37 subjects had HVPG ≥ 10 mmHg (92.5%), 26 had HVPG > 12 mmHg (60%) and 12 had HVPG > 16 mmHg (30%). There was a weak but significant correlation between HVPG and liver cT1 (r = 0.316, p = 0.05) but not with spleen cT1. Liver cT1 was a good predictor for CSPH (AUROC 0.815, 95%CI 0.638–0.991) and a moderate predictor for HVPG > 12 mmHg (AUROC 0.737, 95%CI 0.564–0.911) and HVPG > 16 mmHg (AUROC 0.728, 95% CI 0.567–0.889). Spleen cT1 was not a reliable predictor for any of the pre-determined HVPG thresholds. However, spleen cT1 was found to be an excellent predictor of variceal bleeding, particularly in the subgroup of patients on beta-blocker treatment (AUROC 0.950, 95%CI 0.854–1.000) with 100% sensitivity, 87% specificity, 67% PPV and 100% NPV at a cut-off value of 1395 ms.
Conclusion: Multiparametric MRI is a potential non-invasive biomarker for assessment of portal hypertension. Liver cT1 is a reliable predictor for clinically relevant HVPG thresholds of HVPG ≥ 10, HVPG > 12 and HVPG > 16 mmHg. Spleen cT1 is an excellent predictor of patients at risk of failure of primary prophylaxis for variceal bleeding.

SAT254

Serum keratin 19 (CYFRA 21-1) links ductal reaction with portal hypertension and outcome of advanced liver disease

Karim Hamesch[1], Nurdan Gueldiken[1], Aly Mahmoud[1], Norbert Hueser[2], Daniel Hartmann[2], Pierre Rufat[3], Marianne Ziol[4], Georg Lurje[5], Christian Trautwein[1], Mattias Mandorfer[6], Bernhard Scheiner[6], Thomas Reiberger[6], Sebastian Mueller[7], Tony Bruns[8], Pierre Nahon[9], Pavel Strnad[1]. *[1]University Hospital RWTH Aachen, Medical Clinic III, Aachen, Germany; [2]Technical University of Munich, Munich, Germany; [3]Service d'Biostatistic Hopital Jean Verdier, Paris, France; [4]Université Paris Descartes, Paris, France; [5]University Hospital RWTH Aachen, Departments of Surgery and Transplantation, Aachen, Germany; [6]Medical University Vienna, Vienna, Austria; [7]University of Heidelberg, Heidelberg, Germany; [8]Department of Internal Medicine IV, Jena, Germany; [9]Hopital Jean Verdier, Bondy, France*
Email: khamesch@ukaachen.de

Background and Aims: Keratins (Ks) represent tissue-specific proteins. K18 is produced in hepatocytes while K19 – the most widely used ductal reaction (DR) marker – is expressed in cholangiocytes and hepatic progenitor cells. K18-based serum fragments are commonly used liver disease predictors, while K19 fragments detected through CYFRA 21-1 are established tumor but not liver disease markers yet. Since DR reflects the severity of underlying liver disease, we evaluated the relevance of CYFRA 21-1 in patients with different liver disease severities and etiologies.
Method: Hepatic expression of ductular keratins (K7/K19/K23) was analyzed in 57 patients with chronic liver disease (cohort i). Serum CYFRA 21-1 levels were measured in 52 German alcohol misusers undergoing detoxification (cohort ii), 333 Austrian patients with advanced chronic liver disease (ACLD) of various etiologies undergoing hepatic venous pressure gradient (HVPG) measurement (cohort iii), 231 French patients with compensated alcoholic cirrhosis (median follow-up 73 months; cohort iv), and 280 German patients with decompensated cirrhosis of various etiologies (cohort v).
Results: Hepatic K19 levels were comparable among patients with F0-F3 fibrosis stages, but significantly increased in patients with cirrhosis (i). Hepatic K19 mRNA strongly correlated with expression levels of other DR-specific keratins. Among alcohol misusers (ii), similar CYFRA 21-1 serum levels were seen in individuals before and after detoxification therapy indicating that CYFRA 21-1 is a rather stable parameter. CYFRA 21-1 levels were increased in patients with higher vs. lower liver stiffness (LSM ≥ 15 kPa; 3.71 vs. 1.42 ng/mL, P = .002). In line with that, CYFRA 21-1 levels were strongly associated with the presence of clinically significant portal hypertension (CSPH; HVPG ≥ 10 mmHg) (OR = 5.87 [2.95–11.68]) and mortality (HR = 3.02 [1.78–5.13]) in patients with ACLD (iii). In patients with compensated cirrhosis (iv), elevated CYFRA 21-1 levels indicated increased long-term risk of death/liver transplantation (HR = 2.59 [1.64–4.09]). In hospitalized patients with decompensated cirrhosis (v), CYFRA 21-1 levels predicted 90-day mortality (HR = 2.97 [1.92–4.60]) and its diagnostic accuracy (AUROC 0.64) was

comparable to the composite scores MELD (0.70) and ACLF grade (0.68).
Conclusion: Hepatic K19 mRNA and serum CYFRA 21-1 levels rise in cirrhosis, are strongly associated with the presence of CSPH and reliably predict mortality. The widely available serum CYFRA 21-1 constitutes a novel, DR-related biomarker with prognostic implications in patients with different settings of liver disease.

SAT255

Relationship between Laennec histological subclassification of cirrhosis and clinical stage, grade of portal hypertension and liver stiffness

Clement Lejealle[1], Valérie Paradis[2,3], Mohamed Bouattour[3,4], Nicolas Drilhon[1], Beaufrère Aurélie[2,3], Olivier Roux[1], Claire Francoz[1,3], Olivier Soubrane[3,5], Francois Durand[1,3], Pierre-Emmanuel Rautou[1,3], Castera Laurent[1,3]. *[1]Hôpital Beaujon AP-HP, Service d'Hépatologie, DHU Unity, DMU Digest, Clichy, France; [2]Hôpital Beaujon AP-HP, Service d'Anatomie Pathologique, Clichy, France; [3]Université de Paris, Centre de recherche sur l'inflammation, Inserm, U1149, CNRS, ERL8252, F-75018 Paris, France; [4]Hôpital Beaujon AP-HP, Service d'Oncologie digestive, Clichy, France; [5]Hôpital Beaujon AP-HP, Service de Chirurgie Hépato-biliaire et Transplantation hépatique, Clichy, France*
Email: laurent.castera@aphp.fr

Background and Aims: Currently used histological staging systems group all patients with cirrhosis into a single category, without taking account severity of cirrhosis. Subclassification of cirrhosis using the Laennec staging system has been proposed but has been mainly evaluated in patients with hepatitis B in Asia. In the present study, we assessed, in a well-characterized cohort of Western patients, relationship between Laennec subclassification of cirrhosis and clinical severity, grade of portal hypertension and liver stiffness.
Method: Ninety patients with cirrhosis (median age 59 yrs; Male 66%; etOH 42%, viral 27%, NASH 27%), who underwent hepatic venous pressure gradient (HVPG) measurement and liver stiffness measurement (LSM), using transient elastography (TE), as part of work-up before liver transplant or liver resection were included. Cirrhosis was subclassified on either liver biopsies or explanted/resected livers by a single pathologist (VP) blinded to clinical data, using the Laennec scoring system, into three groups (4a: thin septa; 4b: at least two broad septa and 4c: at least one very broad septum or many minute nodules).
Results: Stages of cirrhosis were distributed as follows: 4a: 38%, 4b: 47% and 4c: 16%. Results are detailed in the figure. As compared with 4a, patients with 4b/4c were more severe clinically (higher Child Pugh and MELD scores), had more severe portal hypertension (higher proportion of patients with HVPG ≥10 mm Hg, increased frequency of variceal bleeding and ascites) and higher LSM values. LSM values significantly increased with Laennec stages (4a: 17 (10–27) kPa; 4b: 38 (27–51) kPa; 4c: 68 (48–75) kPa; $p < 0.001$)

Table: Relationship between Laennec stages, clinical severity, HVPG and LSM

Variables	Laennec 4a n = 34	Laennec 4b n = 42	Laennec 4c n = 14	4a vs 4b/4c *p*
Clinical severity				
Child A/B/C (%)	85/12/3	48/43/9	14/21/64	<0.001
MELD score	9 (7–11)	10 (8–14)	18 (12–23)	0.01
Hemodynamic data				
HVPG (mm Hg)	10 (6–11)	18 (12–21)	18 (14–23)	<0.001
HVPG ≥ 10 mm Hg (%)	53	86	100	<0.001
LSM (kPa)	17 (10–27)	37 (27–51)	68 (48–75)	<0.001

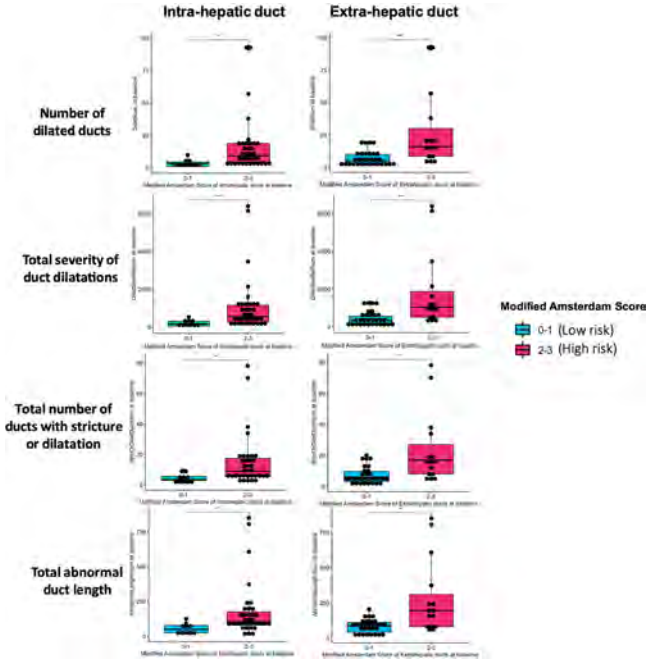
Conclusion: Laennec subclassification of cirrhosis correlates well with clinical stage of cirrhosis and severity of portal hypertension. Liver stiffness, using transient elastography, seems to be a good surrogate of these different cirrhosis stages.

SAT256

Evolving imaging in biliary disease: quantitative magnetic resonance cholangiopancreatography findings correlate with the modified Amsterdam score in patients with primary sclerosing cholangitis

Lin Cheng[1], Katherine Arndtz[2], Marc Goldfinger[1], Palak Trivedi[2], Marija Mavar-Haramija[1], Andrea Dennis[1], Ged Ridgway[1], Carlos Ferreira[1], Andrea Borghetto[1], Matt Kelly[1], John Michael Brady[1], Rajarshi Banerjee[1], Kartik Jhaveri[3], Gideon Hirschfield[4]. *[1]Pespectum Diagnostics Ltd, Oxford, United Kingdom; [2]Centre for Liver and Gastrointestinal Research, NIHR Birmingham Liver Biomedical Research Centre, University of Birmingham, Birmingham, United Kingdom; [3]University Health Network, Mount Sinai Hospital and Women's College Hospital, University of Toronto, Department of Medical Imaging, Abdominal Imaging, Toronto, Canada; [4]Toronto Centre for Liver Disease, University of Toronto, Toronto, Canada*
Email: matt.kelly@perspectum.com

Background and Aims: Quantitative magnetic resonance cholangiopancreatography (MRCP+) is a novel non-invasive imaging technique for quantifying biliary tree volume, duct diameters, and dilated/strictured regions in hepatobiliary disease. It is designed to address the limitations of traditional MRCP interpretation which can have large inter-observer variations. The aim of this study is to investigate the utility of quantitative MRCP in a prospective study of patients with primary sclerosing cholangitis (PSC) and evaluate its correlation with the modified Amsterdam cholangiography score.
Method: In this study, patients with established PSC (n = 45) were recruited and scanned on a Siemens Verio 3 T system with standardised MRCP imaging. The tubular structures of the biliary system were enhanced and quantified by MRCP+ using multi-scale Hessian analysis, gradient vector flow analysis, an intelligent path search algorithm and novel duct modelling algorithms. Each MRCP image was assessed by an experienced radiologist and evaluated using the modified Amsterdam score (mAms, intra-hepatic and extra-hepatic) to assess progression risk and categorized as low risk (0/1) or high risk (2/3).



Results: Assessment of intra-hepatic disease level measured by mAms revealed 10 PSC patients as low-risk and 35 as high-risk. High risk intra-hepatic patients were found to have a significant increase in the number of dilated ducts, the total severity of duct

dilatations, total number of ducts with strictures/dilatations, and total length in abnormal ducts compared to low-risk PSC patients (16.7 vs. 3.7, $p < 0.01$; 1083% vs. 205%, $p < 0.01$, 15.1 vs. 4.5, $p < 0.01$; 175 vs. 55 mm, $p < 0.01$, respectively). For extra-hepatic disease, 30 PSC patients were identified as low-risk, while 15 were assigned to the high-risk group. High-risk extra-hepatic PSC patients had a significantly higher number of dilated ducts (28vs. 7, $p < 0.001$), the total severity of duct dilatations (1791% vs. 437%, $p < 0.001$), total duct number with stricture/dilatation (23 vs.7, $p < 0.01$), and total abnormal duct length (278 vs. 82 mm, $p < 0.01$) when compared to low-risk PSC patients.

Conclusion: Quantitative MRCP reveals significant correlations with both intra-hepatic and extra-hepatic abnormalities as assessed by the modified Amsterdam score in PSC patients by an expert radiologist. Our findings support the ability of quantitative MRCP metrics to contribute to an objective stratification of biliary disease.

SAT257

The tissue balance of liver fibrosis: identification of fibrosis resolution biomarkers and demonstration of increased tissue formation and degradation

Morten Karsdal[1], Natasja Gudmann[1], Martin Pehrsson[1], Karoline Havkrog[1], Aleksander Krag[2], Maja Thiele[2], Mette Juul Nielsen[1], Diana Leeming[1]. *[1]Nordic Bioscience Clinical Studies A/S, Biomarkers and Research, Herlev, Denmark; [2]Odense University Hospital, Gastroenterology, Odense, Denmark*
Email: mk@nordicbio.com

Background and Aims: Fibrosis is described as accumulation of extracellular matrix (ECM) proteins and has long been considered a slow turnover disease with more tissue formation than degradation. A direct quantification of the tissue turnover balance, i.e. the ratio between formation and degradation, has been hampered consequent to the lack of available technologies.

The dense liver ECM, the fibrotic bands, consists of interstitial matrix (IM) produced by fibroblasts. Novel biomarkers reflecting tissue formation (fibrogenesis) and degradation (fibrolysis) separately may be able to quantify the velocity of tissue turnover including type I or III collagen formation (PRO-C1 or PRO-C3) as well as MMP-9 mediated degradation of type I and III collagen, C1M and C3M respectively.

We aimed to quantifying the relative amount of tissue balance by assessment of fibrogenesis and fibrolysis assays in vitro and in serum.

Method: Human primary fibroblasts were cultured in the scar-in-a-jar system. Soluble fibrogenesis and fibrosis resolution biomarkers were measured in the conditioned medium. After culture, the ECM of the fibroblasts were digested with MMP-9 to quantify fibrinolysis products, C3M and C1M. In addition, PRO-C3 and C3M were assessed in serum from 302 asymptomatic alcoholic liver disease (ALD) patients with biopsy confirmed Kleiner Fibrosis stage F0-F4 recruited in the EU H2020 GALAXY study.

Results: TGF-β induced collagen type III formation by 800% ($p < 0.0001$) and type I collagen formation by 250% ($p < 0.001$) quantified by PRO-C3 and PRO-C1, respectively. C1M and C3M were undetectable in the conditioned medium. After MMP digestion, C1M and C3M were 100 times ($p < 0.001$) higher as compared to undigested ECM. The ECM digest of TGF-β treated fibroblasts had 10 times increased levels of C1M and C3M as compared to vehicle control.

ALD patients with advanced fibrosis (F3-F4) showed an imbalance favoring fibrogenesis over fibrolysis with PRO-C3 elevated by 228% ($p < 0.0001$) for F0-2 vs. F3-4 whereas C3M was elevated 51% ($p < 0.0001$).

Conclusion: TGF-β clearly induced fibrogenesis biomarkers PRO-C3 and PRO-C1. In contrast, fibrolysis biomarkers were not detectable. After MMP-9 digestion, fibrolysis biomarkers were highly elevated suggesting that these biomarkers may be approximated of cell mediated tissue degradation. Interestingly, patients had 4X higher collagen formation than degradation in fibrosis, although both fibrogenesis and fibrinolysis were elevated.

SAT258

Systemic light chain AL with cardiac and liver involvement can be predicted by transient elastography

Speranta Iacob[1,2,3], Andreea Jercan[4,5], Sorina Badelita[4], Camelia Dobrea[4,5], Ruxandra Jurcut[6,7], Monica Popescu[4], Mihaela Ghioca[1], Razvan Iacob[1,2,3], Liana Gheorghe[1,2,3], Daniel Coriu[4,5]. *[1]Fundeni Clinical Institute, Digestive Diseases and Liver Transplantation Center; 258, Romania; [2]Fundeni Clinical Institute, Center of Excellence in Translational Medicine; [3]University of Medicine and Pharmacy "Carol Davila", Gastroenterology and Hepatology, Bucuresti, Romania; [4]Fundeni Clinical Institute, Hematology, Bucuresti, Romania; [5]University of Medicine and Pharmacy "Carol Davila", Hematology, Bucuresti, Romania; [6]Emergency Institute of Cardiovascular Diseases "Prof. Dr. C. C. Iliescu", Department of Cardiology, Expert Center for Rare Genetic Cardiovascular Diseases, Bucuresti, Romania; [7]University of Medicine and Pharmacy "Carol Davila", Euroecolab, Bucuresti, Romania*
Email: msiacob@gmail.com

Background and Aims: Transient elastography is the first elastography technique developed to quantitatively and noninvasively assess soft biological tissue stiffness. Liver stiffness (LS) is not specific to liver fibrosis and can be influenced by many factors, including amyloid deposits. The aim of our study was to examine whether amyloid deposition in the liver or other organs modifies LS and if there is any correlation with the liver functional tests.

Method: LS was measured prospectively in 72 patients with systemic light-chain amyloidosis (AL) that were investigated in the Hematology Department from Fundeni Clinical Institute. The diagnostic accuracy and cut-off values of LS for amyloidosis and its sensitivity and specificity were calculated.

Results: There was a significantly strong positive correlation between LS values and GGT ($r = 0.62$, $p < 0.0001$) or alkaline phosphatase values ($r = 0.49$, $p = 0.0001$), but a moderate positive correlation with serum total bilirubin ($r = 0.36$, $p = 0.003$) and AST values ($r = 0.26$, $p = 0.04$). There were significantly higher mean LS values in patients with hepatic AL involvement (37.4 ± 4.4 kPa vs 7.1 ± 0.9 kPa, $p < 0.0001$) patients with cardiac AL (25.2 ± 3.9 kPa vs 13.6 ± 3.5 kPa, $p < 0.0001$) and patients with splenic AL (30.8 ± 6.0 kPa vs 17.7 ± 3.1 kPa, $p < 0.0001$), but not in patients with renal AL. A cut-off value of 9.7 kPa, with an AUROC of 0.94, sensitivity and specificity >90%, is proposed for routine screening and diagnosis of significant AL liver infiltration. A cut-off value of 10.8 kPa, with an AUROC of 0.81 and a 100% sensitivity can be used to screen patients for multiple AL involvement (liver, cardiac and spleen).

Conclusion: LS > 9.7 kPa is suggestive of AL hepatic disease in patients with non-fibrotic liver changes, while higher levels (>10.8 kPa) are suggestive of multiple organs AL deposits.

SAT259

Validating the Swansea criteria in a single-centre study with cohorts of patients with acute fatty liver of pregnancy and haemolysis, elevated liver enzymes and low platelets syndrome: is it time to modify the criteria?

Mussarat Rahim[1], Emmanouil Kountouris[2], Nick Kametas[3], Michael Heneghan[1]. *[1]Institute of Liver Studies, King's College Hospital, London, United Kingdom; [2]Institute of Fetal Medicine, Harris Birthwright Centre, London; [3]Institute of Fetal Medicine, Harris Birthwright Centre, London, United Kingdom*
Email: michael.heneghan@nhs.net

Background and Aims: In clinical practice, it is very difficult to differentiate between acute fatty liver fatty of pregnancy (AFLP) and severe haemolysis, elevated liver enzymes and low platelet count (HELLP) syndrome. Although this does not impact on immediate

management, it is important to make the right diagnosis to aid long-term management, counselling and monitoring of future pregnancies. This study aims to ascertain the diagnostic value of the Swansea criteria in a cohort of patients with HELLP, as well as a group of women with AFLP.
Method: 30 patients with HELLP and 29 patients with AFLP were identified between 2000 and 2019 in our single centre study. Patients were identified as having AFLP based on clinical expertise, fulfillment of the Swansea criteria and liver biopsy where possible. The HELLP patients were identified through an Obstetrics database and were defined as having new onset hypertension during pregnancy with elevated liver enzymes and a platelet count of <150. Retrospective analysis of the patient demographics, biochemistry and clinical notes took place. Differences between the groups were analyzed with Fisher's Exact test.
Results: All the 29 patients with AFLP fulfilled the Swansea criteria with a score >/ = 6 (mean 8.1, range 6–11). Within the HELLP cohort, 11/30 patients (37%) fulfilled the Swansea criteria (mean 4.5, range 2–8). The Swansea criteria had a sensitivity of 100% in our cohort, with a specificity of only 63%. Polydipsia/polyuria (p = 0.0001), hypoglycaemias (p = <0.0001) and bilirubin to AST ratio >0.5 (p = 0.0002) were significantly more common in the AFLP group compared to the HELLP group. There were no significant differences in leucocytosis, urate levels and renal impairment between the groups. The liver enzymes post-delivery recovered quicker in the HELLP group compared to the AFLP group.
Conclusion: The Swansea criteria needs to be modified to allow better distinction between HELLP and AFLP in a clinical setting.

SAT260
Diagnostic performance of a new algorithm combining simple, non-invasive and inexpensive tests for predicting the presence of liver severe fibrosis and cirrhosis in patients with chronic hepatitis B
Jean Nana[1], Skaare Kristina[1], Tarik Asselah[2], Adler Michael[3], Marie-Noëlle Hilleret[1], Vincent Leroy[1], Marlu Alice[1], Jean Luc Bosson[1], Jean-Pierre Zarski[1]. *[1]Centre Hospitalier Universitaire Grenoble-Alpes, Grenoble, France; [2]Hôpital Beaujon, Paris, France; [3]Hôpital Erasme, Brussels, Belgium*
Email: nanakjean@yahoo.fr

Background and Aims: Various non-invasive methods for scoring fibrosis have been developed to overcome the limitations of liver biopsy. These technics have been not fully validated for the assessment of liver fibrosis in chronic hepatitis B. The objective of this study was to evaluate the usefulness of combining simple, non-invasive and inexpensive tests in terms of predicting liver severe fibrosis and cirrhosis in patients with chronic hepatitis B.
Method: This is a prospective cross-sectional study conducted on 408 consecutive patients from 3 centers who benefited from a liver biopsy for chronic hepatitis B. Using our cohort, we derived a decision tree, with a cost matrix penalizing type II error, predicting patients in stages F0-F1, F2 or F3-F4. The final decision contains nine leafs using the following variables: prothrombin time, platelets, ALT, GGT and age. We subsequently validated the decision three in an external cohort (n = 194).
Results: 408 patients in training set were used to create a "decision tree algorithm." In the validation cohort (n = 194), our "decision three algorithm" classified patients in F0-F1, F2 or F3-F4. Considering F0-F1 and F2 as negative test result, specificity was 94% for F0F1 and 67% for F2 patients respectively. Only 3 (1.5%) F3-F4 patient were classified as F0-F1. Negative predictive value was 96% and 89% for F0-F1 and F2 respectively.
Conclusion: A new algorithm combining simple, non-invasive and inexpensive test has a better diagnostic value than usual scores in predicting fibrosis in patients with chronic hepatitis B.

SAT261
Heat shock protein 47 is associated with fibrogenesis in alcoholic liver disease
Natasja Gudmann[1], Maja Thiele[2], Tina Manon-Jensen[1], Ydalina Maria Moreno[1], Mette Juul Nielsen[1], Morten Karsdal[1], Aleksander Krag[2], Diana Leeming[1]. *[1]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark; [2]Odense University Hospital, Gastroenterology, Odense, Denmark*
Email: nsg@nordicbio.com

Background and Aims: Heat shock protein (HSP)47 is a collagen-specific intracellular chaperone essential for the formation of fibrillar collagens, known to be involved in pro-fibrotic wound-healing processes in comparison to the structural, laminar collagens. We hypothesized that a fragment of HSP47 is measurable in serum, related to biopsy-verified liver fibrosis reflected by histological assessment and associated with the type III collagen synthesis marker PRO-C3. For serological HSP47 assessment we developed a novel competitive enzyme-linked immunosorbent assay (ELISA).
Method: We included serum samples from a biopsy-controlled cross-sectional study of 301 alcoholic liver disease (ALD) patients and 50 gender, age and BMI matched healthy controls. Biopsies were scored according to Kleiner fibrosis stage (F0-4). A competitive ELISA employing a monoclonal antibody targeting the C-terminus of HSP47 (HSP47-C) was developed and technical validation was performed. PRO-C3 was evaluated for comparison. Mann Whitney and Kruskal Wallis tests were applied for intergroup comparisons in addition to Receiver operating characteristics (ROC) analysis and Spearman Rank correlation test. This study was conducted on behalf of the EU H2020 GALAXY consortium.
Results: The HSP47-C assay was technically robust and specific for the target sequence. Linearity was within the accepted range ± 20%. HSP47-C was elevated by 43% in ALD patients (mean 19.9 ng/ml, SD 13.3, p = 0.008) compared to healthy controls (mean 13.9, SD 6.8). In addition, HSP47-C was 73% higher for patients with F3–4 compared to F0-2 (p < 0.0001) with an AUC of 0.73 (p < 0.0001). In comparison PRO-C3 was elevated by 228% for F3-4 vs. F0-2 (p < 0.0001) with an AUC of 0.88 (p < 0.0001). HSP47-C was associated with PRO-C3 (rho = 0.26, p < 0.0001). When HSP47 and PRO-C3 were combined patients with F3-4 were 393% higher compared to F0-2 and with an AUC of 0.81.
Conclusion: The elucidation of collagen machinery may identify fibrosis drug targets and aid in segmenting liver fibrosis patients at the molecular level. The serological level of HSP47-C was higher in ALD as compared to healthy individuals and associated with the fibrogenesis markers PRO-C3 and Kleiner fibrosis stage. This suggests that HSP47 may be a potential target for anti-fibrotic therapy as well as being a marker for liver fibrosis.

SAT262
Dysregulation of wound healing status and activity is associated with fibrosis and inflammation in early alcohol associated liver disease
Natasja Gudmann[1], Maja Thiele[2], Diana Leeming[1], Morten Karsdal[1], Mette Juul Nielsen[1], Aleksander Krag[2]. *[1]Nordic Bioscience Clinical Studies A/S, Biomarkers and Research, Herlev, Denmark; [2]Odense University Hospital, Gastroenterology, Odense, Denmark*
Email: nsg@nordicbio.com

Background and Aims: Wound healing is often discussed as being altered in fibrosis, but only assessed by standard biomarkers such as platelets and Von Willebrand factor (vWF). More advanced biomarkers of wound healing may provide additional knowledge. The aim of this study was to gain insights of the dynamics of fibrin/fibrinogen and vWF in patients with compensated alcoholic liver disease (ALD). PRO-Fib was selected to assess the conversion of fibrinogen to fibrin, as it measures the concentration of the pro-peptide when it is cleaved

of during the process. X-Fib was selected as a marker for fibrinolysis as it targets a fragment released from dissolved clots. vWF formation and degradation were evaluated by the N-terminal vWF propeptide (VWF-N) and a vWF fragment generated by ADAM-TS13 (VWF-A), respectively.
Method: Blood samples from 301 ALD patients were prospectively recruited and the ELISA based markers were evaluated: PRO-Fib, Fib-X, VWF-N and VWF-A. Histological assessment of inflammation (lobular and balloning, stage 0–5) and Kleiner fibrosis stage F0-4 were evaluated in liver biopsies from patients with a transient elastography >6 kPa, but without known cirrhosis. Associations between the biomarkers and histological findings were assessed by Kruskal-Wallis multiple comparison test. This study was conducted on behalf of the EU H2020 GALAXY consortium.
Results: FPA was significantly decreased according to fibrosis stages ($p < 0.0001$) and inflammation stage ($p < 0.0001$). In contrast, FPA in plasma, reflecting the active conversion of fibrin/fibrinogen was unaffected by fibrosis and inflammation. D-dimer was elevated in patients with inflammation ≥3 ($p < 0.02$) including portal inflammation ≥1 ($p < 0.0001$) or a fibrosis stage ≥2 ($p < 0.01$) compared to those without inflammation or fibrosis respectively. VWF-N was significantly higher in fibrosis stage F4 compared to F0-2 ($p < 0.04$). Also, VWF-A was significantly higher in F4 compared to F2 ($p = 0.005$). None of the vWF markers were associated with inflammation.
Conclusion: The dynamics of fibrin/fibrinogen and vWF are associated with pathological processes in progressive ALD. We found that the status of fibrin turnover was unbalanced with lower concentration of the fibrinogen/fibrin formation marker (FPA) evaluated in patients with presence of fibrosis or inflammation. High fibrinogen degradation activity (D-dimer) was associated with high fibrosis and inflammation scores. By contrast, both vWF formation (VWF-N) and degradation (VWF-A) were associated with increasing fibrosis stage. All together the presented data point towards an impaired wound healing response and quality in patients with fibrosis and compensated ALD.

SAT263
Liver stiffness measurement using acoustic radiation force impulse elastography is a good predictor of hepatic decompensation in pregnant cirrhotic patients
Omar Elshaarawy[1,2], Rasha Abdelaziz[3], Naglaa Zayed Zayed[3], Ayman Hany[4], Zeinab Hammam[3], Sebastian Mueller[1], Hend Shousha[3]. *[1]Salem Medical Center, University of Heidelberg, Internal Medicine Department and Center of Alcohol Research, Heidelberg, Germany; [2]National Liver Institute, Menoufia University, Hepatology and Gastroenterology Department, Shebine Elkom, Egypt; [3]Faculty of Medicine, Cairo University, Endemic Medicine and Hepatogastroenterology Department, Cairo, Egypt; [4]Faculty of Medicine, Cairo University, Obstetrics and Gynaecology Department, Cairo, Egypt*
Email: oelshaarawy@liver.menofia.edu.eg

Background and Aims: During pregnancy, elevated liver stiffness (LS) measured by transient elastography has been identified as a novel non-invasive screening parameter to predict women at risk for pregnancy-related complications such as preeclampsia. However, feasibility and safety of LS measurement (LSM) has not been studied using acoustic radiation force impulse elastography (ARFI). In addition, it's utility to predict hepatic decompensation post-delivery in pregnant cirrhotic patients is still unexplored.
Method: We prospectively recruited 224 pregnant women at the clinic of liver disease with pregnancy, Department of Endemic Medicine and Hepatology and Obstetrics and Gynaecology Department, Cairo University Hospital. LS was measured using ARFI elastography by Siemens ACUSON S3000 ultrasound system. LS was measured during the second trimester and 8–12 weeks post-delivery. Outcome of pregnancy (normal vs. complicated e.g. abortion, preterm labor, still birth & maternal mortality) and incidence of hepatic decompensation were assessed. All clinical and laboratory data were collected from patients records.
Results: In 224 pregnant women, we were able to measure LS with ARFI in 81% of the recruited subjects. Our cohort comprised 128 normal pregnancies, 37 patients with pregnancy related liver disease (Intrahepatic cholestasis (n = 6), preeclampsia (n = 23), and hyperemesis gravidarum (n = 8)) and 59 patients with established chronic liver disease not related to pregnancy (chronic viral hepatitis B and C and autoimmune hepatitis). In all patients LS significantly decreased after delivery from 1.19 m/s to 0.94 m/s ($P < 0.001$). Of note, in multivariate analysis, LS was an independent predictor for the outcome of pregnancy in all patients with an odds ratio (OR) 5.442 (3.01–6.82) and cut-off value of 1.21 m/s. In a subgroup analysis of patients with established chronic liver disease, mean LS was 1.57 m/s (±0.66) and 44% (n = 26) of the patients had hepatic decompensation in the form of hepatocellular jaundice (n = 8), ascites (n = 9) and variceal bleeding (n = 6). In multivariate analysis, LS, platelet, albumin and bilirubin were independent predictors of decompensation post-delivery and the OR for LS was 6.141 (4.32–7.98). Noteworthy, the optimal cut off value of LS to predict hepatic decompensation post-delivery was 1.36 m/s with AUROC of 0.827.
Conclusion: LSM using ARFI is feasible and safe during pregnancy. Hepatic decompensation post-delivery in cirrhotic pregnant patients could be predicted by LSM using ARFI.

SAT264
Reliablility criteria will discriminate accuracy of blood liver fibrosis tests
Paul Cales[1,2], Hunault Gilles[2], Lannes Adrien[1,2], Frédéric Oberti[1], Valérie Moal[2], Isabelle Fouchard Hubert[1,2], Rousselet Marie Christine[2], Jerome Boursier[1,2]. *[1]Angers University Hospital, Hepato-Gastroenterology, Angers, France; [2]Angers University, HIFIH Laboratory, Angers, France*
Email: paul.cales@univ-angers.fr

Background and Aims: In liver fibrosis staging, reliability criteria have been well described for liver biopsy and elastography but not for blood tests (BT). Our aim was to develop reliability criteria for liver fibrosis BT.
Method: The principle was to develop intrinsic reliability based on the composite markers of BT. We hypothesized that BT reliability depends on homogeneity between markers. We developed a homogeneity index based on the impact of each marker on the BT score. Then, we developed a reliability score (RS) by logistic regression including BT markers, homogeneity index and etiology. The outcome was the accuracy of FibroMeter (FM2G including 8 markers) for Metavir fibrosis (F) staging with liver biopsy as reference. 4981 patients (pts) were recruited.
Results: The derivation population included 3505 pts; age: 49 ± 13 yrs, 66.2% males, etiology: virus: 66.0%, NAFLD: 17.4%, alcohol: 16.7%; Metavir: F0: 8.2%, F1: 36.5%, F2: 25.1%, F3: 15.6%, F4: 14.6%; FM2G characteristics were: homogeneity index: 86 ± 8%, accuracy: 81%, RS: 81 ± 13%. The FM2G RS AUROC for accuracy (F staging) was 0.70 and the RS was well calibrated (Spearman's $r = 0.27$, $p < 0.001$). RS was classified into 3 reliability classes: low, fair and high. FM2G accuracy was, low RS (10% pts): 48%, fair RS (20% pts): 73%, high RS (70% pts): 87% ($p < 0.001$). FM2G AUROC for cirrhosis increased from 0.88 in all pts to 0.92 in 70% of pts with high RS. In a validation population of 1476 pts with Fibroscan, FM2G accuracy was, low FM2G RS (12% pts): 44%, fair RS (26% pts): 74%, high RS (62% pts): 87% ($p < 0.001$). In high FM2G RS, FM2G and Fibroscan had similar AUROC for cirrhosis at 0.93 ($p = 0.910$). Considering reliability criteria of Fibroscan (Hepatology 2013), AUROC for cirrhosis was, FM2G & Fibroscan respectively, low Fibroscan reliability: 0.87 & 0.82 ($p = 0.324$), fair: 0.84 & 0.90 ($p = 0.007$), high: 0.92 & 0.95 ($p = 0.117$). Finally, we deduced a sequential algorithm using first FM2G in high FM2G RS (62% pts) then Fibroscan in low or fair FM2G RS; accuracy increased from 78% for FM2G to 83% for algorithm ($p < 0.001$).

Algorithm accuracy was according to its own reliability classes (provided by FM2G and Fibroscan): low reliability (0.6% pts only): 44%, fair (11.5% pts): 68%, high (88% pts): 85% ($p < 0.001$).
Conclusion: Intrinsic reliability can be determined in blood tests, especially if they include many markers. This is useful for clinical practice since reliability score highly discriminates accuracy. Thus, FM2G BT is as accurate as Fibroscan for cirrhosis in 2/3 of patients with highly reliable BT.

SAT265

The usual blood liver markers provide a performant fibrosis test thanks to artificial intelligence

Paul Cales[1,2], Hunault Gilles[2], Jerome Boursier[1,2], Maeva Guillaume[3,4], Valérie Moal[2], Lannes Adrien[1,2], Frédéric Oberti[1,2], Isabelle Fouchard Hubert[1,2], Rousselet Marie Christine[2], Christophe Bureau[3,4]. *[1]Angers University Hospital, Hepato-Gastroenterology, Angers, France; [2]Angers University, HIFIH Laboratory, Angers, France; [3]Toulouse University Hospital, Hepato-Gastroenterology, Toulouse, France; [4]Cardiomet, Fédération Hospitalo-Universitaire Impact, Toulouse, France*
Email: paul.cales@univ-angers.fr

Background and Aims: The usual liver fibrosis blood tests are constructed for a single target, usually significant fibrosis. The accuracy can be increased by multi-targeting different fibrosis stages. We have improved the multi-targeting thanks to Artificial Intelligence (AI). We hypothesized that AI could make indirect tests, including only indirect markers, as accurate as direct or mixed tests, including only or partially direct markers. Our goal was to compare the accuracy of classical single-targeted tests with a new multi-targeted indirect test.
Method: We compared the accuracy of 8 published single-targeted tests (indirect, direct or mixed) with a new multi-targeted test developed by AI, called FIBS-MT. It included 6 indirect markers (AST, ALT, INR, platelets, urea adjusted on sex and age). FIBS-MT was compared to the single-targeted test including the same 6 markers called FIBS-ST. Thus, the comparison of the 2 FIBS tests reflects the gain brought by AI. The FIBS tests were derived in 1013 patients with chronic hepatitis C and were compared in a validation population of 3206 patients with CLD of various etiologies. FIBS tests were compared to APRI, Fib4, Hepascore, FibroMeters (FM) 2G and 3G in 2796 patients, Fibrotest in 1461 patients, NAFLD fibrosis score (NFS) and ELF in 410 patients with NAFLD. The reference was Metavir or Kleiner fibrosis stages by liver biopsy. AUROCs for 3 fibrosis targets were compared by the Delong test: significant fibrosis ($F \geq 2$) severe fibrosis ($F \geq 3$) or cirrhosis (F4).
Results: 1/Comparison between indirect tests: all 3 FIBS-MT AUROCs were significantly higher than FIBS-ST, Fib4 and APRI, e.g. for $F \geq 3$: 0.83, 0.80, 0.79, 0.74 respectively ($p < 0.001$). 2/Comparison with mixed tests: FIBS-MT AUROC was significantly lower than FM2G or FM3G for significant fibrosis ($F \geq 2$) but not significantly different for $F \geq 3$ and F4, e.g. for $F \geq 3$: 0.83, 0.84, 0.82, respectively ($p > 0.05$). FIBS-MT AUROCs were not significantly different from Hepascore or Fibrotest for $F \geq 2$ and F4 but significantly higher for $F \geq 3$. 3/In NAFLD evaluated by F Kleiner, AUROCs of FIBS tests were not significantly different from ELF or NFS (except significantly higher vs NFS for $F \geq 3$), e.g. for $F \geq 3$: 0.77, 0.77, 0.80, 0.71, respectively (FIBS-MT vs NFS: $p < 0.037$, FIBS-ST vs NFS: $p = 0.025$).
Conclusion: The multi-targeting by AI provides an indirect test that is most accurate than the classical indirect tests and as accurate as the current mixed or direct tests for the main diagnostic targets (severe fibrosis or cirrhosis). FIBS-MT could be automatically provided by standard liver work-up.

SAT266

A gut microbiota and liver co-metabolized biomarker to monitor liver cirrhosis progression with different etiologies in humans

Jia-Bo Wang[1], Ying Huang[1], Zhengsheng Zou[1], Yue-Cheng Yu[2], Xiao-He Xiao[1]. *[1]Fifth Medical Center of Chinese PLA General Hospital, Beijing, China; [2]General Hospital of PLA Eastern Theater Command, Nanjing, China*
Email: pharm_sci@126.com

Background and Aims: As cirrhosis is the most important and independent predictor of adverse outcomes in a variety of chronic liver diseases, we aimed to find the shared biomarker(s) related to liver cirrhosis of different etiologies.
Method: A total of 676 patients with three liver diseases, namely drug-induced liver injury (n = 184), autoimmune liver disease (n = 301), alcoholic liver disease (n = 141), and viral hepatitis (n = 50) from two centers were included in this study to screen for cirrhosis-related biomarkers using serum metabolomics.

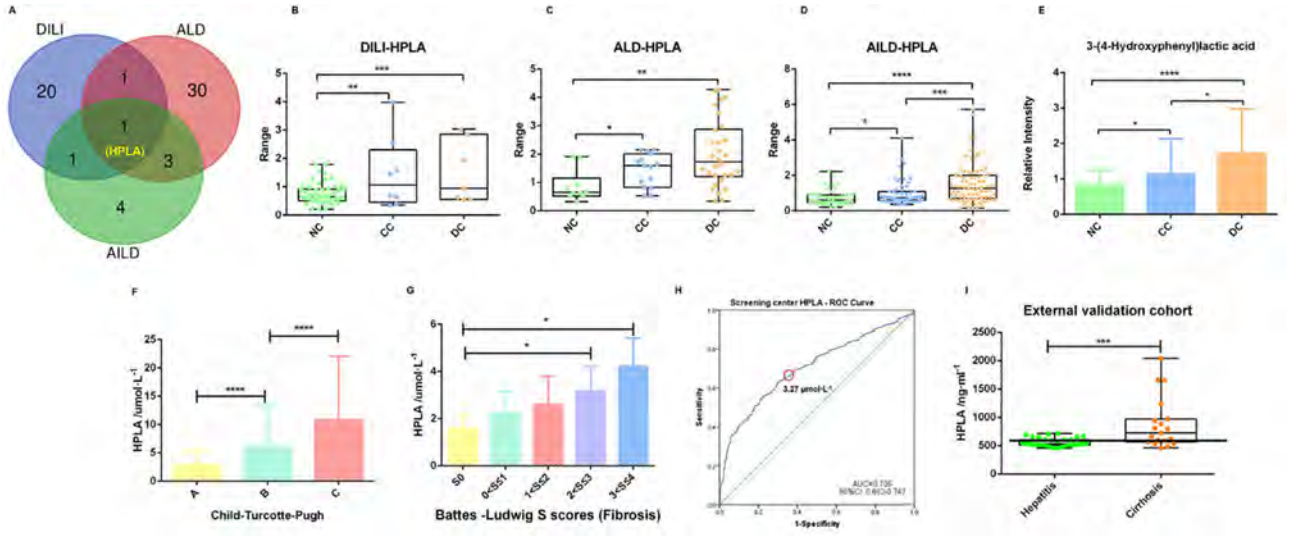


Figure: (abstract: SAT266): **A**, the Venn diagram shows the shared metabolite(s) related to cirrhosis among the different liver diseases (DILI, ALD, AILD). **B-E,** the increasing trends of HPLA along with the progression from non-cirrhosis to decompensation cirrhosis in DILI, AILD, ALD, and internal validation cohort respectively. **F** shows significant correlation between HPLA content and CHILD grades. **G** demonstrates the HPLA content increased along with the raise of Battes-Ludwig grades. **H,** Non-cirrhosis and cirrhosis groups are well separated by HPLA in screening center. The cutoff value is set at 3.27 $\mu mol \cdot L^{-1}$

Results: At the screening center discovery cohort, we separately screened for cirrhosis-related biomarkers using two strategies that did not differentiate or differentiated the three etiologies, of which only one cirrhosis biomarker, 3-(4-hydroxyphenyl) lactic acid (HPLA) was shared by the three liver diseases. Serum HPLA levels increased significantly with the progression of liver disease from non-cirrhosis stage to compensated and decompensated cirrhosis, regardless of different etiologies. This finding was subsequently verified in the internal validation cohort. By the cutoff value (3.27 μmol·L-1) of serum HPLA content, patients with cirrhosis were identified in an external prospective cohort with discrimination sensitivity and specificity of 68.42% and 61.76%, respectively. Further analysis revealed that serum HPLA content was significantly and positively correlated with either CHILD grade or MELD score in patients with different types of liver disease, and positively correlated with Battes-Ludwig fibrosis grade in liver biopsy.
Conclusion: Serum HPLA is a shared cirrhosis biomarker to monitor the progression of cirrhosis in chronic liver diseases.

Email: rociorm@usal.es

Background and Aims: The accurate diagnosis of adenocarcinomas located in the head of the pancreas -distal cholangiocarcinoma (dCCA) and pancreas ductal adenocarcinoma (PDAC)-, represents a clinical challenge since both types of tumors share symptoms and they cannot be distinguished by imaging techniques. At present there are no accurate serum biomarkers that allow early and differential diagnosis of these tumors. Omics technologies facilitate the profiling and analysis of disease-specific signatures and are powerful sources of candidates. The aim of this study was to determine serum metabolomics profiles in patients with dCCA or PDAC to identify novel biomarkers for the early and differential diagnosis.
Method: Chloroform/methanol and methanol extracts were obtained from the serum of patients with diagnosis of dCCA (n = 34) or PDAC (n = 38) confirmed by histopathology, attended in the University Hospitals of Donostia and Salamanca, and healthy individuals (n = 25) divided in two cohorts. Ultra-high performance liquid chromatography coupled to mass spectrometry (UHPLC-MS) was used to determine amino acids and lipids.
Results: A total of 484 metabolites in serum samples were identified in both cohorts and included in the univariate and multivariate data analyses. Compared to controls, serum samples of patients with dCCA and PDAC had higher levels of several metabolites, mainly triglycerides, diglycerides and bile acids in dCCA and triglycerides, diglycerides and diacylphosphatidylethanolamines in PDAC. Fewer changes were found between the circulating metabolomes of dCCA and PDAC, although several species of phosphatidylethanolamines (PE), lysophosphatidylethanolamines and triglycerides were more elevated in PDAC than in dCCA.
Among other metabolites, glutamic acid and aspartic acid distinguished tumors from controls with an AUC>0.91 and 0.94, respectively. To determine a predictive model for the discrimination between patients with dCCA and PDAC based on circulating metabolites both cohorts were merged and divided into three cohorts: training (70%) and validation (20%) for cross-validation and parameter optimization and test (10%) for blind validation. A logistic regression model with six metabolites [PC(17:0/0:0), PI(18:0/20:3), 12-HETE, PE(0:0/16:0), hydrocortisone and phenylalanine] was found, with an AUC of 0.92 in training, 0.84 in validation and 0.85 in test cohorts.
Conclusion: Specific panels of serum metabolites can be useful to distinguish dCCA from PDAC. Validation of the clinical usefulness of these biomarkers in further prospective studies is granted.

SAT268

Proteomic identification of serum factors that correlate with reduction of HVPG following curative treatment for hepatitis C virus infection

Shola Richards[1], Florian Nigsch[1], Anna Baiges[2,3], Nancy Finkel[4], Alok Pachori[4], Sabela Lens[3,5], Dale Mongeon[4], Yiming Zhang[6], Fanny Turon[2,3], José Ferrusquia[2], Michel Blé Caso[2], Marta Magaz[2], Xavier Forns[3,5], Chinweike Ukomadu[4], Virginia Hernandez-Gea[2,3], Juan Carlos Garcia Pagan[2,3]. *[1]Novartis Institutes for Biomedical Research, Basel, Switzerland; [2]Barcelona Hepatic Hemodynamic lab, Liver Unit, Barcelona, Spain; [3]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain; [4]Novartis Institute for Biomedical Research, Cambridge, United States; [5]Liver Unit, Hospital Clinic, Barcelona, Spain. IDIBAPS; [6]Novartis Institutes for Biomedical Research, East Hanover, United States*
Email: Chinweike.ukomadu@novartis.com

Background and Aims: Estimation of portal hypertension through measurement of the hepatic venous portal pressure gradient (HVPG) is the best predictor of clinical outcome in advanced chronic liver disease. Several non-invasive markers (NIMs) have shown good accuracy in identifying clinically significant portal hypertension (CSPH: HVPG ≥ 10 mmHg). What is missing are NIMs that can predict reductions in HVPG. The aim of this study is to evaluate whether blood-based proteomic biomarkers are able to detect reductions in HVPG in patients with cirrhosis from Hepatitis C virus (HCV) after achieving sustained virologic response at 24 weeks post treatment (SVR24).
Method: This is a retrospective analysis of prospectively collected blood samples from patients with HCV cirrhosis, treated with direct acting antivirals. The study was IRB-approved and informed consent was obtained. Patients were from a single centre in Spain. Patients had HVPG ≥10 mmHg at baseline and a repeat measurement at SVR24. Blood samples were also taken at baseline and at SVR24. We conducted a proteomics-based study on serum samples using Somascan™, an aptamer-based technology that measures ~4500 human proteins. We determined proteins that correlate with reductions in HVPG in our patient population.
Results: Forty patients were included. Mean age was 66 years, 58% women, mean Child-Pugh score of 5 and mean HVPG of 14 mmHg (range 10 mmHg–20 mmHg). All patients achieved SVR. HVPG decreased by a mean of 2.1 mm Hg (95%CI: −3.5, −0.5; p = 0.008) from baseline. Heatmap and cluster analysis showed that the patients were grouped based on hemodynamic response to treatment. We performed Spearman correlation analysis for each of the ~4500 proteins versus change in HVPG for all 40 patients. The correlation with decrease in HVPG for all patients was 0.49 increasing to 0.77 for

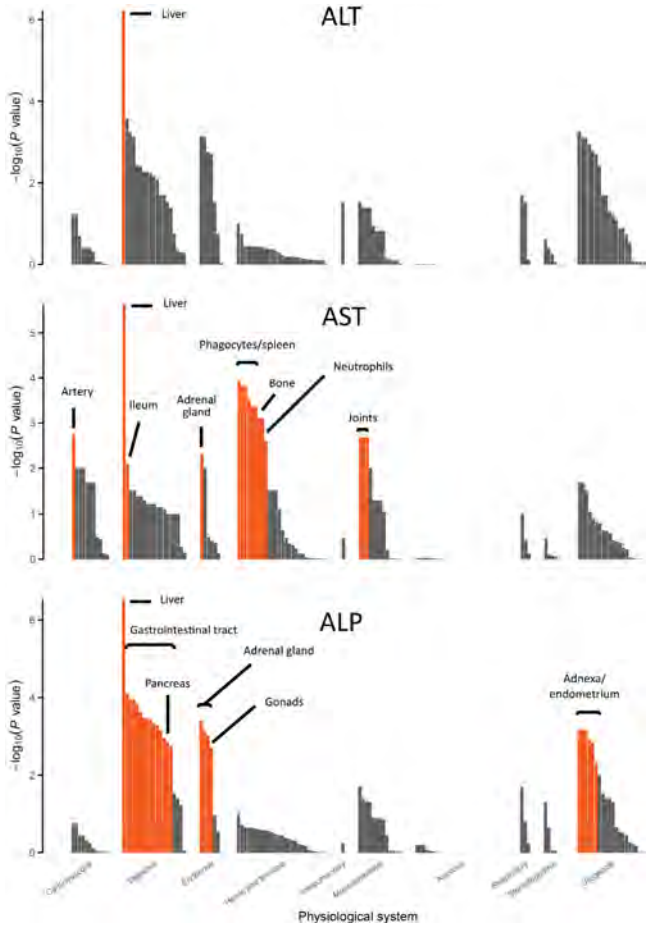
responders (decrease to ≤10 mm Hg or reduction of ≥20% from baseline). To identify a proteomic signature that correlated with HVPG reduction, we performed a 10-fold cross-validated LASSO regression. We identified 14 proteins (SOMAmers™) with coefficients above 0.4, which were previously associated with either chronic liver disease progression or HCV treatment response.
Conclusion: We used a proteomic platform and machine learning algorithms to identify proteins that correlate with clinically significant decreases in HVPG. The utility of these factors as predictive biomarkers for the improvement of portal hypertension will require data from studies in larger population of patients.

SAT269

Genome-wide association study (GWAS) of circulating liver enzymes identifies >300 novel variants with distinct tissue expression patterns and gene set enrichment

Vincent Chen[1,2], Xiaomeng Du[1], Yanhua Chen[1], Samuel Handelman[1,2], Elizabeth Speliotes[1,2]. [1]*University of Michigan Medical School, Division of Gastroenterology and Hepatology, Ann Arbor, United States;* [2]*University of Michigan Medical School, Department of Computational Medicine and Bioinformatics, Ann Arbor, United States*
Email: vichen@med.umich.edu

Background and Aims: Alanine transaminase (ALT), aspartate transaminase (AST), and alkaline phosphatase (ALP) are liver enzymes frequently used as indicators of liver pathology. Liver enzyme levels are partially genetically-determined, but the genetic etiology underlying this variation remains incompletely understood. We aimed to evaluate the genetic underpinning of liver enzyme levels with a cohort nearly ten times the size of the last such GWAS.



Method: We conducted a GWAS of inverse normally-transformed ALT, AST, or ALP controlling for age, sex, and principal components in >390,000 white individuals from the UK BioBank (>20,717,468 imputed single nucleotide polymorphisms [SNPs]), followed by meta-analysis with ALT, AST, or ALP GWAS results from >130,000 individuals of Japanese ancestry from BioBank Japan (5,951,600 imputed SNPs) using METAL. We characterized genome-wide significant ($P < 5 \times 10^{-8}$) SNPs using unbiased analyses including DEPICT and phenome-wide association study (PheWAS).
Results: We identified 176 total independent (163 novel) ALT, 205 (195) AST, and 221 (204) ALP SNPs. These variants represented 384 independent loci and 157 alleles affected >1 liver enzyme at genome-wide significance. Coheritability was higher between ALT and AST (0.67) than between ALT and ALP (0.24) or AST and ALP (0.21; $p < 0.0001$ for both comparisons). DEPICT analyses showed that the liver was the most enriched tissue for all three traits' associated genes. While ALT-implicated genes were relatively liver-specific, AST-implicated genes were expressed widely including in white blood cells, artery, adrenals, and joints, and ALP-implicated genes were expressed throughout the gastrointestinal tract and sex organs (Figure). Gene sets enriched among all three liver enzyme SNPs include lipid metabolism, retinoid X receptor, carbohydrate metabolism, and complement/coagulation cascades. While ALP-specific pathways included other metabolic pathways such as steroid synthesis, as well as intestinal absorption, AST-specific pathways were notable for several cytokine signaling cascades and lysosome function. PheWAS found that SNPs affecting all three liver enzymes altered risk of metabolic disease and cholelithiasis.
Conclusion: We identified >300 novel alleles that elevated ALT, AST, or ALP in UK BioBank and BioBank Japan. These variants identify genes with distinct tissue and gene set enrichment and implicate different aspects of normal liver physiology and pathophysiology.

SAT270

Virtual touch quantification using acoustic radiation force impulse technology versus transient elastography for the non-invasive assessment of liver fibrosis in patients with chronic hepatitis B or C using liver biopsy as gold standard

Victor Baldea[1], Ioan Sporea[1], Lupusoru Raluca[1], Alina Popescu[1], Roxana Sirli[1]. [1]*Victor Babeş University of Medicine and Pharmacy, Timişoara, Romania*
Email: victorbaldea07@gmail.com

Background and Aims: Our aim was to assess the diagnostic performance of Transient Elastography (TE) and Virtual Touch Quantification (VTQ), a point Shear Wave Elastography (pSWE) technique using Acoustic Radiation Force Impulse (ARFI) technology for liver fibrosis assessment, as compared to percutaneous liver biopsy (LB) in patients with chronic hepatitis B or C.
Method: We analyzed 157 patients with reliable liver stiffness (LS) measurements (80 with HBV and 77 with HCV chronic hepatitis) in which we compared TE and VTQ to the LB performed during the same session (evaluated according to the Metavir scoring system: F0-F4). LS was assessed by TE (FibroScan, EchoSens, Paris, France) and VTQ using Siemens Acuson S2000TM ultrasound system (Siemens AG, Erlangen, Germany). We defined reliable LS measurements the median value of 10 measurements with an IQR/M < 30% for both TE (obtained using the M probe) and VTQ. The areas under receiver operating characteristic curve (AUROC) were used to assess the diagnostic performance of TE and VTQ. Correlation analysis was used to determine the relationship between LSM values and liver histology.
Results: On LB, from the 157 patients, 31 (19.7%) had F0, 35 (22.3%) had F1, 43 (27.4%) had F2, 28 (17.8%) had F3 and 20 (12.8%) had F4. A strong, linear correlation (Spearman r = 0.82; $p < 0.0001$) was found

between TE and VTQ measurements. Also, we found a strong and significant correlation between TE and liver histology ($r = 0.74$, $p < 0.0001$) and between VTQ and liver histology ($r = 0.70$, $p < 0.0001$). By comparing the AUROC curves, TE and VTQ had similar predictive values for the presence of $F \geq 1$ Metavir : AUROC TE = 0.847, AUROC VTQ = 0.838 ($p = 0.867$); $F \geq 2$ Metavir : AUROC TE = 0.805, AUROC VTQ = 0.862 ($p = 0.151$); $F \geq 3$ Metavir : AUROC TE = 0.883, AUROC VTQ = 0.880 ($p = 0.949$) and for $F = 4$ Metavir : AUROC TE = 0.954, AUROC VTQ = 0.974 ($p = 0.192$). For rulling in significant fibrosis ($F \geq 2$) the optimal cutoff value was 5.5 kPa for VTQ (Se = 87.9%, Sp = 72.7%, PPV = 81.6%, NPV = 81.4%) and 7 kPa for TE (Se = 72.5%, Sp = 80.3%, PPV = 83.5%, NPV = 67.9%). For rulling out cirrhosis ($F = 4$) the optimal cutoff value was 8.9 kPa for VTQ (Se = 90%, Sp = 90.5%, PPV = 58.1%, NPV = 98.4%) and 10.7 kPa for TE (Se = 90%, Sp = 91.2%, PPV = 60%, NPV = 98.4%).

Conclusion: Both methods, TE and VTQ (pSWE) offer excellent diagnostic accuracy for liver fibrosis assessment in patients with chronic hepatitis B or C, with similar performance.

SAT271

Quantitative magnetic resonance cholangiopancreatography imaging in patients with primary sclerosing cholangitis - feasibility and preliminary analysis for prediction of clinical outcomes

Vijay Are[1], Raj Vuppalanchi[1], Ray Ren[2], Lin Cheng[2], Mariana Marieiro[2], Carlos Ferreira[2], Marija Mavar-Haramija[2], Andrea Dennis[2], Matt Kelly[2], Ged Ridgway[2], Rajarshi Banerjee[2], Carla Kettler[1], Mark Gromski[1], Fatih Akisik[1], Naga Chalasani[1]. *[1]Indiana University School of Medicine, Indianapolis, United States; [2]Perspectum Diagnostics, United Kingdom*
Email: rvuppala@iu.edu

Background and Aims: Magnetic resonance cholangiopancreatography (MRCP) is a non-invasive imaging technique commonly used for the evaluation of biliary disease. Despite its widespread use, MRCP relies on subjective assessments, lacking robust quantitative metrics and cannot predict the onset of liver related events. Quantitative MRCP (MRCP+^{TM}) is a novel technique that can quantitively assess biliary tree metrics. This study sought to understand the utility of MRCP+ in predicting clinical outcomes for primary sclerosing cholangitis (PSC).

Method: In this retrospective study, 35 PSC patients (69% Male; 82.9% Caucasian; mean age 54 years [7–70]) underwent standardised MRCP imaging. Images were post-processed using MRCP+ software, which enhances and quantifies the tubular biliary structures. The underlying algorithms combine an intelligent path search algorithm and novel duct modelling algorithms. The duration (in days) between the date of clinical event (liver transplant surgery or death) and the date of MRCP scan was calculated for the survival analysis; the Cox regression and Kaplan-Meier Estimator have been used to investigate the utility of MRCP+ derived metrics in predicting clinical outcomes.

Results: From the 35 patients, 13 (37%) PSC patients experienced a clinical event. The Cox survival analysis showed that MRCP+ derived metrics (the number of dilated ducts, the number of ducts with stricture or dilatation, and the total length of abnormal ducts) predicted the probability of a clinical outcome (either liver transplantation or death) ($p = 0.048$, 0.046 and 0.037, respectively). Optimal thresholds (of 12, 2 and 102 mm, respectively) of the above-mentioned MRCP+ metrics were calculated and applied. Low-risk patients (values below cut-off) had significantly higher liver-event-free survival than high-risk patients (values above cut-off) ($p = 0.012$, 0.0041 and 0.0027, respectively) (Figure 1).

Conclusion: Quantitative MRCP (MRCP+) has been used for the first time to predict clinical outcomes in patients with PSC. Further analysis with a larger sample size and comparison to risk scores such as mayo risk score and UK-PSC risk score are in progress and will be presented at the meeting.

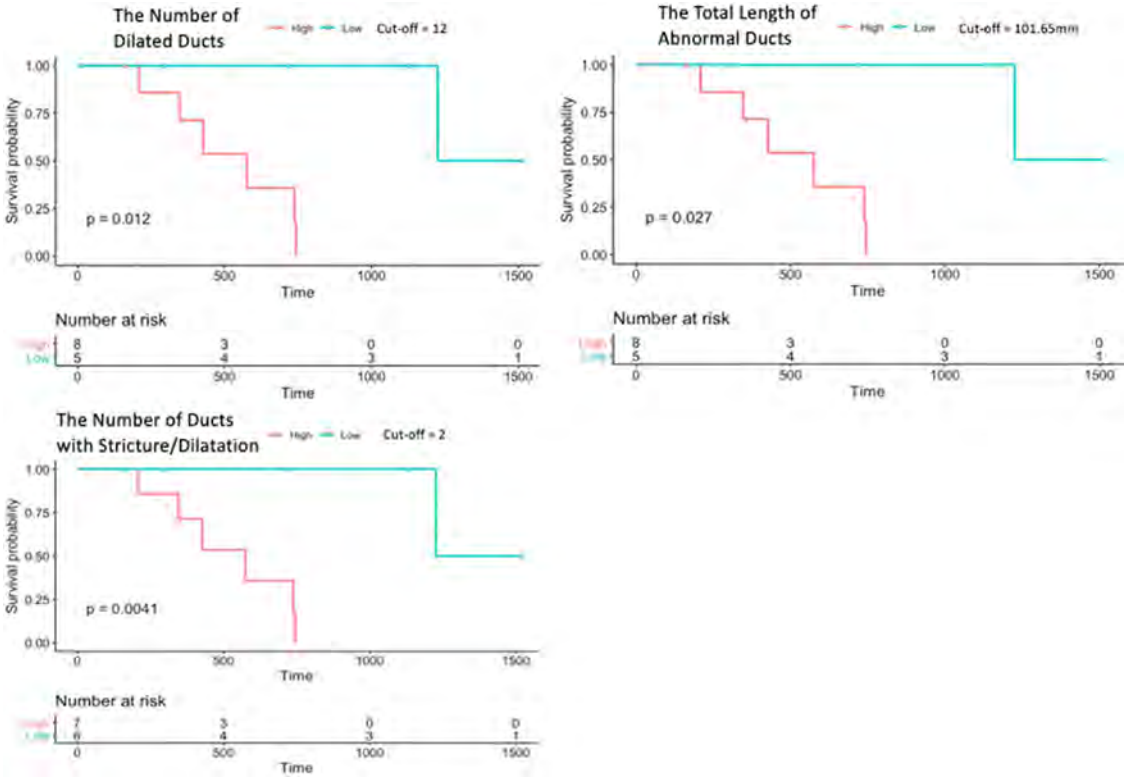


Figure: (abstract: SAT271): Kaplan-Meier Survival Curves for MRCP+ metrics.

SAT272

Two-dimensional real-time shear wave elastography and risk for de novo hepatocellular carcinoma in patients with advanced chronic liver disease

Email: wenyi.gu@kgu.de

Background and Aims: Liver cirrhosis is the most important risk factor in the development of de novo hepatocellular carcinoma (HCC) regardless of etiologies. Early non-invasive screening for cirrhosis using liver stiffness (LS) may also give information on the risk of HCC. This is the large-scale international multicenter study to evaluate clinically relevant end-point in liver cirrhosis using two-dimensional real-time shear wave elastography (2D-SWE).

Method: Chronic liver disease patients were screened from 15 centers from Europe and China. Besides, they were included if they had valid 2D-SWE at baseline. Clinical and laboratory parameters were assessed at baseline. We conducted the follow-up regularly after first assessment. De novo HCC was diagnosed according to the 2018 Practice Guidance by the American Association for the Study of Liver Diseases. Univariate and multivariate logistic regression model were used to explore risk factors of de novo HCC. Area under the receiver operating characteristic curve (AUROC) and Youden index were analyzed to find out the optimal cutoff for LS with SWE.

Results: A total of 1881 were included in the study with a median follow-up of 2.3 years. Most of the patients were male (61.5%) and middle-aged (median [IQR]: 55 [45–63] years). Non-alcoholic fatty liver disease (31.0%) accounted for the major etiology, followed by viral hepatitis (15.8%) and alcoholic liver disease (8.6%). Eighty-five (4.5%) patients were diagnosed with de novo HCC, and had a doubled median 2D-SWE value than those without HCC (22.0 vs. 11.1, $p < 0.001$). LS value of SWE (odds ratio [OR]: 1.013, 95% confidence interval [CI]: 1.002–1.024, $p = 0.022$) was independently associated with developing de novo HCC in multivariate analysis after adjusting for age, creatinine, INR, platelets and bilirubin. The AUROC of 2D-SWE was 0.701 (95%CI: 0.657–0.746). At the best cut-off of 13.6 kPa, a 78% of sensitivity and a 60% of specificity were obtained, with a negative predictive value of up to 98%. Patients with LS values above the cutoff (>13.6 kPa, OR: 2.040, 95% CI: 1.122–3.709, $p = 0.019$) and lower platelet counts were markedly associated with de novo HCC (Figure).

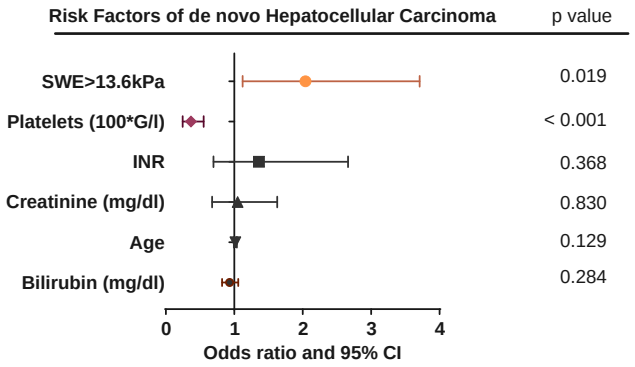

Figure: (abstract: SAT272)

Conclusion: The LS of SWE is associated with de novo HCC with the optimal cutoff of 13.6 kPa. If further confirmed in other populations, SWE could be used as a convenient auxiliary diagnostic tool to assess the risk of de novo HCC.

Progress in hepatitis C testing as a part of the hepatitis C elimination program in Georgia

Amiran Gamkrelidze[1], Tamar Gabunia[2], Alexander Turdziladze[1], Irma Khonelidze[1], Maia Tsereteli[1], Vladimer Getia[1], Ekaterine Adamia[2], Tinatin Kuchuloria[3], Irina Tskhomelidze[3], Muazzam Nasrullah[4], Shaun Shadaker[4], Lia Gvinjilia[3], Francisco Averhoff[4]. *[1]National Center for Disease Control and Public Health Georgia, Tbilisi, Georgia; [2]Ministry of IDPs from the Occupied Territories, Labour, Health, and Social Affairs of Georgia, Tbilisi, Georgia; [3]TEPHINET for Hepatitis C Elimination Program in Georgia, Tbilisi, Georgia; [4]National Center for HIV/AIDS, Viral Hepatitis, STD and TB Prevention, CDC, Division of Viral Hepatitis, Atlanta, United States*
Email: a.gamkrelidze@ncdc.ge

Background and Aims: The country of Georgia, with a population of 3.7 million and an estimated 150,000 adults with chronic hepatitis C virus (HCV) infection, initiated the world's first national hepatitis C elimination program in April 2015. Through the elimination program, screening for hepatitis C is available to all citizens free of charge. The aim of this analysis is to describe progress in hepatitis C testing as part of hepatitis C elimination program.

Method: This analysis utilizes data from the national screening registry and treatment databases linked by national ID, and 2014 general population census. An information system was created to collect data from the elimination program utilizing the national ID to monitor and evaluate program performance and surveillance.

Results: As of November 10, 2019, 1,628,452 adults have been tested for hepatitis C (56.9% of the adult population), of whom 125,016 (7.7%) were anti-HCV positive. In 2015 the positivity rate averaged 27.0%, but has fallen to 4.4% in the first half of 2019. Overall, 98,134 individuals received viremia testing, of whom 80,074 (81.6%) were found to have chronic HCV. Screening rates are similar for men and women (55.9% vs. 57.9%, respectively). Among men screening rates are highest among those aged ≥60 (64.2%) and lowest among those aged 18–29 (51.7%). The overall positivity rate for adult males is 12.4%. The highest positivity rate is seen in men aged 30–59 (18.6%). Among women screening rates are highest among those (60.7%) aged 18–29 (60.7%) and lowest among those aged 30–59 (56.4%). The overall positivity rate for adult females is 3.7%. The highest positivity rate is seen in women aged ≥60 (5.3%).

Conclusion: The overall anti-HCV prevalence was higher in males and among those aged 30–59 years. The anti-HCV positivity rate has been declining since the launch of the HCV elimination program in April 2015. Although significant progress has been made, a substantial proportion of infected people need to be identified, confirmed, and linked to care.

Evaluation of hepatitis B virus (HBV) epidemiology, vaccine impact and treatment eligibility: a census-based community serological survey in Blantyre, Malawi

Alexander Stockdale[1,2], James Meiring[2,3], Isaac T. Shawa[2,4], Deus Thindwa[5], Niza Silungwe[2], Maurice Mbewe[2], Collins Mitambo[6], Rabson Kachala[6], Benno Kreuels[7], Pratiksha Patel[2], Priyanka Patel[2], Stephen Gordon[2,8], Anna Maria Geretti[1], Melita Gordon[1,2]. *[1]University of Liverpool, Institute of Infection and Global Health, Liverpool, United Kingdom; [2]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi; [3]University of Oxford, Oxford Vaccine Group, Department of Paediatrics, Oxford, United Kingdom; [4]College of Medicine, Faculty of Biomedical Science and Health Professions, Blantyre, Malawi; [5]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom; [6]Ministry of Health Malawi, Lilongwe, Malawi; [7]Bernhard Nocht Institute for Tropical Medicine, Department of Tropical Medicine, Hamburg, Germany; [8]Liverpool School of Tropical Medicine, Liverpool, United Kingdom*
Email: a.stockdale@liverpool.ac.uk

Background and Aims: Hepatitis B is the leading cause of cirrhosis and hepatocellular carcinoma in sub-Saharan Africa. To achieve WHO targets of reducing mortality by 65% by 2030, antiviral treatment programmes are needed. Epidemiological data are required to inform an effective public health response and anticipate treatment needs.
Method: Infant HBV vaccination began in Malawi in 2002. We conducted a census and serological survey in Blantyre in 2016–18. We selected individuals from the census for serosurvey participation by probability sampling. We estimated HBV prevalence using post-stratification proportional fitting to census age-sex distribution. HBsAg-positive participants were evaluated for treatment eligibility. We estimated vaccine impact by comparing HBsAg prevalence of individuals born 5 years before and after vaccine implementation.

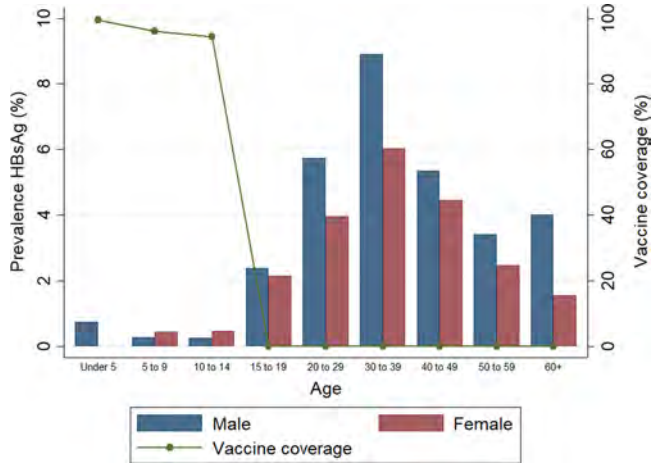

Figure: HBsAg prevalence among serosurvey participants stratified by age and sex and vaccine coverage.

Results: Of 97,386 censused individuals, 6,073 were sampled in the serosurvey and tested for HBsAg. HBV prevalence was 5.1% (95% CI 4.3–6.1) among adults and 0.3% (0.1–0.6) among children born after vaccine introduction. Three-dose vaccination coverage was 97.4% (1141/1172) in children ≤10 years. Vaccine impact was 95.8% (70.3–99.4). Treatment eligibility was assessed in 94/150 HBsAg positive adults, among whom 24 (26%) were HIV positive and 16/24 (67%) were receiving tenofovir-containing antiretroviral therapy. Among 69 HIV negative individuals, 2%, 6% and 9% were eligible for treatment by WHO, EASL and AASLD criteria respectively. Projected to the national population, 25586 (95% CI 7172–65519) people will require HBV treatment by EASL criteria.
Conclusion: In an urban township in Malawi, HBV prevalence was 5.1% among unvaccinated adults and infant HBV vaccination was associated with a vaccine impact of 96%. Among HBsAg-positive adults, one quarter were HIV-positive and 3–9% of HIV-negative adults required antiviral therapy.

SAT275

HCV in addiction care: different epidemiology, excellent treatment results

Ana Arencibia Almeida[1], Andrea Afonso Díaz[2], Silvia Acosta-López[1], Luz Goretti Santiago Gutierrez[3], Pilar Díaz Ruiz[4], Magdalena Lara[5], Antonio González Rodríguez[1], Javier García Solo de Zaldívar[1], Francisco Andrés Pérez Hernández[1], Angel David Febles Gonzalez[1]. *[1]Hospital Nuestra Señora de La Candelaria, Gastroenterology & Hepatology, Santa Cruz de Tenerife, Spain; [2]Hospital Nuestra Señora de La Candelaria, Internal Medicine; [3]San Miguel Adicction Care Unit, Santa Cruz de Tenerife; [4]Hospital Nuestra Señora de La Candelaria, Pharmacy Department, Santa Cruz de Tenerife, Spain; [5]Hospital Nuestra Señora de La Candelaria, Department of Microbiology, Santa Cruz de Tenerife*
Email: a.arencibiaa@yahoo.es

Background and Aims: Patients treated in addiction care units (ACU) have a higher prevalence of hepatitis C virus (HCV). There is not much evidence about its access to treatment and its results. Our aim is: 1) To determine the epidemiological characteristics and results of treatment in the registered population in ACU treated with direct-acting antivirals (DAA). 2) Compare with a general cohort treated in the same period of time.
Method: 1) Inclusion criteria: population with positive RNA-HCV test treated with DAA. 2) 2 groups were analyzed: HCV population registered in ACU and/or Penitentiary Center (HACU) and general population (GP). 3) Variables: age, sex, viral genotype, fibrosis stage, response to treatment (SVR12). Using the statistical package SPSS version 25. Continuous variables as means ± SD, discrete as frequencies (%). Correlation between qualitative variables using Pearson's Chi square (significant $p < 0.05$).
Results: HACU (n = 198 patients) and GP (n = 948 patients). Mean age (interval) years: HACU 46 (24–63) and GP 53 (18–56). Men (%): HACU 92%, GP 61%. Genotypes (1a/1b/2/3/4)%: HACU (42.3/9.5/0/29.6/8.46) vs. GP (30.2/38.7/2.11/18.5/9.07). 16 patients (8 from each group) were not genotyped. Fibrosis stage was determined by hepatic elastography and cirrhosis was defined by obvious clinical and/or image data. The distribution by stages (F0-1/F2/F3/F4)% was: HACU (31.2/20.6/18/29.6) vs. GP (27.3/22.7/16/32.5). Fibrosis stage was not established in 1 patient of the HACU group and 14 of the GP. We found no significant differences when comparing sex and genotype, age and fibrosis stage, genotype and fibrosis stage within the patients of the HACU group.
When comparing HACU against GP significant differences were observed by genotype (p: 0.001) observing a higher prevalence of genotype 3 in HACU. However, no significant differences were observed by fibrosis stage (p: 0.55).
We have the result of treatment in 189 patients of the HACU group (4 patients lost were recovered and sustained virological response -SVR12- was confirmed and 2 who abandoned therapy are currently in re-treatment). The SVR12 for ITT was 91.4% in HACU vs. 95.2% in GP; in the PP analysis SVR 12 was 100% in HACU vs. 99.5% in GP.

Conclusion:

1. In relation to GP treated with DAA, HACU population is younger, with male predominance and different genotype distribution (1a most frequent, 3 more represented).
2. More than 40% of the patients in the HACU group have advanced stage of fibrosis or cirrhosis.
3. SVR12 is excellent in both groups with proper strategies that avoid tracking losses.

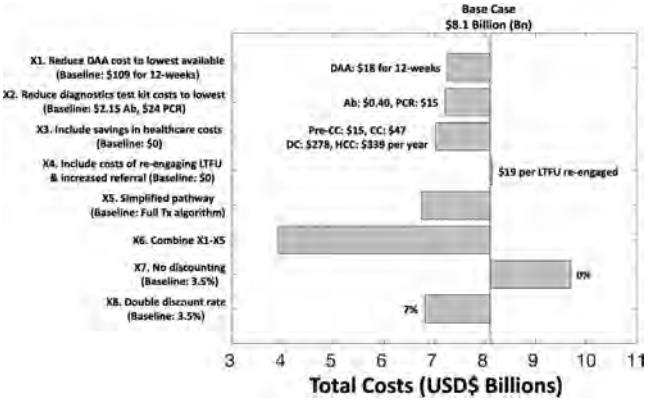
Email: aaron.lim@bristol.ac.uk

Background and Aims: Pakistan has the world's second-largest hepatitis C virus (HCV burden). The World Health Organization (WHO) HCV-elimination strategy advocates for a reduction in HCV incidence by 80% by 2030, but little is known about how this could be achieved and the costs of doing so in Pakistan.

Method: A general population HCV transmission, screening, and treatment model was developed and calibrated using available data from Pakistan, incorporating cost data on diagnostics and HCV treatment. We modelled the impact and costs of alternative strategies for scaling-up screening and HCV treatment to determine what is needed and the resulting costs of achieving the WHO HCV incidence target in Pakistan.

Results: One-time screening of 90% of the 2018 population by 2030, with 80% referral to treatment, leads to 14 million individuals being screened and 350,000 treated annually, decreasing incidence by 27% over 2018–2030. Prioritising screening to higher prevalence groups (people who inject drugs (PWID) and adults >30 years) and introducing re-screening (annually for PWID, otherwise 10-yearly) increases the number screened and treated by half and decreases incidence by 51%. Decreasing HCV incidence by 80% requires doubling the primary screening rate, increasing referral to 90%, re-screening the general population every 5-years, and re-engaging those lost-to-follow-up every 5-years. This could cost USD$8 billion, reducing to USD$4 billion with lowest costs for diagnostic tests and drugs, including healthcare savings, and implementing a simplified treatment algorithm.



Conclusion: Pakistan will need to invest up to 9% of their yearly health expenditure to enable sufficient scale-up in screening and treatment to achieve the WHO HCV-elimination target for incidence.

SAT277

The best strategy for retrieval of hepatitis C patients lost to follow up: randomized clinical trial

Alberto Hernández Bustabad[1], Dalia Morales Arraez[1], María Cristina Reygosa Castro[1], Orestes Crespo[2], Felicitas Diaz-Flores[3], Enrique Quintero[1], Manuel Hernandez-Guerra[1]. *[1]Hospital Universitario de Canarias, Hepatology and Gastroenterology Department, La Laguna, Spain; [2]Hospital Universitario de Canarias, Administrative Unit, La Laguna, Spain; [3]Hospital Universitario de Canarias, Central Laboratory, La Laguna, Spain*
Email: mhernandezguerra@gmail.com

Background and Aims: In order to achieve hepatitis C virus (HCV) WHO 2030 elimination goals, stakeholders should increase the rate of new diagnoses and linkage to care those lost to follow-up. Different strategies have been implemented to overcome barriers related to diagnosis, but there is a lack of studies approaching the best retrieval strategy for those lost to follow-up . Our aim was to evaluate the efficacy and effectiveness of two different strategies for retrieval of previously diagnosed HCV patients lost to follow-up, which is key to reach microelimination in our healthcare area.

Method: from data files of laboratory and microbiology charts since 2005 we identified patients with positive HCV antibodies without RNA request or positive RNA without a subsequent negative RNA lost to follow-up . Those still alive with currently available data for contact (by phone and mail) and in our healthcare area were randomly assigned (NCT04153708) (n = 176 each arm) in any of the two strategies: 1) phone calls to provide patients an appointment and 2) invitation mail letter with a scheduled appointment. We evaluated efficacy as the rate of patients who turn up for the appointment in each strategy and effectiveness taking into account the use of resources. Statistical analysis was performed with Chi2, t-student and Poisson regression. The study was approved by the local Hospital Ethics Committee.

Results: 352 subjects were included in both strategies (74.6% men, mean age 51.3 ± 13.3 years-old) with no differences between groups. In strategy 1, 8.7% of the patients were excluded due to change of the holder of the phone line, whereas, in strategy 2, 11% of the letters failed to reach the address and were returned. Eventually, in strategy 1, 42.4% did not answer the phone call and 10.2% were not interested to participate. The rate of patients that turned up for the scheduled appointment was higher in the strategy 1 (median 9 days, [1–17])

than in strategy 2 (median 12 days, [11–13]) (46.5% vs 28.2%, p = 0.033). The number of phone calls needed for one retrieval was 11:1 in the strategy 1, whereas the number of letters which correctly reached the address needed for one retrieval was 4:1 in strategy 2 (OR 3.03, IC 95% [1.653–5.549], p < 0.001).
Conclusion: the retrieval of patients with HCV diagnosis lost to follow-up is feasible through both strategies. However, our results suggest that the strategy of phone calls seems to be more effective, although the invitation mail letter is more efficient.

SAT278

Is hospital admission an ideal condition for HCV screening? A survey from the Venetian area (north-east of Italy)

Alessandro Caroli[1], Irene Franceschet[1], Federica Fascì-Spurio[1], Lisa Girardi[1], Roberto Cappuccio[1], Davide Checchin[1], Francesca Lamboglia[1], Andrea Forti[2], Claudio Scarparo[3]. *[1]Dell'Angelo Hospital, Gastroenterology and Hepatology, Venezia-Mestre, Italy; [2]Dell'Angelo Hospital, Laboratory Medicine, Venezia-Mestre, Italy; [3]Dell'Angelo Hospital, Microbiology, Venezia-Mestre, Italy*
Email: alessandro.caroli@aulss3.veneto.it

Background and Aims: The best strategy to bring out the hidden chronic HCV infection in order to plan the virus elimination remains uncertain. Current guidelines recommend screening in high risk populations, but other strategies should be defined according to the local HCV epidemiology. In Veneto Region (North-East of Italy) the actual prevalence of HCV infection is not well-known but is estimated between 0.5–1% of the general population, that seem a too low value to justify a community screening in terms of cost-benefit. Nevertheless hospitalized patients may represent an ideal population for HCV screening and for referral to treatment, but few data are available in this specific setting of subjects. Aim of this study was to determine the prevalence of HCV infection in unselected hospitalized subjects in the Venetian area, North-East of Italy, in order to identify hidden infection and to plan a micro-elimination strategy of the virus.
Method: All patients consecutively admitted to the surgical departments of the "dell'Angelo" Hospital, Venezia-Mestre, from 01/01/2017 to 30/06/2018, were tested for anti-HCV antibodies (CMA Abbott laboratories). In case of borderline values, a confirmatory RIBA test (INNOLIA HCV) was carried out. Positive patients were tested for HCV-RNA (RT-PCR Abbott laboratories) and HCV-genotype
Results: Overall, 11166 patients were tested at admission (40.4% males). 237 subjects resulted anti-HCV positive, with a prevalence of 2.1%. The prevalence was significantly higher in men (2.5%) than in women (1.7%) and increased with age (from 0.6% in 15–30 years patients to 2.8% in 51–60 and over 70 years patients). The highest prevalence was observed in Vascular Surgery (3.5%), Traumatology (3.4%) and Neurosurgery (2.8%), the lowest in Gynecology (1.0%) and Urology (1.6%). HCV RNA was detectable in 66% of patients and the most represented genotype was genotype 1 (80%). The large majority of subjects (70%) were unaware of their status and are now being recruited for the treatment.
Conclusion: Our data show a significant prevalence of HCV infection in hospitalized subjects, two to three times higher than that expected in the general population of the Veneto region. Screening for HCV infection in this specific setting of subjects may thus represent a simple and cost-effective strategy to identify hidden HCV-infection and for treatment referral, in order to achieve HCV micro-elimination.

SAT279

A novel microsimulation model of chronic hepatitis B (HBV): validation of HBV viral dynamics and cumulative incidence of hepatocellular carcinoma

Amir Mohareb[1,2,3], Arthur Kim[2,3], Anders Boyd[4,5], Farzad Noubary[6], Menan Gérard Kouamé[7], Serge Paul Eholié[7,8,9], Kenneth Freedberg[1,2,3], Rochelle Walensky[1,2,3], Emily Hyle[1,2,3].
[1]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States; [2]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States; [3]Harvard Medical School, Boston, United States; [4]GGD Amsterdam, Amsterdam, Netherlands; [5]Stiching HIV Monitoring, Amsterdam, Netherlands; [6]Northeastern University, Department of Biostatistics, Boston, United States; [7]Programme PACCI, Abidjan, Côte d'Ivoire; [8]Treichville University Teaching Hospital, Department of Infectious and Tropical Diseases, Abidjan, Côte d'Ivoire; [9]Université Félix Houphouët-Boigny, Medical School, Abidjan, Côte d'Ivoire
Email: amohareb@mgh.harvard.edu

Background and Aims: Hepatitis B virus (HBV) is a leading cause of cirrhosis and hepatocellular carcinoma (HCC) worldwide. Existing HBV models do not simulate viral parameters. Our objective was to develop a microsimulation model of chronic HBV that incorporates dynamic changes in HBV DNA.
Method: We simulated a cohort of individuals after perinatal HBV infection, progressing through the natural history of HBV in 1 month time steps from birth until age 75 y. Simulated patients can progress through up to 4 phases of chronic HBV natural history, which are correlated with clinical outcomes: *Phase 1* eAg+ chronic infection; *Phase 2* eAg+ hepatitis; *Phase 3* eAg- chronic infection; and *Phase 4* eAg- hepatitis. Data from cohort studies informed key input parameters: initial DNA distribution; changes in DNA, conditional on HBV phase; transition rates between HBV phases; rates of sAg loss and HCC incidence, both conditional on HBV phase and HBV DNA. Model outcomes included: HBV DNA during each phase; cumulative incidence of eAg seroclearance (transition to Phase 3); cumulative incidence of sAg loss and HCC in Phases 3 and 4. We validated model-based results by visual comparison with data from the REVEAL cohort in Taiwan.

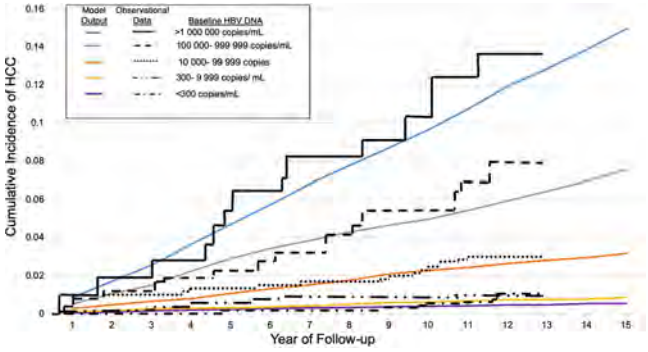


Figure: Validation of model-simulated HCC cumulative incidence in Phases 3 and 4, stratified by HBV DNA compared to observational data from the REVEAL cohort (adapted from Chen CJ, et al. JAMA 2006;295:65-73.)

Results: Consistent with published observational data, HBV DNA was highest in Phase 1 (median [IQR]: 7.98 [7.50–8.49] log copies/mL) and lowest in Phase 3 (median [IQR]: 2.79 [2.00–3.58] log copies/mL). HBV DNA showed the most fluctuations within and among simulated

subjects in Phase 2 (median [IQR]: 5.14 [3.52–6.58] log copies/mL) and Phase 4 (median [IQR]: 4.81 [3.35–6.62] log copies/mL). By the end of the simulation, 95% of the cohort achieved eAg seroclearance, as observed in the REVEAL study. Cumulative incidence of sAg loss was 30% in Phase 3 and 4, corresponding to 1.51/100 person-years (PY), with higher rates among those achieving undetectable HBV DNA. Model-estimated HCC incidence was 6.4% in Phases 3 and 4, corresponding to 319/100 000 PY, consistent with published data. HCC incidence was greater among patients with higher HBV DNA, as per observations from the REVEAL cohort [Figure].
Conclusion: This novel simulation model projects trajectories of HBV DNA, sAg loss, and HCC cumulative incidence validated to published cohort data. This model will be useful to assess the cost-effectiveness of different HBV screening, monitoring, and treatment strategies.

Rapid test & treat programme successfully facilitating hepatitis C micro-elimination in a women's prison

Andrew Ustianowski[1], Marie White[1], Sandra Bell[1], Jayne Bennett[1], Karren Pavey[2], Leanne O'Connell[3], Jacob Smiles[3], Simon Hammond[4], Maxine Horne[4], Dai Roberts[4], F Javier Vilar[1]. *[1]North Manchester General Hospital, Regional Infectious Diseases Unit, Manchester, United Kingdom; [2]HMP Styal, Manchester, United Kingdom; [3]North Manchester General Hospital, Pharmacy, Manchester, United Kingdom; [4]Health Innovation Manchester, Manchester, United Kingdom*
Email: andrew.ustianowski@pat.nhs.uk

Background and Aims: Hepatitis C (HCV) is more prevalent amongst those in prison than in many other populations. However, despite significant work and investment, testing and treatment rates in many prisons have remained disappointing. We therefore developed a Rapid Test & Treat (RT&T) programme for a woman's prison with an aim to increase uptake of testing, commencement & completion of treatment.
Method: Cepheid testing was performed as an opt-out at entry into a female prison (with approximately 1500 new entrants per year) Those determined to have active infection were fast-tracked onto pan-genotypic regimens. Outcomes were compared to data from 2018 (prior to programme commencement).
Results: Rates of testing, diagnosis, and treatment are shown in the Figure. During the RT&T programme (March – October 2019) a total of 79 prisoners were commenced on treatment (with only 21 treated in the entire of 2018 - before the programme commenced). The median times from prison entry to diagnosis, and from diagnosis to treatment, were significantly decreased (from several weeks to less than 5 days). This programme, in combination with initiatives to diagnose existing prisoners, has resulted in prison micro-elimination (currently >96% prisoners tested & treated). Satisfaction with the RT&T programme was very high.

	Prior to Programme	During Rapid Test&Treat Programme
% of entrants tested at entry to prison	38.6	69.6
% of those who are positive for HCV	51.0	9.6
% of those HCV positive commencing treatment	17.9	93.8

Conclusion: Establishing opt-out point of care testing at entry to prison is feasible and results in markedly increased testing, increased treatment, shorter delays and improved satisfaction. The programme is now being rolled out to other local prisons and is a pivotal component of the regional HCV elimination programme. Further updated data including SVR rates will be available at the conference.

SAT281

Role of immigration in chronic HBV and HCV infection in our environment. Origin and characteristics of the patients

Ángela Suárez-Noya[1], Celia Del Caño Cerdán[1], Alejandro Nieto Jara[1], Victor J Beltrán[1], Pablo Florez Díez[1], Noelia Rodríguez Ferreiro[1], Mercedes Rodriguez-Perez[2], Carmen Álvarez-Navascués[1], Maria Luisa Gonzalez Dieguez[1], Maria Varela[1], Valle Cadahía-Rodrigo[1], Manuel Rodríguez[1]. *[1]Hospital Universitario Central de Asturias, Liver Unit, Division of Gastroenterology&Hepatology, Oviedo, Spain; [2]Hospital Universitario Central de Asturias, Microbiology Department, Oviedo, Spain*
Email: angelasuareznoya@gmail.com

Background and Aims: Migration is one of the most influential factors in the dynamics of hepatitis B and C epidemiology. To know the relevance of immigration in chronic hepatitis/infection by HBV (CHB) and chronic hepatitis C (CHC) in our environment and to compare characteristics of immigrants with each infection.
Method: All patients with CHB (n = 624) and CHC (n = 1405) from Jan/2014 to Oct/2019 were analyzed. Clinic and demographic variables were collected prospectively. Evaluation of liver fibrosis was performed by elastography.
Results: The proportion of immigrants was 36% (222/624) in CHB and 5% (70/1405) in CHC (p < 0,001) and was higher in incident than in prevalent cases, both in CHB [62% (124/199) vs 23% (98/425); p < 0,001] and CHC [7.4% (51/688) vs. 2.6% (19/717); p < 0,001]. Only 1 immigrant had CHB and CHC. There were no differences between immigrants with CHB and CHC in sex (male: 48% vs 53%; p = 0,08) not in HIV coinfection (2.3% vs. 1.4%;p = 1). Those with CHC were older [50 vs. 35 years; p < 0,001], consumed alcohol more frequently (13% vs. 3.3%; p = 0,009) and a higher proportion had F3-F4 (42% vs. 7.6%;p < 0,001). The main mechanism of infection was drug use (DU) in CHC (22%) and vertical/intrafamilial transmission in CHB (36%); none of the last referred DU. Immigrants with CHB came from 30 countries; the highest number of cases from Romania [ROM] (45), Senegal [SEN] (40), China [CHI] (37), Equatorial Guinea [EG] (17) and Portugal [POR] (13). Immigrants with CHC came from 22 countries; the highest number of cases from ROM (14), EG (10), Dominican Republic [DR] (7), Russia [RUS] (5) and POR (5), none from CHI or SEN. The geographic areas with the highest CHB proportion were Sub-Saharan Africa [SA] (31%), Eastern Europe [EE] (27%) and Asia (18%), while for CHC they were EE (44%), SA (14%) and Central America-Caribbean (14%). Taking into account the number of immigrants in our area and their origin, the countries with the highest proportion of CHB were EG (28%), SEN (9%), CHI (7.2%), DR (3.9%) and POR (2.9%), while for CHC they were GE (16%), RUS (3.6%), RD (1.4%), POR (0.8%) and RUM (0, 5%).
Conclusion: The role of immigration in CHB and CHC is increasing and it is significantly greater in CHB. However, immigrants with CHC have more advanced liver disease. There are important differences between both in the acquisition mechanism and patient origin. Although ROM is the country with the highest number of cases of both infections, the high proportion of patients from EG with CHB and CHC is notable.

SAT282

From stagnation to elimination: tracking hepatitis C elimination policy implementation in Europe in partnership with patient organizations

Adam Palayew[1], Samya R Stumo[2], Graham Cooke[3], Sharon Hutchinson[4], Marie Jauffret-Roustide[5], Mojca Maticic[6], Magdalena Harris[7], Ammal M Metwally[8,9], Jeffrey Lazarus[2]. *[1]McGill University, University Department of Epidemiology, Biostatistics, and Occupational Health, Montreal, Montreal, Canada; [2]Barcelona University, Institute for Global Health (ISGlobal), Barcelona, Spain; [3]Imperial College, Division of Infectious Diseases; [4]Glasgow Caledonian University, School of Health and Life Sciences; [5]Paris Descartes*

University, Cermes3; [6]University Medical Centre Ljubljana, Clinic for Infectious Diseases and Febrile Illnesses; [7]London School of Hygiene & Tropical Medicine, Department of Public Health, Environments and Society; [8]National Research Centre, Community Medicine Research Department, Medical Research Division; [9]Association of Liver Patient Care, Dakhlyia, Egypt
Email: apalayew@gmail.com

Background and Aims: New hepatitis C virus (HCV) treatments spurred the World Health Organization (WHO) in 2016 to adopt a strategy to eliminate HCV as a public health threat by 2030. To achieve this, key policies must be implemented. In the absence of monitoring mechanisms, this study aims to assess the extent of policy implementation.
Method: Thirty liver patient organizations were surveyed in Oct 2018. They were queried on how policies were implemented in practice. Respondents received two sets of questions: 1. addressing WHO recommendations; and 2. from validated data sources verifying an existing policy in their country. Experts selected key variables from each set for inclusion into index scores. The index scores were calculated with a multiple correspondence analysis (MCA). Proxy reference countries StagNation (no policies) and ElimiNation (all policies implemented) were included to contextualize answers. In the second index, ProcrastiNation (all policies in place, but none implemented) was also included. We extracted scores for each country and standardized them from 0 to 10 (best).
Results: In total, 25 countries responded. In the WHO recommendations index, we included: microelimination in migrants, people who inject drugs, prisoners, sex workers and service integration of blood safety, harm reduction, and migrant services. The WHO MCA yielded a 1-Dimension (1D) solution explaining 75.5% of the variation. Bulgaria had the lowest score with all negative responses while 5 countries had perfect scores (Figure 1A). In the verified policy index, we included the variables: fibrosis restrictions, drug alcohol restrictions, needle-syringe program (NSP) community, NSP prison, opioid substitution therapy (OST) community, OST prison, HCV testing in prisons, and HCV treatment in prisons. The verified policy MCA yielded a 2D solution with D1 (if policies were in place) accounting for 44.3% of the variation and D2 (the proportion of policies in place that were implemented) accounting for 34.6%. Spain had the highest scores for D1 and D2, while Bosnia Herzegovina and Finland had the lowest scores for D1 and D2, respectively (Figure 1B).
Conclusion: Patient groups reported that WHO recommendations and the implementation of HCV policies is low in practice in Europe with major differences among countries. If countries are to meet HCV elimination, they need to further expand efforts, especially to vulnerable populations

SAT284

Treatment cascade of hepatitis C in a non-university hospital setting, that uses a hub-and-spoke model, in southern Switzerland

Adriana Baserga[1], Benedetta Terziroli[2], Lorenzo Magenta[2], Antonella Robatto[2], Manuela Balmelli[2], Alberto Moriggia[2], Daniel Hagara[2], Odile Stadler[3], Sheila Appadoo[3], Andrea De Gottardi[2,4], Andreas Cerny[5]. *[1]Fondazione Epatocentro Ticino, Lugano, Switzerland; [2]Epatocentro Ticino, Lugano, Switzerland; [3]University of Bern, Clinical Trial Unit, Bern, Switzerland; [4]Ente Ospedaliero Cantonale, Gastroenterologia e Epatologia, Lugano, Switzerland; [5]Epatocentro Ticino, Lugano, Switzerland*
Email: adriana.baserga@hin.ch

Background and Aims: Despite the introduction of direct-acting anti-viral agents (DAA), the management of HCV (hepatitis C virus) still represents a public health challenge. Universal DAA access has been available in Switzerland since 2017. The present study aimed to describe the cascade of care of anti-HCV positive individuals in a non-university hospital setting where a decentralized approach is used.
Method: This is a retrospective study in which we collected the data of all positive anti-HCV antibodies individuals (still alive and deceased) seen at the Epatocentro Ticino since 2007 till the end of 2017. The following data were collected: age at presentation, country

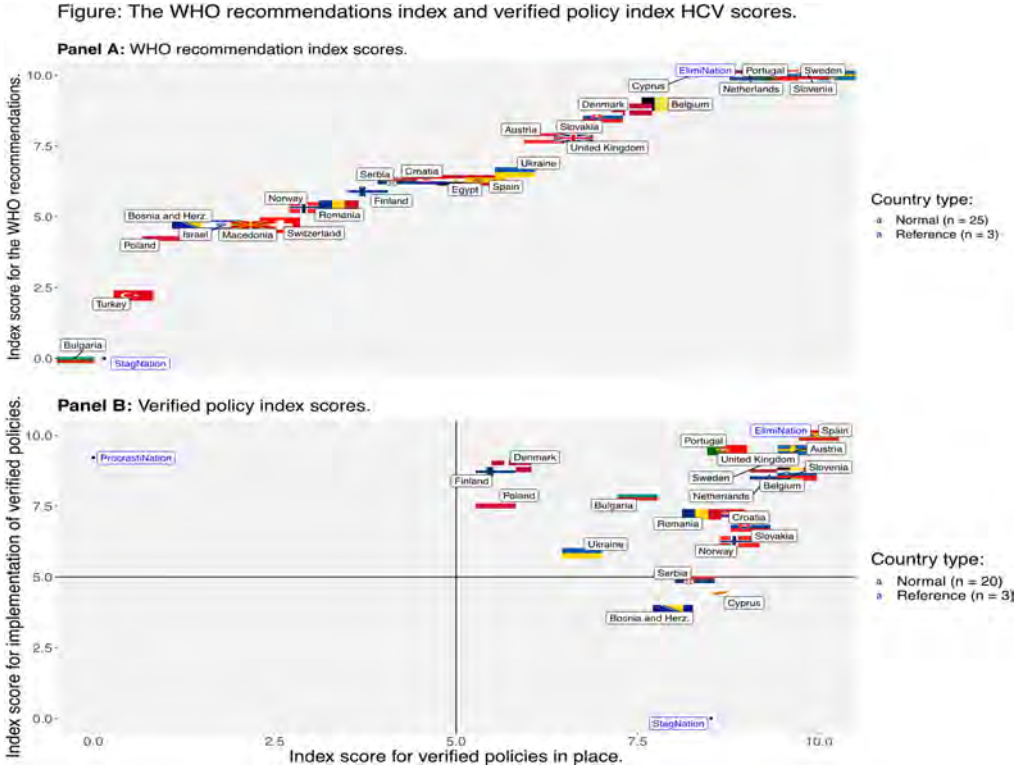

Figure: (abstract: SAT282)

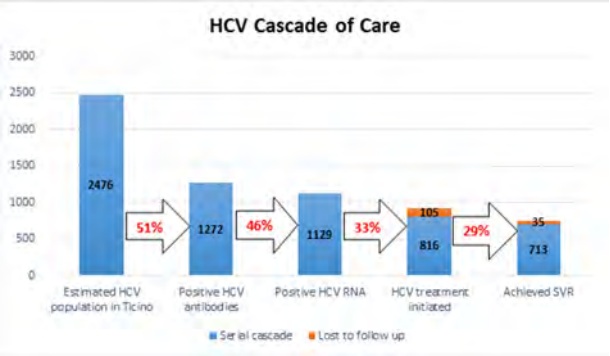
of birth, fibrosis stage, mortality, anti-viral treatment status, treatment outcome, and lost to follow-up status. Two time-points have been considered for data analysis: firstly, the year of the first visit at our center and secondly, the most recent time-point the subject has been seen in our center.

Results: A total of 1272 anti-HCV positive patients were identified and included in the data analysis. Median age at the first visit was 51.0 years (IQR 44–63). A total of 1129 patients (89%) had positive HCV RNA in plasma at baseline, 136 were HCV RNA negative, 35% of them had been treated before the first visit at the center and 27% had spontaneously cleared the virus. HCV genotype distribution in the study population was: 45% genotype 1, 15% genotype 2, 22% genotype 3, 8% genotype 4, and less than 1% genotypes 5 and 6 or mixed genotypes. 446 patients (35%) had significant fibrosis at baseline, assessed by either liver biopsy (>stage F2), clinical signs of portal hypertension or liver transient elastography above 10 kPa. A total of 816 patients (72% of the patients with positive HCV RNA at baseline) had access to HCV treatment (Figure 1). Of them, 383 patients were treated by (peg)interferon and ribavirin, 633 were treated by DAA, of whom 197 received DAA as re-treatment after failure of (peg) interferon-based treatment. A total of 713 patients (87%) that had access to treatment were cured (data on treatment outcome were missing in 35 patients).



Conclusion: At least 29% (Figure 1) of the estimated HCV population in Ticino achieved sustained virological response (SVR) in the last 10 years, of whom 71% had been cured since the DAA therapies had been available. In Kantonsspital St. Gallen, characterized by a centralized model, the achievement of SVR in a similar period of time (2004–2016) was 13%. If we compare the two models, the hub-and-spoke model used by our center, has allowed the treatment and healing of more than twice as many individuals as the centralized model.

SAT285

A nurse led hepatitis C model of care in primary care and community services in Melbourne, Australia

Brendan Harney[1,2], Bradley Whitton[1], Amanda Wade[2,3], Rebecca Brereton[4], Sarah Nolan[5], Alexander Thompson[6,7], Stuart Roberts[8,9], Margaret Hellard[1,2], Joseph Doyle[1,2]. *[1]Alfred Health & Monash University, Department of Infectious Diseases; [2]Burnet Institute, Disease Elimination Program; [3]Barwon Health, Department of Infectious Diseases; [4]Alfred Health, St Kilda Road Clinic; [5]Launch Housing; [6]St Vincent's Hospital Melbourne, Department of Gastroenterology; [7]Melbourne University, Department of Medicine; [8]Alfred Health, Department of Gastroenterology; [9]Monash University, Department of Medicine*
Email: brendan.harney@burnet.edu.au

Background and Aims: Hepatitis C virus (HCV) testing and treatment at primary care and community based services will be a critical component of HCV elimination. We conducted an analysis of a nurse-led service at nine sites to evaluate progression through the HCV care cascade from January 2017-September 2019.

Method: People accessing services from nine sites including seven primary care services, a homeless service and a mental health service were either referred to nurses or engaged by nurses directly during regular visits. Nurses provided HCV education, testing and follow-up services. Those who tested HCV RNA positive were contacted by the nurse to discuss treatment and prescription was provided by an affiliated doctor or nurse practitioner. People with suspected cirrhosis based on transient elastography were referred to gastroenterology specialists. Logistic regression was used to examine factors associated with treatment commencement and sustained virological response (SVR) testing.

Results: A total of 688 people were referred to and/or engaged by the nurses; 564 had a HCV test of whom 420 (74%) were HCV RNA positive. Treatment was commenced by 324 (77%) with 207 (64%) prescribed by a general practitioner or a nurse practitioner. SVR testing was due for 288 by end September 2019, 174 (60%) were known to have had a SVR test, 169 (97%) were cured. Of those not cured, two were suspected reinfection, two were non-adherence and one was a relapse.

Adjusted for age, gender and Aboriginal or Torres Strait Islander status, there was no significant difference in treatment commencement among people who reported injecting drug use in the last six months (aOR 0.58, 95%CI 0.26–1.31) compared to those who did not. Compared to people seen in primary care services, treatment uptake was significantly lower among those engaged through the homeless service (aOR 0.21, 95%CI 0.08–0.51). There were no significant differences in SVR testing among those who started treatment based on injecting in the last six months (aOR 1.75, 95%CI 0.83–3.72) nor engagement through the homeless service (aOR 1.96, 95%CI 0.45–8.56).

Conclusion: A nurse-led model of care can lead to high levels of HCV treatment and cure among people attending primary care and community services. While specialist referral pathways are required for people with cirrhosis, restricting all HCV treatment to specialists is unjustified, as is restriction based on active injecting drug use. More tailored models of care are required for people attending homeless services.

SAT286

Barriers to hepatitis C virus elimination in Germany: why aren't diagnosed patients initiating therapy?

Email: buggisch@ifi-medizin.de

Background and Aims: Despite the availability of effective and well-tolerated direct-acting antivirals, many patients with chronic hepatitis C virus (HCV) infection delay or never initiate treatment. This observational study compared characteristics of patients who did and did not initiate HCV treatment and identified the reasons for this according to physicians. There were no budget constraints, as reimbursement is not a barrier to treatment in Germany.

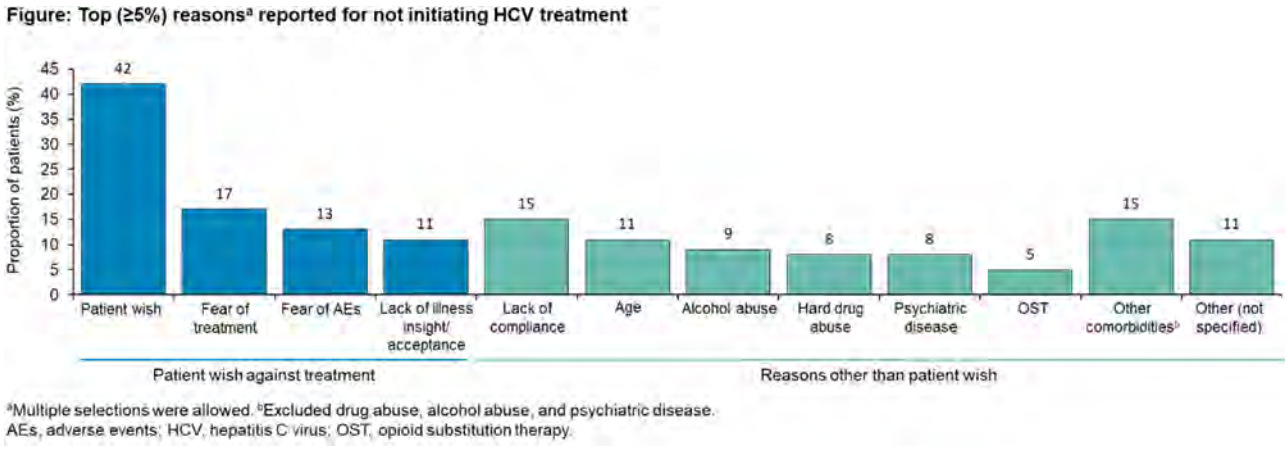

Figure: (abstract: SAT286)

Method: The CURRENT-C study was an epidemiologic, non-interventional, case-control study that identified patients with chronic HCV infection in 43 sites in Germany (1 September 2017–30 June 2018). Baseline characteristics of patients who did or did not initiate treatment were evaluated. Reasons why physicians and/or patients decided against initiating or for delaying HCV treatment were collected.
Results: Of 793 patients, 573 (72%) initiated treatment and 220 (28%) did not. Of those not initiating treatment, 88 (40%) delayed treatment and 132 (60%) had no therapy planned. In patients who did vs did not initiate treatment, 102 (18%) vs 76 (35%) were >60 years of age, 86 (15%) vs 32 (15%) were cirrhotic, 70 (12%) vs 40 (18%) were heavy alcohol users (>40 g/day [men]/>30 g/day [women]), 45 (8%) vs 48 (22%) had a history of injecting drug use, and 166 (29%) vs 93 (42%) were on opioid substitution therapy (OST), respectively. The most frequently reported reason for not initiating treatment was patient wish (93, 42%), particularly due to fear of treatment (38, 17%) or adverse events (29, 13%). Additional frequently observed reasons for not initiating treatment included perceived or expected lack of compliance, high patient age, comorbidities, drug/alcohol abuse, and OST (Figure).
Conclusion: In this real-world population, 28% of documented patients with chronic HCV infection did not initiate treatment. Reasons to not initiate treatment other than patient wish included high age, drug abuse, and heavy alcohol abuse. Educating hesitant patients on the importance of treatment and overcoming historic barriers to initiating treatment, such as drug and alcohol use, is needed to achieve HCV elimination.

Email: camila.picchio@isglobal.org

Background and Aims: There are an estimated 248 million people living with chronic hepatitis B in the world. Since 2008, there has been a consistent increasing trend in reported chronic HBV cases and continued importation of cases from high endemic countries to many EU countries. Despite Spain having screening and vaccination policies in place and unrestricted access to therapy, people present late to specialist care. We describe the characterists and country of origin of HBV-infected patients in Spain.
Method: We conducted a retrospective cohort study through clinical history revision of patients seeking first time care with a liver specialist in ten tertiary Spanish hospitals between January 2018 and June 2019. Late presentation includes advanced liver disease (ALD) defined by significant fibrosis (≥F3 assessed by either APRIscore >1.5, FIB-4 >3.2, transient elastography (FibroScan) >9.5 kPa or biopsy ≥METAVIR stage F3) with no previous antiviral treatment. Prevalence of ALD at first consultation, country of origin, and risk factors were analyzed.
Results: 398 patients were identified of which 59.8% were male and 54.5% were non-Spanish born. The average age was 46 and the average time from diagnosis to arriving in specialist care was 5.1 years. Patients whose country of origin was Africa made up 19.3% of all HBV cases with 28.5% (22/77) from Senegal followed by Guinea (15; 19.5%) and Ghana (7; 9.1%) (See Fig 1).11% of HBV cases were in Chinese-born individuals (n = 44) and four presented late to care. Non-Spanish born were significantly younger than Spanish born (38 vs 57 years; $p < 0.0001$) and Senegalese and Chinese migrants had a similar average age (34 and 38 years, respectively). Late presentation was detected in 11.6% (n = 46) of all cases and men were more likely than women to present late (6.9% vs 14.7%; $p = 0.006$). Those who presented late were older than those who did not (57 vs 46 years; $p < 0.0001$) and Spanish-born were more likely to present late to care compared to foreign-born individuals (17% vs 7%; $p < 0.0001$).
Conclusion: Late presentation to HBV care is an issue in Spain. Targeted screening programs for high-risk Spanish populations and migrants arriving from high-endemic countries like Senegal and China need to be implemented. More than half of all reported HBV cases were in non-Spanish born persons. If Spain is to meet WHO targets to eliminate viral hepatitis as a major public health threat, efforts need to be made to identify HBV patients sooner.

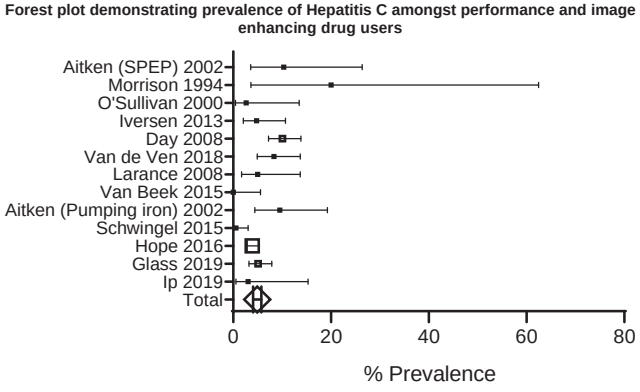
The prevalence of hepatitis C amongst people who use performance and image enhancing drugs - a systematic review

Charlotte Cook[1], Ryan Buchanan[1], Julie Parkes[1], Salim Khakoo[2], Melissa Zhao[3]. [1]*University of Southampton, Primary Care, Population Sciences and Medical Education, Southampton, United Kingdom;* [2]*University of Southampton, School of Clinical and Experimental Sciences, Southampton, United Kingdom;* [3]*University Hospital Southampton, Southampton, United Kingdom*
Email: charlottecook@doctors.net.uk

Background and Aims: The injection of performance and image enhancing drugs (PIEDs) is an emerging health concern and the prevalence of Hepatitis C virus (HCV) in this population is poorly understood. To guide the NHS England HCV elimination strategy, the prevalence of HCV within this population needs to be established. We therefore conducted a systematic review to quantify HCV prevalence among people injecting PIEDs.

Method: The systematic review was conducted in accordance with the PRISMA statement. EMBASE, Medline, PsycINFO, CINAHL and Scopus databases were searched. Inclusion criteria were any study reporting HCV prevalence among any population that injected PIEDs. Quality was assessed using an adapted Newcastle-Ottawa Quality Assessment Scale.



Results: Thirteen studies met the inclusion criteria. These included 2491 PIED users in studies from Australia (n = 8), United Kingdom (n = 3), Brazil (n = 1) and United States of America (n = 1). The weighted pooled prevalence was 5.06% (range 0-20%) amongst a demographic that was predominantly male. The Forest plot demonstrates the individual prevalence per study and the pooled prevalence with calculated confidence intervals (for total users, 4.26–5.99%). There was heterogeneity between studies due to inconsistent sampling strategies.

Conclusion: Prevalence rates within the included studies indicate PIED users are a high risk group for HCV. This justifies the need for a public health focus on this population as part of the global elimination strategy. However, study heterogeneity and low quality highlights the need for cross-sectional studies to accurately quantify the scale of the epidemic.

°EASL guidelines.
*Weakly dominated strategy: higher ICER than that of a more effective alternative strategy

and its complications; this raises the question of expanding treatment eligibility. The aim of this study was to evaluate the cost-effectiveness of providing treatment to all patients with chronic HBV infection.

Method: A Markov model was developed to simulate disease progression in naïve HBV mono-infected adults, from diagnosis to death. Outcomes were compared for 4 strategies (Table). Patients characteristics were obtained from the French ANRS CO22 HEPATHER cohort. Background and liver disease-related mortality, disease progression rates, viral and biochemical response, and quality adjusted life years (QALYs) inputs were from French and international literature. Direct costs related to health states, including ambulatory and hospital fees, were obtained from French chronic HCV-infected patients. Prices of generic NAs were set at €1333.80 per year. The study perspective was societal. Discount rate was 2.5% for costs and effectiveness. Incremental cost-effectiveness ratios (ICERs) were interpreted according to French GDP per capita (€39,350 in 2017). Extensive sensitivity analysis was performed.

Results: Treating all patients (S4) was the most expensive but also the most effective strategy (with a lifetime mean gain of 0.06, 0.25 and 0.26 QALYs compared to S3, S2 and S1, respectively) and was cost-effective compared to S3 (ICER = 31,682 €/QALY). S2 was dominated by S3 that was highly cost-effective compared to S1 (ICER = 11,572 €/QALY). In sensitivity analysis, parameters having the greatest impact were utilities values under treatment, with or without response: a 10% decrease in health-related utilities for non-responsive patients increased the ICER beyond the French GDP per capita (44,986 €/QALY).

Conclusion: At current NAs efficacy and costs, expanding treatment eligibility to all patients with chronic HBV infections is cost-effective.

SAT291

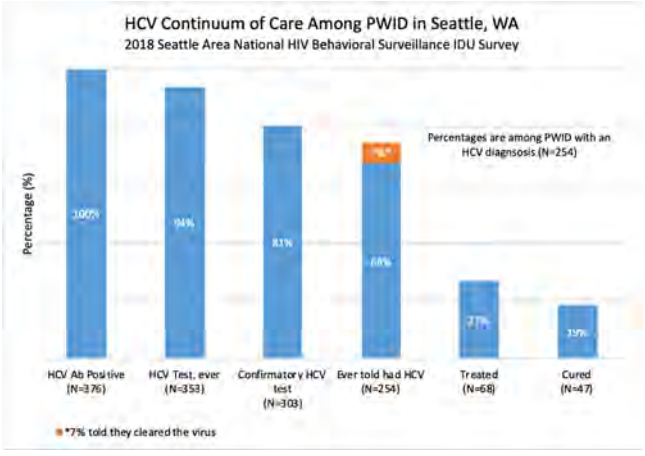
Hepatitis C continuum of care and predictors of direct acting antiviral treatment among persons who inject drugs in Seattle, Washington, USA

Maria Corcoran[1], Judith Tsui[2], John D Scott[1], Julia C Dombrowski[1], Sara N Glick[1]. [1]*University of Washington, Division of Allergy and Infectious Diseases, Department of Medicine, Seattle, United States;* [2]*University of Washington, Division of General Internal Medicine, Department of Medicine, Seattle, United States*
Email: corcom@uw.edu

Background and Aims: Direct acting antivirals (DAAs) have revolutionized the landscape of hepatitis C (HCV) care. However, treatment rates among persons who inject drugs (PWID) have historically been low, and it is unclear whether DAA receipt in this population is sufficient to reach elimination goals. We report the continuum of care for HCV and describe predictors of treatment with DAAs among PWID in Seattle, Washington, USA.

Method: This study analyzed data from the 2018 Seattle area National HIV Behavioral Surveillance (NHBS) survey of PWID. Persons were included in the study if they were ≥18 years of age; injected drugs in the past year; and completed the core NHBS survey, a local survey supplement, and rapid HCV antibody test. Among those who were HCV antibody positive, we calculated the proportion who self-reported prior receipt of: 1) any HCV test, 2) a confirmatory HCV test, 3) a diagnosis of HCV, 4) HCV treatment, and 5) HCV cure. Proportions were subsequently stratified by gender and age. Multivariable logistic regression, accounting for the respondent driven sampling method, was used to calculate the adjusted odds ratios (AOR) for having received DAA therapy among those who tested HCV antibody positive.

Results: The sample included 533 PWID, 376 (71%) of whom tested positive for antibodies to HCV. Among those who were HCV antibody positive, 94% reported any prior HCV test, 81% reported a prior confirmatory HCV test, and 68% were previously told they had HCV. Of those reporting a prior diagnosis of HCV, 27% had undergone treatment, with 19% of those diagnosed achieving a cure. Among those diagnosed, fewer women had received HCV treatment (16%) than men (31%), and fewer PWID <40 years of age had been treated (13%) than PWID ≥40 years of age (33%). In a multivariate model, age (AOR 1.04 per year, 1.02–1.05), homelessness (AOR 0.52, 0.31–0.88) and gender were strong predictors of DAA therapy, with women being 58% less likely than men to have received prior treatment with DAAs (AOR 0.42, 0.23–0.75).



Conclusion: Despite high rates of HCV testing among PWID in Seattle, treatment rates remain low in the DAA era. In particular, treatment of women, young adults and persons experiencing homelessness is lagging behind in this high-risk urban cohort. While falling drug costs and the recent removal of DAA prior authorization requirements for Medicaid patients in Washington State may improve treatment uptake in the coming years, increased efforts are needed to link PWID into care, particularly women, young adults and homeless individuals.

SAT292

Dried blood spots are a useful tool for hepatitis A screening in the pandemic areas with medical resource-limited condition

Chikako Yamamoto[1], Junko Tanaka[1,2], Vichit Ork[3], Shintaro Nagashima[1], Channarena Chuon[4], Ko Ko[1], Mao Bunsoth[5], Md. Shafiqul Hossain[6]. *[1]Hiroshima University, Department of Epidemiology, Infectious Disease Control and Prevention, Graduate School of Biomedical and Health Sciences, Hiroshima, Japan; [2]Hiroshima University, Project Research Center for Epidemiology and Prevention of Viral Hepatitis and Hepatocellular Carcinoma, Hiroshima, Japan; [3]Ministry of Health, National Immunization Programme, Phnom Penh, Cambodia; [4]Public Health Units of Doctor Alliance of Union of Youth Federations of Cambodia, Phnom Penh, Cambodia; [5]University of Health Sciences, Senior Researcher, Lecturer, and Head of Library, Phnom Penh, Cambodia; [6]World Health Organization Regional Office for the Western Pacific, Expanded Programme on Immunization, Phnom penh, Cambodia*
Email: jun-tanaka@hiroshima-u.ac.jp

Background and Aims: Approximately 1.4 million people are infected with hepatitis A virus (HAV) worldwide each year and it caused approximately 11,000 of deaths in 2015 (WHO, 2018) due to its complication. The majority of HAV infection is transmitted fecal-orally via contaminated food and water especially in the areas where water drainage and sewage system are suboptimal. Therefore, HAV infection is closely related to the public health environment. Furthermore, It is difficult to conduct the sero-epidemiological survey by venous blood collection and to grasp anti-HAV prevalence accurately in the medical resource-limited areas. However, Dried Blood Spot (DBS) is a test kit that can collect blood with less invasive and easier than venous blood collection, and measurement of HAV sero-markers using DBS has not been reported so far. In this study, we aimed to establish the method for epidemiological survey of HAV infection using DBS in the developing countries.
Method: This study was conducted in 2017 among 5–7 years old children and their mothers living around Phnom Penh, Cambodia using multi-stage cluster sampling method. The samples were collected using both DBS (HemaSpot-HF blood collection device (HS), 60μl whole-blood/kit) and venipuncture. HS comprises absorbent paper equally separated into eight fragments with desiccant and is covered by a clear rubber with a hole in the centre. Three fin of absorbent paper were mixed and stirred with lysis buffer in 2 ml tube to get supernatant fluid. Then, a mixture of 20μl of supernatant fluid and 60μl of 5% albumin was measured for total anti-HAV (CLEIA) using Vitros Immunodiagnostic Product (Ortho Clinical Diagnostics). Cut off index (COI), sensitivity and specificity for anti-HAV measurement from HS sample were calculated by Receiver Operating Characteristic curve (ROC) analysis.
Results: DBS and serum samples were collected from 517 children aged 5–7 years and their 405 mothers. Anti-HAV positive rate by serum samples was 41.0% {positive: 212/517, borderline: 3/517, negative: 302/517} in children and 99.8% {positive: 404/405, border line: 0/405, negative: 1/405} in mother. By ROC analysis, C.O.I, the sensitivity and specificity of DBS samples (N = 922) were 2.1, 94.8% and 99.0% respectively.
Conclusion: The method for epidemiological survey of HAV infection using DBS was succeeded to be established.

Viral hepatitis in Belgian prisons: a first-time multicenter prevalence study

Dana Busschots[1,2], Rob Bielen[1,2], Özgür Koc[1,2,3], Eefje Dercon[4], Christian Brixko[5], Pierre Laukens[6], Pascal Bilaey[6], Francis De Smet[6], Geert Hellemans[6], Gaetan Muyldermans[7], Luc Van Baelen[7], Hans Van Vlierberghe[8], Geert Robaeys[1,2,9]. *[1]Hasselt University, Health and Life Sciences, Diepenbeek, Belgium; [2]Ziekenhuis Oost-Limburg, Department of Gastroenterology, Genk, Belgium; [3]Maastricht University, Medical Microbiology, School of NUTRIM, Maastricht, Netherlands; [4]zorGGroep Zin vzw (fusie van CGG VGGZ en CAD Limburg), Hasselt, Belgium; [5]CHR de la Citadelle, Department of Gastroenterology and Hepatology, Liège, Belgium; [6]Fod Justitie, Spf Justice, Dienst Coördinatie Medische Zorg, Brussel, Belgium; [7]Sciensano, Epidemiology and Public Health, Brussels, Belgium; [8]Ghent University Hospital, Department of Gastroenterology and Hepatology, Gent, Belgium; [9]UZ Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium*
Email: dana.busschots@uhasselt.be

Background and Aims: Prevalence of hepatitis C virus (HCV) and hepatitis B virus (HBV) infection among prisoners is many times higher than in the general population. The high rates of viral hepatitis infection in prisoners, and the substantial risks associated with an untreated infection underline the need for screening and access to treatment in prisons. To date, there is no targeted screening in Belgian prisons and currently there are no data on the prevalence of HCV or HBV infections in prison. Through targeted screening, we want to map the prevalence of HCV and HBV in prisons in Belgium.
Method: The study started on 1 April 2019 in several prisons for both prisoners in pre-trial detention and long-term convicts throughout Belgium. The eligible candidates (>18 y and signed informed consent form) were tested by finger prick for HCV antibodies (Ab) using the Oraquick® test and hepatitis B surface antigen (HBsAg) using the HBsAg Rapid Test Device®. While waiting for the results (20 minutes), an encoded questionnaire was filled out.
Results: From 1 April 2019 till 7 November 2019 a total of 456 prisoners were screened. Of these, 21 (4.6%) tested positive for HCV Ab and 5 (1.1%) tested positive for HBsAg. The prevalence of HCV Ab did not differ in prisoners in pre-trial detention compared to long-convicts, respectively 10/160 (6.3%) and 11/285 (3.9%, p = 0.159). All participants who tested positive on one of the tests was referred to the physician in prison for a vene puncture to determine HCV RNA. To date, HCV RNA was determined in 12/21 and was present in 8 (66.7%).
Conclusion: These preliminary results show an increased prevalence for HCV Ab in prisons in Belgium. This is markedly lower than mentioned in previous European studies.

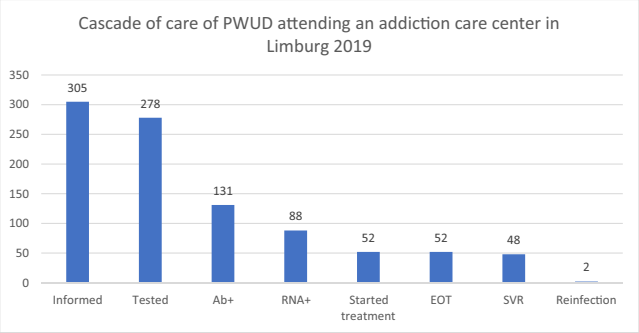
SAT294

Limburg is the first Belgian province on track for hepatitis C virus eradication in the most important group at risk: People who use drugs

Dana Busschots[1,2], Rob Bielen[1,2], Özgür Koc[1,2,3], Eefje Dercon[4], Rita Verrando[4], Geert Robaeys[1,2,5]. *[1]Hasselt University, Health and Life Sciences, Diepenbeek, Belgium; [2]Ziekenhuis Oost-Limburg, Department of Gastroenterology, Genk, Belgium; [3]Maastricht University, Medical Microbiology, School of NUTRIM, Maastricht, Netherlands; [4]zorGGroep Zin vzw (fusie van CGG VGGZ en CAD Limburg), Hasselt, Belgium; [5]UZ Leuven, Department of Gastroenterology and Hepatology, Leuven, Belgium*
Email: dana.busschots@uhasselt.be

Background and Aims: Hepatitis C virus (HCV) is one of the leading causes of chronic liver disease and liver-related deaths worldwide. HCV and HCV reinfection is most prevalent in Belgian people who inject drugs (PWID). PWID are at the heart of the ongoing HCV epidemic. To avert future liver disease and new infections, prevention of HCV transmission among PWID is crucial. Recent modelling shows that to eliminate HCV in Belgium, more people must be tested and linked to care, and the average percentage of patients to be treated per year out of the total pool of patients to be treated needs to be fixed at a minimum of 8% of the current patient pool. The aim of this project is to eradicate HCV in people who use drugs (PWUD) in an addiction care centre in Limburg and to monitor reinfection after therapy.
Method: In this ongoing prospective cohort study started in November 2016 in an addiction care centre, case management is performed by an HCV nurse. The nurse informs PWUD about HCV, and performs on-site screening of HCV anti-bodies (Ab) using the OraQuick® rapid test by finger prick or HCV RNA by vene puncture upon informed consent. All HCV RNA positive PWUD are referred to

the hospital for potential treatment. The HCV nurse accompanies them if necessary. After cure, these PWUD are monitored by the HCV nurse for potential reinfection by yearly screening.
Results: In Limburg 357 clients received opiate agonist therapy in 2019. The case manager personally informed 305/357 (85.4%). Out of 305 informed clients 278 (91.1%) accepted on-site screening. Of those who were chronically infected, 52/88 (59.1%) started therapy. All 52 (100%) PWUD were cured successfully. From the start of the project to the present only two out of 52 (3.8%) treated PWUD got reinfected due to ongoing intravenous drug use.



Conclusion: Limburg is as the first Belgian province on track to meet the goals of the World Health Organization to eradicate HCV by 2030 in a PWUD population. With the case management program every PWUD attending an addiction care center in Limburg can be screened and after treatment they are closely monitored for reinfection.

Early treatment of hepatitis C virus improves health outcomes and yields cost-savings: A modeling study in Argentina

Diego Kanevsky[1], María Rodriguez[1], Yuri Sanchez[2], Jorge Elgart[3], Mariana Glanczspigel[4], Natalia Albaytero[4], Manuel Mendizabal[5].
[1]AbbVie, Argentina; [2]AbbVie, Mettawa, United States; [3]Cenexa, La Plata; [4]3Eff, Buenos Aires, Argentina; [5]Hospital Universitario Austral, Pilar Centro, Argentina
Email: diego.kanevsky@abbvie.com

Background and Aims: Patients with hepatitis C virus (HCV) face increased healthcare costs due to hepatic and extrahepatic complications. The new all-oral direct-acting antivirals have dramatically improved the sustained virological response (SVR) rates. Achieving SVR has shown to increase health benefits and reduce medical costs. While treatment in early stages of liver fibrosis has been shown to reduce liver-related complications and lower healthcare costs compared to treatment in later disease stages, it is often delayed and patients in early fibrosis stages have limited access to effective treatment. Thus, this study evaluated the clinical and economic impact of treating patients in Argentina with HCV at early vs late stages of liver disease.
Method: A Markov model of the natural history of HCV was used to forecast liver-related and economic outcomes over a lifetime from the perspective of Argentina's social security sector. Health utilities and transition probabilities were drawn from published literature. Treatment attributes and patient demographics were based on registrational clinical trials of glecaprevir/pibrentasvir. Costs were based on tariffs from Argentina's social security system. Analyses were conducted for patients with HCV genotypes 1–6 and different fibrosis stages of liver disease: mild (F0-F1); moderate (F2-F3), and compensated cirrhosis (F4). Health outcomes included lifetime risks of compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), liver transplant (LT), and liver-related death (LrD). Other outcomes included lifetime costs and quality-adjusted life years (QALYs), both discounted at a 5% rate.
Results: In this simulated model, treating HCV infection at early stages of fibrosis appeared to reduce the risk of CC, DCC, HCC, LT and LrD (Table). Delaying treatment increased long-term total lifetime costs and provided fewer QALYs. Early treatment was a dominant strategy regardless of time of delay as it delivered more QALYs at lower costs.

Outcome	Liver fibrosis stages		
	Mild (F0-F1)	Moderate (F2-F3)	CC (F4)
CC Risk (%)	7.2	17.6	100.0
DCC Risk (%)	2.0	6.1	8.3
HCC Risk (%)	0.9	2.6	27.7
LT Risk (%)	0.2	0.6	1.9
LrD Risk (%)	1.8	5.8	30.7
SVR (%)	97.9	97.9	98.9
Total Costs (AR$)	954,018	967,673	1,437,816
Total QALYs	11.5	9.9	7.5

Conclusion: This analysis suggests that treating HCV at early stages improves health outcomes and reduces the total cost in Argentina. Hence, clinical and policy decision-makers should avoid delays and restrictions in HCV treatment.

SAT296

Tailored message interventions promote the number of participants in viral hepatitis screening for Japanese workers - multicenter trial of 1,127,596 general checkup applicants

Masaaki Korenaga[1], Chieko Ooe[2], Keiko Kamimura[3], Tatsuya Ide[4], Satoshi Mochida[5], Takako Inoue[6], Jun Fukuyoshi[7], Tatsuya Kanto[1].
[1]National Center for Global Health and Medicine, The Research Center for Hepatitis and Immunology, Hepatitis Information Center, Ichikawa Chiba, Japan; [2]Japan Health Insurance Association, Fukuoka; [3]Japan Health Insurance Association, Fukuoka, Japan; [4]Department of Medicine, Kurume University School of Medicine, Division of Gastroenterology, Kurume, Fukuoka, Japan; [5]Saitama Medical University, Department of Gastroenterology & Hepatology Faculty of Medicine, Iruma-gun, Saitama, Japan; [6]Nagoya City University Hospital, Department of Clinical Laboratory Medicine, Nagoya, Japan; [7]Keio University, Graduate School of Health Management, Fujisawa, Kanagawa, Japan
Email: dmkorenaga@hospk.ncgm.go.jp

Background and Aims: Although more than 20 million community residents have been provided an opportunity to undergo hepatitis B virus (HBV) and hepatitis C virus (HCV) screening by the Japanese government, actions against hepatitis at work sites in Japan have not yet been fully implemented. In Japan Health Insurance Association, which is belonged to about 40 million Japanese who are working in Medium and Small Sized Companies, the attendance rates of hepatitis screening were low prevalence even the cost of only € 5. The aim of this study was to investigate the effectiveness of a tailored message intervention promoted the numbers of viral hepatitis screening, compared with a typical message.
Method: A leaflet which was a tailored message condition for the screening was individually sent to more than one million Japanese workers at 3 brunches of Japan Health Insurance Association who wish to get annual general checkup in 2018 as multicenter trial. For control subjects, we enrolled general checkup applicants with a a typical message condition in 2017. The main outcome measure was attendance rates in HBV and HCV screening which were examined HBs antigen (HBsAg) and Anti-HCV antibody (anti-HCV), respectively.
Results: There was a significant difference in viral hepatitis screening attendance rates between the tailored matched-message condition (n = 112,581 10%) and the control (n = 13,452 1.3%; $p < 0.001$). One thousands thirty workers (1.2%) were positive of HBsAg (n = 588, 0.52%) and anti-HCV (n = 442, 0.39%), respectively. Among them, four hundred ninety-four (48%) were confirmed to visit specialists within 6 months after the screening. One hundred fourteen in HCV positive

	The number of General Checkup		The number of screening (rate)		The number of positive (rate)	
Branch	Control	Tailored Message	Control	Tailored Message	HBsAg	Anti-HCV
A	376,223	404,838	4,791	72,508	413	227
B	213,396	256,650	2,365	20,292	96	54
C	418,649	466,108	6,296	19,781	79	161
Total	1,008,268	1,127,596	13452(1.3%)	112581(10%)	588(0.52%)	442(0.39%)

Figure: (abstract: SAT296)

(26%) were treated with IFN-free direct-acting antivirals and five males in their 50–60 s (0.4%) were detected hepatocellular carcinoma.

Conclusion: There are still many patients who infected HBV and HCV at work sites in Japan. A tailored-message intervention designed to increase the viral hepatitis screening rates in the Medium or Small Sized Companies. Promoting hepatitis virus screening for workers at general check-up can help detect carriers who are unaware of their infection and require to therapy for viral elimination and cancer.

SAT297

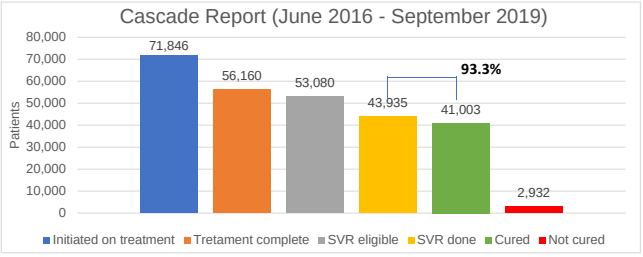
Data from a large, public sector hepatitis C program in Punjab, India

Sajal Marwaha[1], Radha Krishan Dhiman[2], Siddharth Sindhwani[1], Caroline Boeke[1], Karishma Mutreja[1], Gagandeep Singh Grover[3]. *[1]Clinton Health Access Initiative, New Delhi, India; [2]PGIMER, Chandigarh, Department of Hepatology, Chandigarh, India; [3]National Viral Hepatitis Control Program, Government of Punjab, State Program Officer, Department of Health and Family Welfare, Chandigarh, India*
Email: smarwaha@clintonhealthaccess.org

Background and Aims: Hepatitis C virus (HCV) is a rising challenge in India, with an estimated 5.2–13 million people anti-HCV antibody positive. The state of Punjab has a higher prevalence of HCV compared to national prevalence estimates (3.3% vs. 0.5–1.5%). In 2016, the Punjab government launched the 'Mukh Mantri Punjab Hepatitis-C Relief Fund' to provide free HCV treatment to all infected residents. The Clinton Health Access Initiative, in collaboration with the Punjab government, developed an online Monitoring & Evaluation (M&E) system, the first in the country for HCV, to measure outcomes of program implementation, identify gaps and areas for improvement, and ultimately optimize effectiveness of the program. This analysis documents the results achieved to date in Punjab's HCV program based on M&E system data.

Method: Data from 25 medical facilities was downloaded using the M&E system in Punjab. Descriptive statistics were utilized to assess the demographics and clinical characteristics of the patient population and the percentage of patients achieving cure as determined by the sustained virological response 12 weeks (SVR12) following treatment.

Results: From June 2016-September 2019, 71,846 patients were initiated on direct acting antiviral (DAA) therapy for HCV in Punjab. 60.1% of patients were 31–60 years and 66.4% of patients were male. 86.2% of patients were non-cirrhotic. Unsafe injection use and intravenous drug use were the most common risk factors reported by patients (32.0%). The most common drug regimen prescribed was SOF/DCV for 12 weeks (81.1%). Since initiation, 56,160 patients have completed treatment (78.2% of those who initiated treatment), 5,643 patients are currently on treatment, and 10,043 (14.0%) were lost to follow-up after treatment initiation. SVR12 was conducted for 43,935 patients (78.2% of those who completed treatment), of which 41,003 (93.3%) demonstrated cure.



Conclusion: Punjab successfully underwent a massive scale-up of HCV treatment in the public sector. Although loss to follow-up was significant, among those who returned for follow-up, SVR12 was high. Generic SOF/DCV performed very well across a variety of genotypes in this real-world setting. Future areas of research should focus on improving retention and addressing the small but significant problem of virologic failure with first line DAAs.

SAT298

Implementation of electronic monitoring and evaluation system for hepatitis C in Punjab, India

Sajal Marwaha[1], Radha Krishan Dhiman[2], Umesh Chawla[1], Siddharth Sindhwani[1], Caroline Boeke[1], Karishma Mutreja[1], Gagandeep Singh Grover[3]. *[1]Clinton Health Access Initiative, New Delhi, India; [2]PGIMER, Chandigarh, Department of Hepatology, Chandigarh, India; [3]National Viral Hepatitis Control Program, Government of Punjab, State Program Officer, Department of Health and Family Welfare, Chandigarh, India*
Email: smarwaha@clintonhealthaccess.org

Background and Aims: Hepatitis C virus (HCV) is a rising challenge in India, especially in the northern state of Punjab where the prevalence is estimated to be 3.3%. Nowadays, information plays a key role in disease prevention planning and decision-making processes. Thus, the Clinton Health Access Initiative (CHAI), in collaboration with Punjab government, developed an online Monitoring and Evaluation (M&E) system for the state to record the patient information and create meaningful interventions. This abstract documents the implementation process of the first ever electronic HCV M&E system in Punjab.

Method: CHAI designed treatment cards and a corresponding electronic M&E system to capture relevant patient information. The system is comprised of eight patient modules across the cascade of care: Registration, screening, viral load testing, base-line liver and blood testing, co-infection history, drug prescription, dispensation schedule and Sustained Virologic Response testing (SVR). A combination of open source technologies (PHP & MySQL) and an android application were utilized to capture patients' data offline, as some health facilities did not have stable internet connection. The data from the application can be stored offline and later synced online once internet connection is established. A web-based reporting dashboard was also developed to enable program managers to monitor program outcomes and take timely corrective action as

needed. Reports on the patient cascade and missed appointments were designed to identify trends in loss to follow-up at different stages and identify areas/facilities/patients needing additional support. To roll out the system efficiently, CHAI conducted comprehensive trainings for healthcare workers and partners which included hands-on practice, and assisted with additional on-site trainings as needed.

Results: As of today, the system has been successfully implemented in 25 medical facilities (22 district hospitals and 3 government colleges) in Punjab and captured data from ~100,000 patients screened for HCV. Results show that an electronic M&E system for the management of hepatitis was a requirement in Punjab because the infrastructure provided useful information to all the stakeholders. This system has enabled the government and key stakeholders to maintain accurate patient records, monitor results, and follow-up efficiently. Follow-up actions taken based on information provided by the M&E system have led to program improvements around diagnostic algorithms, treatment, and patient retention in care.

Conclusion: Overall, Punjab's M&E system has generated meaningful information that has been utilized to design targeted interventions for high risk groups and strategies for screening scale-up. In 2019, the system was used as a blueprint for India's national HCV M&E system to track program scale-up and mitigate challenges along the way.

SAT299

Hepatitis C elimination in hemodialysis population of a county - an innovative collaborative care model in Taiwan

Tsung-Hui Hu[1], Wei-Wen Su[2], Chi-Chao Yang[3], Chi-Chieh Yang[4], Sam Li-Sheng Chen[5], Hsiao-Ching San[6], Yen-Po Yeh[6], Hsiu-Hsi Chen[7].
[1]Kaohsiung Chang Gung Memorial Hospital, Division of Hepato-Gastroenterology, Department of Internal Medicine, Kaohsiung, Taiwan; [2]Changhua Christian Hospital, Changua, Taiwan; [3]Changhua Hospital, Ministry of Health and Welfare, Changhua, Taiwan; [4]Show Chwan Memorial Hospita, Changhua, Taiwan; [5]Taipei Medical University, School of Oral Hygiene, College of Oral Medicine, Taipei, Taiwan; [6]Changhua County Public Health Bureau, Changhua, Taiwan; [7]National Taiwan University, Graduate Institute of Epidemiology and Preventive Medicine, College of Public Health, Taipei, Taiwan
Email: dr.hu@msa.hinet.net

Background and Aims: HCV micro-elimination, which focuses on smaller, targeted high-risk subpopulations, has been proposed for achieving global elimination of HCV. Patients with end stage renal disease (ESRD) had a high incidence of HCV infection (8–12%). There are several barriers to treat HCV patients in dialysis centers due to unawareness, unwillingness, and difficulty of referral due to long journey and patients' disability. The objective of this study is to demonstrate the efficiency of the novel delivery model in achieving

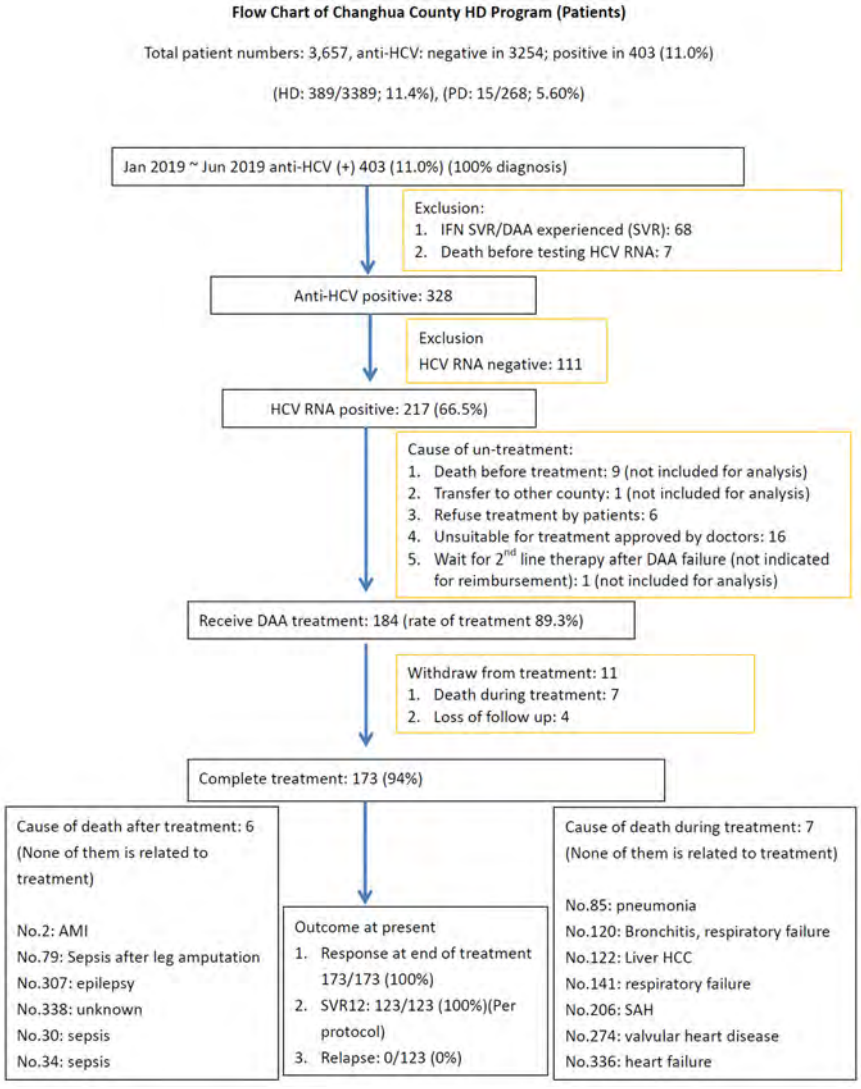


Figure: (abstract: SAT299)

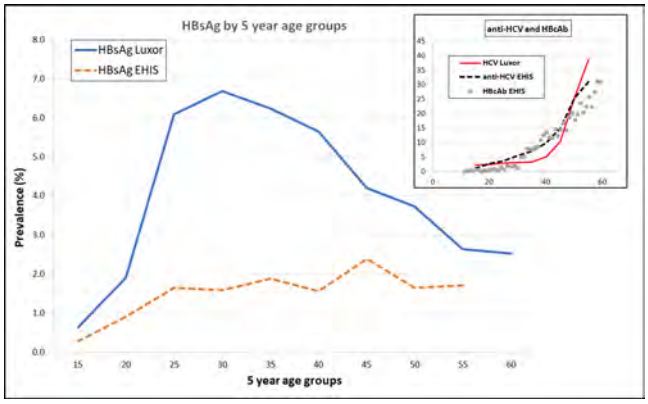
the elimination of HCV among hemodialysis patients in 31 dialysis centers in the jurisdiction area under a Public Health Bureau of Changhua County in Taiwan.
Method: A total of 31 hemodialysis (HD) centers are managed and the micro-elimination program was implemented (led by the public authority). To overcome the barrier of HCV treatment, mobile clinics were set up at HD centers that did not have a hepatologist/gastroenterologist. This team was responsible for delivering a continuum of care from screening, diagnosis, treatment, and follow-up on site. The treatment regimen included either grazoprevir/elbasvir (GZP/EBV; Merck) or glecaprevir/pibrentasvir (GLE/PIB; AbbVie). The primary outcome includes the achievement of HCV micro-elimination, which was defined as per WHO criteria and sustained virological response rates at 12 weeks after treatment (SVR12).
Results: A total of 3,657 patients visiting Changhua County HD and peritoneal dialysis (PD) centers from Jan 2019 to Jun 2019 were screened. Among the patients, 403 (11.0%) patients were seropositive for HCV. Finally, a total of 184 viremic patients received treatment (coverage rate 89.3%). The flow chart of diagnosis and treatment is shown figure. The mean age is 66 years, ranged from 40 to 90 years old, and the longest dialysis period is 30 years. Genotype (GT)-1 patients made up 50%, and GT-2 made up about 40% of patients. Finally, 83% of patients were treated with the GLE/PIB, the others were GZP/EBV and LDV/SOF. Among the treated patients, 173 patients (94%) completed the course of treatment. Seven patients died during treatment, and 6 patients died after EOT and before SVR12. None of the death was considered to be related to DAA therapies. The response rate at EOT and SVR12 are all 100% according to per protocol analysis. Notably, we also surveyed the incidence of HCV for the 619 staff at HD centers with a coverage rate of 98.7%. Only 5 patients were positive for anti-HCV (0.82%) in which 4 patients have been already treated. Only 1 patient was viremic but has since completed DAA therapy under this program.
Conclusion: Our study has demonstrated that the novel treatment-delivery approach with mobile clinics can achieve elimination of HCV in ESRD subpopulation in a very short period of time. We hope that the success of this program would encourage the implementation of methods to accelerate HCV eradication globally.

SAT300

Unusual occurrence of hepatitis B infection in Upper Egypt

Gamal Soliman[1], Mahmoud S. Elzalabany[2], DeWolfe Miller[3]. [1]*Faculty of Medicine, Al-Azhar University, Tropical Medicine, Gastroenterology and Hepatology Department, Cairo, Egypt;* [2]*Ahmed Maher Teaching Hospital, Internal Medicine Department, Cairo, Egypt;* [3]*John A. Burns School of Medicine, University of Hawaii, Honolulu, Hawaii, United States*
Email: dr_msf@hotmail.com

Background and Aims: The high prevalence of HCV in Egypt is well documented. The Egyptian government has implemented a countrywide program to control HCV, which includes mass screening campaigns to diagnose and treat asymptomatic cases at a national level. Much less is known on the prevalence of HBV in Egypt.
Method: Luxor HCV Treatment Center was established in 2016 by the national Tahya Misr Fund to screen and treat HCV infection in Luxor city and the surrounding areas in Upper Egypt. The center adopted a unique mass screening program for both HBV and HCV. Participants aged 16 years and older were screened, at no cost, for anti-HCV antibodies (anti-HCV) and hepatitis B surface antigen (HBsAg) using third generation enzyme immunoassays (Enzygnost® Anti-HCV and HBsAg). This report focuses on HBV screening results in Luxor with comparison to the national level HBV results of the 2015 Egyptian Health Issues Survey (EHIS).
Results: From June 2016 to May 2017, 67,007 persons were screened for HBsAg at Luxor center, including 31,945 males (47.7%) and 35,062 females (52.3%). The mean age was 43.6 years. There were 2,947 persons (4.4%) positive for HBsAg. HBsAg prevalence was significantly higher in males versus females (6.2% vs. 2.75% OR = 2.3; $p < 0.0001$). The age specific pattern of HBsAg prevalence has a steep increase to age 31 (7.7%) followed by a decline to age 60. In EHIS 2015, 26,047 persons aged 1-59 years were screened for anti-HCV, Hepatitis B core antibody (HBcAb) and HBsAg, including 12,319 males (47.3%) and 13,728 females (52.7%). The overall prevalence of HBcAb was 9.9% (11.3% in males - 8.7% in females), compared to 1% for HBsAg (1.2% in males - 0.8% in females). This included 274 persons sampled from the Luxor area, in which HBcAb and HBsAg prevalence was 18% and 1.7% respectively. The age specific patterns of anti-HCV, HBcAb and HBsAg in EHIS and Luxor study are compared in Figure (1). Age specific HBsAg is higher in Luxor than the national estimates. Age specific HBcAb is strongly associated with anti-HCV in both the Luxor and EHIS estimates.



Conclusion: HBV infection is very high in Egypt as indicated by the high prevalence of HBcAb (9.9%) reported in EHIS. Most of these infections spontaneously resolve (HBcAb positive), and 1% of the patients remain chronically infected (HBsAg positive). Our results from Luxor showed an epidemiologically significant higher HBsAg prevalence (4.4%), which is higher in males and among those in middle age. This is a source of ongoing HBV transmission in the community. HBV screening and vaccination should be strengthened in this area of Upper Egypt.

SAT301

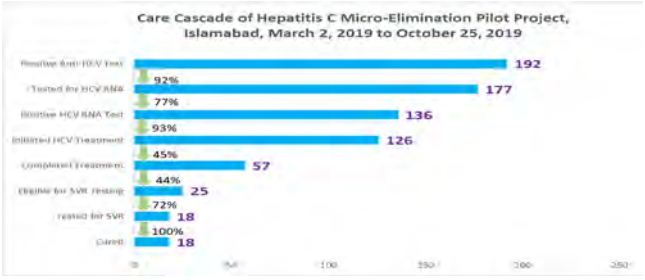
A novel test and treat hepatitis C micro-elimination project among underserved communities in Islamabad, Pakistan

Huma Qureshi[1], Hassan Mahmood[1], Nabil Ahmed[1], Jacqueline Safstrom[1], Lillian Lou[2], Muazzam Nasrullah[3], Francisco Averhoff[3], Ameer Abutaleb[4], Shyamasundaran Kottilil[4]. [1]*Integral Global Consulting, Atlanta, United States;* [2]*John C Martin Foundation, Palo Alto, United States;* [3]*Centers for Disease Control and Prevention, Division of Viral Hepatitis, Atlanta, United States;* [4]*University of Maryland, Institute of Human Virology, College Park, United States*
Email: nabil@integralglobal.net

Background and Aims: Pakistan has a large burden of hepatitis C virus (HCV) infection, and access to care and treatment is limited. In order to increase access for underserved populations, a same-day testing and treatment initiation model program for adults in marginalized communities (i.e *slums*) in Islamabad was launched on March 02, 2019. We describe the early results of the program.
Method: A total of 17 slums with an estimated total population of 50,000 in Islamabad have been selected by the Ministry of National Health Services, Regulations and Coordination for the project. This project includes free of charge hepatitis C testing and treatment and utilizes trained community health workers (CHWs). The CHWs visit every dwelling in the slum and offer household members aged ≥18 years screening for hepatitis C by a rapid hepatitis C antibody (anti-HCV) test. Those that test positive are referred to an established clinic

for diagnosis of active HCV infection (RNA) by GeneXpert. RNA results are made available to patients within two hours. If found to be infected with HCV, additional blood is obtained and tested to calculate the AST to Platelet Ratio Index (APRI). Subjects then receive counseling, and their first 4-week supply of sofosbuvir plus daclatasvir and the first of three doses of hepatitis B vaccine during the initial clinic visit. A treatment regimen of 12 weeks for non-cirrhotic (APRI<1.5) patients is prescribed and given by the medical officer of the project. Patients with an APRI ≥1.5 are treated by a staff hepatologist. Patients are seen every 4 weeks at the clinic and given refills on their medications and queried about adverse reactions, until the end of treatment. RNA testing is conducted at 12 weeks following completion of treatment to determine cure i.e. sustained virologic response (SVR). The CHWs ensure referral and follow-up of HCV infected persons.

Results: As of October, 25 2019, a total of 5,209 participants have been screened from three *slums*, 192 (3.6%) tested positive for anti-HCV and were referred to receive testing for active infection. Of those, 177 (92%) were tested for RNA, of which 136 (77%) had active HCV infection. A total of 126 individuals (93%) had initiated treatment, of which 57 (45%) had completed treatment. To date, 18 of 25 eligible persons were assessed for SVR and all of them achieved SVR. None of the 126 individuals who initiated treatment had been previously tested or treated for hepatitis C.



Conclusion: Same day hepatitis C testing and treatment initiation is feasible among underserved communities in urban slums in Pakistan. CHWs can be effective in reaching "*hard-to-reach*" populations with limited access to health services and achieving high rates of linkage to care and adherence with treatment for hepatitis C.

SAT302

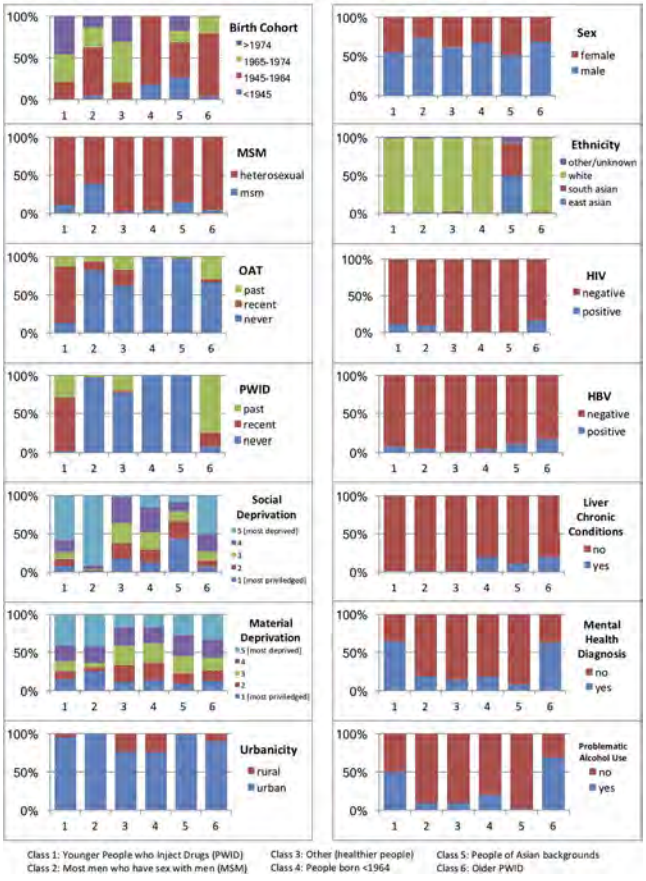
Classifying people living with hepatitis C virus using a population-level latent class analysis to inform optimal integration of health services

Emilia Clementi[1], Sofia Bartlett[2,3,4], Naveed Janjua[1], Stanley Wong[2], Amanda Yu[2], Dr. Margo Pearce[1,2], Mawuena Binka[2], Maria Alvarez[2], Dahn Jeong[1], James Wilton[2], Prince Adu[1,2], Younathan Abdia[1,2], Dr. Jason Wong[1,2], Mel Krajden[2,3], Jane Buxton[1,2], Michael Otterstatter[1,2], Zahid Butt[5], Geoff McKee[6]. [1]*University of British Columbia, School of Population and Public Health, Vancouver, BC, Canada;* [2]*BC Centre for Disease Control, Vancouver, Canada;* [3]*University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada;* [4]*Kirby Institute, University of New South Wales, Sydney, Australia;* [5]*University of Waterloo, Waterloo, Canada;* [6]*Vancouver Coastal Health Authority, Powell River, Canada*
Email: emilia.clementi@bccdc.ca.

Background: Since the advent of direct acting antivirals (DAAs), hepatitis C virus (HCV) treatment uptake has dramatically increased. As of 2018, only 54.4% of those diagnosed HCV RNA positive have been treated. HCV affects diverse and often overlapping populations, such as people who inject drugs (PWID), men who have sex with men (MSM), and immigrants from endemic regions. Assessing patterns of shared sociodemographic and clinical characteristics among subpopulations using Latent Class Analysis (LCA) may allow for targeted HCV program planning and services.

Method: The BC Hepatitis Testers Cohort includes all HCV cases in BC from 1990 to 2015 followed up to 2018 and linked with data on medical visits, hospitalizations, cancers, prescription drugs, and deaths. LCA was used to group 73,665 people diagnosed with HCV according to shared characteristics previously shown to be related to HCV treatment uptake (age, gender, ethnicity, sexual identity, urbanicity, socioeconomic status, use of injection drugs or opioid agonist therapy, alcohol use, mental illness, co-infections, and liver disease). Models were fit using 1–10 classes, with the best fitting model chosen based on fit statistics, epidemiological meaningfulness, and maximisation of posterior probability for class assignment. Classes were named by defining characteristics.

Figure 1: Characteristics of Latent Classes [on x-axis] of People Living with Hepatitis C in British Columbia.



Results: The best fitting LCA model had 6 classes with the following characteristics: 1. *Younger PWID:* (n = 11,123), included 46% born>1974, 69% recent PWID, 24.0% treated, top prescriber (TP) = general practitioners–36.4%; 2. *Most MSM* (n = 9,751) including 39% MSM, 100% urban, 92% most socially-deprived, 27.7% treated, TP = gastroenterologists (GAS)–32.7%; 3. *Other—healthier people* (n = 8,285): 24% rural, 0% liver disease, 22.1% treated; TP = GAS–35.6%; 4. *People born <1964* (n = 24,244) including 95% born <1964, 19% liver disease, 32.7% treated, TP = GAS–44.1%; 5. *People of Asian backgrounds* (n = 4,744) including 27% born <1945, 92% East/South Asian, 34.2% treated, TP = GAS–61.9%; and 6. *Older PWID* (n = 15,518) including 76% born 1945–1964, 16% HIV+, 76% past PWID, 21.0% treated; TP = infectious disease (ID)–29.3%. The treatment uptake and provider type differed by the LCA class; treatment uptake was lower among PWID and they were mainly prescribed treatment by general practitioner or ID specialists while GAS was the main prescriber for other groups.

Conclusion: LCA identified 6 classes with distinct characteristics which could be utilized to align services. Observed differences in HCV treatment between the classes suggests that the co-occurrence of multiple factors may influence uptake likelihood. Further analysis of health service utilization patterns related to patient profiles may inform optimal layout of services. This analysis may also inform approaches to address systemic barriers that impede care-cascade engagement.

SAT303

Comparison of risk factors for cirrhosis and hepatocellular carcinoma: a large prospective study of UK women

Emily He[1,2,3], Angela Balkwill[4], Bette Liu[5], Karen Canfell[1,2], Sarah Floud[4], Jane Green[4], Valerie Beral[4], Gillian Reeves[4]. [1]*University of Sydney, Sydney School of Public Health, Sydney, Australia;* [2]*Cancer Council NSW, Cancer Research Division, Sydney, Australia;* [3]*Concord Hospital, Gastroenterology and Liver Services, Sydney, Australia;* [4]*University of Oxford, Cancer Epidemiology Unit, Nuffield Department of Population Health, Oxford, United Kingdom;* [5]*UNSW Sydney, School of Public Health and Community Medicine, Sydney, Australia*
Email: emily.he@sydney.edu.au.

Background and Aims: Alcohol, smoking, adiposity and diabetes are associated with increased risk of cirrhosis and of hepatocellular carcinoma (HCC), but it is unclear whether the magnitude of the associated risks differ. This study aims to compare the magnitude of these risk factors for cirrhosis and HCC in a large cohort of UK women.
Method: In 1996–2001, a UK prospective study recruited 844,715 women, mean age 57 years (SD 5), with no prior liver disease or cancer who reported drinking at least one alcoholic drink per week. Participants completed a questionnaire at recruitment and were followed by record linkage to routinely collected National Health Service databases on hospital admissions, cancer registrations and deaths for first record of cirrhosis or hepatocellular carcinoma (HCC). Cox regression yielded adjusted relative risks (RRs) for both conditions in relation to alcohol, smoking, body mass index (BMI) and diabetes at recruitment.
Results: During a mean follow up of 18 years (SD 3), 5,999 incident cirrhosis and 1,603 HCC cases were identified. For all the four risk factors, the magnitudes of the associated relative risks were greater for cirrhosis than for HCC, particularly alcohol consumption and current smoking. The respective relative risks were: for ≥15 drinks of alcohol/week vs 1–2 drinks/week, 4.76 (95% CI 4.38–5.18) and 1.21 (95% CI 1.00–1.47); for current vs never smoking, 3.08 (95% CI 2.88–3.28) and 1.81 (95%CI 1.59–2.07); for each 5 unit increase in BMI, 1.40 (95% CI 1.34–1.45) and 1.31 (95% CI 1.21–1.41); and for a history of diabetes vs no history of diabetes, 3.10 (95%CI 2.77–3.47) and 2.26 (95%CI 1.78–2.87). All differences were statistically significant, except for BMI.
Conclusion: The magnitude of the relative risks associated with alcohol consumption, smoking, and to a lesser extent, diabetes and adiposity, were generally greater for cirrhosis than for HCC.

SAT304

Hepatitis C virus testing and treatment in children: results from a global paediatric policy review

Farihah Malik[1], Claire Thorne[1]. [1]*UCL Great Ormond Street Institute of Child Health, London, United Kingdom*
Email: farihah.malik.18@ucl.ac.uk.

Background and Aims: The first World Health Organization (WHO) global health sector strategy on viral hepatitis calls for the elimination of hepatitis B and C viruses (HBV and HCV) as a major public health threat by 2030. Our aim was to describe current status of hepatitis C policies in WHO Member States with a particular focus on paediatric diagnosis and treatment.
Method: Information on paediatric hepatitis C policies was extracted from current national strategic plans and clinical guidelines available online or through WHO's repository of viral hepatitis national policies, between January and June 2019. Policies on paediatric testing and treatment were summarised and coded.
Results: National policies for hepatitis C were available for 118 of the 194 WHO Member States. Of these 118, most had no policy recommendation for paediatric HCV (n = 77, 65%). HCV testing for children born to mothers with HCV was covered in only 34 (29%) national policies; earliest age at which testing was recommended varied. National policies in only 25 countries (21%) specifically mentioned HCV treatment for children (with a further 20 policies specifying a general "treat all" policy). Countries with recommendations on both testing and treating children (n = 18) were mostly from the European (n = 10), Americas (n = 3) and Eastern Mediterranean (n = 3) regions (Figure 1). Countries with policies only on testing (n = 16) were more geographically diverse but mostly high-income (n = 9) or upper-middle income (n = 3). Seven countries had policies on treatment only and most were high- or upper-middle income (n = 6). At the time of review, 25 country policies included details of paediatric treatment: 8 recommended Direct Acting Antiviral (DAA)-based regimens for adolescents > = 12 years (all published 2017–2019) and the rest recommended interferon/ribavirin-based regimens.

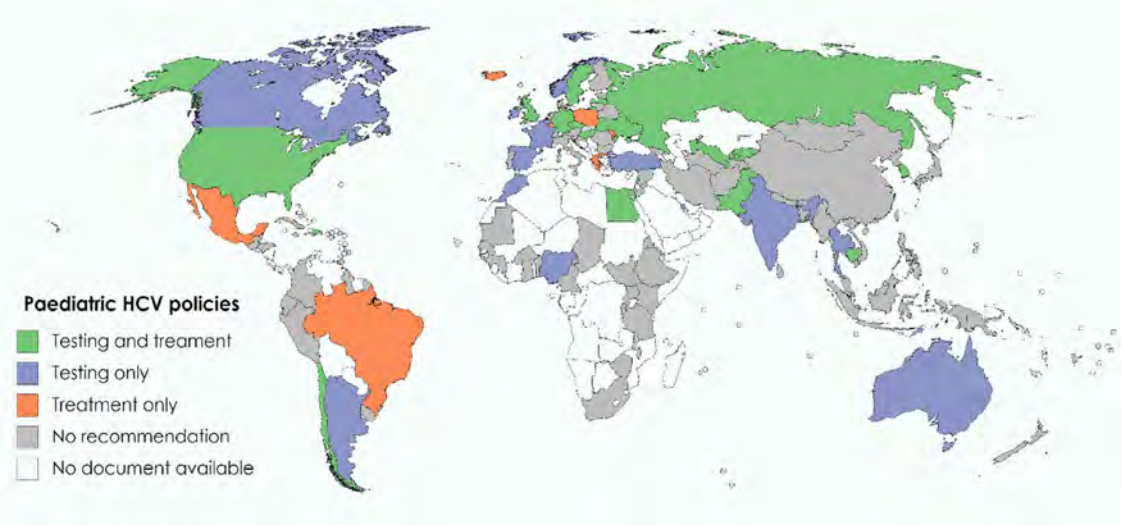


Figure: (abstract: SAT304): Countries with recommendations for paediatric HCV testing and treatment in national policy documents.

Conclusion: While countries have made progress in developing national strategies for elimination of HCV, this review highlights a gap in paediatric HCV policies. As Member States align their national programs with the ambitious WHO targets, children and adolescents must not be forgotten.

SAT305

HCV screening strategies targeting prisoners and immigrants from endemic countries: are they cost-effective?

Francesco Manca[1], Kathleen Boyd[1], Emma Robinson[2], John Dillon[2]. [1]*University of Glasgow, Health Economics and health Technology Assessment, Glasgow, United Kingdom;* [2]*University of Dundee*
Email: francesco.manca@glasgow.ac.uk.

Background and Aims: The World Health Organization target for HCV elimination by 2030 has broadened the boundaries of the debate around HCV to strategic and economic considerations. Understanding how to prioritize screening to reach the infected undiagnosed populations is crucial. This is imperative in the UK, where nearly half of the people infected are undiagnosed. This study evaluated the cost-effectiveness of a range of strategies for diagnosing HCV in specific high-risk populations in Scotland (UK) as a case study.
Method: Two high risk populations were identified: prisoners and high prevalence ethnic minorities. A cost-effectiveness analysis was undertaken for each population considering novel screening strategies such as opt-out testing policies in prisons and community outreach activities offering dry blood spot testing compared against the standard care diagnostic pathways for the specific subpopulations. The data sources were anonymised prison testing data and a previously published pilot study on a local outreach testing initiative. A decision tree explored the incremental cost per additional positive patient detected, and a Markov model was employed to present incremental cost per Quality Adjusted Life Years (QALYs) gained and Net Monetary Benefit (NMB) over a lifetime horizon.
Results: Screening prisoners for HCV with opt-out testing resulted in a 7.82-fold increase in detecting positive individuals compared to screening based on symptomatic detection, costing £366 per any additional detected individual. Offering tests at community outreach locations with individuals from countries of increased prevalence costs approximately £2100 per additional detected patient. In the lifetime analysis, both the strategies are highly cost-effective considering a £20,000/QALY threshold, with an incremental cost effectiveness ratio of £1,195 per QALY for the prison population and £4275/QALY for the ethnic-minority community outreach program.
Conclusion: Targeting high risks populations with screening established in prisons and at community outreach locations for ethnic minorities from endemic countries are both highly cost-effective strategies for reaching undiagnosed HCV patients. A combination of these strategies with others targeting high-risk populations such as injecting drug users would be vital to eradicate HCV by 2030.

SAT306

Relationship between metabolic syndrome and ALT level with normal range in the general population

Ju-Yeon Cho[1], Jae Yoon Jeong[2], Jung Hee Kim[3], Hong Joo Kim[4], Yong Kyun Cho[4], Byung Ik Kim[4], Won Sohn[4]. [1]*Chosun University Hospital;* [2]*National Medical Center;* [3]*Hallym University Dongtan Sacred Heart Hospital;* [4]*Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Internal Medicine, Seoul, Korea, Rep. of South*
Email: hand0827@naver.com.

Background and Aims: This study aimed to investigate the risk of metabolic syndrome in subjects with normal ALT level for the general population.
Method: Between 2007–2015, nationally representative samples from the Korean National Health and Nutrition Examination Survey was used to conduct a cross-sectional study. A total of 43,402 adults (men: 17,535 and women: 25,867) with ALT ≤40 U/L and without a history of hepatitis B, hepatitis C, liver cirrhosis, or liver cancer were analyzed. Stratification of the ALT level (men: <15 U/L, 15~30 U/L, and 30~40 U/L/women: <10 U/L, 10~20 U/L, 20~40 U/L) was done to evaluate for the risk of metabolic syndrome. Metabolic syndrome was defined by the updated National Cholesterol Education Program Adult Treatment Panel III standards.
Results: The prevalence of metabolic syndrome is significantly increased as ALT increases regardless of sex. The proportion of metabolic syndrome in men is 12.6%, 25.2%, and 39.7% in ALT <15 U/L, 15~30 U/L, and 30~40 U/L, respectively ($p < 0.001$) and that of metabolic syndrome in women is 7.2%, 23.3%, and 44.7% in ALT <10 U/L, 10~20 U/L, and 20~40 U/L, respectively ($p < 0.001$). There is an ALT-dependent relationship in the risk of metabolic syndrome within normal ALT level adjusting for age, alcohol intake, and body mass index. The adjusted odds ratios (ORs) of metabolic syndrome in men are 1.55 (95% confidence interval [CI]: 1.38–1.74), and 2.48 (95% CI: 2.16–2.85) in ALT 15~30 U/L, and 30~40 U/L, respectively ($p < 0.001$). And, the adjusted ORs of metabolic syndrome in women are 1.58 (95% CI: 1.35–1.86), and 2.67 (95% CI: 2.26–3.15) in ALT 10~20 U/L, and 20~40 U/L, respectively ($p < 0.001$).

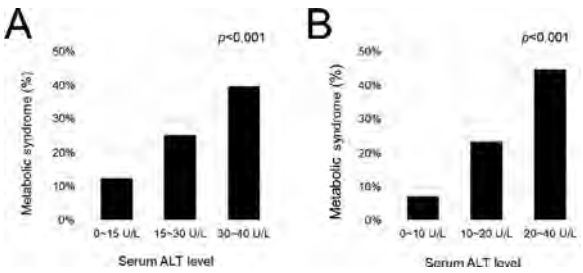

Figure: The prevalence of metabolic syndrome in subjects with ALT ≤40: male (A) and female (B). Abbreviations: ALT, alanine aminotransferase.

Conclusion: Although within the normal range, there is a greater risk of metabolic syndrome as ALT levels increase. ALT levels may potentially be a useful marker in detecting metabolic syndrome in the general population.

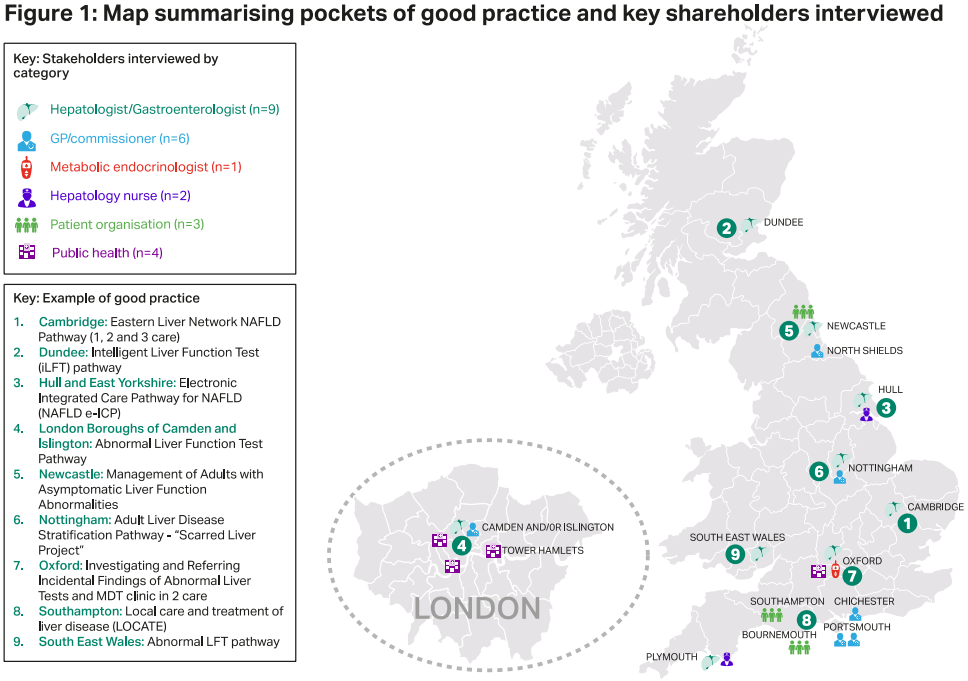
SAT307

Are UK NAFLD/NASH referral pathways ready to tackle the emerging epidemic? A rapid systematic public health evidence synthesis

Hannah Pheasant-Oldfield[1], Catherine Brogan[1], Adriana Wiesinger[2], Cheryl Westmacott[1], Murad Ruf[3]. [1]*Public Health Action Support Team, United Kingdom;* [2]*Gilead Sciences Ltd, National Market Access, London, United Kingdom;* [3]*Gilead Sciences Ltd, Medical Department, London, United Kingdom*
Email: hannah.pheasant@phast.org.uk.

Background and Aims: Non-alcoholic fatty liver disease (NAFLD/NASH) is an emerging and under-recognised global public health problem, primarily being driven by the "Diabesity" epidemic (obesity and type 2 diabetes). Real-world prevalence of NAFLD is unknown but synthetic UK estimates suggest ~20–30% (>13 million) adults. The majority of patients are undiagnosed and diagnosis is often in specialist care at an advanced stage associated with significantly greater risk of liver-related mortality. Primary care support is ad hoc with an inappropriate reliance on liver function tests. We aimed to understand the current provision of UK NAFLD care pathways.
Method: Phase 1: rapid review and comparative analysis of national and international guidelines; database search of peer-reviewed UK publications and grey literature on NAFLD pathways. Phase 2: qualitative semi-structured interviews with key stakeholders identified using purposive and snowball sampling; framework analysis to identify key themes.

Figure 1: Map summarising pockets of good practice and key shareholders interviewed



Results: Phase 1: we found divergence across all three NAFLD guidelines (EASL 2016, NICE 2016 and AASLD 2018) throughout the recommendations for assessment, diagnosis and management. 27 UK publications on NAFLD pathways were identified. These identify pockets of good practice across the UK (fig 1): innovative, yet differing, pathways that transfer diagnosis from specialist to primary care and lead to earlier and increased diagnosis of patients. Phase 2: key themes identified from 25 interviews (fig 1) included: **1. Challenges:** (a) limited public and professional disease awareness; (b) conflicting guidelines; (c) paucity of evidence within primary care; (d) gaps in treatment pathway (eg licenced pharmacotherapy, lifestyle services); (e) inadequate integration with obesity/diabetes pathways; (f) limited workforce capacity and capability; (g) no sustainable funding for NAFLD pathways **2. Success factors:** (a) emerging evidence for using non-invasive stratification tools in primary care; (b) innovative IT solutions (eg patient assessment templates, automated pathology algorithms); (c) importance of local champions (GPs, hepatologists).
Conclusion: At present no single generalisable NAFLD pathway exists for national implementation. UK case studies show both effectiveness and cost-effectiveness of implementing local pathways. Wider roll-out of integrated NAFLD referral pathways will be crucial to maximise patient benefit once effective treatment options become available.

SAT308
The case for testing and treating all HBV patients

Homie Razavi[1], Shakhlo Sadirova[2], Shokhista Bakieva[2], Kathryn Razavi-Shearer[1], Rick Dunn[1], Erkin Musabaev[2]. [1]*Center for Disease Analysis Foundation, Lafayette, United States;* [2]*Research Institute of Virology, Tashkent, Uzbekistan*
Email: homie.razavi@centerforda.com.

Background and Aims: Every 30 seconds someone dies of complications associated with HBV, and, >95% of all HBV infections are in low and middle-income countries (LMIC) where access to diagnostics can be limited. In addition, with few exceptions, the patients are expected to pay for their own screening, lab tests and treatment in these countries. The current clinical guidelines use a combination of viral load, age, ALT, and HBeAg results to determine treatment eligibility. This study examined the impact of a test & treat strategy where all HBsAg+ individuals are treated.
Method: A literature search was conducted to find studies that report long-term HCC incidence in populations that follow the current guidelines and in HIV/HBV infected cohort where all HBV patients are put on treatment. A separate search was conducted for find studies that report the long-term adverse events of TDF and TAF in HIV patients. Finally, an economic model was used to estimate the cost of a test & treat strategy as compared to the current guidelines after taking into consideration loss to follow up.
Results: The limited available data suggest a lower incidence of HCC in the HIV/HBV cohorts, where all HBV patients are put on treatment, as compared to HBV mono-infected cohorts where the current guidelines are followed. The long-term adverse events of TDF were nominal with much fewer side-effects associated with TAF treatment. The economic impact analysis showed the loss to follow-up, and presentation with advance liver disease was much more expensive than test & treat-all approach.
Conclusion: A test & treat-all strategy may result in fewer HCC incidence and limited side-effects at a significantly lower overall cost. However, the risk of flare-up remains with intermittent treatment if patients discontinue and restart treatment. A test & treat strategy will require patient education programs to keep patients on chronic treatment.

SAT309
Opportunities to enhance linkage to hepatitis C care among people hospitalised for injection drug use-related complications: a population-based study

Figure: (abstract: SAT309): Proportion of top ten ICD-10 primary diagnoses for long stay hospitalisations compared to total hospitalisations occurring 2015–2018 among people with HCV, by drug dependence.

Sydney, Australia; [3]Department of Health Systems and Populations, Maquarie University, Sydney, Australia; [4]British Columbia Centre for Disease Control, Vancouver, Canada; [5]School of Population and Public Health, University of British Columbia, Vancouver, Canada; [6]Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, Canada; [7]Storr Liver Centre, Westmead Millennium Institute, University of Sydney and Westmead Hospital, Westmead, Australia; [8]National Drug and Alcohol Research Centre, UNSW Sydney, Sydney, Australia
Email: hvalerio@kirby.unsw.edu.au.

Background and Aims: To achieve HCV elimination by 2030, testing and treatment among high risk populations need to be enhanced. The primary aims were to: (1) characterise subpopulations of people with HCV based on indicators of recent and distant drug dependence during the direct-acting antiviral era (2015–2018) and (2) evaluate the potential for hospital admissions to improve linkage to HCV care among people with evidence of recent drug dependence.
Method: HCV notifications in New South Wales, Australia (1995–2017) were linked to opioid agonist therapy (OAT) (2001–2018) and hospital admissions (2001-June 2018) and deaths (1993–2018). Drug dependence was defined as injecting drug use-related hospitalisation (admissions occurring due to injectable drugs and/or injection-related infections) or receipt of OAT. Drug dependence occurring between 2015–2018 was considered as recent and 2001–2014 as distant. Primary diagnosis associated with each hospital episode was categorised using International Classification of Disease (ICD) version 10 major chapters, and re-categorised into cause-specific outcomes including mental health, drug, alcohol, and liver-related admissions occurring in 2015–2018.
Results: Among 90,590 people with HCV notification alive during 2015–2018, 20.4% (n = 19,376) had evidence of recent drug dependence, 22.4% (n = 20,280) had evidence of distant drug dependence, and 56.2% (50,934) had no evidence of drug dependence post-2001. Among those with recent drug dependence, 78.4% (n = 15,193) had been to hospital a total of 77,616 times (median 4 visits per hospitalised individual), compared to distant drug dependence, 36.9% (n = 7,485; 20,517 total visits, median 2 visits) and neither, 26.3% (n = 13,384; 33,668 total visits, median 2 visits) groups. Over the period 2015–2018, incidence of mental health (13.6 per 100PY), drug (19.04 per 100PY), alcohol (6.05 per 100 PY), and liver-related (4.20 per 100PY) hospitalisations were highest among those with recent drug dependence. 42.2% (n = 8,118) of those with recent drug dependence contributed to a total of 19,682 long-stay (≥7 days) hospital admissions, the majority due to mental and behavioural disorders, most commonly for schizophrenia (Figure).
Conclusion: Among people with HCV notification who have evidence of recent drug dependence, frequent hospitalisation – particularly mental health, drug, and alcohol admissions – presents an opportunity for engagement in HCV testing and linkage to care.

SAT310

Searching for patients lost in the system with chronic hepatitis C in a tertiary hospital: a problem still to be solved

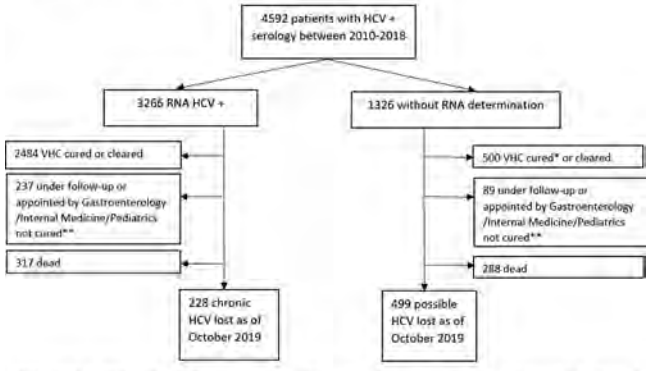
Irene Andaluz[1], María del Mar Arcos[2], María Dolores Montero[3], Marisa Montes[2], Pilar Castillo[1], Luz Martin Carbonero[2], Francisco Javier Garcia-Samaniego Rey[1], Miriam Romero[1], Araceli García-Sánchez[1], José Carlos Erdozaín[1], Carmen Busca[2], Juan González[2], Antonio Olveira Martin[1]. *[1]Hospital Universitario La Paz, Department of Gastroenterology, Madrid, Spain; [2]Hospital Universitario La Paz, HIV Unit, Department of Internal Medicine, Madrid, Spain; [3]Hospital Universitario La Paz, Department of Microbiology, Madrid, Spain*
Email: irene.an.gar@gmail.com.

Background and Aims: Following the widespread use of direct-acting antivirals for the treatment of patients diagnosed with chronic hepatitis C, there is a growing interest in the elimination of this infection. Various strategies to detect undiagnosed patients have been recommended.

Method: Patients with positive HCV-antibody between 2010–2018 from our Microbiology laboratory (tertiary Hospital covering 660.000 healthcare population) were analyzed. Those with consecutive negative PCR-RNA HCV were excluded. The Hospital and Regional databases were reviewed and sorted as: 1) chronic HCV: last determination of HCV RNA available positive, 2) cured HCV: last determination of HCV RNA available negative after ≥12 weeks of end of treatment, 3) possible HCV: positive HCV serology without determination of HCV RNA available. Patients with chronic HCV or possible HCV without follow-up or scheduled with Gastroenterology/Internal Medicine were considered lost. A descriptive analysis of all variables was performed. The study was reviewed and approved by the center's Ethics Committee.

Results: 4592 patients with HCV positive serology were identified: 3266 with detectable RNA and 1326 without RNA determination. 677 patients (14.7%) lost in the system were detected: 61% male, 12% foreigner, 95% mono-infected (non-HIV), median age 54 years (45–69). The serological study of the lost patients was requested by Internal Medicine (11%), Gastroenterology (14%), Primary Care (33%) and other specialties (42%). Of the 677 lost patients, 288 had positive PCR-RNA HCV and 449 only positive serology. The classification of the remaining patients is shown in Figure 1.

Figure 1. Study patient flowchart



** Cured before 2010 or after 2018 in our center or in other centers/other Regional Healthcare Systems (data obtained through medical reports).*

*** Upcoming appointments, on-going treatment not currently finalized or decision of no treatment based in age, comorbidity, patient refusal, drug abuse, therapeutic poor compliance...*

Conclusion: Despite the widespread possibility of HCV treatment in Spain since 2015, there is a significant number of hepatitis C patients lost in the system. It is necessary to implement active detection strategies for these patients in order to achieve the goal of elimination.

SAT311

Economic evaluation of the hepatitis C virus screening and treatment program in Georgia

Irina Tskhomelidze[1], Shaun Shadaker[2], Tinatin Kuchuloria[1], Lia Gvinjilia[1], Maia Butsashvili[3], Muazzam Nasrullah[2], Francisco Averhoff[2], Peter Vickerman[4], Josephine Walker[4]. *[1]TEPHINET, Georgia; [2]Centers for Disease Control and Prevention, United States; [3]Neolab, Georgia; [4]University of Bristol, United Kingdom*
Email: irinkatskhomelidze@gmail.com.

Background and Aims: In spring 2015, the country of Georgia initiated an HCV elimination program with directly acting antivirals (DAA) donated by Gilead, alongside outstanding political commitment, and allocation of resources for a comprehensive program. We evaluated the cost-effectiveness of the screening and treatment undertaken in the HCV elimination program from 2015 to November 2017 compared to if no treatment had been done, from the perspective of the Ministry of Health (MoH) and patients.

Method: We adapted an HCV transmission and progression model calibrated to Georgian data on HCV prevalence and demographics of the general population and people who inject drugs (PWID) to project the impact of treatment of 41,483 patients during the study period. Quality adjusted life year (QALY) weights for liver disease stages including pre-cirrhosis, compensated and decompensated cirrhosis were estimated from EQ-5D-5L data collected from a subset of HCV-infected patients enrolled in the elimination program.

Unit costs were gathered from the financial module of the MoH on reimbursement schemes for healthcare providers. Cost of screening tests, diagnostics and monitoring during treatment, and the annual cost of care for patients with advanced liver disease, were then calculated per patient treated. Indirect costs of public awareness campaigns, infrastructure investment, administrative costs, and logistics were included as fixed costs. Case-finding costs were estimated based on the cascade of care. Estimated economic costs of DAA drugs (sofosbuvir and sofosbuvir/ledipasvir) were included in sensitivity analysis.

The incremental cost-effectiveness ratio (ICER) in terms of cost per QALY gained was calculated in 2015 US dollars accounting for all costs and outcomes from 2015–2030 with a discount rate of 3% for both costs and outcomes, and compared to a willingness-to-pay threshold of $3765 per QALY gained (1x GDP per capita in 2015).

Results: The total cost of screening and treatment per patient was $555. The average cost of liver disease care per patient was $416 with no treatment or $311 under the treatment scenario, with 0.78 QALYs gained per patient treated due to reduced disease progression. The intervention also prevented 2,673 HCV-related deaths and averted 16,225 new infections by 2030 compared to no treatment. The ICER of the intervention excluding DAA costs was $959/QALY, while including the cost of DAAs at a minimal generic cost of $143 per patient results in an ICER of $1,244.

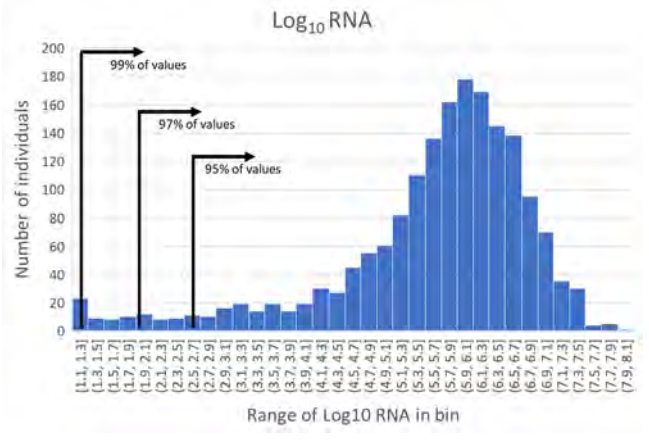
Conclusion: The first phase of the HCV elimination program was highly cost-effective in Georgia. This provides valuable data on efficiency of national programmes for scaling up HCV treatment for achieving HCV elimination.

SAT312

Assessing the level of detection of hepatitis C virus RNA in individuals with detectable viremia following treatment with direct acting antivirals: and opportunity for new testing technologies

Jake Morgan[1], Pamela Belperio[2], Alexandra Savinkina[3], Timothy Morgan[4], Benjamin Linas[3], Lisa Backus[2]. *[1]Boston University School of Public Health, Boston, United States; [2]U.S. Department of Veterans Affairs, Menlo Park, United States; [3]Boston Medical Center, Boston, United States; [4]US Veterans Affairs Department, Long Beach, United States*
Email: jakem@bu.edu.

Background and Aims: Seventy five percent of the 130–150 million cases of chronic Hepatitis C Virus (HCV) infection in the world occur in low to middle income countries. The World Health Organization (WHO) has targeted HCV infection for elimination, but testing standards to confirm the success of treatment – sustained virologic response (SVR) – is a barrier to this goal. A low-cost, near-patient test is the highest priority target product profile in a global consensus process, and could streamline and potentially decentralize the testing process. To make a convincing argument to change the WHO pre-qualification level of detection (LOD) approval criteria requires characterizing the lowest reliable threshold to assess for SVR in those treated. Our aim is to better understand the level of HCV viremia after failing to achieve SVR and the characteristics of patients experiencing low-level detectable viremia after treatment with direct-acting antivirals (DAAs).
Method: We leveraged data from a large US cohort of veterans who underwent treatment to calculate the LOD for SVR. We used SVR testing data up to 24 weeks following the end of treatment to describe the range of HCV RNA levels found among patients with detectable viremia after DAA treatment completion. We characterized the HCV viral load distribution for individuals with detectable viremia and described the 95% 97%, and 99% percentiles of HCV RNA values – the level of HCV RNA below which treatment failure may be missed if a test could only detect that level of RNA. To better understand the types of patients who are at higher risk of being miscategorized as achieving SVR when they have low levels of detectable virus, we examined patients with the lowest 3% of the distribution of rebound HCV RNA. We conducted a logistic regression predicting low-level rebound viremia as a function of demographics including age, sex, race, and clinical characteristics of fibrosis stage, HIV co-infection, and HBV co-infection.
Results: Between January 2014 and March 2018 we identified 2,246 cases of detectable viremia following DAA treatment. Of those, 1,779 (79%) occurred within 24 weeks of the end of treatment. The 95th, 97th, and 99th percentiles of HCV RNA were 2.66, 1.97, and 1.25 $\log_{10}$ IU/mL, respectively with an associated distribution shown in the figure. In this sample, only age was significantly associated with experiencing low-level viremia on detection (OR = 0.96, 95% confidence interval 0.93–0.98).



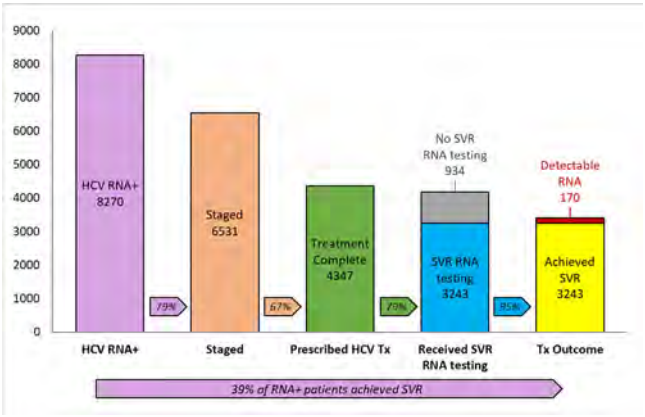
Conclusion: While current HCV RNA testing can detect as little as 12 IU/mL of virus, our findings suggest that increasing the LOD to 100 IU/mL ($\log_{10}$ IU/mL = 2) or 450 IU/mL ($\log_{10}$ IU/mL = 2.7) would maintain good test accuracy, capturing 95% and 97% of detectable viremia cases following DAA treatment. These results should inform the development of more affordable portable tests for use in low- and middle-income countries.

SAT313

A population-based intervention to improve care cascade of patients with hepatitis C infection

John D Scott[1], Meaghan Munn[2], Atar Baer[2], Sarah Glick[2], Elizabeth Barash[2], Hilary Armstrong[2], Matt Golden[1], Alexander Millman[3], Noele P. Nelson[3], Lauren Canary[3], Kris V. Kowdley[4], Jeff Duchin[2]. [1]*University of Washington, Medicine, Seattle, United States;* [2]*Public Health Seattle King County, Seattle, United States;* [3]*Centers for Disease Control and Prevention, Atlanta, United States;* [4]*Swedish First Hill Campus, Seattle, United States*
Email: jdscott@uw.edu.

Background and Aims: Hepatitis C virus (HCV) infection is common in the general US population, leading to significant morbidity, mortality, and economic costs from chronic liver disease and hepatocellular cancer. New HCV infections increased nearly 300 percent from 2010 and 2015, and in 2012, HCV-related deaths surpassed deaths from all other reportable infectious diseases combined. However, simplified screening recommendations and highly effective direct acting antivirals for HCV present an opportunity to reverse this trend. We report the results of a community-based program to increase the testing, linkage to care, treatment and cure of persons with HCV infection.
Method: Public Health - Seattle & King County collaborated with three community health centers, three large multi-clinic health care systems (private, public and capitated), and an HCV patient education and advocacy group. Patients seen at least once at a partner clinical site were included. In order to increase screening of baby boomer patients (born during 1945–65), electronic health record (EHR) prompts and reports were created, as well as lower cost interventions such as birthday card reminders and posters. Case management linked patients to care. Primary care providers received education and training through class-room didactics, an online customized curriculum, specialty clinic shadowing and through a telemedicine program, Project ECHO. Data were extracted from partner EHRs to assess screening of baby boomer patients and monitor the progress of all diagnosed patients along the continuum of care during the project period (9/30/13–9/29/18).
Results: At baseline, 18% of baby boomer patients seen at partner primary care clinics had documentation of HCV testing; this proportion increased to 54% by the end of the project period. Of the 77577 baby boomer patients screened at 87 partner clinics, 2401 (3%) were newly HCV antibody positive. Among 8270 patients of any age with active HCV infection (RNA+), the majority were male (66%) and white (59%); 607 (7%) were HIV infected. The number of patients staged for treatment (either by genotype or a fibrosis test) increased by 391% during the project period and those treated increased by 1263%. Among the 79% of treated patients who were tested for sustained viral response (SVR), 95% achieved SVR.



Conclusion: A combination of EHR-based healthcare system interventions, active linkage-to-care, and educational and training strategies resulted in a tripling in the number of patients screened and more than tenfold increase of those treated. The interventions are scalable and foundational to the goal of HCV elimination.

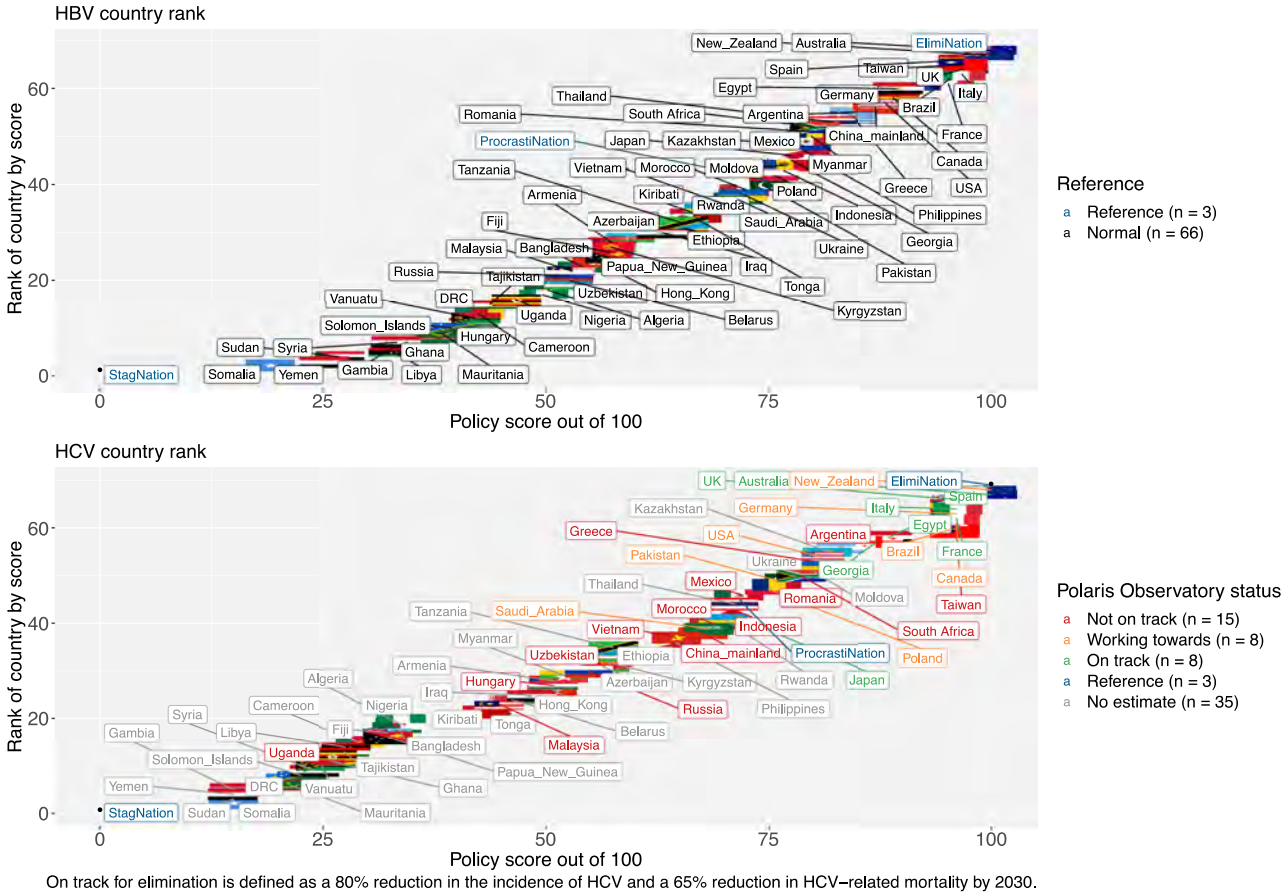
SAT314

Do countries have the right policies to eliminate viral hepatitis B and C: a secondary analysis of the Lancet GastroHep viral hepatitis commission

Adam Palayew[1], Graham Cooke[2], Sharon Hutchinson[3], Homie Razavi[4], Jeffrey Lazarus[5]. [1]*McGill University, Epidemiology, Biostatistics, and Occupational Health;* [2]*Imperial College, Division of Infectious Diseases;* [3]*Glasgow Caledonian University, School of Health and Life Sciences;* [4]*Center for Disease Analysis Foundation;* [5]*University of Barcelona, Barcelona Institute for Global Health (ISGlobal)*
Email: Jeffrey.Lazarus@isglobal.org.

Background and Aims: In 2019, the Lancet Gastroenterology & Hepatology Commission reported on the status of 11 viral hepatitis policy indicators in 66 countries. Policies were reported as either being in place, in development, or not in place. Of the 11 viral hepatitis policies, 6 related to both hepatitis B virus (HBV) and hepatitis C virus (HCV), 3 policies applied only to HBV, and 2 policies were specific to HCV. This study used the commission findings to estimate country HBV and HCV policy scores and rankings.
Method: Two groups of variables were created: one for all policies relating to HBV and the other for all HCV related policies. We then applied a multiple correspondence analysis data reduction technique to each group of policies to reduce the policy indicators into a weighted summary of each possible different response to the policy indicators and generate scores for each country. Reference countries (StagNation, ProcrastiNation, and ElimiNation) were included in the analysis to help contextualize responses so that the minimum score was no policies and the maximum all policies. Values of the scores for countries were standardized to range from 0 to 100 (Best).
Results: The analysis estimated a summary factor that explained 58.1% of the variation for HBV and 70.3% for HCV. The highest scoring country for HBV was Australia while Somalia had the lowest score followed by Yemen and Sudan. For the HCV policy score, Australia and New Zealand had perfect scores while Somalia, Sudan, and Yemen had the lowest scores, all having only 1 indicator in place: mandatory screening of donated blood (Figure panel A). For HCV, countries were further analyzed by elimination status according to the Polaris Observatory (Figure panel B). Countries that were on track had a mean score of 91.4, countries that were working towards elimination had a mean score of 86.0, and countries that were not on track had a mean score of 66.1. Countries that did not have an estimate from Polaris had a mean score of 41.7 suggesting that a certain level of commitment is needed before a country receives a score.
Conclusion: In this study, we calculated HBV and HCV country policy scores for 66 countries. Countries that received higher scores had more policies in place than countries with lower scores. The index does not account for a country's disease burden and heavily burdened countries such as Nigeria, Russia, and Vietnam scored relatively poorly, despite having some policies in place.

Figure: Country (n = 66) HBV and HCV policy scores and rankings



On track for elimination is defined as a 80% reduction in the incidence of HCV and a 65% reduction in HCV–related mortality by 2030.

SAT315

Validation of a novel rapid point-of-care ALT test in patients with viral hepatitis

Jessica Howell[1,2,3,4], Huy Van[2], Rohit Sawhney[1], Joseph Doyle[2,4], Mary Garcia[2], Zhimei Zhang[5], Fan Li[2], Brendan Harney[2], Rosemary Ffrench[2,6], Alexander Thompson[1,3], Margaret Hellard[2,4], David Anderson[2,5]. *[1]St Vincent's Hospital Melbourne, Gastroenterology, Fitzroy, Australia; [2]Burnet Institute, Disease Elimination; [3]University of Melbourne, Medicine, Fitzroy, Australia; [4]Monash University, Epidemiology and Preventive Medicine, Melbourne, Australia; [5]Nanjing BioPoint Diagnostics, Nanjing, China; [6]National Reference Laboratory, Quality, Fitzroy, Australia*
Email: jessica.howell@svha.org.au.

Background and Aims: Alanine aminotransferase (ALT) level is an important marker of liver inflammation. Limited access to laboratory resources makes ALT measurement challenging in low resource and remote regions. ALT1 protein antigen is cleared slowly from plasma than enzymatic ALT and is more stable at ambient temperature when stored for long periods outside cold chain. We validated a novel point-of-care (POC) ALT1 test in patients with viral hepatitis.

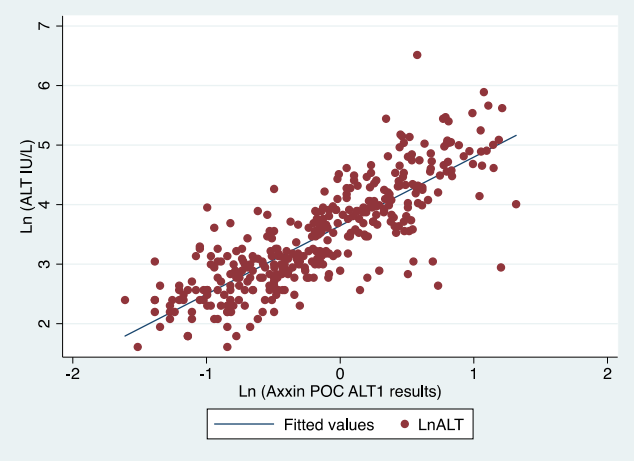

Figure: Linear regression plot of the association between ln (ALT) and ln (POC ALT1) values ($R^2 = 0.68$, $p < 0.0001$).

Method: The BioPoint® POC ALT1 test is an antigen immunoassay-based lateral flow test, which uses 40 μL whole blood or 15 μL plasma to provide ALT measurement two ways: 1. quantitative ALT result (Axxin handheld lateral flow reader) or 2. visual semi-quantitative result (cutoff 40 IU/mL), within 20 minutes. Quantitative POC ALT1 results were compared to standard laboratory assay ALT using Spearman correlation. A linear regression model was used to derive comparable values from POC ALT1 results (Axxin reader, arbitrary units) to standard ALT. Accuracy of POC ALT1 to detect ALT > upper limit of normal (ULN) was calculated by ROC analysis and agreement determined by Bland-Altman plot.

Results: 240 patients were included: 74 (31%) with hepatitis B and 166 (69%) with hepatitis C. 168 (70%) were male, mean age was 39 +/– 7.9 years and 18 (11.5%) had cirrhosis. Median ALT was 32 IU/mL (IQR 19–50).

Quantitative (Axxin Reader): There was moderate correlation between quantitative POC ALT1 results and ALT measured by laboratory assay ($R^2 = 0.68$; $p < 0.0001$). Derived POC ALT1 values had excellent accuracy for laboratory-based ALT > ULN in males and females. Bland-Altman plot showed a small mean difference 0.039 (95% CI –4.54–4.62) and significant variance difference (Pitman's test <0.0001).

Conclusion: The BioPoint® POC ALT1 test had good correlation with laboratory assay ALT and good accuracy for identifying hep B patients with ALT levels > ULN using AASLD and EASL criteria. Further validation of the POC ALT1 test in prospective clinical trials is needed.

SAT316

Cost-effectiveness of screening and treatment using direct-acting antivirals for chronic hepatitis C virus in low- and middle-income settings

ALT >40 IU/mL**	0.929 (95% CI 0.901–0.956)	91%	84%	77%	93%

*ULN men 30 IU/mL, women 19 IU/mL; AASLD guidelines.
**ULN 40 IU/mL; EASL 2017 guidelines.
Semi-quantitative (visual read): Visual POC ALT1 results (cutoff 40IU/mL) had good accuracy for assay measured ALT > 40IU/mL (sensitivity 80%, specificity 82%, PPV 73%, NPV 87%).

Table: (abstract: SAT316)

Intervention	ICER	Threshold of 1x Gross Domestic Product per Capita	Cost-effective?	% Simulations Below Cost-Effectiveness Threshold
Cambodia: full model of care	$149/QALY	$1,270/QALY	Yes	100%
Cambodia: simple model of care	−$129/QALY	$1,270/QALY	Cost-saving	100%
Myanmar	$1,289/DALY	$1,299/DALY	Yes	51%
Pakistan	$488/DALY	$1,468/DALY	Yes	99%
Kenya	$805/DALY	$1,509/DALY	Yes	100%

screening and treatment programs implemented by Médecins Sans Frontières (MSF) in Pakistan, Myanmar, Cambodia and Kenya. The Myanmar intervention served HIV-HCV coinfected patients, Kenya served people who inject drugs (PWID), while Cambodia and Pakistan served the general population.

Method: The incremental cost-effectiveness ratio (ICER) was modelled as the cost (2018 US$) per disability-adjusted life year (DALY: Myanmar, Kenya, Pakistan) averted or quality adjusted life year (QALY: Cambodia) gained by HCV screening and treatment compared to no treatment from the provider's perspective over a life-time horizon. Cost and treatment outcome data were collected retrospectively from each program. Disease progression models were used for Myanmar, Cambodia and Pakistan, assuming low re-infection risk, while a dynamic HCV transmission model was used for Kenya because PWID have higher reinfection risk. The robustness of the projections were evaluated using deterministic and probabilistic sensitivity analyses.

Results: For current costs of DAA drugs in each setting ($120–524 per 12 week course of treatment), the ICER for each program varied from cost saving in Cambodia to $1,289/DALY averted in Myanmar, with mean ICERs all below country-specific thresholds for cost-effective interventions (Table). Higher laboratory and DAA costs in Myanmar increased the ICER compared to other settings. Kenya had high costs due to directly observed therapy but also had greatest impact due to the prevention benefit of treating PWID. Each country's ICER reduced most if the DAA costs were reduced or if the model of care was simplified with fewer visits and tests, and task shifting from doctors to nurses.

Conclusion: HCV screening and DAA treatment were shown to be cost-effective in four treatment programs in LMICs, supporting expanded access to HCV treatment in other LMICs.

SAT317

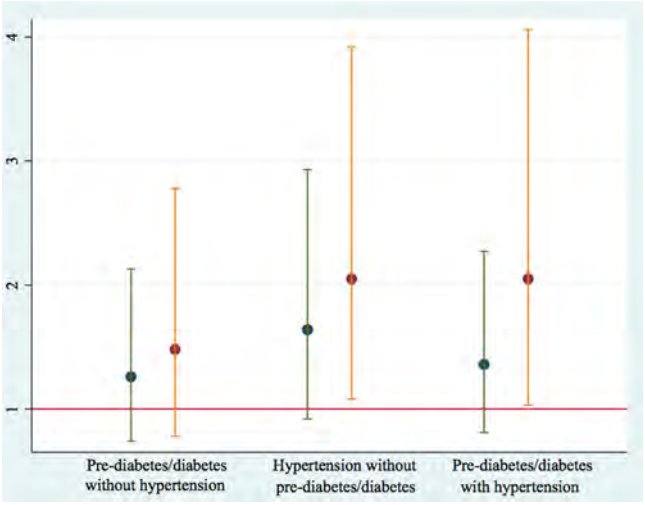
Cross-sectional associations between suspected non-alcoholic fatty liver disease, diabetes, and hypertension in hispanic adults living in the San Juan metropolitan area

Josheili Llavona-Ortiz[1], Cynthia Perez-Cardona[1], Erick Suarez-Perez[1], Loida A. Gonzalez-Rodriguez[2]. [1]*University of Puerto Rico - Medical Sciences Campus, Biostatistics and Epidemiology, Puerto Rico;* [2]*University of Puerto Rico - Medical Sciences Campus, Internal Medicine, Puerto Rico*
Email: josheili.llavona1@upr.edu

Background and Aims: Evidence suggests that there is a high prevalence of cardiometabolic diseases, such as diabetes and hypertension in Puerto Rico. These diseases have been directly linked to non-alcoholic fatty liver disease (NAFLD), yet there is no data available regarding the prevalence of suspected NAFLD among Puerto Ricans living in the archipelago. This study was undertaken to assess the prevalence of suspected NAFLD and its association with hypertension and pre-diabetes/diabetes among Puerto Rican adults living in the San Juan Metropolitan Area.

Method: A secondary data analysis of a household survey on diabetes and hypertension was performed. A total of 432 participants who had complete data on sociodemographic, behavioural, and cardiometabolic factors, including levels of aminotransferase, were included. Suspected NAFLD was defined on the basis of increased level of aminotransferase in the absence of excessive alcohol consumption. The estimated prevalence of suspected NAFLD was age-standardized using the 2010 USA population. In multivariate analyses, the associations between NAFLD and pre-diabetes/diabetes or hypertension status were adjusted for age, physical activity, waist circumference, triglycerides, high-sensitivity C-reactive protein, and alcohol consumption.

Results: The estimated age-standardized prevalence of NAFLD was 35.3% (95% CI: 28.2%, 43.6%) among women and 37.8% (95% CI: 29.0%, 48.5%) among men, with a statistically significant difference between groups ($p < 0.05$). In multivariate analysis, the estimated odds of having hypertension was 1.66 (95% CI: 1.05, 2.61) times greater for participants with suspected NAFLD relative to those without suspected NAFLD. Furthermore, in the multinomial logistic regression model, the estimated odds of having hypertension without pre-diabetes/diabetes among subjects with suspected NAFLD were 2.05 (95% CI: 1.08, 3.92) times the estimated odds among subjects without suspected NAFLD.



Conclusion: This study suggests that suspected NAFLD is highly prevalent among Puerto Rican adults living in the San Juan Metropolitan Area. Suspected NAFLD was positively associated with hypertension, but not with prediabetes/diabetes. Given the high prevalence of suspected NAFLD observed in this study, the replications of these findings could have substantial implications in the prevention of these chronic conditions.

SAT318

HCV care cascade of PWID enrolled in methadone substitution treatment program in Georgia - is this the first group of population in which hepatitis C will be eliminated in Georgia?

Ketevan Stvilia[1], Amiran Gamkrelidze[1], Irma Khonelidze[1], Vladimer Getia[1], Lia Gvinjilia[2], Tinatin Kuchuloria[2], Maia Tsereteli[3].
[1]National Center for Disease Control and Public Health, Georgia, Global Fund Programs Implementation Unit, Tbilisi, Georgia; [2]CDC office in Georgia, TEPHINET for Georgia Hepatitis C Elimination Program, Tbilisi, Georgia; [3]National Center for Disease Control and Public Health, Georgia, HIV, Viral Hepatitis, TB and STI Unit, Tbilisi, Georgia
Email: k.stvilia@ncdc.ge

Background and Aims: Since April 2015 Georgia has started hepatitis C elimination program with elimination goals by 2020. PWIDs enrolled in the Methadone Substation Treatment (MST) Program are also included in the large-scale screening program aimed to accelerate active HCV case detection. There are a total of 22 MST sites providing long term substation treatment to PWIDs in Georgia. HCV antibody screening is provided to patients at the enrollment in the MST program. The aim is to describe HCV care cascade among MST program beneficiaries.
Method: HCV care cascade was generated for the period of January, 2018 through October, 2019. The data linkage between MST database and national screening registry was done by matching national personal ID number. Cascade of care was generated using the matched data.
Results: Overall 9,552 PWIDs registered in MST database by November 1, 2019. A total of 8,265 (87%) MST patients had HCV screening of whom 7,041 (85%) tested positive and 5,998 (85%) were tested for viremia with the positivity rate of 85% (n = 5073). A total of 4,237 (83%) initiated treatment. By the date of the analysis 3,956 (93%) have already completed treatment of whom 3,808 (97%) were eligible for SVR. The cure rate among SVR tested was 96% (2,531/2,622).
Conclusion: The analysis of HCV care cascade for MST program beneficiaries shows high rates for screening and viremia testing uptake, treatment initiation and SVR rates. Meeting HCV elimination goals by 2020 is feasible however, requires more efforts.

SAT319

Screening and linkage to care of prisoners with HCV infection: the resist-HCV project

Lorenza Di Marco[1], Prestileo Tullio[2], Fabrizio Scalici[3], Rosario Insinna[3], Margherita Rossi[1], Ciro Celsa[1], Massimo Licata[1], Sabina Marchese[2], Andrea Di Lorenzo[2], Maurizio Milesi[2], Giacomo Emanuele Maria Rizzo[1], Anita Busacca[1], Vincenza Calvaruso[1], Fabio Cartabellotta[4,5], Vito Di Marco[1].
[1]University of Palermo, Gastroenterology and Hepatology Unit, Department of Health Promotion Sciences Maternal and Infantile Care, Internal Medicine and Medical Specialities, PROMISE, Palermo; [2]U.O.C. Malattie Infettive, ARNAS-Civico, Palermo; [3]Area Medica della Casa Circondariale "Pagliarelli-Lorusso," Palermo; [4]Buccheri La Ferla Hospital, Palermo; [5]Rete Sicilia Selezione Terapia HCV (RESIST-HCV), Sicily
Email: lor.dimarco@gmail.com

Background and Aims: In prisons there is high prevalence of hepatitis C virus (HCV) infection, high rate of PWID and a substantial risk of HCV transmission. Epidemiological studies are needed to evaluate the rate of prisoners with chronic HCV hepatitis and to establish how many of them need Direct Acting Antiviral (DAA) therapy.
Methods: We conducted a cross-sectional study to explore the prevalence of HCV infection in all prisoners of Pagliarelli-Lorusso prison in Palermo (Sicily). At July 2019 prisoners received information on the virological test, the diagnosis of chronic hepatitis and the possibility of obtaining antiviral therapy inside the prison. Anti-HCV antibodies was detected by OraQuick HCV rapid oral test. Prisoners with positive screening performed serum HCV-RNA and viral genotype, evaluated liver disease stage by Fibroscan and received antiviral therapy. All prisoners signed an informed consent to use demographic, clinical and virological data. Chi-square test was used to analyze differences between groups.
Result: Among 1,147 prisoners (86.3% of entire population of the prison) who participated in the study, 1,139 (99.3%) accepted to perform oral test for HCV antibodies. Prisoners had a mean age of 42 ± 13 years without differences in 1,053 males (92.5%) and 86 females (7.5%). Overall, 55 prisoners (4.8%) resulted HCV antibody-positive: 46 out of 1,053 males (4.4%) and 9 out of 86 females (10.5%) ($p = 0.02$). Twenty-five out of 99 people (25%) who inject drug (PWID) and followed a program of opioid substitution therapy (OST) and 28 out of 1,040 no-PWID prisoners (2.9%) were anti-HCV positive ($p < 0.0001$). The prevalence of HCV antibodies was 22% (19/87) among males PWID and 50% (6/12) among females PWID ($p = 0.06$). Prisoners were more frequently infected with genotypes 1a (38.7%) or 3 (35.5%). Eleven out of 25 anti-HCV positive PWID (44%) and 16 out of 30 anti-HCV positive prisoners (53.3%) without history of drugs addict had a previous diagnosis of HCV infection ($p = 0.7$). Thirteen out of 27 prisoners (48.1%) with a previous diagnosis of HCV infection (6 of 25 PWID and 7 of 30 no-PWID) had already received a cycle of antiviral therapy.
Conclusions: Overall prevalence of HCV infection among prisoners is at least 4 times greater than in the general population and the main risk factor is a history of injecting drug use. About half of the prisoners with positive screening did not know their HCV infection. Only 36% of people with a known HCV infection had received antiviral therapy before arriving in prison. In prisons, it should be mandatory to program on-side screening for HCV infection and linkage to care patients with chronic liver disease.

SAT320

Frequency of prenatal hepatitis C screening and diagnosis in British Columbia, 2008–2018

Dr. Margo Pearce[1,2], Amanda Yu[1], Maria Alvarez[1], Sofia Bartlett[1], Mawuena Binka[1], Dahn Jeong[2], Emilia Clementi[1], Agatha Jassem[1], Eric Yoshida[3], Dr. Jason Wong[1], Neora Pick[4], Mel Krajden[1], Naveed Janjua[1].
[1]BC Centre for Disease Control, Vancouver, Canada; [2]UBC, School of Population and Public Health, Vancouver, Canada; [3]UBC Faculty of Medicine, Vancouver, Canada; [4]BC Women's Hospital & Health Centre, Oak Tree Clinic, Vancouver, Canada
Email: margo.pearce@bccdc.ca

Background and Aims: Hepatitis C (HCV) is not part of routine prenatal screening in British Columbia (BC) Canada: pregnant people may be tested if they have risk factors or their prenatal care providers request HCV testing. We aimed to calculate frequency of prenatal HCV antibody testing and HCV diagnoses, as well as follow-up testing (RNA and/or genotype) among prenatally screened women in BC, from 2008–2018.
Method: We used BC Centre for Disease Control Public Health Laboratory (PHL) data linked with provincial surveillance data to estimate the number of women (female sex) aged 13–49 who received routine prenatal serological screening (HIV, hepatitis B, syphilis, and rubella) between 2008 and 2018. PHL performs >95% of all HCV screening tests in BC. HCV tests ordered on the same day as routine prenatal screens were considered prenatal HCV tests. Previously known HCV positive status was determined by HCV positive result prior to prenatal test. Seroconversion was a negative test at any time prior to a first positive test. Any follow-up RNA and/or genotype testing was assessed after prenatal anti-HCV screening.
Results: Prenatal HCV screening increased significantly from 2008 (Cochran-Armitage test for trend: $p < 0.001$), reaching nearly half of women receiving routine prenatal screening in 2018. Overall HCV prevalence among prenatally HCV screened women declined from 0.6% in 2008 to 0.36% in 2018. New HCV diagnoses due to prenatal HCV screening fluctuated over the ten year study period. Overall,

prenatal HCV screening identified 337 new HCV diagnoses, 24.3% were seroconversions and 75.7% were first time reactive results. In 2018, most women newly diagnosed with a prenatal HCV screen received follow-up RNA and/or genotype tests; 100% (9/9) of those who seroconverted and 90.1% (30/33) of those with first time reactive results; this compared to 82.5% (572/693) of all new HCV diagnoses among all women in BC the same year. Of 1,524 women who had previously tested HCV positive before receiving a prenatal HCV screen between 2008 and 2018, 97% had any RNA and/or genotype testing.

Figure: Proportion of all prenatal screens that included an anti-HCV test and number of women diagnosed anti-HCV positive as a result of a prenatal HCV screen, including new diagnoses (seroconversion or first time reactive) and previously known diagnoses (repeat testers) in BC, 2008–2018.

Conclusion: Risk-based prenatal HCV testing identifies undiagnosed HCV infections, and most women identified appear to be receiving appropriate follow-up testing. Further research is needed to understand differences in risk-based vs. routine prenatal HCV screening, as well as HCV vulnerability, infection, and care among pregnant women in BC.

SAT321

Re-capturing a lost population - the benefits of a nurse-delivered HCV community cirrhosis clinic

Maryam Noeman[1], Sehar Farooq[1], Lourdes Cumlat[1], Will Blad[1], Rajan Patel[1], Indrajit Ghosh[1], Deepak Suri[1]. [1]*Whittington Hospital NHS Trust*
Email: rajan.patel@nhs.net

Background and Aims: The current landscape of service provision for patients with liver disease does not match that of disease burden. A North London-based drug and alcohol dependency unit ('Better Lives') provides blood borne virus (BBV) screening and opioid substitution therapy (OST) as well as Hepatitis C Virus (HCV) treatment. These patients are often complex with marginalised social needs, have chaotic lifestyles and don't engage with conventional care models. We aimed to describe the demographics of a cohort of patients seen in a novel community outreach clinic (OC).
Method: Approximately 1000 patients per year receive OST from 'Better Lives' via a multidisciplinary clinic with doctors, nurses and recovery workers. 117 (11.7%) screened positive for chronic HCV. 22 (18.8% of chronic HCV patients, 2.2% of those receiving OST) with advanced liver fibrosis or cirrhosis (F3/F4) were referred to OC between November 2018 and September 2019. We used electronic hospital records to assess 'Did Not Attend' (DNA) rates to outpatient appointments (OPA) and emergency department (ED) attendances prior to review in OC and completion of key investigations afterward.
Results: 22 patients referred to OC in the study period (median age 52 (IQR 46.3–57), 81.8% male, 40.9% white). 14 patients (63.6%) attended. Chronic HCV primary aetiology in 12 (54.5%), 11 (50%) self-reported ongoing alcohol intake and 4 (18%) were people who inject drugs (PWID). Median liver stiffness 19kPa (IQR 12.95–36.1). 12 (54.5%) did not have registered GPs. 15 (68.2%) DNA hospital appointments prior to OC clinic.
Conclusion: This is the first UK-based nurse-delivered community liver cirrhosis outreach clinic aimed to improve treatment and supportive medical care and offer a link to hospital cirrhosis services. We re-engaged two-thirds of complex marginalised patients with advanced fibrosis via OC that would otherwise have been lost to follow up. Patients attending OC had an average of 2 prior DNA to hospital OPA and 6 ED attendances. 35% and almost 50% of patients had their surveillance US abdomen and gastroscopies, respectively, following attendance to OC compared with only 12% who did not attend. Further work to investigate if a community based liver outreach clinic can improve the trajectory of marginalised patients is required.

Table: (abstract: SAT321)

	All F3/F4 patients referred (n = 22)	Patients attending OC (n = 14)	Patients not attending OC (n = 8)
Age (median, IQR)	52 (46.3–57)	53.5 (45–57.75)	50.5 (28.5–53)
Gender (Male), n (%)	18 (81.8)	11 (78.6)	7 (87.5)
HCV Aetiology, n (%)	12 (54.5)	9 (64.2)	3 (37.5)
Ongoing alcohol intake, n (%)	11 (50)	11 (78.6)	0 (0)
Prior DNA OPAs, mean (SD)	2.14 (2.14)	2.07 (1.64)	2.25 (2.96)
Prior ED attendances, mean (SD)	5.05 (6.94)	6 (7.2)	3.38 (6.57)
US Abdomen after OC, n, (%)	7 (31.8)	6 (42.86)	1 (12.5)
Gastroscopy after OC, n (%)	6 (27.3)	5 (35.71)	1 (12.5)

SAT322

Strengthening HCV elimination policies through community-based research

Chase Perfect[1], Maria Donatelli Klinger[2], Rosemary Delabre[3], Daniela Rojas Castro[3,4]. [1]*Coalition Plus, Pantin, France;* [2]*Coalition Plus;* [3]*Coalition PLUS Research Laboratory;* [4]*Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille*
Email: cperfect@coalitionplus.org

Background and Aims: Community-based approaches are known to be effective means of reaching marginalized populations that are not in contact with traditional health structures. Coalition PLUS–an international union of community-based NGOs involved in the fight against HIV and viral hepatitis–collaborated with partners in 5 low-middle income countries to carry out a study aimed at collecting data regarding HCV-related barriers encountered by communities in order to inform policies addressing HCV care and elimination in the targeted populations.

Method: Community-based research in an approach in which researchers and community actors collaborate at all stages of the research project: from identification of the research subject to dissemination of study results and advocacy. Community-based research applies rigorous methodologies to problems identified by and subsequent questions formulated through engagement with the communities affected by a given health issue.
Coalition PLUS applied these principles to the Mind the Gap (2018) study, a qualitative exploratory cross-sectional study in 5 countries included in the Unitaid-funded Coalition PLUS's HIV/HCV Drug Affordability project (India, Malaysia, Indonesia, Thailand, Morocco). Via surveys (240 focus group participants) and interviews (51 healthcare workers) with at-risk populations (people who inject drugs (PWID), former PWID, and people living with HIV) and healthcare workers, the study focused on gaps in the translation of HCV policies on paper into access to HCV services in practice.
Results: The study found insufficient HCV awareness among communities and insufficient HCV capacity in the health system. Participants described the HCV service pathway as too long, too complex, and too costly. For example, a majority of participants in several of the study countries highlighted the following as important service access barriers: travel distance, time off work, and costs. With these results, Coalition PLUS and partners approached the governments in the countries concerned and contributed to the following results:

12. Adoption of Standard Operational Practices for Hepatitis C by the MoH in Manipur stressing the importance of community care and of the specific needs of key populations;
13. Development of the discussion on simplification of diagnosis cascade in Morocco and India;
14. Development of a HCV service decentralisation pilot project in Malaysia.

Conclusion: The Mind the Gap study demonstrates how community-based research can serve as a key approach to evaluate problems, elaborate solutions, and advocate for evidence-based reforms. It is also a reminder of the importance of community engagement in the evaluation of policy impact and in the development of pertinent policies which meet the needs of those concerned. Building from this study, a second iteration of the Mind the Gap study will be launched in early 2020.

SAT323

Preliminary results of the prevalence of non-alcoholic fatty liver disease among the greater Toronto area population

Anish Jammu[1], Silva Cortez[1], Hasan Akhtar[1], Sirajuddaula Kausar[1], Hamed Dallali[1], Justin Lee[1], Muhammad Khurram[1], Marzena Magnes[1], Magdy Elkhashab[1]. [1]*Toronto Liver Centre, Toronto, Canada*
Email: melkashabmd@yahoo.ca

Background and Aims: The incidence and prevalence of NAFLD is on the rise. The natural history of this increasingly common condition is not well understood. Liver fibrosis is the most important predictor for morbidity and mortality among patients with NAFLD. This aim of this study was to undertake a retrospective analysis of the Fibroscan® results of a diverse patient population in the Greater Toronto Area (GTA) to understand the demographic composition of the population and the prevalence & severity of non-alcoholic fatty liver disease (NAFLD) within the GTA in Ontario, Canada, which is populated by individuals from different ethnic backgrounds.
Method: Retrospective review of 4486 charts was conducted in order to evaluate the status of fatty liver among a diverse patient population in the GTA. Patient geographical location, age, sex, fibrosis and steatosis scores were studied using descriptive statistics.
Results: Retrospective review of 4486 patient charts from the GTA revealed geographical distribution spanning 18 different cities/ regions in the GTA among 3147 patients. Of the study patients, 2344 male patients (52.3%) & 1860 female patients (41.5%) and in terms of age distribution: <30–1.9%, 30–39–7.3%, 40–49–16.9%, 50–59–28.3%, 60–69–26.4%, 70–79–15.1%, 80–89–3.2%, <90–0.2%. Fibroscan® results were registered in 3777 of the cases and the relative proportion of fibrosis staging was: F0–25.8%, F0 to F1–18.9%, F1–15.4%, F1 to F2–9.9%, F2–10.5%, F2-F3–4.6%, F3–4.1%, 3 to F4–2.7%, F4–8.2%. Steatosis results were available in 1759 of the 3777 available Fibroscan® results: S0–7.3%, S0-S1–3.0%, S1–14.1%, S1-S2–4.2%, S2–20.8%, S2-S3–13.8%, S3–36.8%.

Table 1: Patient Demographic Information

	Frequency	Percentage
Gender		
Female	1860	41.5
Male	2344	52.3
Age		
<30	85	1.9
30–39	326	7.3
40–49	759	16.9
50–59	1271	28.3
60–69	1185	26.4
70–79	678	15.1
80–89	145	3.2
>90	7	0.2
FibroScan® Results		
Fibrosis		
F0	973	25.8
F0-F1	712	18.9
F1	582	15.4
F1-F2	373	9.9
F2	398	10.5
F2-F3	173	4.6
F3	154	4.1
F3-F4	103	2.7
F4	309	8.2
Steatosis		
S0	129	7.3
S0-S1	53	3.0
S1	248	14.1
S1-S2	73	4.2
S2	366	20.8
S2-S3	243	13.8
S3	647	36.8

Conclusion: The majority of patients were between the ages of 50 and 69 and were male (52.3%). The Fibroscan® results range from no fibrosis to severe fibrosis/ cirrhosis. Moderate to severe fibrosis (F2-F4) was present in 30% of the patients, which cirrhosis (F4) was present in 8%. The majority of the charts where steatosis results were available reveal moderate to severe steatosis.

SAT324

Suboptimal linkage to care after identification of serum hepatitis B surface antigen-positive individuals in territory-wide screening: a need for educational and public health policies

KL Ko[1], Kevin Liu[1], Yan Yue James Fung[1], Lung Yi Mak[1], Man-Fung Yuen[2], Wai-Kay Seto[2]. [1]*Queen Mary Hospital, Medicine, Hong Kong;* [2]*The University of Hong Kong, Medicine, Hong Kong*
Email: wkseto@hku.hk

Background and Aims: Ensuring linkage to care is a key element to achieve the World Health Organization's goal of eliminating hepatitis B virus (HBV) as a public health threat by 2030. Data on linkage to care in chronic HBV patients under Asian health care systems remains lacking.
Method: Hepatitis B surface antigen (HBsAg)-positive individuals identified during a territory-wide hepatitis seroprevalence study in 2015–2016 in Hong Kong were referred to regional secondary care for further management. We assessed subsequent linkage to care using surveys conducted via telephone and text messaging. The first survey in 2018 focused on their follow-up status, reasons for refusing referral

among those without follow-up, and suggestions on improving linkage to care. The second survey in 2019 assessed their latest follow-up status, any active anti-HBV treatment and the presence of liver-related complications including cirrhosis and hepatocellular carcinoma (HCC).

Results: Among 10,256 Chinese participants from the initial seroprevalence study, we identified 803 HBsAg-positive individuals (7.8%), of which 382 (47.6%) had no prior knowledge of their HBV carrier status. 539 (67.1%) responded to the first survey, with 388 (72.0%) having active follow-up for their HBsAg-positive status. 279 (71.9%) were followed up at in the public sector, while 247 (63.4%) had received liver ultrasonography. Common reasons for patients refusing referral include: believing they were healthy and not requiring clinical care (38%), no available time (20.0%), lack of disease knowledge (12.6%) and long appointment waiting times (4.6%). Suggestions to improve linkage to care include text message reminders (43.0%), patient education programs (10.8%), availability of patient support groups (10.4%) and shortened appointment waiting times (1.7%). Among 402 individuals responding to our second survey, only 149 (37.1%) remained in active follow-up. 78 (19.4%) had commenced anti-HBV treatment, 10 (6.7%) had biochemical or radiological evidence of cirrhosis. Two patients had developed HCC, both detected during surveillance and were amenable to curative resection.

Conclusion: Post-screening linkage to care for chronic HBV patients remained suboptimal in Hong Kong, with low rates of engagement to clinical care and high rates of dropout. Considerable proportion of patients required treatment or developed complications. Systematic reminders and patient education coupled with timely referrals may facilitate linkage to care and prevent defaulting of follow-up.

SAT325

Changes in the hepatitis C cascade of care among individuals attending primary and community health services before and after the introduction of direct-acting antiviral treatment in Australia

Michael Traeger[1,2], Alisa Pedrana[1,2], Daniela van Santen[1,2], Joseph Doyle[1,3], Jess Howell[1,4], Alexander Thompson[4], Carol El-Hayek[1], Jason Asselin[1], Victoria Polkinghorne[1], Dean Membrey[5], Frances Bramwell[5], Allison Carter[6], Rebecca Guy[6], Mark Stoove[1,2,7], Margaret Hellard[1,2,3]. *[1]Burnet Institute, Melbourne, Australia; [2]Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia; [3]Alfred Health and Monash University, Department of Infectious Diseases, Melbourne, Australia; [4]St Vincent's Hospital, Department of Gastroenterology, Melbourne, Australia; [5]Cohealth General Practice, Melbourne, Australia; [6]University of New South Wales, Kirby Insitute, Sydney, Australia; [7]La Trobe University, School of Psychology and Public Health, Melbourne, Australia*
Email: michael.traeger@burnet.edu.au

Background and Aims: Realisation of global hepatitis C elimination targets will require widespread access to treatment for people living with hepatitis C virus (HCV) as well increased testing among populations at risk of HCV infection, including people who inject drugs (PWID). We used sentinel surveillance data to explore HCV testing and changes in the hepatitis C cascade of care before and after universal access to direct-acting antiviral (DAA) treatment in Australia.

Method: De-identified clinical data were retrospectively extracted from eighteen primary care and community health clinics providing services targeted towards PWID and participating in the ACCESS surveillance project in the state of Victoria. Individuals were linked across clinics using a highly sensitive matching algorithm. We calculated the proportion of individuals attending a clinic who were tested for HCV antibodies and/or RNA, and the proportion of those tested with an RNA positive result, during the three-year periods immediately prior to (pre-DAA) and following (post-DAA) DAA introduction on 1st March 2016, as well as the total number of antibody tests in each period. Two cross sectional care cascades were then constructed to classify all individuals ever diagnosed RNA-positive as having reached one of four cascade stages by 28th February 2016 and 28th February 2019, respectively; (1) diagnosed RNA-positive; (2) HCV genotype/viral load tested; (3) treated within the clinic network; and (4) evidence of cure (RNA negative ≥48 weeks [interferon treatment] or ≥8 weeks [DAA treatment] post treatment initiation).

Results: Of the 113,248 individuals visiting a clinic in the pre-DAA period, 13,784 (12.2%) had an HCV test, of whom 1,918 (13.9%) had a positive RNA result, within the period. Of the 139,082 individuals visiting a clinic in the post-DAA period, 14,507 (10.4%) had an HCV test, of whom 2,070 (14.3%) had a positive RNA result, within the period. The total number of antibody tests conducted was 14,267 and 14,236 in the pre- and post-DAA periods, respectively. The February 2016 care cascade included 2,515 individuals ever RNA-positive of which; 1,977 (78.6%) were viral load/genotype tested; 19 (0.8%) initiated treatment; and 12 (0.5%) had evidence of cure. The February 2019 care cascade included 3,713 individuals ever RNA-positive of which; 3,276 (88.2%) were viral load/genotype tested; 1,674 (45.1%) initiated treatment; and 863 (23.2%) had evidence of cure.

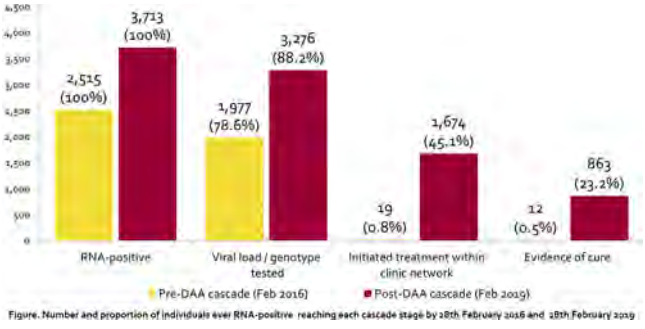


Figure. Number and proportion of individuals ever RNA-positive reaching each cascade stage by 28th February 2016 and 28th February 2019

Conclusion: Marked improvements in the cascade of hepatitis C care among patients attending this network of primary care clinics were observed following the universal access of DAA treatments in Australia, although antibody testing remained stable across periods. Increased diagnostic testing will be necessary to identify individuals chronically infected with hepatitis C to maintain adequate levels of treatment uptake and achieve elimination.

SAT326

Microelimination of chronic hepatitis C in Romania - another pathway to achieve national elimination goals by HepC ALERT project

Liliana Simona Gheorghe[1,2], Speranta Iacob[1,2], Laura Huiban[3,4], Monica Cojocaru[1,2], Camelia Cojocariu[3,4], Roxana Nemteanu[3,4], Irina Girleanu[3,4], Roxana Sirli[5], Ana Maria Singeap[3,4], Corina Pop[2,6], Dan Dumitrascu[7], Razvan Iacob[1,2], Mircea Mihai Diculescu[1,2], Anca Trifan[3,4], Ioan Sporea[5], Cristian Gheorghe[1,2]. *[1]Fundeni Clinical Institute, Digestive Diseases and Liver Transplantation Center, Bucuresti, Romania; [2]University of Medicine and Pharmacy "Carol Davila", Gastroenterology and Hepatology, Bucuresti, Romania; [3]Institute of Gastroenterology and Hepatology, Iasi, Romania; [4]"Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania; [5]"Victor Babeș" University of Medicine and Pharmacy, Gastroenterology and Hepatology, Timisoara, Romania; [6]University Emergency Hospital, Internal Medicine & Gastroenterology Department, Bucuresti, Romania; [7]"Iuliu Hatieganu" University of Medicine and Pharmacy; 2nd Department of Internal Medicine, Cluj Napoca, Romania*
Email: drgheorghe@xnet.ro.

Background and Aims: There is consensus in the application of micro-elimination for achieving HCV eradication worldwide that is why we adopted it in Romania, a country with a previously known high prevalence. The aim of our study was to perform screening of

HCV in specific populations in certain sub-regions of Romania and link them to treatment right away after diagnosis.
Method: We conducted a screening program by Gastroenterology specialists from 4 different Regions of Romania. Screening was offered to all patients admitted into the hospital Departments. We used rapid diagnostic tests, the positive HCV Ab subjects were further evaluated for viral load and fibrosis and antiviral treatment was started immediately. A questionnaire with 17 questions was given at the time of testing in order to identify risk factors for HCV infection.
Results: Between March and November 2019, 17497 persons were screened. Overall 1.45% had a positive HCV test, with the highest prevalence in Cluj (1.84%) and the lowest in Bucharest (1.26%). Patients found positive were older (64.9 ± 12.8 vs 52.2 ± 16.8years, $p < 0.0001$), from rural areas (2.36% rural vs 1.17% urban, $p < 0.0001$), with a higher prevalence in the Gypsy population (3.67% Gypsy vs 1.46% Romanians and 0.76% Hungarians, $p = 0.16$). In patients with positive HCV the following risk factors were identified in a significantly higher proportion: previously known infection with HBV/HDV, blood transfusions and unsafe abortions before 1990, multiple surgical interventions and multiple hospitalizations during lifetime, multiple stomatology interventions and IV drug users.
Conclusion: During the HEPC A.L.E.R.T. micro-elimination program in Romania, a viremic prevalence of 1.45% was detected, significantly lower compared to the previous reported data. Testing all out- and in-patients attending different departments of regional hospitals might be an efficient approach of screening and link to care cascade of hepatitis C management.

SAT327

What is required for achieving HCV elimination in Singapore? A modeling study

Antoine Chaillon[1], Prem Harichander Thurairajah[2], John Chen Hsiang[3], Natasha Martin[1]. [1]*University of California San Diego, Medicine, San Diego, United States;* [2]*Changi General Hospital, Gastroenterology, Singapore;* [3]*Sengkang General Hospital, Gastroenterology, Singapore*
Email: achaillon@ucsd.edu.

Background and Aims: Singapore is a country with a low general population HCV seroprevalence (0.37–0.54%). The vast majority of hepatitis C virus (HCV) infection in Singapore is among those with a history of injecting drug use (IDU, 45% of whom having history of current or past HCV infection), yet what is required to achieve the World Health Organization (WHO) HCV elimination targets (80% incidence reduction, 65% mortality reduction by 2030) is unknown. We model the intervention scale-up and targeting required to achieve WHO targets in Singapore.
Method: A dynamic model of HCV transmission and progression among those with a history of IDU was calibrated to Singapore, a setting with approximately 11,000 people with a history of IDU in 2017 and recent declines in IDU (based on a decline in arrests of new heroin users by ~30%/year from 2012–2018), among whom 45% are seropositive for HCV. We projected HCV treatment scale-up from 2019 required to achieve the WHO targets with varying treatment targeting scenarios (no prioritization, prioritize PWID, prioritize cirrhotics, prioritize PWID and cirrhotics). We explored the impact of opiate substitution therapy (OST) implementation (to 40% among PWID) on treatments required.
Results: In 2019 in Singapore, there were an estimated 3855 (95% CI:2635–5446) chronically HCV infected individuals with a history of IDU and 148 (95%CI: 87–284) incident HCV cases. To reach the HCV incidence target in Singapore, 272 (95%CI 187–384) treatments are required in 2019, totaling 2444 [95%CI 1683–3452] across 2019–2030. By prioritizing PWID or PWID and cirrhotics, 60% or 30% fewer treatments are required, respectively, whereas the target cannot be achieved with cirrhosis prioritization. OST scale-up could reduce treatments required by 21–24% depending on treatment targeting. Achieving both WHO targets requires treating 631 (95%CI: 359–1047) in 2019, totaling 3816 (95%CI: 2664–5423) across 2019–2030. Similar 2019 treatments but fewer cumulative treatments are needed if prioritized to PWID and cirrhotics.
Conclusion: HCV elimination is achievable in Singapore, but even in a setting of declining IDU requires immediate treatment scale-up among PWID. Combination harm reduction and treatment could reduce treatments required and provide additional benefits.

SAT328

Hepatitis C virus screening of people with severe mental illness: a cost-effectiveness analysis

François Girardin[1], Chris Painter[2], Natalie Hearmon[2], Lucy Eddowes[2], Stefan Kaiser[3], Francesco Negro[4], Nathalie Vernaz[5]. [1]*Geneva University Hospitals, Medical Direction, Division of Clinical Pharmacology and Toxicology, Genève 14, Switzerland;* [2]*Costello Medical, London, United Kingdom;* [3]*Geneva University Hospitals, Adult Psychiatry Division, Genève 14, Switzerland;* [4]*Geneva University Hospitals, Divisions of Gastroenterology and hepatology and of Clinical pathology, Genève 14, Switzerland;* [5]*Geneva University Hospitals, Medical Direction, Finance Direction, Genève 14, Switzerland*
Email: nathalie.vernaz@hcuge.ch.

Background and Aims: Hepatitis C virus (HCV) has been shown to be more common among people with severe mental illness (PSMI) than in the general population, with a prevalence ranging between 4.6–17.4%, compared to 0.5–2.3% in the general population worldwide. Moreover, HCV prevalence in the PSMI population with a history of drug abuse screened at the Psychiatry department at the Geneva University Hospitals (Psy-HUG) was estimated to be 25.7%. We aim to assess a generalized screening approach of all PSMI, including those without a history of drug abuse with a prevalence of 3.49%.
Method: Prevalences were estimated from unpublished anonymous data obtained from the HUG electronic patient record. The inclusion criteria were all patients hospitalized at Psy-HUG from January 2016 until July 2019 who were screened either for antibodies to HCV, or HCV RNA from 1990 onwards. To identify PSMI with a history of substance abuse, text data mining techniques employing natural language processing were used to search for terms such as 'heroin', 'methadone' or 'cocaine' in the patient electronic records. This study adapted a previously published cohort decision tree screening model to estimate the cost-effectiveness of routine PSMI HCV screening compared to the current risk-based screening approach (i.e. only PSMI with a history of drug abuse).

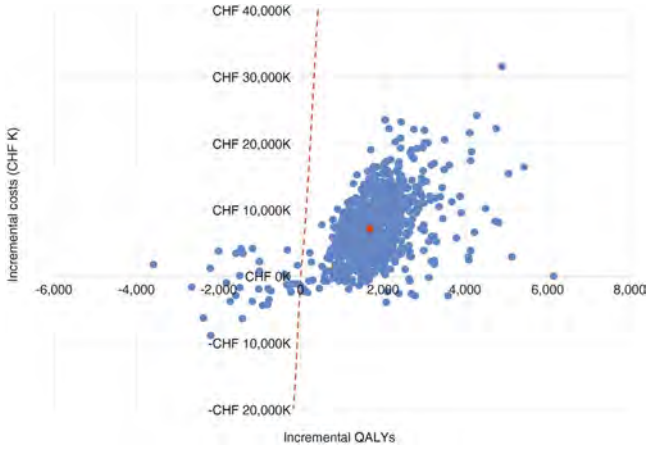

Figure: Scatter plot of the probabilistic sensitivity analysis on the cost-effectiveness plan.

Results: The total population size was 4,548. Generalized PSMI screening was found to be cost-effective compared to current risk-based screening, with a base-case incremental cost-effectiveness ratio of CHF 4,217 per quality-adjusted life year (QALY). The total incremental cost of the generalized screening programme at the

population level was CHF 7,360,028. The results of a probabilistic sensitivity analysis of 1,000 model simulations showed that 96.4% of simulations predicted generalized screening of PSMI to be cost-effective at the willingness-to-pay threshold of CHF 100,000 per QALY (Figure).

Conclusion: Accrued screening and treatment of HCV-infected individuals, particularly in higher prevalence population subgroups, is necessary to reduce the global burden of HCV and move towards the World Health Organization's goal of viral hepatitis elimination by 2030. Model results show that generalized screening of PSMI is cost-effective compared to current risk-based screening at a range of WTP thresholds, demonstrating that screening for HCV of all PSMI should be considered by Swiss policy-makers.

SAT329

Incidence of HCV infection among gbMSM in British Columbia, Canada: a population-based cohort study

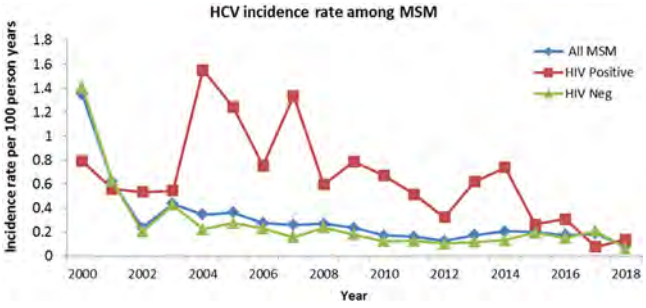
Naveed Janjua[1,2], Stanley Wong[1], James Wilton[1], Prince Adu[1,2], Zahid Butt[3], Hasina Samji[1], Geoff McKee[4], Mawuena Binka[1], Younathan Abdia[1,2], Amanda Yu[1], Sofia Bartlett[1,5], Dahn Jeong[1,2], Emilia Clementi[1,2], Dr. Margo Pearce[1,2], Maria Alvarez[1], Dr. Jason Wong[1], Mel Krajden[1,5]. *[1]BC Centre for Disease Control, Vancouver, Canada; [2]School of Population and Public Health, Vancouver, Canada; [3]University of Waterloo, Waterloo, Canada; [4]Vancouver Coastal Health, Vancouver, Canada; [5]The University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada*
Email: naveed.janjua@bccdc.ca.

Background and Aims: Gay, bisexual, and other men who have sex with men (gbMSM) are at high risk of HCV infection. Monitoring incidence of HCV among gbMSM is critical to achieve hepatitis elimination goals. However, there is lack of data from the population-based systems to monitor incidence of HCV among gbMSM. In this study, we estimated the incidence of HCV infection among gbMSM in a large population-based cohort in Canada.

Method: This analysis included all gbMSM in the BC Hepatitis Testers Cohort (BC-HTC) who have been tested for HCV at least twice between Jan 1, 2000 and Dec 31, 2018, with a first test being negative. Incident HCV infection was defined as a positive anti-HCV, RNA, or genotype test following a negative anti-HCV test among gbMSM. gbMSM were identified based on self-report. Status for those with missing information was imputed based on a validated algorithm with 95% specificity. Annual incidence rates for HCV infection from 2000 to 2018 were estimated and Cox proportional hazards models were constructed to identify risk factors associated with HCV infection among gbMSM.

Results: Among 44,172 eligible gbMSM, 641 HCV seroconversions occurred over 286,253 person-years (PY) of follow-up with an overall incidence rate of 0.22/100PY (95%CI: 0.21–0.24). The incidence rate was highest among gbMSM with drug dependence (1.44, 95%CI: 1.28–1.61), especially those with history of opioid misuse (2.45, 95% CI: 2.07–2.9) and stimulant misuse (1.79, 95%CI: 1.53–2.1). Incidence declined from 1.3/100PY in 2000 to 0.078/100PY in 2018. In the multivariable model, younger birth cohorts (1965–1974: adjusted hazard ratio (HR) 7.54, 95%CI: 3.1–18.37; ≥1975: HR 13.7, 95%CI: 5.64–33.23 compared to <1945), history of drug dependence (HR: 5.56, 95%CI: 4.44–6.98), opioid misuse (HR: 2.08, 95%CI: 1.61–2.68), HIV coinfection (HR: 4.38, 95%CI: 3.61–5.31), and material deprivation (most privileged vs most deprived: HR: 0.55, 95%CI:0.45–0.68) were associated with HCV seroconversion. In models stratified by HIV status, drug dependence and opioid misuse were not significantly associated with HCV seroconversion risk in people with HIV infection.

Conclusion: Overall incidence rate among gbMSM is low, consistent with previous data, with high incidence among those with drug use. gbMSM with HIV infection, drug dependence, opioid misuse, and material deprivation are at higher risk of HCV infection, requiring multi-faceted approaches to reduce the risk of HCV infection among gbMSM subgroups.



SAT330

An OST (opiate substitution therapy)-based hepatology service facility (OHSF) with access to chronic hepatitis C treatment: the example of an one stop shop as a practical step towards HCV elimination in patients who use drugs (PWUD)

Nikolaos Papadopoulos[1], Sofia Vasileiadi[2], Anastasia Drimousi[3], Constantia Alexakou[4], Maria Kollitsida[3], Anastasios Tsantilas[5], Konstantinos Stamatopoulos[3], Argirios Kotsalis[3], Theodoros Papadopoulos[3], Melanie Deutsch[2]. *[1]417 Army Share Fund Hospital; 1st Department of Internal Medicine, Athens, Greece; [2]Hippokration General Hospital of Athens; 2nd Academic Department of Internal Medicine, National and Kapodistrian University of Athens, Medical School, Athens, Greece; [3]Organization Against Drugs (OKANA), Emergency Assistance & Support Unit, Athens, Greece; [4]Organization Against Drugs (OKANA), KAT Unit, Athens, Greece; [5]Organization Against Drugs (OKANA), Asklipieio Voulas Unit, Athens, Greece*
Email: npnck7@yahoo.com.

Background and Aims: Direct Acting Antivirals (DAAs) have improved efficacy and tolerability in the treatment of chronic hepatitis C virus (HCV) infection. However, access is often limited in PWUD patients receiving OST, who may be underserved for health care and face social inequity. We determined the effectiveness of an OST-based hepatology service facility (OHSF) with access to HCV evaluation and treatment.

Method: We prospectively enrolled 265 anti-HCV patients (M/F: 216/49, mean age: 43.2 ± 9.2 years) who have been referred by other OST programs between September 2018 and September 2019. The services provided by the OHSF include complete biochemical evaluation, HCV, HBV and HIV virology screening, access to HCV RNA/Genotype evaluation and liver stiffness measurement (LSM).

Results: 258/265 (97.5%) were Greeks, 36/265 (13.5%) cirrhotics, 35/265 (13%) treatment experienced, 8/265 (3%) HIV positive and 6/265 (2.5%) were HBsAg positive. In total, 217/265 (82%) of the patients underwent HCV RNA/Genotype evaluation and 185/217 (70%) were viraemic with the following genotype distribution: G1a: 23%, G1b: 3%, G2: 2%, G3a: 58.5% and G4: 13.5%. HCV RNA/Genotype evaluation was not initiated more frequently in HIV-positive than in HIV-negative patients [5/42 (12%) vs 3/198 (1.5%), p = 0.005]. Finally, 183/185 (99%) of the viraemic patients have been scheduled for HCV treatment. Treatment initiation was recorded in 144/183 (79%) patients. None of them has been lost in follow-up: 127/144 (88%) have completed the treatment while 17/144 (12%) are still under treatment.

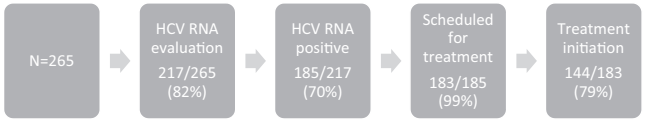


Figure: Treatment scale initiation among OST patients referred at OHSF.

Conclusion: A significant proportion (>75%) of anti-HCV positive patients referred at OHSF with access to chronic hepatitis C treatment receive antiviral treatment. HCV RNA/Genotype evaluation starts significantly less frequently in HIV-positive patients. The vast majority of OST patients referred at OHSF (>80%) will complete treatment.

SAT331

Recent decline in hepatocellular carcinoma rates in the United States

Meredith Shiels[1], Thomas Obrien[1]. [1]*National Cancer Institute, Division of Cancer Epidemiology and Genetics, Bethesda, United States*
Email: obrient5150@gmail.com.

Background and Aims: In the United States, rates of hepatocellular carcinoma (HCC) increased over several decades and were projected to increase ~3%/year through 2030. Here, we provide HCC rates through 2016.

Method: HCC incidence data were obtained from SEER-21, a group of population-based cancer registries covering 37% of the U.S. population. Cases were identified using International Classification of Diseases for Oncology, 3rd edition codes (site: C22.0; histology: 8170–8175).

Incidence rates were age-standardized to the 2000 US population, and estimated overall and by sex, age group and race/ethnicity. Annual percent changes (APCs) were estimated using joinpoint regression, which identifies statistically significant inflection points in rate trajectories. Rate ratios (RRs) comparing 2016 to 2015 were estimated.

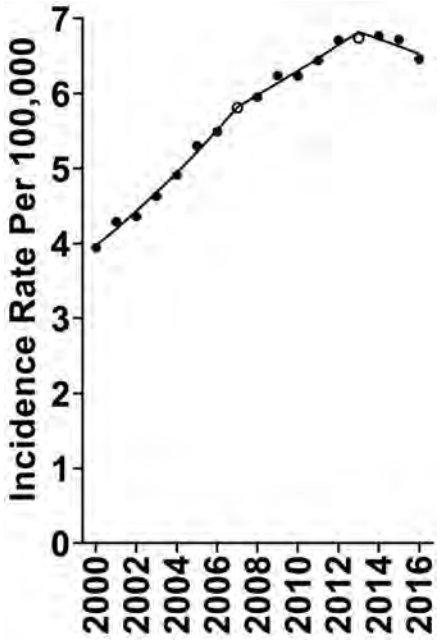

Figure 1: Hepatocellular carcinoma incidence rates in 21 US cancer registries, by year – 2000 to 2016. Open circles indicate joinpoints where the annual percent change differs significantly from zero at the alpha = 0.05 level.

Results: Figure 1 shows that overall HCC rates increased 5.64%/year during 2000–2007 ($p < 0.001$), 2.68%/year during 2007–2013 ($p < 0.001$) and then plateaued starting in 2013 (APC = -1.44%/year; $p = 0.12$). HCC incidence was significantly lower in 2016 compared to 2015 (RR = 0.96; $p = 0.007$).

HCC trends differed by age. Inflections and significant decreases occurred among 35–49-year-olds starting in 2006 (APC = –4.93%/year; $p < 0.001$) and among 50–64-year-olds starting in 2014 (APC = –6.64%/year; $p = 0.04$). For ≥65-year-olds, rates increased during the entire time period (APC = 2.69%/year; $p < 0.001$).

By race, HCC rates plateaued among Whites beginning in 2013 (APC = –0.91%/year; $p = 0.45$) and among Blacks in 2009 (APC = 0.27%/year; $p = 0.65$). Among Hispanics, HCC incidence decreased beginning in 2014 (–6.55%/year; $p = 0.08$) and was significantly lower in 2016 than 2015. Among Asians, starting in 2007, HCC rates decreased –2.72%/year ($p < 0.001$). In contrast, for American Indian/Alaska Natives, HCC rates increased 4.60%/year ($p < 0.001$) across the entire time period.

Conclusion: U.S. HCC incidence increased for decades and was projected to continue rising through 2030, however, recent data indicate HCC rates flattened in 2013 and then declined in 2016. Our analysis suggests the tide has begun to turn for HCC incidence in the United States.

SAT332

HCV screening and linkage to care of homeless people in a major European city. Data from a mobile screening unit (MSU)

Jorge Valencia[1], Guillermo Cuevas[2], Antonio Rodriguez[3], Carlos Cabezon[1], David Lozano[1], Jimmie Paz[1], Alejandro Ramirez[1], Juan Torres[2], Pablo Ryan[2]. [1]*SERMAS, Madrid, Spain;* [2]*Hospital Universitario Infanta Leonor, Madrid, Spain;* [3]*Fundación SEIMC-GESIDA, Madrid, Spain*
Email: pabloryan@gmail.com.

Background and Aims: Homeless people have a higher prevalence of HCV than general population. Due to their life-style, homeless people are in an unfavorable situation to access screening, diagnosis and treatment of any infectious diseases. The aims of this study were to calculate the prevalence of HCV active infection in homeless people in a mayor European city and to evaluate the impact of using a mobile screening unit (MSU) and navigators on the linkage to HCV care in this population.

Method: By means of an MSU and an interdisciplinary health team, those places in Madrid where vulnerable populations gather were detected. From 2/2019–11/2019, HIV, HCV and HBV rapid tests were conducted in these locations. Participants who tested positive, were tested for RNA-HVC using Xpert at the MSU. Those with an active infection were offered referral and accompaniment to their hospital. Descriptive, bivariate and multivariate analysis was used to compare homeless and no homeless people.

Results: During the period of study, the MSU screened 1577 subjects and 1028 (65%) of them were homeless. Of the total number of homeless people, 712 (69%) were male, median age was 43 years, 587 (57%) were from abroad, 256 (67%) had consumed drugs (heroin or cocaine) in the last year, 177 (46%) were in opiate substitute treatment, 275 (27%) consumed alcohol (>50 g/day) and 191 (19%) used benzodiazepines. Of the total homeless people screened, 197 (19%) had a positive HCV rapid test and, 71 (39%) of them had active HCV infection, 59 (6%) had HIV infection (5% new diagnosis). Globally, 59 (85%) patients were referred to a hospital and 44 (62%) initiated HCV treatment.

Homeless people were more frequently born outside Spain (57% vs. 25%, $P < 0.001$) than those who were not homeless. Homeless people were also more frequently evaluated by a hepatologist than those who were not homeless (85% vs. 24%, $P = 0.042$). There were no statistically significant differences in those who initiated HCV therapy (>80% of treatment initiations). Median time to treatment initiation was 38 days.

Conclusion: Active hepatitis C infection remains prevalent in vulnerable populations, particularly in the homeless population. A strategy that uses a mobile unit, improves access to HCV care even in difficult-to-reach populations.

SAT333

Development of a supportive needs assessment tool for cirrhosis (SNAC)

Patricia Valery[1], Christina Bernardes[1], Katherine Stuart[2], Gunter Hartel[1], Steven McPhail[3], Richard Skoien[4], Tony Rahman[5], Paul Clark[6], Leigh Horsfall[2], Kelly Hayward[7], Rohit Gupta[8], Elizabeth Powell[2]. *[1]QIMR Berghofer Medical Research Institute; [2]Princess Alexandra Hospital; [3]Queensland University of Technology; [4]Royal Brisbane and Women's Hospital; [5]The Prince Charles Hospital; [6]Mater Hospitals; [7]The University of Queensland; [8]Sunshine Coast University Hospital*

Email: patricia.valery@qimrberghofer.edu.au.

Background and Aims: Accurate assessment of the supportive needs of individuals with cirrhosis is important to improve patient care. To address the lack of a specific health needs assessment instrument for this patient group, we developed what is, to the best of our knowledge, the first supportive needs assessment tool for cirrhosis. We report the development and psychometric testing of a Supportive Needs Assessment tool for Cirrhosis (SNAC).

Method: The SNAC was developed in three stages, namely: (i) item generation; (ii) pre-testing of the first draft of the SNAC (face and content validity, review, and field-testing of the instrument); and (iii) psychometric evaluation of the newly developed SNAC (Fig). The 50-item SNAC was administered to patients (n = 465) diagnosed with cirrhosis recruited from five metropolitan hospitals in Queensland, Australia. Items were assessed for ceiling and floor effects, and exploratory factor analysis was used to assess the factor structure. Identified factors were assessed for internal consistency and convergent validity to validated psychosocial tools.

Results: Exploratory factor analysis identified 4 factors (39 items), which together accounted for 49.2% of the total variance. The 39-item SNAC met the requirements of a needs assessment tool and identified a range of needs important to patients with cirrhosis that were grouped in four subscales: 'Psychosocial issues', 'Practical and physical needs', 'Information needs', and 'Lifestyle changes'. Cronbach alpha for the total scale was 0.94; values ranged from 0.64 to 0.92 in all subscales. Convergent validity was supported by a strong correlation between the total SNAC score and that of the Chronic Liver Disease Questionnaire (CLDQ; Spearman rho –0.68; $p < 0.001$), and moderate correlations with the Distress Thermometer (Spearman rho 0.53; $p < 0.001$) and seven subscales of a generic health-related quality of life instrument (Short Form 36; Spearman rho ranged from –0.48 to –0.57; $p < 0.001$). The SNAC discriminated patient groups with respect to gender ($p = 0.013$), age group ($p < 0.001$), and hospital admission status (admitted vs. not; $p < 0.001$).

Conclusion: These data provide initial evidence for the validity and reliability of the SNAC, an instrument designed to measure the form and amount of perceived unmet practical and psychological needs of patients with cirrhosis.

SAT334

Inequities in presentation and outcomes for indigenous Australians hospitalised for cirrhosis

Patricia Valery[1], Paul Clark[2], Gregory Pratt[1], Christina Bernardes[1], Gunter Hartel[1], Maree Toombs[3], Katharine Irvine[4], Elizabeth Powell[5]. *[1]QIMR Berghofer Medical Research Institute; [2]Mater Hospitals; [3]University of Queensland; [4]Mater Research; [5]Princess Alexandra Hospital*

Email: patricia.valery@qimrberghofer.edu.au.

Background and Aims: Indigenous Australians experience greater health disadvantage and have a higher prevalence of many chronic health conditions compared to other Australian adults. Liver diseases are among the most common contributors to the mortality gap between Indigenous and other Australian adults. However, differences in presentation and patient outcomes between Indigenous and non-Indigenous Australians hospitalised with cirrhosis have not been investigated.

Method: Using data from the Hospital Admitted Patient Data Collection and the Death Registry, this retrospective, population-based, cohort study including all people hospitalised for cirrhosis in the state of Queensland during 2008–2017 (779 Indigenous and 10,642 non-Indigenous) examined rate of readmission (Poisson regression), cumulative survival (Kaplan–Meier), and assessed the adjusted differences in survival (Multivariable Cox regression) by Indigenous status.

Results: A higher proportion of Indigenous patients were younger than 50 years (346 [44%] vs. 2,063 [19%] non-Indigenous patients), lived in most disadvantaged areas (395 [51%] vs. 2,728 [26%]), had alcohol-related cirrhosis (547 [70%] vs. 5,041 [47%]), had ascites (314 [40%] vs. 3,555 [33%], and presented to hospital via the Emergency Department (510 [68%] vs. 4,790 [47%]). Compared to non-Indigenous patients, Indigenous patients had 3.04 times the rate of non-cirrhosis readmissions (95%CI 2.98–3.10) and 1.35 times that of cirrhosis-related readmissions (95%CI 1.29–1.41), and lower overall survival (17% vs. 27%; unadjusted hazard ratio (HR) = 1.16 95%CI 1.06–1.27). In multivariable analysis, adjusting for age group increased the HR to 1.30 (95%CI 1.18–1.42). Most of the survival deficit was explained by Emergency Department presentation (adj-HR = 1.03 95%CI 0.93–1.13), and alcohol-related aetiology (adj-HR = 1.08 95%CI 0.99–1.19). The remaining survival deficit was influenced by the other

Figure: (abstract: SAT333): Overview of the stages of development of the Supportive Needs Assessment tool for Cirrhosis (SNAC).

clinico-demographic factors and health service use (final adj-HR = 1.08 95%CI 0.96–1.20).
Conclusion: There was evidence of differential presentation, higher rates of readmissions, and poorer survival for Indigenous Australians with cirrhosis, compared to other Australians. The increased prevalence of Emergency Department presentation among Indigenous patients suggests missed opportunities for early intervention to prevent progressive cirrhosis complications and hospital readmissions.

SAT335
Leveraging direct-to-patient messaging: electronic record assimilation and subsequent eradication of hepatitis C (Erase-C)
Aparna Goel[1], Lance Downing[2], Jimmy Dang[3], Channa Jayasekera[4], Paul Kwo[5]. [1]*Stanford University, Medicine/GI and Hepatology, Palo Alto, United States;* [2]*Stanford University, Population Health, Palo Alto;* [3]*Stanford Health Care;* [4]*Kaiser Permanente Washington, Hepatology Program, Seattle, United States;* [5]*Stanford University, Medicine/GI and Hepatology*
Email: goela21@stanford.edu.

Background and Aims: Hepatitis C virus (HCV) screening is a crucial step in HCV elimination. Currently, the United States Preventive Services Task Force recommends a one-time HCV screen in individuals born between 1945 and 1965 (henceforth baby boomer birth cohort, BBBC). Adherence to this guideline in the US population is 14% and within the Stanford primary care clinic, 18%. Direct-to-patient messages via electronic medical record (EMR) improves adherence to other healthcare maintenance recommendations, but has not been studied for HCV screening. We aim to study the efficacy of a direct patient message via EMR in improving HCV screening rates within a large US healthcare system.
Method: Randomized study comparing the effectiveness of a direct-to-patient electronic health message on HCV screening coupled with a lab requisition, versus HCV screening initiated by primary care (PC) clinicians in an unscreened BBCC. Patients were stratified into two strata based on whether they had a PC appointment in the upcoming 6 months. Within each stratum, 400 patients were randomized to receive a one-time EMR message on HCV screening, coupled with a lab requisition for HCV antibody and 400 patients did not receive a message. Patients were followed for six months and rates of HCV screening compared between groups.

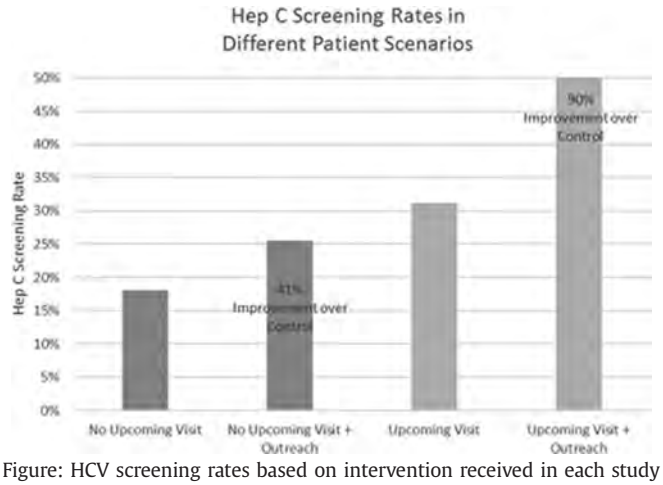

Figure: HCV screening rates based on intervention received in each study cohort.

Results: During the six months intervention period, 598 of 1600 (37.4%) baby boomers in the study cohort had HCV screening test performed. Screening rates were highest at 60.6% among those that received a message *and* had an upcoming PC appointment compared to 34.8% in those that did not receive a message ($p < 0.01$). Similarly, in the stratum without an upcoming PC appointment, HCV screening rate among those that received a message was 30.8% compared to 20.3% in those that did not receive a message ($p < 0.01$; Figure 1). The greatest impact in the cohort with an upcoming PC appointment was seen in patients that had an appointment within three weeks of message being sent. Among 598 screened patients, there were no positive HCV antibody results.
Conclusion: Direct-to-patient messaging via EMR is an effective way of improving HCV screening uptake in unscreened BBCC that is established within a healthcare system. Messaging should ideally occur within three weeks of a patient's upcoming clinic appointment.

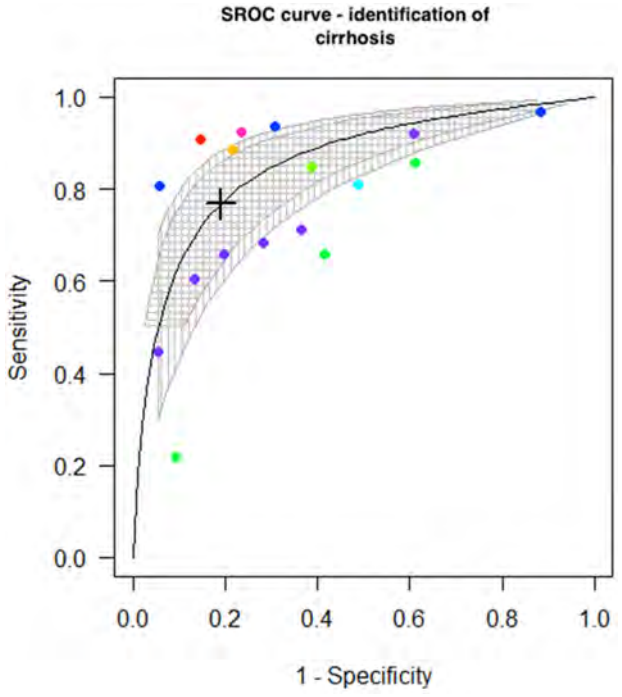
SAT336
Catalytic funding of viral hepatitis elimination program in Uzbekistan
Rick Dunn[1], Erkin Musabaev[2], Shakhlo Sadirova[2], Shokhista Bakieva[2], Kathryn Razavi-Shearer[1], Homie Razavi[1]. [1]*Center for Disease Analysis Foundation, Lafayette, United States;* [2]*Research Institute of Virology, Tashkent, Uzbekistan*
Email: rdunn@cdafound.org.

Background and Aims: Globally, >95% of all HBV infections and >80% of all HCV infections are in low and middle-income countries (LMIC). Except for a handful of countries, most cannot afford to pay for a national hepatitis elimination program to achieve the WHO elimination targets. With the lack donors to support these programs, a new financing mechanism is needed.
Method: A mathematical model was used to estimate the annual funding required to support an elimination program in Uzbekistan. Work Bank data was used to calculate the catastrophic healthcare expenditure (CHE), annual expenditure that will send a family to bankruptcy, for the lowest quartile of the population. It was assumed that 20% of the population could not afford treatment at any price. The number of days required for manufacturing, clearing customs and distribution the product was used to estimate the cash on hand needed to support an elimination program.
Results: In Uzbekistan, the total cost of screening, testing & treatment has to stay below $920 per year, per person. To make the analysis comparable in other countries, a cut off of $250 per year per person was used. Testing & treatment protocols were a key driver of the program cost. We determined that an up-front investment of $1.2 million would support a program to provide free screening for 250,000 people, provide free testing for all HBV+ and HCV+ patients and provide free treatment to 20%. The remaining patients would pay for their treatment at a cost that is below CHE and is 50–80% less than what they are paying today. At the end of the program, the initial investment is recouped to invest in a national program. We are currently conducting a pilot study to demonstrate this novel financing mechanism.
Conclusion: Catalytic investment to fund national programs is a viable option to support hepatitis elimination in LMIC.

SAT337
Meta-analysis: accuracy of the enhanced liver fibrosis (ELF) test in detection of advanced fibrosis or cirrhosis
Hannah Lally[1], Hannah Gibson[1], Ian Rowe[2], Bethany Shinkins[3], Richard Parker[4]. [1]*University of Leeds, School of Medicine, Leeds, United Kingdom;* [2]*University of Leeds, Leeds Institute for Data Analysis, Leeds, United Kingdom;* [3]*University of Leeds, Leeds Institute of Health Sciences, Leeds, United Kingdom;* [4]*Leeds Teaching Hospitals NHS Trust, Leeds Liver Unit, Leeds, United Kingdom*
Email: richardparker@nhs.net.

Background and Aims: Background and Aims: non-alcoholic fatty liver disease (NALFD) and alcohol-related liver disease (ArLD) are common diseases but liver-related ill-health occurs in only a fraction of people. However significant liver disease often presents late with cirrhosis. There is therefore considerable interest in the use of non-invasive tests to identify hepatic fibrosis before symptoms occur. We

examined the accuracy of the enhanced liver fibrosis (ELF) test in the identification of hepatic fibrosis.



Method: systematic review of medical literature databases to identify studies reporting on the accuracy of the ELF test in detecting advanced hepatic fibrosis and/or cirrhosis. Random-effect meta-analysis was performed with adjustment for the multiple cut-offs described in the included papers. Results are reported as sensitivity and specificity. Sub-group analysis for advanced fibrosis and cirrhosis was performed. The risk of bias in each study was assessed with the QUADAS-2 tool.

Results: The literature search identified 436 studies of which 13 were suitable for inclusion. These studies included a total of 2255 patients with or at risk of liver disease. The majority of patients had viral hepatitis (hepatitis C, 927 patients; hepatitis B, 462 patients). A further 289 patients had alcohol-related liver disease (ArLD) and 322 patients were included as "chronic liver disease." Six different histological scoring systems were used for histological staging of liver disease. All studies except one recruited patients from secondary care. A range of ELF cut-offs were used, from 5.2 to 11.3. In meta-analysis, ELF detected significant fibrosis with a sensitivity of 74.8 (95%CI 54.1–88.2) and specificity of 74.2% (53.8–87.6), advanced fibrosis with sensitivity of 81.4% (95%CI 75.5%–86.1%) and specificity of 74.9% (67.6%–80.9%) and cirrhosis with sensitivity of ELF was 75.7% (65.9%–83.4%) and specificity 75.9% (66.1%–83.5%). The optimum ELF cut-off for detection of cirrhosis was 10.26.

Conclusion: ELF can accurately detect advanced fibrosis or cirrhosis. However this is based on research predominantly in people with chronic viral hepatitis and in secondary care populations. There are presently few data to support the use of ELF outside of specialist services or on a population level.

Risk factors for liver disease cluster geographically: precision public health analysis of a UK city

Richard Parker[1,2], Jessica Shearer[1,3], Jennifer Spencer[4], Benjamin Wicks[1], Adam Taylor[5], Rachel Dukes[6], Ian Rowe[1,3]. *[1]Leeds Teaching Hospitals NHS Trust, Leeds Liver Unit, Leeds, United Kingdom; [2]Leeds Institute of Medical Research at St James's, University of Leeds, Leeds, United Kingdom; [3]University of Leeds, Leeds Institute for Data Analysis, Leeds, United Kingdom; [4]Leeds Teaching Hospitals NHS Trust, Blood Sciences, Leeds, United Kingdom; [5]Leeds CCG, Adults and Health Directorate, Leeds, United Kingdom; [6]Leeds City Council, Adults and Health Directorate, Leeds, United Kingdom*
Email: richardparker@nhs.net.

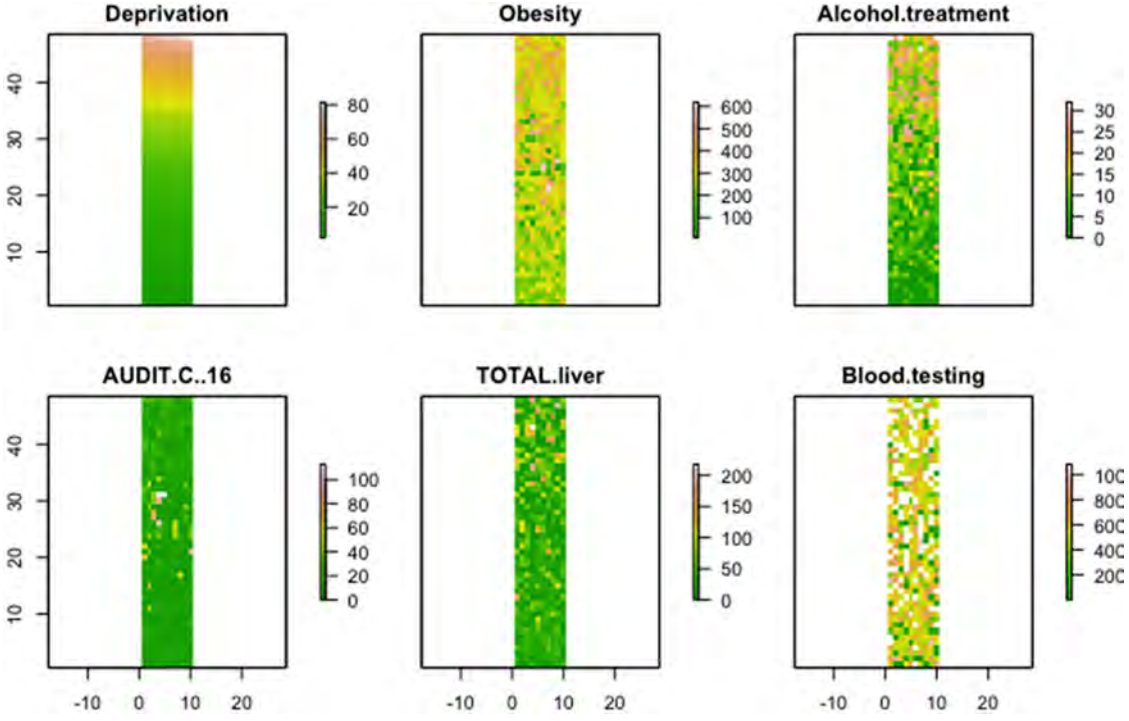

Figure: (abstract: SAT338)

Background and Aims: Liver-related deaths are increasingly common in the UK and are particularly frequent amongst people of working age. Understanding the factors that are associated with liver disease may allow for targeted public health and hepatology interventions to improve health. We investigated liver disease and public health in Leeds, a large city in the north of England.
Method: Leeds is a large city in the north of England with a single hospital provider which also provides laboratory services to primary care. Liver disease was quantified from clinical coding of hospital admissions (number of people admitted to hospital with liver disease). Public health data regarding the prevalence of obesity, diabetes, deprivation and alcohol use from lower output super-areas (LSOA) in Leeds (geographical units of approximately 1500 people) were collated and compared to the incidence of liver disease. Liver blood tests (LBT) were quantified for each LSOA.
Results: Incidence of liver disease was not uniform across Leeds but showed significant variation across LSOA. In multiple linear regression obesity (estimate 0.12, $p < 0.001$), hazardous alcohol use (AUDIT score $\geq$ 16) (estimate 1.14, $p = 0.02$) and severity of deprivation (estimate 0.58, $p < 0.001$) were independent predictors of the incidence of liver disease. These risk factors for liver disease clustered together geographically (figure). The number of LBT from each LSOA was not associated with the incidence of liver disease or the identified risk factors for liver disease.
Conclusion: Deprivation, obesity and alcohol use, measured at a population level are associated with liver disease and tend to occur together. These findings underline the need for robust public-health solutions to reduce the prevalence of liver disease and suggest that case-finding of undiagnosed liver disease could be targeted to areas of high prevalence.

SAT339

Updated estimate for prevalence of chronic hepatitis B among foreign-born persons living in the United States by country of origin

Robert Wong[1], Carol Brosgart[2], Sue Welch[3], Tim Block[4], Mark Chen[3], Chari Cohen[4], W. Ray Kim[5], Kris Kowdley[6], Anna Lok[7], Naoky Tsai[8], John Ward[9], Steven Wong[3], Robert G. Gish[4]. *[1]Alameda Health System Highland Hospital, Oakland, United States; [2]UCSF School of Medicine, San Francisco, United States; [3]Plan A, Mountain View, United States; [4]Hepatitis B Foundation, Doylestown, United States; [5]Stanford University School of Medicine, Palo Alto, United States; [6]liver institute, Seattle, United States; [7]University of Michigan Medical School, Ann Arbor, United States; [8]The Queen's Medical Center, Honolulu, United States; [9]Emory University, Atlanta, United States*
Email: robertwong123@gmail.com.

Background and Aims: Foreign-born (FB) persons contribute disproportionately to burden of chronic hepatitis B (CHB) in the United States (U.S.). In 2009, we estimated 1.3 million (M) FB with CHB living in the U.S. based on systematic review and meta-analysis of HBsAg seroprevalence surveys from 102 countries from which FB migrate to the U.S combined with the number of FB in the U.S. from each country using U.S. Census Bureau. Over the past decade, immigration patterns have changed and CHB prevalence likely declined as some countries have implemented hepatitis prevention and vaccination programs. This study reports 1) updated estimates of prevalence of FB with CHB from all regions in the world living in the U.S. in 2018; and 2) updated estimates of FB living with CHB in the U.S. originating from Southeast and South Central Asia (SE and SoCen Asia).
Method: To estimate total FB with CHB in the U.S. in 2018, country-specific CHB rates from the 2009 systematic review and meta-analysis (surveys published 1980 to 2009) were combined with number of FB living in the U.S. in 2018 by country of origin from U.S. Census Bureau. We also updated the systematic review and meta-analysis for SE and SoCen Asia to include reports of HBsAg seroprevalence among emigrants and general in-country populations published from 2009 to 2018. Country-specific pooled CHB rates were calculated including all studies from 1980 to 2018; and the rates combined with number of FB in the U.S. in 2018 by country of birth to estimate the number of FB with CHB from each country in SE and SoCen Asia.
Results: From 2009 to 2018, overall FB population in the U.S. increased by 16% (38.4M to 44.7M) (Figure). Based on the change in FB population alone—and assuming no change in CHB rates from 2009 estimates—total number of FB with CHB in the U.S. would have increased by 31% (from 1.3 M to 1.7 M); and the number of FB with CHB from SE and SoCen Asia by 18% and 55%, respectively. Accounting for both increased FB population and revised CHB rates from the updated systematic review, FB with CHB in the U.S. from SE and SoCen Asia are estimated to have increased by 13% and 28%, respectively.
Conclusion: Interim analysis of this updated systematic review suggests continued immigration has increased the number of FB living with CHB in the U.S. despite likely declines in CHB prevalence rates in many countries of origin. CHB prevalence rates in all 102 countries of origin included in the 2009 analysis will be presented.

SAT340

Improving access to care for serologically positive hepatitis C blood donors in private sector

Sabeen Shah[1], Uzma Khan[2], Saira Khowaja[2], Uzma Ata[3], Saba Jamal[3], Aamir Javed Khan[2]. *[1]The Indus Hospital, Global Health Directorate, Karachi, Pakistan; [2]Interactive Research and Development, Global; [3]The Indus Hospital Blood Centre, Karachi, Pakistan*
Email: sabeen.shah@ghd.ihn.org.pk.

Background and Aims: 6.8% of adult Pakistani population is reported to be hepatitis C (HCV) seropositive but only 14% are aware of their infection status. Usually, HCV seropositivity is an incidental finding during blood donation process. Due to several factors such as lack of integration between blood centers and clinical services and high cost of care, identified seropositive donors are left to search for treatment on their own, posing major obstacles in patient's journey to access care. In November 2018, we initiated active tracking and linkage to care of seropositive blood donors, through integration of blood bank and HCV services, both of which were available at The Indus Hospital in Karachi, Pakistan.
Method: Standard operating procedures (SOPs) were established to ensure seamless communication between both teams. Blood center recorded donor personal details and demographics, counselled donors regarding test results and ensured linkage with the HCV clinic. The HCV program team tracked them through each step of the care cascade i.e. from diagnostic testing to sustained virological response (SVR 12) response. All eligible were treated with Sofosbuvir and Daclatasvir based treatment regimens. All services were offered free of cost.

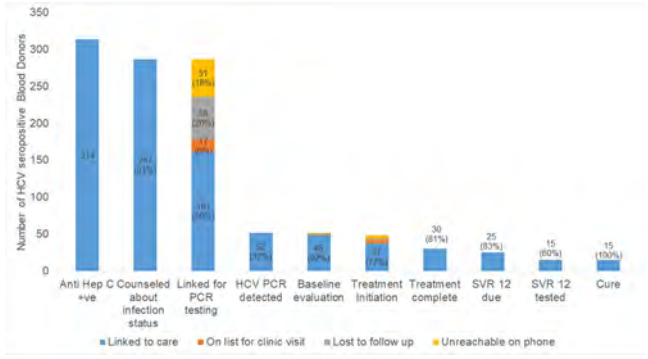

Figure: Linkage to care for PCR testing and treatment uptake

Results: From July 1, 2018 to September 30, 2019, 28,173 donors were registered in blood bank database and majority of whom were male. Blood donation camps were organised in factories, mosques and schools. 314 (1.1%) donors were seropositive for HCV: 307 (98%) were males; mean age was 29 years (range : 17–51 years). 287 (91%) donors were informed about their blood screening results, 8% could not be contacted due to wrong phone number (unreachable) 2% wanted to seek care outside Indus Hospital. Of 287 donors counselled, 161 (56%) have been tested for Polymerase Chain Reaction (PCR), 17 (6%) are scheduled for clinic visit, whereas 51 (18%) remain unreachable and 58 (20%) have not returned to the clinic despite being connected via phone (lost to follow up). Of those PCR tested, 52 (32%) were found to have active infection: of these 48 (92%) returned to the clinic for further evaluation. 37 (77%) were started on treatment and 5 (10%) are scheduled to return to clinic. 30 (81%) patients have completed treatment. Of 25 (83%) due for SVR 12 testing, only 15 (60%) are tested so far and all achieved cure.
Conclusion: Integration of blood bank with clinical care services is possible through the use of minimal resources. There is a dire need for establishing a central database for sharing of information across various health care services including blood centers to improve access to care for hepatitis C.

SAT341

Comparison of costs of different HCV screening and linkage to care interventions across Europe

Sandra Bivegete[1], Zoe Ward[1], Josephine Walker[1], Linda Campbell[1], Nyashadzaishe Mafirakureva[1], Davina Swan[2], Eileen O'connor[2], Geoff McCombe[2], Tina Mchugh[3], Des Crowley[4], Mark Kennedy[5], Enda Kelly[5], Graham Betts-Simmonds[6], Irina Ianache[7], Alma Gabriela Kosa[7], Oprea Anca Cristiana[7], Julian Surey[8], Steven Platts[9], Gordana Avramovic[3], Matthew Hickman[1], Alistair Story[10], Walter Cullen[2], Jack Lambert[3], Peter Vickerman[1].

Email: sandra.bivegete@bristol.ac.uk.

Background and Aims: HCV is a blood borne virus mainly transmitted through injecting drug use in European settings, with long term consequences including liver disease and hepatocellular carcinoma. This study aims to compare the costs per person screened, diagnosed/identified, and linked to care for various pilot interventions undertaken as part of the HepCare Europe programme.
Method: Four interventions were costed: 1. Nurse liaison for GP prescribers of OST in Dublin (HepLink Dublin); 2. Nurse led mobile outreach in London targeting homeless populations and people who inject drugs, with peer support for linkage to HCV treatment in hospital (HepFriend London); 3. Mass opt-out screening in a Dublin prison with a peer based awareness program (HepCheck Dublin); and 4. Screening and linkage to care in targeted high-risk settings in Bucharest (HepCare Bucharest).
For each site, intervention costs were collected by interview with intervention staff using a top down approach, including staff costs, resource use and HCV test costs. Setup costs were annualised over 5 years. The cost (in €) per person screened, diagnosed and linked to care was calculated for each intervention. Costs and patients screened, diagnosed, and linked to care for HepFriend London were taken from the middle year of the intervention.
Results: The costs per year were €64,806, €112,093, €81,505, and €56,647 for HepLink Dublin, HepFriend London, HepCheck Dublin, and HepCare Bucharest, respectively. The cost per patient outcome were impacted by the size of the target population reached and the prevalence of HCV in each setting. The HepFriend London intervention also had a peer support component helping patients to attend hospital appointments and adhere to treatment which cost an additional €775 per patient treated (n = 44).

	Number of outcomes and unit cost per each outcome					
	Screened		Diagnosed/ identified		Linked to care	
Intervention	N	Unit Cost	N	Unit Cost	N	Unit Cost
HepLink Dublin	102	€635	57	€1137	43	€1507
HepFriend London	273	£248	121	£558	110	£1171
HepCheck Dublin	419	€194	50	€1630	40	€2038
HepCare Bucharest	525	€108	230	€246	154	€367

Conclusion: Within HepCare Europe, the unit costs per person differed by 6-fold between the highest (HepLink Dublin) and lowest (HepCare Bucharest) cost interventions. This highlights that the implementation of similar interventions in different settings within Europe can have very different costs. A crucial next step will be to evaluate the impact of these interventions on patient outcomes.

SAT342

High patient acceptability for a hepatitis C mobile outreach service targeting 'vulnerable' homeless communities - an important component for elimination?

Sarah Montague[1], Nick Sevdalis[2], Sabah Boufkhed[2], Monique Curtis[1], Mandeep Sekhon[3], Geoff Dusheiko[1], Kosh Agarwal[1]. [1]*Institute of Liver Studies, King's College Hospital, London, United Kingdom;* [2]*Centre for Implementation Science, King's College London, London, United Kingdom;* [3]*School of Population Health & Environmental Sciences, King's College London, London, United Kingdom*
Email: sarah.montague@nhs.net.

Background and Aims: Given the HCV elimination agenda, finding and treating 'seldom heard' communities such as the homeless is critical. Such populations do not interface well with traditional models of care. In 2018, King's College Hospital, in collaboration with The Hepatitis C Trust, commissioned a mobile clinic to screen and treat homeless people in Lambeth, Lewisham and Southwark for HCV. The 'HCV Mobile Outreach Service' includes point-of-care finger prick HCV screening (InTec anti-HCV antibody) and confirmatory testing (Cepheid finger GeneXpert prick HCV RNA), non-invasive liver assessment by Fibroscan (Echosens), a multidisciplinary medical team (including peer) and needle and syringe programme provision. The aim of this study was to measure the patients' acceptability of the service model (overall service, finger prick testing and peer).

Method: Patient acceptability was assessed using a theoretical framework of acceptability (TFA) survey (Sekhon et al, 2017) which considers cognitive and emotional responses to an intervention. It is formed of seven distinct constructs (affective attitude, burden, ethicality, perceived effectiveness, intervention coherence, self–efficacy and opportunity cost). Each construct is measured by a 5-point Likert scale. Question 1 (Q1) indicates overall performance and either a score (out of 35) for Q2-8 or a composite be calculated. At Q6, patients were asked to elaborate further about their views allowing qualitative insight. A paper survey was administered to patients using a purposive sampling strategy. Consent was received verbally.

Results: Demographics - 35 patients (60% Male, 40% Female), Intravenous drug use (34% current, 26% past use, 40% never), HCV status (11% past infection, 40% current infection, 45% never infected). The results suggest patient acceptability for all components were high. Few chose to elaborate further, (response rates: overall service (37%), finger prick testing (37%) and Peer Navigator (20%)). Most comments were positive describing the benefit of not having to attend appointments at the hospital and a preference for engaging with a Peer. Although patients found the finger prick testing less acceptable than other components of the service, feedback suggests it is more acceptable than venepuncture.

Distribution of the patients' TFA score and composite mean.

Conclusion: The HCV Mobile Outreach Service is considered a highly acceptable intervention by this community and could contribute to HCV elimination efforts, linkage to other facets of care is currently being evaluated.

SAT343

Health and economic burden due to alcohol related liver diseases in New Delhi, India: a Markov probabilistic modelling approach

Samba Siva Rao Pasupuleti[1], Archana Ramalingam[1], Bharathnag Nagappa[1], Shiv Kumar Sarin[1]. [1]*Institute of Liver and Biliary Sciences*
Email: srao113@gmail.com.

Background and Aims: Liver diseases account for nearly one-fifth of all the deaths attributable to alcohol. The current study carefully examines the health and economic burden due to Alcohol related liver diseases (ALD) for the Union territory of New Delhi, India from 1st March 2017 to 28th February 2018.

Method: The current study employs a Markov Probabilistic Modelling approach using the following health states; No ALD, Alcoholic steatosis, Alcoholic steatohepatitis, Alcoholic cirrhosis and death. The model assumed that health transitions and deaths related to liver diseases and other causes occurred uniformly throughout the year. The health impact due to ALD was estimated through 1) Disability adjusted life years (DALYs) and Years of life lost (YLL) due to liver diseases, and, 2) total deaths due to ALD. The economic burden to the health system was assessed for two scenarios; 1) assuming the current health seeking preferences and 2) if all diseased individuals sought care in public health systems. Sensitivity analysis was done by 10000 Monto Carlo simulations and 90% non-parametric confidence intervals (90% CI) were estimated.

Results: The total number of estimated deaths due to ALD was 10,625. The DALYs due to ALD was 0.314 million life years which includes 0.225 million years of premature life lost (YLL) and 0.088 million life years lost due to disability (YLD). The total cost of treating ALD if patients sought care based on current preferences was estimated to be 1.64 billion USD [Table 1].

Table 1: Health and economic burden due to ALD in Delhi

Characteristic	Value (90% CI)
Economic cost based on current preferences (in billions)	
Total cost to the public health care system for treating ALD in USD	0.13 (0.10–0.17)
Total out of pocket expenditure for treatment in USD	1.51 (1.05–1.98)
Total cost for treatment of ALD in USD	1.64 (1.17–2.13)
Economic costs if all patients seek care in public health systems for ALD (in billions)	
Total cost to the public health care system for treating ALD in USD	0.42 (0.34–0.55)
Total out of pocket expenditure for treatment in USD	0.56 (0.38–0.78)
Total cost for treatment of ALD in USD	0.98 (0.74–1.30)

Conclusion: Nearly 10,600 deaths and 0.314 million years of DALY lost and an estimated expense for care amounting to USD 1.64 billion is estimated to be due to ALD in New Delhi in one year. It would be prudent to initiate social engineering and preventive strategies to lessen the growing burden of ALD in India.

Table: (abstract: SAT342) Distribution of the patients' TFA score and composite mean.

	Overall acceptability mean (Q1)	SD	Median	IQR (Interquartile range) 0.25	IQR (Interquartile range) 0.75	Composite score mean (Q2-Q8)	SD	Median	IQR (Interquartile range) 0.25	IQR (Interquartile range) 0.75
Overall service	4.8	0.43	5	5.00	5.00	4.5	0.39	4	4.3	4.7
Finger prick blood testing	4.4	0.73	4	4.00	5.00	4.2	0.54	4	3.9	4.5
Peer	4.7	0.58	5	4.50	5.00	4.4	0.40	4	4.1	4.7

No restrictions should be placed on future treatment for patients who discontinue DAAs on their first or second attempt. A real world experience from the TraP HepC initiative in Iceland

Sigurdur Olafsson[1,2], Thorvardur J. Löve[2,3], Ragnheidur H. Fridriksdottir[1], Thorarinn Tyrfingsson[4], Valgerdur Runarsdottir[4], Ingunn Hansdottir[4,5], Ottar M. Bergmann[1], Einar S. Björnsson[1,2], Birgir Johannsson[6], Bryndis Sigurdardottir[6], Arthur Löve[2,7], Guðrún Erna Baldvinsdóttir[7], Gudrun Sigmundsdottir[8], Ubaldo Benitez Hernandez[3], Maria Heimisdottir[9], Magnús Gottfredsson[2,3,6]. *[1]Landspitali University Hospital, Department of Gastroenterology and Hepatology, Reykjavik, Iceland; [2]University of Iceland, Faculty of Medicine, School of Health Sciences, Reykjavik, Iceland; [3]Landspitali University Hospital, Department of Science, Reykjavik, Iceland; [4]SAA National Center for Addiction Medicine, Reykjavik, Iceland; [5]University of Iceland, Faculty of Psychology, School of Health Sciences, Reykjavik, Iceland; [6]Landspitali University Hospital, Department of Infectious Diseases, Reykjavik, Iceland; [7]Landspitali University Hospital, Department of Virology, Reykjavik, Iceland; [8]Chief Epidemiologist, Directorate of Health, Reykjavik, Iceland; [9]Icelandic Health Insurance, Reykjavik, Iceland*
Email: sigurdol@landspitali.is.

Background and Aims: To achieve elimination of hepatitis C virus (HCV) as a major health threat, the World Health Organization (WHO) has set treatment service coverage targets of 90% diagnosis and treatment of 80% of eligible patients by the year 2030. The TraP HepC program in Iceland aims to eliminate domestic transmission of HCV by offering treatment to all known cases, focusing on those most likely to transmit. To reach the WHO targets, strategies are needed for those patients who discontinue or otherwise fail treatment.

Method: Starting in 01/2016 all HCV positive patients are offered direct acting antivirals (DAAs). People who inject drugs (PWID), prisoners, and patients with advanced liver disease are prioritized. Patients who discontinue treatment and remain viraemic as well as reinfected patients are reengaged in care and offered retreatment. Here we analyzed engagement in care and sustained virologic response rates at ≥12 weeks post treatment (SVR≥12) for all individuals who commenced treatment from Jan 2016 to Jan 2019.

Results: Treatment was initiated for 718 individuals, 98% of the eligible (HCV PCR positive) patient population of whom 703 patients (98%) gave consent for study participation. Mean age was 44 years (IQR 34–54), males 474 (67%). The most common route of infection was injection drug use (IDU, 85%), 33% reported recent (within 6 months) IDU; 7% were homeless, and 5% incarcerated. Stimulants were preferred by 85% of PWID, opioids by 13%. Overall, 9% were on medication assisted therapy for opioid use disorder.

Of 703 who initiated treatment, 650 (92.5%) completed treatment with PCR results ≥12 weeks available for 632. A total of 603 (95%) were PCR negative and 29 positive (12 reinfections, 12 relapses, data pending for 5). Of 53 who discontinued treatment, SVR>12 data are available for 47 of whom 25 (53%) are PCR negative and 22 positive. Overall, if patients with no SVR>12 results are counted as failures, the cure rate for first DAA treatment was 89%.

During the period, a second treatment course was initiated in 70 individuals, 66 completed treatment, and SVR12 results are available for 63. A total of 60 (95%) were cured and 3 PCR positive. Data is missing or pending for two, one died before reaching SVR≥12. Of the 4 (6%) patients who discontinued treatment during round 2, three remained positive and one achieved SVR≥12.

In total 7 patients received a third treatment round, of whom 6 completed treatment. All 6 completers reached SVR≥12, but the remaining patient who discontinued had persistent viraemia.

Conclusion: Patients who discontinue treatment on the first and second attempt are highly likely to complete therapy if they reengage in care for their second or third attempt. Their cure rates are comparable to those who complete the course on their first attempt. No restrictions for future treatment should be placed on patients who discontinue DAAs on their first or second attempt.

SAT345

National survey among people who use drugs (PWUD) on opioid substitution treatment (OST) on their knowledge of hepatitis C virus (HCV) infection and barriers for treatment in Bulgaria

Email: simonova_m@yahoo.co.uk.

Background and Aims: OST in Bulgaria is provided only in OST centers (OSTC). Currently, there are 30 OSTC (5 state and 25 private) in 16 cities in the country with 3247 clients. HCV seroprevalence among PWUD is 68%. OST is not a contraindication for HCV treatment, however treatment rates among HCV – positive OST patients remain low. Only people with health insurance can receive HCV antiviral treatment. No other funding for treatment exists. The aim of the study was to investigate the knowledge of HCV infection and the barriers for treatment among PWUD on OST in Bulgaria.

Method: A survey with multiple choice structured questionnaire (16 questions covering demography, epidemiology of drug use, HCV testing and treatment, barriers to treatment) was offered in all OSTC in Bulgaria. Questionnaires were anonymous, filled by the patients. Statistical analyses were done by Kolmogorov-Smirnov, Chi-Square, Mann-Whitney and Kruskal-Wallis tests.

Results: From 01 May to 31 October 2019 1907 patients (58,7%) from 21 OSTC (70%) in 15 cities participated in the survey. 1495 males/412 females, mean age 38,26 ± 5,78years/36,86 ± 6,85years ($p < 0,001$) completed survey. Mean duration of drug use in males/females −13,19 ± 6,11years/12,16 ± 6,47years ($p < 0,001$). HCV seroprevalence was 61,2%. 95,6% of PWUD have ever been tested for HCV Ab. There was significant correlation between HCV Ab testing and intravenous drug use (IVDUs) ($p < 0,001$): IVDUs were reported from 9,9% people in ≤3 months, 7,7% in ≤6 months, 8,9% in ≤12 months, 60,7% in ≥12

months ago, HCV Ab testing was reported from 15,2% people in ≤3 months, 17,5% in ≤6 months, 15,5% in ≤12 months, 47,4% in ≥12 months ago. Antiviral treatment was conducted in 18,6% of infected individuals, 67,3% had IFN treatment and 32,7% had DAAs, 26,7% were in state and 73,3% in private OSTC. 45,4% from state and 30,9% from private OSTC had no health insurance. According to PWUD main barriers for treatment were: 27,4% lack of health insurance, 19,1% no treatment were offered, 13,0% didn't know were to go for treatment, 13,5% treatment was not a priority for them, 11,5% thought, that treatment had too many side effects, 10,8% thought, that HCV can't be cured, 4,7% didn't want to be treated.

Conclusion: Low treatment rates among PWUD on OST in Bulgaria are related to lack of health insurance, poor linkage to care and low awareness about new treatment options, although there was gut knowledge about IVDUs as a risk behavior for HCV infection acquisition. Join efforts from the government and the stakeholders are needed in order barriers for treatment to be overcome.

SAT346

Demonstration of the feasibility of two innovative models of HCV testing and treatment in two unique populations in Punjab and Delhi, India-head- start project, India

Sonjelle Shilton[1], Gagandeep Singh Grover[2], Ekta Gupta[3], Sundeep Miglani[4], Radha Krishan Dhiman[5], Dr. Manpreet Chhatwal[6], Preetishirin Katapur[7], Navneet Tewatia[8], Mugil Murya[9], Pradeep Sangwan[9], Divya Soni[10], Jessica Markby[11], Sanjay Sarin[12], Babu Entoor Ramachandran[9]. Email: sonjelle.shilton@finddx.org.

Background and Aims: It is estimated that 33 million people with hepatitis C Virus (HCV) live in Asia and approximately 80 million may be chronically infected globally.[1] Despite significant advances in testing technologies, simplified algorithms and effective treatment options, four out of five people infected remain undiagnosed. In 2018, the Foundation for Innovative New Diagnostics (FIND) in collaboration with Ministries of Health (MOH) and local partners initiated the Unitaid-funded Hepatitis C Elimination through Access to Diagnostics (HEAD-Start) across two states in India (Delhi and Punjab) to demonstrate innovative models of HCV care to inform scale up nationally and globally.

Method: Target populations and settings included the general population in polyclinics, district hospitals and screening camps (Delhi) and PLHIV in ART clinics (Punjab, India). All projects employed the use of rapid diagnostic tests (RDT) for HCV screening in decentralised settings. HCV seropositive patients received confirmatory testing using a centralized laboratory-based assay in Delhi, at GeneXpert testing hubs in Punjab. We describe preliminary findings for the retention of patients in the HCV cascade.

Results: Between 23 Jan to 7 Oct 2019 in Delhi, 38,864 patients were screened at 5 Districts Hospitals (22,756), 15 Polyclinics (10,334) and 30 screening camps (5774), of whom 2.2% (837) HCV seropositive. 87% (726) received HCV RNA testing and 77% of the 626 patients confirmed positive were initiated on treatment (483). To date, 32% (155) have completed treatment, 31.6% (49) received SVR-12 testing and 94% (46) achieved cure. In Punjab (22 Oct 18 to 30 Sep 19), 81% (25, 462) of all PLHIV attending (31,613) at all state-wide ART clinics (n = 13) have been screened, with 21% (5354) found HCV seropositive, 91% (4868) received HCV RNA testing and 35% of the 4088 patients confirmed positive, have initiated treatment (1422). To date 28% (397) patients have completed treatment, 40% (160) have had SVR 12 testing and 86% (137) have achieved cure.

Conclusion: In general, the least complicated and most decentralised models of HCV care demonstrated better retention in the care cascade. However, each setting is unique with different populations, settings and policies that requires careful consideration when considering the most appropriate models of HCV care for scale up.

Barking up the wrong tree: why universal hepatitis C virus screening is not enough for its elimination in the US

Pimsiri Sripongpun[1,2], Aparna Goel[1], Ajitha Mannalithara[1], Paul Kwo[1], W. Ray Kim[1]. [1]*Stanford University, Division of Gastroenterology and Hepatology, Redwood City, United States;* [2]*Prince of Songkla University, Gastroenterology and Hepatology Unit, Hat Yai, Thailand*
Email: wrkim@stanford.edu.

Background and Aims: Hepatitis C virus (HCV) screening is a crucial step in HCV elimination. Currently, the United States Preventive Services Task Force proposes universal HCV screening of American adults (ages 18–79), expanding on the prior risk- and age-based recommendations including testing individuals born between 1945 and 1965 (henceforth Baby Boomer Birth Cohort, BBBC). With a hypothesis that the burden of HCV infection is larger in parts of the US population with poor access to healthcare, we compare the prevalence and characteristics of HCV infection in Americans with and without health insurance coverage.

Method: Data from all adult examinees participating in the National Health and Nutrition Examination Survey (NHANES) in 2013–2016 were analysed for demographic and laboratory characteristics as well as insurance status. Subjects were divided into BBBC and post-BBBC (born in 1966 or later). HCV infection was defined by detectable HCV RNA in the serum. Appropriate statistical techniques were used to account for the stratified sampling design of NHANES.

Table 1: Prevalence of HCV infection in NHANES 2013–2016 participants (weighted data)

Prevalence	Overall	Insured	Uninsured	p-value
BBBC (born in 1945–1965)				
Positive anti-HCV (%)	3.31	2.97	6.20	0.015
Positive HCV RNA (%)	1.79	1.49	4.36	0.002
Post BBBC (born after 1965)				
Positive anti-HCV (%)	1.12	0.87	1.98	0.012
Positive HCV RNA (%)	0.50	0.23	1.40	0.002

Results: In the survey, data were complete in 8,640 examinees, projecting to 186 million American adults. Overall, 17.8% lacked insurance coverage. In Table 1, HCV prevalence was higher in BBBC (1.79%) than in post-BBBC (0.50%). In both age groups, HCV was significantly more common among uninsured individuals than insured. The discrepancy was larger in the post-BBBC: HCV infection was 6 times more common in the uninsured than in the insured (1.40% versus 0.23%), compared to 3 times in BBBC. Importantly, the yield of HCV RNA testing among anti-HCV+ subjects differed by

insurance status and age group. In the uninsured, 70% of anti-HCV+ subjects had HCV infection regardless of age. Lower proportions had HCV infection in the insured: 50% in BBBC and 26% in post-BBBC. Among HCV-infected subjects, 63% had insurance. Other than age (those without insurance were younger, 46 versus 56 years, $p < 0.01$), there was no significant difference in individual characteristics by insurance status including liver biochemistry, FIB-4 and awareness of HCV status.

Conclusion: When health insurance is used as a surrogate for access to healthcare, HCV burden and the yield of screening is inversely correlated with healthcare access. In order to make a meaningful progress in HCV elimination, strategies to uncover HCV in individuals without regular access to healthcare need to be pursued.

SAT348

From emergency department automated hepatitis B & C screening to care and cure in a primary care practice

Su Wang[1], Binghong Xu[2], Ruth Brogden[1], Sophia Huang[2], Jaymie Yango[1], Alyssa Gallipani[3], Chris Freer[4]. *[1]Saint Barnabas Medical Center & World Hepatitis Alliance, Center for Asian Health & Viral Hepatitis Programs, Florham Park, United States; [2]Saint Barnabas Medical Center, Center for Asian Health & Viral Hepatitis Programs, Florham Park, United States; [3]Fairleigh Dickinson University School of Pharmacy & RWJBH Corporate Pharmacy, West Orange, United States; [4]Saint Barnabas Medical Center, Emergency Department, Livingston, United States*

Email: suwang8@gmail.com.

Background and Aims: Globally, 20% of people with hepatitis C (HCV) and 9% of those with hepatitis B (HBV) are aware of their infection. In the US, up to 2.2 million are estimated to have HBV and 2.4 million have HCV. Scale-up of screening and care is needed to achieve hepatitis elimination by 2030. We aimed to create a viral hepatitis (VH) screening protocol in the Emergency Department (ED) of a community hospital with about 100,000 visits a year with linkage to a primary care practice to provide hepatitis care.

Method: An automated algorithm was set up in the ED utilizing Cerner electronic health record (EHR). Eligibility criteria for HCV testing is by year of birth (1945–1965) and for HBV is a country of origin endemic for HBV. If a patient is eligible and bloodwork is ordered, a Hepatitis C antibody (HCV Ab) with reflex to HCV RNA or a Hepatitis B surface antigen (HBsAg) order automatically fires and is added to lab orders. EHR alerts notify nursing of patient eligibility and reactive results. Patient navigators (PN) receive notification via encrypted text message in real-time and work with the patient to arrange VH evaluation. PNs directly schedule patients to an outpatient primary care practice and are integrated into the team of 4 internists and a pharmacist trained in VH care.

Results: From March 2018–August 2019, a total of 22,780 VH screening tests were done, with 12,473 for HCV and 10,307 for HBV. There were 137 found to have current HCV infection (1.1%) and 131 HBV infection (1.2%). Linkage to first medical appointment rates were 87.8% for HBV and 88.4% for HCV. There were 38 HCV patients seen at the primary care practice, with 27 initiating HCV therapy and thus far, 23 (77.8%) have undetectable HCV RNA at week 4, and 16 (42.1%) have confirmed cure at 12 weeks post-therapy with others pending. None of those initiating therapy have fallen out of care. The top 3 countries of origins for the HBV infected patients are Haiti, China and Nigeria.

Conclusion: Automated HBV and HCV screening in the ED can significantly scale up screening and target high risk populations. The HCV prevalence rate was similar to the overall US population, but for HBV, it was 3 times the prevalence rate in the US (0.4%). Country of origin is an effective way to identify those at risk for HBV and is more specific than race. Models of care utilizing frontline providers are important for expanding the reach of critical hepatitis services in the quest for hepatitis elimination.

SAT349

Prevention of liver diseases through universal coverage with hepatitis B vaccination in India

Umesh Kapil[1]. *[1]Institute of Liver & Biliary Sciences, Epidemiology, New Delhi, India*

Email: umeshkapil@gmail.com.

Background and Aims: Hepatitis B is a significant public health problem in India. The current prevalence is in the range of 2–8% in the general population. Mother to Child Transmission is the most important route of HBV transmission. HBV is reported to be responsible for 50% of the cases of chronic hepatitis and 35–60% of the cases of cirrhosis of liver. It is estimated that about 60% of the patients with hepatocellular carcinoma are HBV marker positive. There are approximately 50 million HBV infected subjects.

Immunization remains the most effective way to control the spread of HBV infection hence universal vaccination coverage of all infants is being undertaken under the centrally sponsored National Immunisation program. All infants are to be given HBV vaccination at 0 day, 6,10 and 14 weeks.

Method: The data collected in the National Family Health Survey-4 (NFHS-4) conducted in 2015–16 which covered 199,899 children in the age group of 12–59 months in 36 states of country was utilized for present study.

Results: It is found that overall 62.7% of all children received 3 rd dose of HBV. There wa no significant difference for gender or urban vs rural areas for the HBV coverage. Children of first birth order are much more likely to receive HBV than children of birth order 6 or more (66.9% versus 45.3%). The Vaccination coverage increased with the increased in the mother's schooling (no schooling 53% vs 69% 12 yrs or more schooling). Sikh children received HBV vaccinations than Muslim (89% vs 56.6%). Vaccination coverage increased with increasing wealth status; 68.6 percent of children from households in the highest wealth quintile received HBV vaccinations, compared with 55.2 percent of children from households in the lowest wealth quintile. The children from scheduled caste communities communities had loewest coverage as compared to other tribes (55.2 vs 65.1%). Coverage of HBV varied considerably by state and union territory. The coverage is highest in Punjab (91%) and lowest in Nagaland (45%). The other determinants in the HBV coverage of children will be discussed.

Conclusion: There is a need of developing statewise strategies to improve coverage of HBV vaccination based on the determinants which are leading to low coverage of HBV vaccine.

SAT350

Deleterious impact of advanced non-alcoholic steatohepatitis on multiple patient-relevant outcomes: an international, cross-sectional, real-world study

Quentin Anstee[1], Darshini Shah[2], Kate Burslem[2], James Piercy[3], Gary Milligan[3], Nathan Williams[3], Victoria Higgins[3]. *[1]Institute of Translational & Clinical Research, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Allergan plc, Madison, United States; [3]Adelphi Real World, Bollington, United Kingdom*

Email: victoria.higgins@adelphigroup.com.

Background and Aims: Nonalcoholic steatohepatitis (NASH) is often described as an asymptomatic disease. NASH patients with advanced fibrosis (AF; NASH CRN Stage ≥3) are at higher risk of developing adverse health outcomes vs patients with early fibrosis (EF; NASH CRN Stage ≤2). However, data comparing patient-relevant outcomes among patients with AF and EF are lacking. This analysis aimed to evaluate the impact of AF on patients' lives by comparing multiple patient-relevant outcomes among those with AF and EF.

Method: Data were derived from the 2018/19 Adelphi NASH Disease Specific Programme, a real-world, cross-sectional chart review in the US and UK. Physicians completed questionnaires describing 5–6 consecutive NASH patients with any fibrosis stage, then 2 patients with F3–F4 fibrosis. Patients were categorised as AF or EF based on

most recent FibroScan (AF ≥9.6 kPa; EF <7.9 kPa) or FIB-4 result (AF ≥2.67; EF <1.30) and completed voluntary assessments of sleep impairment (Jenkins Sleep Evaluation Questionnaire [JSEQ]; 1–no to 20–constant disturbance); quality of life (Chronic Liver Disease Questionnaire [CLDQ-NASH]; 1–most to 7–least impairment); health status (EQ-5D-5L; VAS); Work Productivity and Activity Impairment (WPAI; % impairment) and impact on activities of daily living with NASH (ADL; 0–not to 3–greatly affected). AF and EF patients were compared using multivariate regression adjusting for age, sex, smoking, education, BMI, type 2 diabetes, and Charlson Comorbidity Index.

Results: 162 physicians provided data on 1245 NASH patients. 696 patients met the criteria for AF or EF and 212 completed the patient survey. Mean age was 53 years and 58% were male. AF patients reported significantly higher impact on patient-relevant outcomes compared to EF patients in multivariate analyses (Table; all $p < 0.05$). Consistent trends were observed across the US and UK.

	AF (n = 157)	EF (n = 55)
JSEQ (score)	5.4	1.7
WPAI (% activity impairment)	32	12
EQ-5D-5L (utility score)	0.86	0.94
EQ-5D-VAS (%)	74.7	83.4
Impact		
Social life	0.8	0.2
Motivation	1.0	0.3
Freedom to eat/drink	1.5	0.6
Feelings about future	1.3	0.6
	AF (n = 113)	**EF (n = 50)**
CLDQ-NASH (score)		
Total score	5.3	6.1
Abdominal	5.1	6.0
Activity	5.2	6.0
Emotion	5.3	6.2
Fatigue	4.9	5.7
Systemic	5.6	6.2
Worry	5.4	6.2

Conclusion: In a real-world setting, AF NASH patients report significant impairment on a range of patient-relevant outcomes vs EF patients. These findings contradict the widely held view that NASH is an asymptomatic disease, highlighting fibrosis severity as a key driver of patient burden.

SAT351

Factors associated with failure to link people who inject drugs to HCV care and treatment: results from a community-based seek-test-treat program in Athens, Greece (ARISTOTLE HCV-HIV)

Psichogiou[3], George Papatheodoridis[8], Angelos Hatzakis[15]. *[1]Medical School, National and Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Athens, Greece; [2]Hellenic Liver Patient Association "Prometheus", [3]Medical School, National and Kapodistrian University of Athens, 1st Department of Internal Medicine, Athens, Greece; [4]General Hospital of Athens "Elpis", Department of Internal Medicine, Athens, Greece; [5]417 Army Share Fund Hospital of Athens, Department of Internal Medicine, Athens, Greece; [6]General University Hospital "Attikon", 4th Department of Internal Medicine, Athens, Greece; [7]Western Attica General Hospital, 1st Department of Internal Medicine, Athens, Greece; [8]Laiko General Hospital, Medical School of National and Kapodistrian University of Athens, Department of Gastroenterology, Athens, Greece; [9]Hippokration General Hospital, 2nd Department of Internal Medicine, Athens, Greece; [10]Evangelismos General Hospital, Department of Internal Medicine, Athens, Greece; [11]Evangelismos-Opthalmiatrion Athinon-Polykliniki Hospitals, Department of Gastroenterology, Athens, Greece; [12]General and Oncology Hospital "Agioi Anargyroi", Department of Internal Medicine, Faculty of Nursing Athens, Athens, Greece; [13]Tzaneion General Hospital of Piraeus, Department of Gastroenterology, Athens, Greece; [14]General Anticancer Hospital "Agios Savvas", Department of Gastroenterology, Athens, Greece; [15]Medical School, National and Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Athens, Greece; [16]Hellenic Scientific Society for the Study of AIDS and Sexually Transmitted Diseases, Athens, Greece*
Email: vsipsa@med.uoa.gr

Background and Aims: Eighty per cent of people who inject drugs (PWID) in Athens, Greece, are HCV infected and linkage to HCV care remains at low levels in this population. A community-based program is implemented in Athens since April 2018 with the aim to screen for HCV and improve access to care and treatment among PWID (ARISTOTLE HCV-HIV). Aim of this analysis is to identify factors associated with failure to link PWID to HCV care and treatment.

Method: ARISTOTLE HCV-HIV is a "seek-test-treat" program where PWID are recruited using chain-referral sampling with monetary incentives. Participation includes interviewing, blood testing, evaluation of liver fibrosis and counseling. All services are provided on site. There is a network of collaborating hepatologists and infectious diseases and a peer-navigator accompanies patients to the clinics for their first appointment. In the first 5 months of recruitment, fibrosis-based treatment restrictions applied. We present data from the first recruitment round (April 2018-January 2019); information on linkage to care (first appointment with the physician) and treatment initiation were updated in September 2019. Logistic regression was used to obtain adjusted odds ratios (aOR) and 95% confidence intervals (95% CI) for the impact of sociodemographic characteristics, injection behaviours and access to harm reduction programs on the two outcomes (linkage to care and treatment initiation).

Results: Of 1,365 participants, 395 had HCV monoinfection and were eligible for treatment with DAAs during the period of HCV diagnosis; 13.7% were women, 77.5% were current users, 24.8% homeless, 14.2% migrants and 72.9% not linked to opioid substitution treatment programs. During the program, 47.6% (188/395) were linked to HCV care and 42.2% (167/395) initiated treatment with DAAs. Factors associated with higher risk of not being linked to care (aOR [95% CI]) were homelessness (homeless vs. not homeless: 2.6 [1.6, 4.4], $p < 0.001$) and being migrant (non-Greek vs Greek origin: 3.7 [1.8, 7.5], $p < 0.001$). An additional factor associated with higher risk of not initiating treatment was gender (aOR (95% CI) for women vs men: 2.1 (3.7 (95% CI: 1.1, 4.0), $p = 0.022$).

Conclusion: The program achieved satisfactory linkage to care rates in a population of current PWID. However, additional efforts are needed for migrants and homeless PWID. Tailored interventions and empowerment in necessary to increase treatment uptake among women PWID.

SAT352

Clinical and economic consequences of antiviral treatment for hepatitis C chronic infection in Europe: analysis of England, Italy, Romania and Spain data

Xhimi Tata[1,2], Andrea Marcellusi[3], Gianluca Fabiano[3,4], Stephen Ryder[5], Maria Buti[6], Liana Gheorghe[7], Carmine Coppola[8], Antonio Craxi[9], Francesco Mennini[3], Loreta Kondili[1]. *[1]Istituto Superiore di Sanità, Rome, Italy; [2]Universiteti "Zoja e Keshillit te Mire"; [3]University of Tor Vergata, Rome, Italy; [4]Institute for Leadership and Management in Health, London, Italy; [5]NIHR NottinghamBiomedical Research Centre, Nottingham, United Kingdom; [6]Hospital Universitario*

Valle Hebron, Barcelona, Spain; [7]Carol Davila University of Medicine and Pharmacy Fundeni Clinical Institute, Bucharest; [8]Gragnano Hospital, Naples, Italy; [9]University of Palermo, Palermo, Italy
Email: xhimitata@hotmail.com

Background and Aims: The development of country-specific models enables evaluation of HCV therapy impact in the liver disease burden and economic consequences according to the treatment eligibility criteria over time across countries. In this study, we built country-specific models for Italy, Spain, United Kingdom and Romania to assess, by country, the clinical and economic impact of antiviral therapy and to predict for each country the necessary time to recover the initial investment for treatment according to differences in the epidemiology and treatment access over time.
Method: A multistate, 20-year time horizon HCV liver disease progression Markov model was developed considering specific DAA treatment eligibility in each of the countries during the years 2015 and 2018. Data stratifications for the disease states, genotypes were retrieved from real world data sources at national level. The period of time required to recover the NHS investment in DAA treatment was calculated on the basis of the cost saved by the avoided clinical events estimated. All data were standardized for 1000 patients treated.
Results: For 1000 standardized patients treated during 2015/16, the estimated number of avoided HCV-clinical related events (HCC, Decompensated cirrhosis, liver related death reported as single events) for 1000 patients during 20 years following viral eradication was: 1136 in Italy; 1310 in Romania; 1040 in Spain and 1134 in England. For 1000 standardized patients, treated during 2017/18, our model estimated: 565, 908, 505 and 546 clinical events to be avoided during 20 years after viral eradication in Italy, Spain and England respectively. The potential clinical outcomes reduction on time, standardized for 1000 of patients treated from 2015–2018, reflect important cost savings over 20 years reported to be as follows: reduction of € 52 million in Italy, of € 57 million in Romania, 194 million in Spain and of 48 million in England. The investment of National Health System for DAA drugs is estimated to be recovered in 5.6 years in Italy, 6.5 years in Romania, 4.6 years in Spain and 7.5 years in England.

Table: Avoided events and costs by country

Country	Year	Return of Investment years	Avoided cases after 20 years	Increasing costs after 20 years (€ million)
Italy	2015/2016	7.5	−1136	−€ 19,670,908

Conclusion: The use of DAA for chronic HCV infection is translated not only in significant clinical benefits but also in substantial cost savings over 20 years period.

SAT353

The head-start project: introduction of rapid diagnostic tests for hepatitis C screening in primary healthcare sites as a first step towards decentralizing hepatitis C care in Malaysia

Muhammad Radzi Abu Hassan[1], Rozainanee Binti Mohd Zain[2], Nazrila Hairizan Binti Nasir[3], Fazidah Binti Yuswan[3], Sasikala Siva[4], Caroline Menetrey[4], Xiaohui Sem[5], Jessica Markby[5], Sonjelle Shilton[5]. *[1]Hospital Sultanah Bahiyah, Alor Setar, Malaysia; [2]Institute for Medical Research; [3]Ministry of Health; [4]Drugs for Neglected Diseases Initiative; [5]Foundation for Innovative New Diagnostics*
Email: sonjelle.shilton@finddx.org

Background and Aims: Malaysia is an upper-middle income country of 32 million people and is estimated to have a hepatitis C virus (HCV) general prevalence of 2.5%. Implementation of the HCV national strategic plan was fraught with obstacles including restrictive drug access policies and a complex and centralized screening algorithm (2 enzyme immunoassay and 1 core antigen). The Foundation for Innovative New Diagnostics collaborated with the Ministry of Health and the Drugs for Neglected Diseases *initiative* on a Unitaid-funded Hepatitis C Elimination through Access to Diagnostics (HEAD-Start) project to introduce decentralised HCV screening at the primary health care (PHC) level. Here, we describe preliminary findings from the study.
Method: The project incorporates a partially decentralised model of HCV care. HCV rapid diagnostic tests (RDTs) were introduced at 25 PHC sites offering methadone maintenance therapy services. Participants, aged 18 to 70 years and at risk of HCV infection, were enrolled and screened. Seropositive patients were subsequently referred to one of the 5 tertiary hospitals for confirmatory testing via a centralized laboratory.
Results: 15,148 participants were screened using HCV RDT, of whom 20% had piercings, 17% had a prior invasive medical procedure, 13% were injecting drug users, 10% were intranasal drug users, 8% were previously incarcerated, 7% were people living with HIV, 5% were men who had sex with men and 5% had chronic liver disease. Of those screened, 13.4% were HCV seropositive, of whom 61.1% received RNA confirmatory testing and 63.5% of those confirmed RNA-positive received pre-treatment assessments. The mean time between RDT screening and RNA sample collection at hospitals was 17 days; between RNA sample collection and testing at a centralised lab, 13 days; between sample collection and results returned to patients and between results returned to patients and treatment referral were both 41 days each.
Conclusion: Introduction of HCV RDTs at PHC sites has helped to increase screening coverage with positive case findings and has catalysed national uptake of a simplified HCV screening algorithm. Further optimisation and scale-up of this HCV model of care will involve a fully decentralised care pathway at the PHC sites including RNA sample collection for seropositive patients and treatment of uncomplicated cases to improve retention in the care cascade and decrease the turn-around time for patients to receive treatment.

SAT354

Enhancing the hepatitis B care cascade in Australia using a country-based testing program targeting new migrants: a cost-effectiveness model

Yinzong Xiao[1,2,3], Jess Howell[1,3], Nick Scott[1], Alexander Thompson[2,3], Margaret Hellard[1,4]. *[1]Burnet Institute; [2]University of Melbourne; [3]St Vincent's Hospital Melbourne; [4]Monash University, Melbourne, Australia*
Email: margaret.hellard@burnet.edu.au.

Background and Aims: If Australia is to successfully eliminate hepatitis B as a public health threat it will need to enhance the hepatitis B care cascade. Although the major population living with chronic hepatitis B (CHB) in Australia are born overseas from high endemic countries, there is no clear program or strategy to ensure this group are offered hepatitis B virus (HBV) testing or treatment. We postulate that incorporating an HBV testing program based on migrants' country of origin within the existing immigration medical exam (IME) currently undertaken by all permanent visa applicants to Australia is likely to increase the HBV care cascade. This study used a Markov model to assess the impact, costs and cost-effectiveness of a country-based pre-immigration hepatitis B testing program in Australia.
Method: The model calculated the difference in care cascade projection, disability-adjusted life-years (DALYs), difference in costs

and incremental cost-effectiveness ratio (ICER) among all people living with CHB in Australia in 2016–2030 in two scenarios: 1) status-quo: continued hepatitis B testing criteria for people taking the IME; and 2) a country-based testing program: migrants from countries with > = 2% hepatitis B prevalence were tested for HBV when taking the IME. Main model inputs included published demographics data of visa applications in 2014–2017 in Australia, country-specific CHB prevalence, Australia's care cascade progression data and CHB progression parameters. Healthcare funder's perspective was taken and costs were calculated based on all HBV testing costs paid by Australian Government.

Results: Under status-quo, an estimated 12% of new migrants with CHB were tested for HBV at the IME each year; the projected HBV care cascade among all people living with CHB in Australia in 2030 was 74% diagnosed, 35% in care and 20% on treatment. A country-based testing program was expected to diagnose around 83% of new migrants with CHB when they entering Australia; this scenario had a significant impact on the HBV care cascade in Australia, which was estimated to be 86% diagnosed, 47% in care and 26% on treatment among all people living with CHB in Australia in 2030. Compared to status quo, the scenario with a country-based testing program had an additional cost of A$0.3 billion if the HBV testing were at Australian Government's costs and averted 14,239 DALYs, giving an ICER of A $21,001 per DALY averted between 2016 to 2030. Sensitivity analysis showed that cost-effectiveness was influenced by disease progression rates and hepatitis B treatment costs.

Conclusion: A pre-immigration hepatitis B testing program based on migrants' country of origin would facilitate Australia to achieve 2030 hepatitis B elimination targets. Our model showed that such a program is likely to be highly cost-effective.

SAT355

Cost-effectiveness of mass screening for HCV in an Irish prison

Zoe Ward[1], Nyashadzaishe Mafirakureva[1], Jack Stone[1], Mary Keevans[2], Graham Bett-Simmonds[3], Des Crowley[4], Tina Mchugh[5], Gordana Avramovic[5], Jack Lambert[5,6], Peter Vickerman[1]. [1]*Univeristy of Bristol, Population Health Sciences, United Kingdom;* [2]*Irish Prison Service, Dublin, Ireland;* [3]*Irish Red Cross, Dublin, Ireland;* [4]*Irish College of General Practitioners, Dublin, Ireland;* [5]*Mater Misericordiae Univeristy Hospital, Dublin, Ireland;* [6]*University College Dublin, School of Medicine, Dublin, Ireland*
Email: zoe.ward@bristol.ac.uk.

Background and Aims: A high proportion of PWID have ever been incarcerated in Ireland (70%) and a high proportion of prisoners have a history of injecting drug use (26%). Because of this, there is a high prevalence of HCV in prison populations (16%) in Ireland, which makes prison a high priority setting for undertaking HCV testing and treatment. We evaluate the cost-effectiveness of a mass HCV screening intervention in Mountjoy Prison in Dublin that screened 419 individuals, diagnosed 50 chronic HCV infections, and initiated 32 individuals on treatment. This is compared to the standard of care of intermittent screening on committal and in the community.

Method: An ingredients-based costing was used to cost of the screening and treatment in prison. Top down costings estimated the set-up and overhead costs. Standard of care costs were estimated through interview. A dynamic model of HCV transmission and disease progression among incarcerated and community PWID and ex-PWID was parameterised and calibrated using incarceration, demographic, HCV epidemiological and cascade of care data for Dublin or Ireland. The model used data directly from the intervention to project the resulting health benefits in terms of quality adjusted life years (QALYs) of the 1-year screening and linkage to care intervention over 50 years. The incremental cost effectiveness ratio (ICER) was calculated as the difference in costs divided by the difference in QALYs between the mass screening intervention and the standard of care comparator. Probabilistic sensitivity analysis (PSA) was used to determine the probability that the intervention was cost-effective compared to a willingness to pay threshold of €30,000 per QALY.

Results: The total direct costs of the intervention (not including treatment costs) was €81,415, with most costs being due to staff (43%). Over 50 years, the overall incremental cost of the intervention was €15,334 and the intervention gained 13 QALYs, giving a mean ICER of €1,200. All runs in the PSA were under the willingness to pay threshold.

Conclusion: Our analysis suggests prison mass screening could be a cost-effective initiative for increasing testing and linkage to care in prison in Ireland.

Hormone replacement therapy is associated with reduced liver cirrhosis risk and improved survival in treatment-naive hepatitis B- and/or C- infected postmenopausal women: a nationwide long-term population-based cohort study

Chun Hsiang Wang[1], Yuan-Tsung Tseng[2]. [1]*Tainan Municipal Hospital, Hepatogastroenterology, Tainan, Taiwan;* [2]*Tainan Municipal Hospital, Committee of medical research, Tainan, Taiwan*
Email: chunhsiangwang1@gmail.com.

Background and Aims: Post-*menopausal hepatitis B virus (HBV) or hepatitis C virus (HCV) infected women* are likely to speed a *liver*

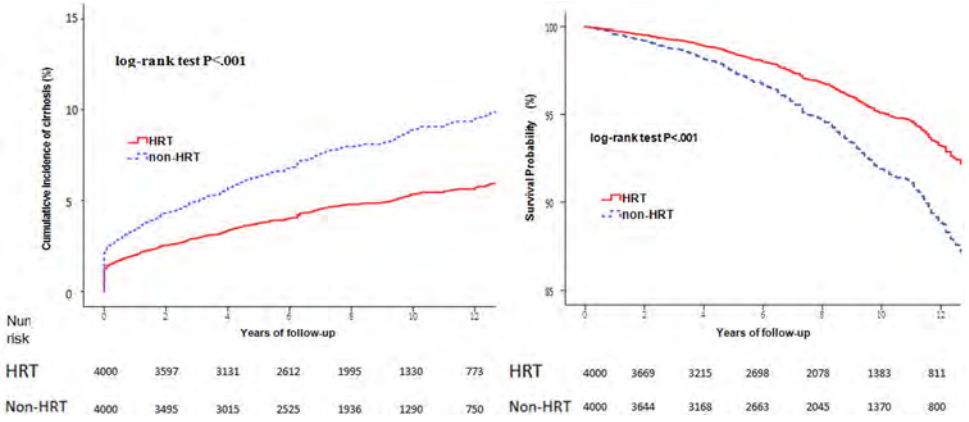

Figure: (abstract: SAT356)

fibrosis process, which will eventually advance to liver cirrhosis. It has not been fully investigated whether hormone replacement therapy (HRT) is beneficial to HBV and/or HCV infected women when they reach menopause age. The aim of this study was to evaluate the *severity of HBV and/or HCV* related *liver disease* in women in relation to the menopause and HRT.

Method: We enrolled 81,593 patients with hepatitis B virus (HBV) and/or hepatitis C virus (HCV) infection between January 2000 and December 2013 from Taiwan's National Health Insurance Research Database (NHIRD). All diagnoses were coded according to the International Classification of Disease, Ninth Revision, Clinical Modification (ICD-9-CM). After excluding pre-existing other liver diseases, liver cirrhosis, or liver malignancies, the remaining 25,427 untreated HBV and/or HCV infection patients were grouped into patients (n = 11112) who were identified to have undergone HRT for at least 3 months and postmenopausal patients (n = 14315) who had not received HRT. After propensity score matching, 4000 patients with HRT were matched one to one to participants without HRT. The impact of HRT on liver cirrhosis and its major complications (esophageal varix, ascites, hepatic encephalopathy, hepato-pulmonary hypertension, hepato-renal syndrome, spontaneous bacterial peritonitis, coagulation disorders) were evaluated using multivariate analyses considering all putative confounding factors.

Results: In postmenopausal women, the estimated incidence rate of liver cirrhosis was lower in women who had received HRT, compared with a non-HRT cohort ($p < 0.001$) (left panel of the figure). Among cirrhotic patients, the estimated incidence rates of cirrhosis related esophageal varix, ascites, and hepatic encephalopathy were lower in women who had received HRT, compared with a non-HRT cohort ($p < 0.001$). The chance of survival was significantly higher in the HRT cohort than in the non-HRT cohort ($p < 0.001$) (right panel of the figure).

Conclusion: Our study reported that *HRT* significantly reduced the *risk* of *liver*-related complications. Menopause is associated with an increased liver cirrhosis risk in HBV- and/or HCV-infected women and it is preventable by HRT.

SAT357

Hepatitis B virus core protein variants observed in a first-in-human placebo-controlled study of a core protein inhibitor

Amy C.H. Lee[1], Emily P. Thi[1], Andrzej Ardzinski[1], Joanne Brown[1], Timothy Eley[1], Nagraj Mani[1], Rene Rijnbrand[1], Karen Sims[1], Michael J. Sofia[1], Gaston Picchio[1]. [1]*Arbutus Biopharma, Warminster, United States*
Email: alee@arbutusbio.com.

Background and Aims: Functional cure rates for chronic hepatitis B (CHB) virus infection are low, necessitating the development of new therapeutic strategies such as core protein inhibitors (CIs). AB-506 is a class II CI that binds hepatitis B virus (HBV) core protein, accelerating and misdirecting capsid assembly resulting in formation of empty viral particles. One of 20 subjects on active drug in the AB-506-001 first-in-human study did not show a serum HBV DNA response, which was subsequently found to correlate with a pre-existing core I105T variant. Here we describe additional HBV core variants observed in recruited subjects focusing on amino acid positions that may be of relevance to other molecules which access the same binding pocket.

Method: HBV DNA extraction was performed on plasma collected from the 24 non-cirrhotic, HBeAg-positive or -negative, HBV DNA-positive subjects enrolled in AB-506-001 (randomized 10:2 per cohort to AB-506 versus placebo) and 28 subjects that were screened but not enrolled in the study. Extracted DNA samples were subjected to HBV-specific PCR amplification followed by Illumina MiSeq next generation sequencing.

Results: Sequence analysis of viral genomes in the blood of CHB subjects at baseline revealed the pre-existing presence of multiple CI-relevant HBV core variants > HBVdb reported prevalence and in some cases co-existing in the same subject. In cell culture, T33N, T33S, I105T and T109S as single point mutations resulted in 2.5- to 356-fold change in EC_{50} of AB-506. In addition to the previously reported I105T non-responder (NR), the 1 active subject with T109S had the weakest response (−1.3 log_{10} HBV DNA) other than the NR. Subjects with T33N and T33S were not treated.

Table: Frequency of pre-existing HBV core variants in CHB subjects recruited to AB-506-001

	Screened Subjects (n=52)			Prevalence		
Variant	Placebo (n)	Active (n)	Not Randomized (n)	Observed (%)	HBVdb (%)[a]	AB-506 FC[b]
T33N	-	-	1	1.9	0.02	356
T33S	-	-	1	1.9	0.04	2.5
Y38F	1	3	9	25	3.1	1.6
Y38H	-	1	1	3.8	1.2	0.5
I105T	-	1	3	7.7	0.6	19
I105V	-	2	5	13	1.1	1.3
T109S	-	1	1	3.8	0.1	2.7
T109M	-	1	2	5.8	0.7	1.9
Y118F	-	-	1	1.9	0.4	not tested

[a]Within 10,975 HBV genome sequences archived as of Sep 12, 2019 at https://hbvdb.ibcp.fr.
[b]Fold-change (FC) of *in vitro* AB-506 EC_{50} values against point mutation in a genotype D background.

Conclusion: These findings highlight the importance of conducting molecular epidemiology studies to assess the prevalence of circulating CI-resistant variants as well as developing next-generation CIs with improved coverage of these variants.

SAT358

Clinical and molecular characterization of the human kidney as extrahepatic site of hepatitis E virus infection

Email: avista.wahid@twincore.de.

Background and Aims: During infection with the hepatitis E virus (HEV), viral RNA can be detected in a variety of patient's body-fluids including the urine. Recently, the excretion of infectious virions via the urine has been demonstrated. However, until know it is unclear whether detection of the virus in the urine reflects an extrahepatic replication site in kidney cells of the host.
Extrahepatic HEV replication might serve as a reservoir causing viral relapse after treatment and has implications for viral transmission.

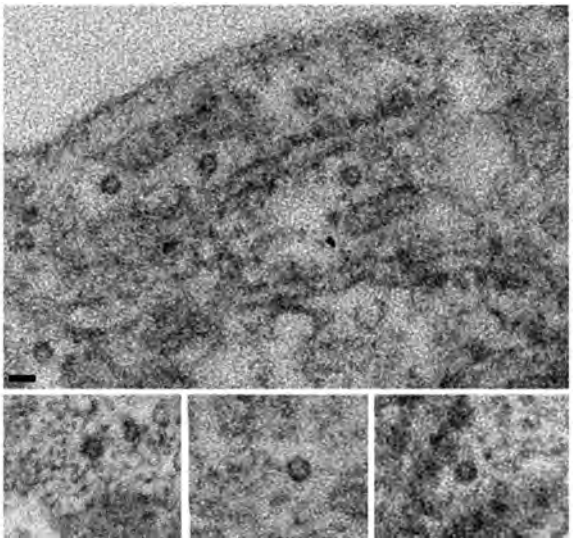
In this study we characterized virus particles in the urine of long-lasting chronically infected patients and evaluated kidney-derived cells in vitro for their ability to support viral propagation.
Method: We utilized body-fluids (plasma, stool, urine) of patients within the SofE-trial (Clinical Trial Number: NCT03282474) which includes patients with long-lasting HEV infection. RNA-positive samples were analysed by density gradient and deep-sequencing methods of viral ORFs 1 and 2. Five different kidney-derived cell-lines (cancer and non-cancer) were evaluated for their ability to support viral propagation of Kernowp6 (HEV GT3) and for response to antiviral treatment. Furthermore, infection of primary porcine kidney cells and testing of kidney biopsies from HEV infected patients for HEV-RNA via FISH analysis to proof extrahepatic replication are ongoing.
Results: Out of 9 patients within the SofE-trial, all had detectable RNA in stool and plasma. In the urine (uRNA) 4/9 patients were HEV-RNA positive at screening and 2/9 at baseline (both uRNA positive at screening). uRNA abundance did neither correlate with viral titers in plasma nor kidney function. Gradient analysis revealed a quasi-enveloped status of the virus in the urine.
Deep-sequencing analysis of viral ORF1 and ORF2 identified point mutations specifically occuring in uRNA.
Two kidney cell-lines efficiently supported viral infection and replication to similar levels as the hepatoma cell-line HepG2. Of note, they displayed lower susceptibility to ribavirin treatment as compared to the control cell-line.
Conclusion: Our results point to a possible extrahepatic replication of HEV within the kidney. This has important implications for understanding viral extrahepatic tropism and may improve surveillance during treatment of chronically HEV-infected patients to avoid recurrence/relapses possibly caused by a remaining reservoir at extrahepatic sides such as the kidney.

SAT359

Establishment of human induced pluripotent stem cell-derived hepatocyte-like cells permissive for serum-originated hepatitis B virus infection and allowing for covalently closed circular DNA inhibitor drug screening

Chau-Ting Yeh[1], Bei-Chia Yang[2], Yi-Hsing Tseng[2], Ming-Wei Lai[1], John Yu[2]. [1]*Chang Gung Memorial Hospital, Liver Research Center, Taoyuan, Taiwan;* [2]*Chang Gung Memorial Hospital, Institute of Stem Cell & Translational Cancer Research, Taoyuan, Taiwan*
Email: chautingy@gmail.com.

Background and Aims: Several lines of induced pluripotent stem cell-derived hepatocyte-like cells (iPS-HLCs) were established, permissive for hepatitis B virus (HBV) infection. However, such systems are limited by infection with a single, recombinant viral source, not suitable for studying infectivity of HBV containing sequence variations. Here, we established a line of iPS-HLCs permissive for serum-derived HBV infection.
Method: Human iPSC were differentiated into iPS-HLCs through a modified protocol. Permissiveness of iPS-HLCs for serum-derived HBV infection was verified. Serum samples from 119 chronic hepatitis B patients of various clinical conditions were used for infection. Virological factors including genotypes, HBV-DNA concentrations, qHBsAg levels, BCP mutations, precore mutations, and pre-S deletions were assayed for correlation with infectivity. Comparative cDNA microarray analysis was performed. Antiviral drug screening was conducted through assessing cccDNA levels under treatments of a panel of FDA-approved drugs.
Results: The differentiated iPS-HLCs contained a high level of sodium taurocholate cotransporting polypeptide, 9 folds higher than that in primary hepatocytes. Infection of serum-derived HBV was performed under a multiplicity of infection (MOI) of 10. The success of infection was confirmed by detection of HBV-RNA, viral proteins, viral particles under electron microscopy, and cccDNA. Post-infection cellular HBV-DNA levels could be suppressed by entecavir and tenofovir treatments. Comparative gene expression profiling showed activation of several cancer-related pathways after HBV infection. Under the same MOI, 119 samples were used for iPS-HLCs infection assays. Univariate followed by multivariate linear regression analysis revealed that the BCP G1719T mutation ($P = 0.002$) and qHBsAg level ($P = 0.016$) were independent predictors for infectivity. The iPS-HLCs were permissiveness for serum-derived vaccine escape HBV mutants. Finally, a panel of FDA-approved drugs ($n > 1400$) was used for cccDNA inhibitor drug screening. Suppression of cccDNA was observed in several candidate drugs, which were known inhibitors of signaling pathways capable of enhancing HBV replication.



Conclusion: A line of iPS-HLCs permissive for serum-derived HBV infection were established. This system was suitable for studying infectivity of HBV carrying naturally occurring or pathological mutations. It also served as a useful tool for anti-HBV drug discovery.

Email: christophe.ramiere@inserm.fr.

Background and Aims: Hepatitis delta virus (HDV) is a satellite of hepatitis B virus (HBV), both using the Sodium Taurocholate Co-Transporting Polypeptide (NTCP), the main transporter of bile acids (BA) in the liver, to enter hepatocytes. Links between BA and HBV infection are not limited to the entry step as we previously showed that the farnesoid X receptor alpha (FXR), the nuclear receptor of BA, was a proviral factor for HBV and that FXR ligands acted as inhibitors of HBV replication. Regarding HDV, excepting the role of NTCP in viral entry, putative links between BA metabolism and HDV replication have not been yet explored. We thus wanted to determine whether FXR also played a role in HDV life cycle.
Method: In vitro HDV mono-infections or HDV/HBV co-infections and super-infections were performed in differentiated HepaRG (dHepaRG) cells and primary human hepatocytes (PHH). Cells were

treated with several FXR ligands: 6 -ECDCA, a BA analog and two synthetic ligands, GW4064 and tropifexor. The impact on distinct forms of HDV RNAs was analysed by quantitative PCR, Northern Blot and Run-On experiments. Analysis of HDV proteins was performed by immunofluorescence (IF) and Western Blot (WB), using antibodies against HDV antigens.

Results: In HDV/HBV co- or super-infection models, a 10 -day treatment with 10 μM of GW4064 decreased total intracellular HDV RNA in dHepaRG cells and PHH by 60% and 40%, respectively. Northern blot and Run-On experiments showed that both HDV genomic RNA and nascent viral RNA were affected by such treatment. IF staining and WB of infected cells showed that FXR ligands also decreased the amount of intracellular viral proteins. Both forms of delta antigens, small and large, were equally decreased, by around 75%, as revealed by WB analysis. Importantly, this inhibitory effect of FXR ligands on HDV replication was also observed in HDV mono-infected dHepaRG cells. Finally, three distinct FXR ligands, i.e. GW4064, 6 -ECDCA and tropifexor, showed comparable efficacy, indicating the specificity of action.

Conclusion: FXR ligands inhibit in vitro HDV replication. This inhibitory effect is independent of their previously identified antiviral properties against HBV. Mechanisms underlying this inhibitory effect are under investigation. As current therapeutic strategies are limited for HDV-infected patients, FXR may represent a new and attractive target for HDV antiviral therapy.

Email: cristina.godoy@vhir.org.

Background and Aims: The study of Hepatitis B virus (HBV)-RNA containing virion-like particles allows monitoring intrahepatic HBV-RNA levels and is potentially useful for viral quasispecies (QS) analysis in patients with suppressed circulating HBV-DNA. Up to date, the HBV-RNA QS has not been studied in untreated chronic hepatitis B (CHB) patients with detectable levels of circulating HBV-DNA. The aim of the present study was to compare circulating HBV-DNA and RNA QS in a group of untreated CHB patients.

Method: A serum sample from 10 untreated CHB patients was selected: 6 (60%) HBeAg positive (+), median levels of HBV-DNA 1.25×10^8 IU/mL (IQR 1×10^8–3.9×10^8 IU/mL) and ALT 134 IU/L (IQR 74.3–159.3 IU/L). HBV-DNA and HBV-RNA were isolated from each serum sample. Isolated HBV-RNA was treated with DNAse I and retro-transcribed into cDNA. To ensure that no HBV-DNA was present, a qPCR was performed after DNase I treatment. HBV genotype and QS complexity were determined by next-generation sequencing (NGS, Miseq, Illumina) in the 5′ region of the HBV X gene (HBX, nt 1255-1611). HBV QS complexity was analyzed by the Rare Haplotype Load (RHL), a non-biased diversity index that measures enrichment of QS in very low frequency minority genomes, with little sensitivity to the differences in sequence coverage (PLoS ONE 2018;13:1–17).

Results: A total of 1.90×10^6 sequence reads were obtained, 1.22×10^6 for HBV-DNA and 6.77×10^5 for HBV-RNA. The HBV genotype mixtures were similar in DNA and RNA in all patients, main genotypes were 2 A, 1 C, 2 D, 2 E and 3 F. HBV QS complexity showed a heterogeneous behaviour between patients, but globally it was greater in DNA than in RNA ($p = 0.037$). Comparing the results according to the HBeAg, the DNA and RNA QS complexity was similar in HBeAg (+) patients (Figure A) while 3/4 HBeAg (–) patients showed a greater complexity in DNA (Figure B).

Conclusion: The HBV genotype mixture did not show significant differences between HBV-DNA and RNA QS, suggesting that circulating viral RNA could be an appropriate substrate to analyse QS during HBV-DNA suppression. Greater QS complexity in DNA than RNA suggests an increased presence of low frequency HBV genomes in DNA QS [more evident in HBeAg (–) than (+)], likely due to the error-prone reverse transcription origin of HBV-DNA. Funding: Instituto de Salud Carlos III (grant PI18/01436), co-financed by the European Regional Development Fund (ERDF).

Mitochondrial DNA damage and mitochondrial dysfunction in patients with chronic hepatitis B

Dimitri Loureiro[1], Abdel Mansouri[1], Ahmad Sleiman[1], Boyer Nathalie[1], Stephanie Narguet[1], Issam Tout[1], Marcellin Patrick[1], Valérie Paradis[1], Tarik Asselah[1]. *[1]Hospital Beaujon AP-HP, Hepatology, Clichy, France*
Email: dimitri.loureiro@inserm.fr.

Background and Aims: Mitochondria serve as a platform for the antiviral innate immune and inflammatory responses. Some hepatitis B virus (HBV) proteins are imported into the mitochondria, increase the mitochondrial oxidative stress and impair mitochondrial function which may account for fibrosis progression.

The aim of our study was to investigate the effects of HBV-induced mitochondrial oxidative stress on mitochondrial (i) DNA (mtDNA), (ii) function, (iii) dynamics and (iv) unfolded protein response (UPRmt) in Chronic Hepatitis B (CHB) patients with minimal to advanced fibrosis.

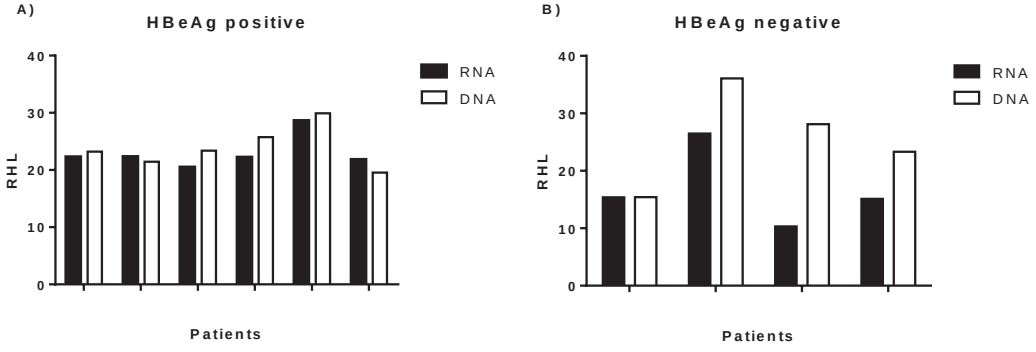

Figure: (abstract: SAT361): Analysis of rare haplotype load (RHL) in HBeAg positive (A) and negative patients (B).

Methods: Fifty naïve CHB patients (n = 50) with different fibrosis stages [Metavir Scores: F0 (n = 10), F1-2 (n = 25) and F3-4 (n = 15)] were evaluated for mtDNA damage, mitochondrial function and dynamics. Total DNA, RNAs and proteins were purified from liver samples of these patients. Liver ATP was determined by chemiluminescence and mtDNA damages were investigated by Southern blot and PCR. The expression of the following genes was assessed (RT-qPCR and Western-Blotting): subunits 1 (CO1), 2 (CO2) and 4i1 (COX4i1) of the complex IV of the respiratory chain, PGC1α and mTFA (transcriptional factors for mitochondrial biogenesis), LonP1 peptidases, HSP60 and HSP70 chaperones (mitochondrial unfolded protein response, UPR^{mt}).
Results: Massive mtDNA damage associated with a significant drop of Hepatic ATP levels were observed in livers from CHB patients. Compared to CHB patients with moderate fibrosis (F1-2), we observed in CHB patients with an advanced fibrosis (F3-4) alterations in the mRNA expression of the complex IV of the mitochondrial respiratory chain with a significant decrease of CO1 (1,09 ± 0,57 *vs* 0,49 ± 0,26; $p < 0.001$) and CO2 (1,34 ± 1,0 *vs* 0,99 ± 0,62; $p < 0.05$), alterations of the mitochondrial biogenesis process with a significant decrease of PGC1α (0,8 ± 0,6 *vs* 0,5 ± 0,3; $p < 0.05$) and mTFA (1,2 ± 0,9 *vs* 0,6 ± 0,4; $p < 0.05$) transcription factors and alterations of UPRmt process with a significant decrease of HSP60 (1,1 ± 0,6 *vs* 0,7 ± 0,3; $p < 0.05$), HSP70 (0,8 ± 0,4 *vs* 0,5 ± 0,2; $p < 0.05$) chaperones and LonP1 peptidase (1,3 ± 0,6 vs 0,8 ± 0,2; $p < 0.01$). COX4i1 mRNA expression remained unchanged whatever fibrosis stage. Protein expression of CO1, CO2, PGC1α and mTFA was significantly decreased (at least 50%) and correlated with the severity of fibrosis.
Conclusion: Massive mtDNA damage associated with alterations of the mitochondrial function, biogenesis and unfolded protein responses were observed in CHB patients. The extent of these mitochondrial lesions is associated with advanced HBV-mediated fibrosis. HBV increased mitochondrial oxidative stress which is known to degrade mtDNA. Combined together, such mitochondrial alterations concomitantly contribute to a major mitochondrial dysfunction that may play an important role in the pathophysiology of CHB and the development of fibrosis in these patients.

SAT363
Differential HBV RNA and quantitative HBsAg kinetics between HBeAg(+) and HBeAg(−) patients with chronic hepatitis B on nucleos(t)ide analogues (NA)

Pir Ahmad Shah[1], Rizwan Ishtiaq[1], Satinder Pal Kaur[1], Jeffrey Gersch[2], Saad Choudhry[1], Mary Kuhns[2], Gavin Cloherty[2], Daryl Lau[1]. *[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Medicine, Boston, United States; [2]Abbott Diagnostics, Infectious Disease Research*
Email: dlau@bidmc.harvard.edu.

Background and Aims: Functional cure with HBsAg clearance is a desirable treatment goal. Patients with HBeAg (−) chronic hepatitis B (CHB) have lower baseline quantitative HBsAg (qHBsAg) levels but do not have higher rate of HBsAg loss on NA therapy. We aim to examine the on-treatment HBV RNA and qHBsAg kinetics between HBeAg (+) and (−) patients.
Method: CHB patients on NA for at least 1 year with available stored serial sera from baseline were included in this analysis. Serum HBV RNA was measured using the Abbott research assay (Sensitivity: 1.65 log U/ml). Serum qHBsAg titers were determined by Abbott Architect assay (Sensitivity: 0.05 IU/ml).
Results: This predominantly Asian (95%) cohort consisted of 29 HBeAg(+) and 12 HBeAg(−) CHB patients. The duration of therapy was similar for the HBeAg (+) and (−) groups (58 vs. 55 months, p = 0.9). 14 subjects achieved HBeAg loss after 5 to 74 months of therapy. None of the HBeAg(−) subjects had functional cure. The HBeAg(−) patients had significantly lower baseline DNA, RNA and qHBsAg levels compared to the HBeAg(+) ones, and reached optimal HBV DNA suppression (<1.3 log IU/ml) fastest. The decline of RNA and qHBsAg from baseline to time of DNA <1.3 log IU/ml, in contrast, was much slower among the HBeAg(−) patients [Table]. The 14 patients who achieved HBeAg loss had the greatest initial reduction in RNA and qHBsAg levels associated with HBV DNA suppression. At last follow up, 5 of 14(35%) had RNA <1.65 U/ml but only 1 had HBsAg loss. In contrast, none of the patients who remained HBeAg(+), and only 5 (42%) HBeAg(−) patients, achieved RNA <1.65 U/ml. The annual log reduction of qHBsAg from baseline to last follow up was significantly slower among the HBeAg(−) patients. [Table].
Conclusion: In this cohort, HBV RNA kinetics differentiated HBeAg (+) CHB patients with and without HBeAg loss on long-term NA therapy. HBeAg(−) subjects achieved optimal HBV DNA suppression the fastest but had the slowest decline in HBV RNA and qHBsAg levels over time. The kinetics of HBV RNA and qHBsAg decline elucidated the low rate of treatment-related HBsAg loss among the HBeAg(−) patients.

Table: (abstract: SAT363)

Mean	NA-induced HBeAg loss (N = 14)	No NA-induced HBeAg loss (N = 15)	HBeAg(−) (N = 12)	Anova P value
Baseline HBV DNA (log IU/ml)	7.3	7.4	4.9	0.0001
Baseline HBV RNA (log U/ml)	6.0	7.0	2.9	0.0001
Baseline qHBsAg (log IU/ml)	4.1	4.1	2.7	0.0001
Time to HBV DNA<1.3 log IU/ml (months)	27.8	33.8	7.6	0.03
% RNA decline from baseline to DNA<1.3	47%	25%	16%	0.01
% qHBsAg drop from baseline to DNA<1.3	26%	15%	6%	0.04
Annual reduction of qHBsAg from baseline to last follow up (log IU/ml/year)	0.36	0.23	0.09	0.01

SAT364
Role of hepatitis C virus core antigen in HIV-HCV co-infected and chronic kidney disease patients on hemodialysis: expanding the HCV horizon of diagnostics

Ekta Gupta[1], Nitin Kumbhar[2], Krithiga Ramachandran[2], Guresh Kumar[3], Manoj Kumar[4], Rajendra Prasad Mathur[5]. *[1]Institute of Liver and Biliary Sciences, Clinical Virology, New Delhi, India; [2]Institute of Liver and Biliary Sciences, Clinical Virology; [3]Institute of Liver and Biliary Sciences, Clinical Epidemiology; [4]Institute of Liver and Biliary Sciences, Hepatology; [5]Institute of Liver and Biliary Sciences, Nephrology*
Email: ektagaurisha@gmail.com.

Background and Aims: The prevalence of Hepatitis C Virus (HCV) infection in chronic kidney disease patients (CKD) on hemodialysis (HD) patients and in patients with HIV-HCV co-infection is greater than in the general population. Screening for HCV infection in this population is associated with false negative HCV antibody results. HCV core antigen (cAg) can be an important diagnostic marker to screen for HCV infection in such patients. This study investigates the correlation of HCV c Ag with the current gold standard of HCV RNA test in both of these difficult to diagnose patient groups.
Method: Stored sera of 111 consecutive treatment-naive patients tested anti-HCV positive for whom HCV-RNA (Abbott RealTime PCR) was requested were analysed for HCVAg (Abbott ARCHITECT) in order to evaluate the correlation between the two parameters in both HIV-

HCV co-infected, n = 83 and HCV infected CKD patients on HD, n = 28. The differences between percentages were evaluated by Fisher's exact test, while mean and median values were compared by Student's t test, respectively. All differences were considered significant for a p value <0.05.

Results: Overall in 111 anti-HCV-positive sera, 101 were positive for both HCV Ag (≥3 fmol/L) and HCV RNA (>15 IU/mL), 6 were negative for both tests, while 4 were positive to HCV RNA only. The sensitivity and specificity for HCV Ag in predicting HCV RNA were 96.1% and 100%, respectively. This was similar in both the groups of patients. Out of 105 patients (94.5%) tested positive for HCV viremia, 65 (61.9%) were of genotype 3, 25 (23.8%) of genotype 1 and 15 of other genotypes. In HIV -HCV coinfected group a strong positive correlation was seen between HCV RNA and HCV-Ag ($r = 0.960$, $p < 0.001$). Similarly in CKD group on HD correlation between RNA and Ag was ($r = 0.83$, $p < 0.001$). No false positive Ag was detected in any of the group and RNA was positive in only 4 patients with Ag negative (3 in HIV-HCV coinfected and 1 in CKD on HD group). In all these 4 patients HCV RNA levels were <3 $\log_{10}$ IU/ml.

Conclusion: Given the strong positive correlation between HCV-Ag and HCV RNA in both these HCV infected patient population, we propose that HCV-Ag can be a more cost and time efficient alternative to the current two-step diagnostic process.

SAT365

Characterization of acute hepatitis C virus infection and transmission clusters by next-generation sequencing among people who inject drugs in Catalonia

Adrian Antuori Torres[1], Vincent Montoya[2], Verónica Saludes[1,3], Jeffrey Joy[2,4], Mel Krajden[5], Sara González-Gómez[1], Cinta Folch[3,6], Jordi Casabona[3,6], Joan Colom[7], Elisa Martró[1,3]. *[1]Germans Trias i Pujol University Hospital and Research Institute (IGTP), Badalona, Spain, Microbiology Department, Clinical Laboratory North Metropolitan Area, Spain; [2]BC Centre for Excellence in HIV, Vancouver, Canada; [3]Instituto de Salud Carlos III, Biomedical Research Networking Centre in Epidemiology and Public Health (CIBERESP), Madrid, Spain; [4]University of British Columbia, Department of Medicine, Vancouver, Canada; [5]Hepatitis – Clinical Prevention Services British Columbia Centre for Disease Control (BCCDC), Public Health Laboratory, British Columbia, Canada; [6]Centre for Epidemiological Studies on Sexually Transmitted Infections and HIV/AIDS of Catalonia (CEEISCAT), Catalonia Public Health Agency (ASPCAT), Badalona, Spain; [7]Program for the Prevention, Control and Care of HIV, Sexually Transmitted Infections and Viral Hepatitis, Catalonia Public Health Agency (ASPCAT), Barcelona, Spain*
Email: emartro@igtp.cat.

Background and Aims: Dried-blood spot (DBS) samples have proven useful to improve access to hepatitis Hepatitis C virus (HCV) testing among people who inject drugs (PWID). We previously showed that HCV isolates can also be genetically characterized from DBS samples by next-generation sequencing generating useful epidemiological information, such as the identification of acute infections and transmission clusters. In order to inform preventive public health interventions, we aimed to assess factors associated with acute HCV infection and belonging to a transmission cluster.

Method: Current PWID (N = 410) attending harm reduction services in Barcelona were recruited in 2016–17 (HepC*detect* II study). DBS samples were collected from all participants, and plasma from 300 cases. All samples were tested for HCV RNA, and a 389-bp region of the NS5B gene was amplified in viremic individuals. Sequence libraries were indexed and subjected to Illumina paired-end sequencing (2 × 250 cycles, MiSeq). The HCV intra-host genetic variability estimate Shannon entropy (SE) was used to identify acute infections. A set of well-defined acute (<6 months) and chronic infections were used to establish a SE cut-off by ROC curve analysis. Transmission clusters were also identified from sequencing data. An epidemiological questionnaire was administered and risk factors for acute infection and phylogenetic clustering were identified by multivariate logistic regression analysis.

Results: Based on ROC curve analysis, 13.5% (29/215) viremic individuals were identified as acute HCV infection (five mixed infections were excluded). Factors associated with acute infection included age <30 (AOR = 8.09), injecting less than daily (AOR = 4.35), ≤5 years of injected drug use (AOR = 3.43), sharing cocaine snorting straw (AOR = 2.89), and being unaware of their HCV status (AOR = 3.62). Additionally, 46.8% (103/220) of viremic cases were involved in transmission pairs/clusters; age ≤30 years (AOR = 6.16), acute infection (AOR = 5.73), and infection with subtype 1a (AOR = 4.78) were independently associated with this condition.

Conclusion: The molecular epidemiology techniques carried out, which can also be performed from minimally invasive DBS samples, have allowed us to characterize for the first time in our setting the profile of PWID with acute infection and those currently involved in HCV transmission. This information could help assess harm reduction programs and monitor incidence of HCV infection in this key collective.

SAT366

Mathematical modeling of early hepatitis D virus kinetics in transgenic-hNTCP mice

Preeti Dubey[1], Elham Shirvani Dastgerdi[2], Hannah Shanes[1], Susan Uprichard[1], Andrew Berneshawi[2], Harel Dahari[1], Alexander Ploss[2]. *[1]Loyola University Chicago, Medicine, Maywood, IL, United States; [2]Princeton University, Department of Molecular Biology, Princeton, United States*
Email: harel.dahari@gmail.com.

Background and Aims: Understanding early hepatitis D virus (HDV) dynamics post infection is lacking. Here, we characterized the early kinetics of HDV post inoculation (pi) and used mathematical modeling to provide insights into HDV-host dynamics.

Method: Transgenic (tg) mice expressing human NTCP (hNTCP) (n = 20), the receptor for hepatitis B virus and HDV, and non-tg control animals (n = 30) were inoculated intravenously with 10^9 genome equivalents (GE) of cell-culture produced HDV (genotype 1). Serum HDV viremia was quantified by RTqPCR at 1 min and then every 2 hour (hr) in the serum over the first 96 hr post inoculation (pi). An additional 9 non-tg mice were inoculated with 10^9 GE at time 0 and again at 4 hr pi. A mathematical model was developed and calibrated to measured serum HDV kinetics.

Results: No significant difference ($p = 0.07$) was found in median HDV RNA 1 min pi between non-tg (8.5 $\log_{10}$ cps/ml) and tg-hNTCP mice (8.8 $\log_{10}$ cps/ml). A biphasic decline in HDV was observed in both non-tg and tg-hNTCP mice consisting of rapid decline first phase (slope = 1.4 $\log_{10}$/hr and 1.6 $\log_{10}$/hr, respectively) that was lasted 2 hr pi, followed by a slower decline second phase (slope = 0.14 $\log_{10}$/hr and 0.2 $\log_{10}$/hr, respectively) until 14 hr pi when HDV RNA became lower than the limit of detection (Fig. 1 left). Notably, there was no difference in HDV decline slopes between non-tg and tg-hNTCP mice suggesting negligible effect of HDV entry on viral decline and no evidence of viral production. As such, we developed a mathematical model assuming no production of new virions and that free HDV can be cleared (parameter c) or bound to a non-specific binding compartment (parameter k_{on}) and released into the circulation with off-rate constant, k_{off}. The model reproduces the biphasic decline (Fig. 1 left) and suggests that the first phase of HDV decline mainly reflects HDV clearance with estimated HDV half-life $t_{1/2} = 2.4$ min with 95% confidence interval, [1.2, 46.2] min in both non-tg and tg-hNTCP mice, respectively. The second phase of HDV decline mainly represents the binding compartment off-rate, which was 0.39 [0.02, 0.7]/hr for non-tg mice and 0.48 [0.02. 0.9]/hr for tg-hNTCP mice. To validate the model, we challenged the model with the HDV kinetics obtained from non-tg mice that were re-inoculated with HDV at 4 hr pi (Fig. 1 right). Interestingly, the model reproduces the data if a

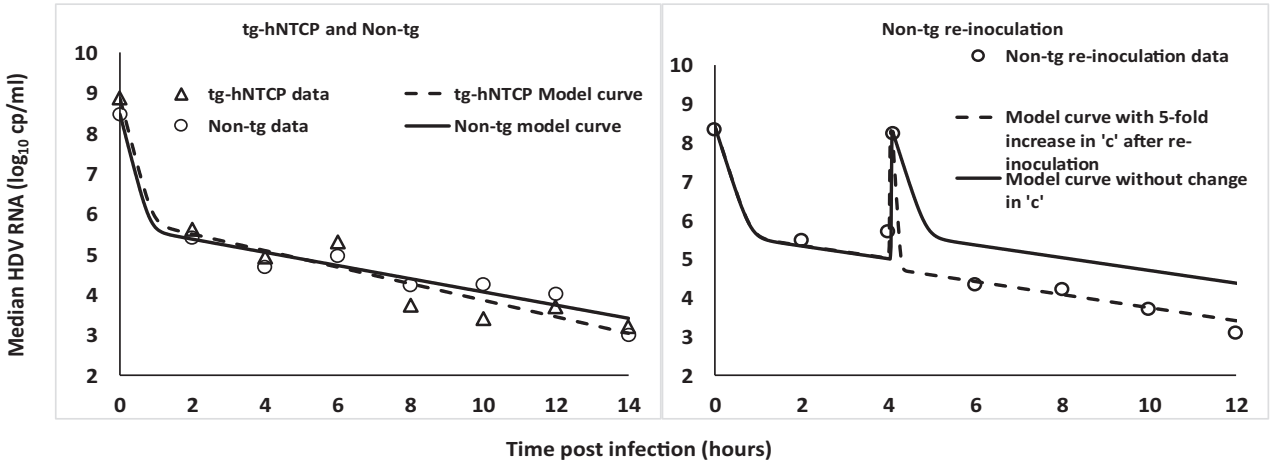

Figure: (abstract: SAT366)

5-fold increase in the HDV clearance rate is assumed after the re-inoculation at 4 hr pi (Fig. 1 right).
Conclusion: The unexpected biphasic early HDV kinetics observed in mice can be modeled by assuming the existence of a binding compartment with a constant off rate. The model predicts that HDV clearance is ~5-fold enhanced after re-inoculation of HDV after 4 hr pi. However, further experiments and theoretical efforts are needed to formalize these results and predictions.

SAT367
Prospective study of viral hepatitis in pregnancy and its vertical transmission in the northeast region of India
Harpreet Kaur[1], Vijaya Kumar Karra[2], Sangit Dutta[3], Lokeshwar Singh[4], Kyrshanlang G Lynrah[5], Tapan Majumdar[6], Subhash Medhi[7], Provash Chandra Sadhukhan[8], Biswajyoti Borkakoty[9]. *[1]Indian Council of Medical Research, Division of Epidemiology and Communicable Diseases, New Delhi, India; [2]Indian Council of Medical Research, Division of Epidemiology and Communicable Diseases, New Delhi, India; [3]Gauhati Medical College & Hospital, Department of Medicine, Guwahati, Assam, India; [4]Jawaharlal Nehru Institute of Medical Sciences & Hospital, Department of Medicine, Imphal, Manipur, India; [5]North Eastern Indira Gandhi Regional Institute of Health and Medical Sciences, Department of Medicine, Shillong, Meghalaya, India; [6]Agartala Government Medical College & GB Pant hospital, Department of Microbiology, Agartala, Tripura, India; [7]Gauhati University, Department of Bioengineering & Technology, Guwahati, Assam, India; [8]National Institute of Cholera and Enteric Diseases, Virology, Kolkata, West Bengal, India; [9]Regional Medical Research Centre, Virology, Dibrugarh, Assam, India*
Email: harpreet.icmr16@gmail.com.

Background and Aims: Acute viral hepatitis is the most common cause of jaundice in pregnancy and pregnant women are at increased risk of morbidity and mortality.
Methods: This is a prospective, ongoing multi centric study; Sera of 1046 pregnant women in any trimester, attending the antenatal clinics of 4 selected hospitals were analyzed for markers of hepatitis A, B, C and E viruses. Cord blood from the positive mothers is being collected and evaluated for vertical transmission, if any.
Results: Of the pregnant women tested, 1.9% (20/1046) were found positive for HBsAg, 0.6% (6/1044) for anti HCV, 0.5% (4/734) for IgM anti HEV, 5.8% (32/548) for IgG anti HEV, 0.1% (1/782) for IgM anti HAV, and 19.8% (93/469) for IgG anti HAV. While, 16 HBsAg positive pregnant women have delivered and 56.2% (9/16) of cord blood was found to be positive, on the other hand, none of the cord blood was found positive in the 3 HCV positive pregnant women delivered.
Conclusion: Prevalence of HBsAg and anti HCV in pregnant women was found to be 1.9% and 0.6% respectively. The rate of vertical transmission is reported to be 56.2% among HBsAg positive pregnant women tested, which was however not observed in anti HCV positive mothers. Further, the prevalence of acute hepatitis E was 0.5% and the marker for previous infections was 5.8%, whereas acute hepatitis A was prevalent in mothers with 0.1% and the marker for previous infection to be 19.8%.

SAT368
Usefulness of dried plasma spots using a plasma separation card for serological diagnosis of chronic hepatitis B and C and reflex viral load testing
Joan Martinez[1], Ariadna Rando[2], Fernando Velasquez[2], Mar Riveiro Barciela[3,4], Paula Salmerón[2], Adriana Palom[5], David Tabernero[6], María Nieves Palomo[5], Ed G. Email: jmc3689@gmail.com.

Background and Aims: Increasing diagnosis rate of hepatitis B and C is one WHO objective to achieve viral hepatitis elimination in 2030. However, access to diagnosis in certain regions with suboptimal infrastructure or in special populations is limited by the lack of accessibility to blood extraction methods and low accuracy of rapid diagnosis tests. In these circumstances, the WHO guidelines recommends the use of alternative sample types. The cobas® Plasma Separation Card (PSC) in a new device that generates dried plasma spots however there is no data on its usefulness for HCV and HBV serology screening (HBsAg and/or anti-HCV). Our goal was to correlate the results of HBsAg, anti-HBc, anti-HCV, HBV-DNA and

HCV-RNA in PSC vs plasma in chronic hepatitis B (CHB) and/or C (CHC) patients and its usefulness in reflex molecular testing.
Method: Observational study of consecutive samples of CHB and/or CHC patients. HBV and HCV serology and viral loads were tested on plasma samples obtained by venepuncture and on the PSC (Roche Diagnostics) prepared from finger puncture. HBsAg, anti-HBc and anti-HCV were determined in the cobas® 8000 System (Roche Diagnostics). In HBsAg positive or anti-HCV positive cases, HBV-DNA or HCV-RNA were respectively quantified as reflex test using a second spot in the same PSC in the cobas® 6800 System-(Roche Diagnostics).
Results: 98 patients were included: 56 HBsAg positive, 40 anti-HCV positive, 2 HBsAg+, anti-HCV positives. A 100% correlation was observed in serological markers between PSC card and the conventional method. HCV RNA in PSC and in conventional plasma samples was detectable in 16 (38%) of 42 anti-HCV positive with a R^2 of 0.91 (HCV-RNA 5.6 ± 1.7 logUI/mL vs 3.9 ± 1.4 PSC). HBV DNA in PSC was detected in 29 (50%) of 58 HBsAg positive samples with an R^2 of 0.95 to plasma (3.5 ± 1.9 logUI/mL vs. 1.5 ± 2 PSC). In plasma samples with HBV-DNA>3 logUI/mL 93% was detectable by PSC while in those with HBV DNA ≤3 logUI/mL PSC was only detectable in 20% of samples.
Conclusion: The performance of dried plasma samples in PSC for detection of serological markers of hepatitis B and C virus infection is excellent and comparable with conventional techniques. Viremia studies on PSC cards correlates very well with conventional systems allowing viral load reflex testing, but detecting 2 log less of HBV-DNA. However, this does not impact on the selection of patients candidates to therapy since this is recommended when HBV-DNA levels are >3 logUI/mL.

SAT369
Validity of a point-of-care viral load kit for hepatitis B in a low-income setting
Gezahegn Woldemedihn[1], Corina Rueegg[2], Nega Berhe[3], Hailemichael Desalegn[4], Hanna Aberra[4], Asgeir Johannessen[5].
[1]Hawassa University, Awassa, Ethiopia; [2]Oslo University Hospital, Norway; [3]Addis Ababa University, Addis Ababa, Ethiopia; [4]St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia; [5]Oslo University hospital Ullevål, Norway
Email: johannessen.asgeir@gmail.com.

Background and Aims: A major obstacle to scale up treatment of chronic hepatitis B (CHB) in low-income countries is the lack of access to hepatitis B virus (HBV) viral load testing. The recent launch of the first point-of-care HBV viral load kit from GeneXpert could overcome this problem. Such new technology needs, however, real-life testing before it can be implemented into routine use. The current study aimed to validate the new GeneXpert viral load kit against the gold standard from Abbott.
Method: In 2015, we established a cohort of patients with CHB in Ethiopia. We randomly sampled 123 patients from this cohort and assessed viral load with both the new GeneXpert kit and the Abbott RealTime HBV assay (gold standard) at the same time in each patient. We assessed the validity of GeneXpert by calculating the correlation between the two tests and performing a Bland-Altman plot. We assessed the diagnostic performance of GeneXpert (sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV)) in identifying CHB patients with a viral load ≥2000 IU/mL in the Abbott assay. We used the Youden index of the receiver operator characteristics (ROC) curve to suggest an optimal cut-off for GeneXpert to identify CHB patients with a viral load ≥2000 IU/mL in the Abbott assay.
Results: We found a high correlation between the viral load assessed by GeneXpert and Abbott (r = 0.943, p < 0.001, Figure). The Bland-Altman plot showed no bias between the two tests and an on average 0.24 log10 IU/mL higher viral load result with the GeneXpert compared to Abbott. Using the European cut-off of 2000 IU/mL in both tests, the GeneXpert had a sensitivity of 94%, specificity of 69%, PPV of 68%, and NPV of 94% to identify the same individuals above the threshold in the Abbott assay. The optimal GeneXpert cut-off suggested by the ROC curve is 4190 IU/mL. With this cut-off, sensitivity and specificity are both 90%, PPV = 86% and NPV = 93% (area under the ROC curve = 0.95).

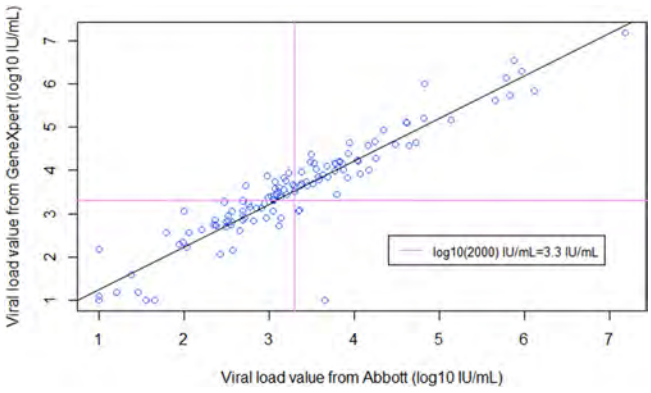

Figure: Correlation of viral load measurement from GeneXpert and Abbott on the logarithmic scale (n = 123). The pink lines represent a cut-off of 2000 IU/mL.

Conclusion: We found good validity of the new GeneXpert kit in a real-life setting with a high correlation with the Abbott assay and good sensitivity and specificity. This new point-of-care viral load kit can enable access to treatment for CHB patients in low-income countries.

Email: k.chiokcasimiro@wsu.edu.

Background and Aims: In the Phase IIa Achieve® clinical trials, Inarigivir caused significant reductions of HBV DNA, HBV RNA, HBsAg and HBcrAg. Inarigivir, an oral dinucleotide prodrug, metabolizes to the active SB 9000 *in vivo*. As a pan antiviral agent, it activates human Retinoic Acid-Inducible Gene (hRIG-I), for the induction of innate and adaptive immunity. Summarized here are the mechanism of action (MOA) studies.
Method: Demonstration of direct binding to hRIG-I by SB 9000. a) Dissociation constant Kd of hRIG-I binding was ascertained by surface plasmon resonance using streptavidin chips coated with biotin-conjugated SB 9000 (BSB). b) BSB was incubated with anti-DDK antibody bound to FLAG-tagged hRIG-I and ELISA performed using Avidin/HRP-conjugate. c) Fluorescent enhancement assays were performed to assess Inarigivir/SB 9000-mediated translocation of hRIG-I on dsRNA. d) BSB was incubated with A549 cell lysates expressing FLAG-tagged hRIG-I, the bound proteins visualized by Western blot using anti-FLAG antibody. e) Binding of SB 9000 to the *Helicase* domain of hRIG-I was assessed by immuno-precipitation using hRIG-I mutants in A549 cells. f) Cellular co-localization of SB 9000 with hRIG-I in A549 cells was assessed using confocal microscopy. Demonstration of hRIG-I-dependent induction of pIRF3 and IFNs. a) SB 9000 was incubated ± ATP with a reconstitution complex of hRIG-I, IRF3, ubiquitin, ubiquitin *ligases*, mitochondrial/cytosolic fractions, and phosphorylated IRF3 detected by Western blot. b) HepG2/A549 cells were treated with Inarigivir and IFN-beta

assessed by ELISA; hRIG-I specificity was ascertained using siRNA silencing of hRIG-I. c) WHV-infected woodchucks (n = 5/group) were treated once daily orally with Inarigivir for 12 weeks at 15 or 30 mg/kg and IFNs, IL-6, CXCL10, OAS1 and ISG15 mRNA in blood and liver measured by qPCR and hepatic RIG-I assayed by immunohistochemistry.

Results: SB 9000 directly bound to hRIG-I *via* its *Helicase* domain with Kd of 12 picomolar and co-localized with hRIG-I in cells. SB 9000 activated hRIG-I to induce ATP-dependent phosphorylation of IRF3. SB 9000 induced hRIG-I-dependent IFN production in cells. The antiviral activity of Inarigivir in woodchucks was associated with dose-dependent induction of IFNs, ISGs and RIG-I.

Conclusion: The *in vitro* and *in vivo* studies support the MOA of Inarigivir involving the activation of hRIG-I to produce IFNs and cytokines and mediate antiviral activity in CHB patients.

SAT372

A systematic assessment of acute viral hepatitis and chronic liver diseases in northeast India with special reference to strengthening of laboratories in the region

Background and Aims: In India, viral hepatitis caused by hepatitis viruses A through E remains to be a major public health problem. HAV and HEV are important causes of acute viral hepatitis and acute liver failure (ALF). On the other hand, infection with HBV, HCV or HDV, which may present as acute hepatitis some time have the potential to cause persistent infection and may progress to liver cirrhosis or liver cancer to become life-threatening.

Methods: In this cross-sectional ongoing multicentric study, serological prevalence analysis of viral hepatitis A, B, C, and E was performed in 536 randomly selected subjects across selected tertiary care and district hospitals of 8 northeastern states of India. Cases were divided into acute hepatitis, acute liver failure, chronic hepatitis, cirrhosis and hepatocelluar carcinoma and were tested for serological markers.

Results: The overall prevalence of hepatitis B virus surface antigen (HBsAg), anti hepatitis B virus surface protein antibody (HBsAb), anti hepatitis B virus core protein anti body (HBcAb), hepatitis B envelope antigen (HBeAg) and anti hepatitis B envelope antibodies (HBeAb) was 30.4% (163/536), 18.6% (87/468), 35.8% (168/469), 6.8% (27/398) and 18.7% (75/402) respectively. The prevalence of hepatitis D antibody was 1.8% (3/163). The prevalence of hepatitis C virus antibody (anti-HCV) was 11.3% (60/531). The prevalence of acute hepatitis A anti HAV IgM and hepatitis E anti HEV IgM was 9.1% (22/240) and 5.6% (21/374) respectively. Meanwhile, the serological markers for previous infection of hepatitis A anti HAV IgG and hepatitis E anti HEV IgG was 36.9% (150/407) and 9.8% (40/407) respectively.

Conclusion: The data so far shows the epidemiological transition of hepatitis A leading to an increased incidence of symptomatic HAV infection in adults. Further, the pattern of HEV infection was observed different among the different ethnic groups and regions of the country.

SAT373

From in vivo to in vitro: ex vivo studies using primary human hepatocytes from chronically diseased liver-humanized FRG® KO mice

Lander Foquet[1], Edward Henson[1], Markus Grompe[2], Rob Copenhaver[1]. [1]*Yecuris, Portland, United States;* [2]*Oregon Health & Science University, Portland, United States*
Email: landerfoquet@yecuris.com.

Background and Aims: Liver-humanized FRG KO mice are useful for in vivo studies in many application areas including infectious diseases, NAFLD/NASH, gene editing/therapy, metabolism, and pharmacology/toxicology.

Cryopreserved primary human hepatocytes can be thawed and plated, but have a limited life-span in vitro. Fresh primary human hepatocytes, either isolated from biopsies or from liver-humanized mice, have a longer life-span in vitro of at least 30 days.

The life-span of in vitro cultures of primary hepatocytes is too short to study chronic liver diseases like hepatitis B or non-alcoholic fatty liver disease. It takes up to 14 days to induce a chronic infection state with HBV, after which only a small window remains to test novel therapeutics. For the study of NAFLD or NASH, there is currently no standardized in vitro model available.

Method: Chronic liver diseases were induced in liver-humanized FRG KO mice. Animals were either infected with HBV, or received a high-fat diet to induce NAFLD/NASH. Eight to twelve weeks after the start of the experiment, animals were sacrificed and after perfusion, human hepatocytes were purified and plated for in vitro studies.

Results: Primary human hepatocytes isolated from liver-humanized FRG KO mice infected with HBV were up to 100% positive for HBcAg. Without the need to infect the hepatocytes in vitro, the efficacy of novel therapeutics can be tested the day after plating and during multiple days, followed by a wash-out period during which a rebound can be measured. No negative effects on cell health or plating efficacies were observed when comparing naïve vs infected primary hepatocytes isolated from liver-humanized mice.

The isolation of hepatocytes from liver-humanized FRG KO repopulated with human PNPLA3-148M hepatocytes and fed HFD is not hampered by the steatotic state of the cells. After plating, the cells survived comparable to hepatocytes from control humanized animals. The culture media was supplemented with lipogenic factors to maintain the diseased state of hepatocytes isolated from mice that received a high-fat diet. In comparison, when using standard hepatocyte culture media, lipid droplets gradually decreased over the course of 5 days. This can be explained by the lack of lipogenic triggers.

Conclusion: Liver-humanized mice are proven to be useful for long-term in vivo studies for several applications. For high-throughput in vitro studies, they can be a valuable source of chronically diseased hepatocytes. Compared to patient-derived hepatocytes, the liver-humanized mice can provide a readily available source of hepatocytes of known origin, with a specific disease induced, and for which control animals can provide hepatocytes from the same donor but without the disease of interest.

SAT374

The head-start project Georgia: a three-armed, cluster, non-randomised trial of the effectiveness of two novel models of HCV confirmatory testing in harm reduction sites (HRS) in Georgia

Maia Japaridze[1], Jessica Markby[2], Irma Khonelidze[3], Maia Butsashvili[4], Maia Alkhazashvili[3], Sonjelle Shilton[2]. [1]*Foundation for Innovative New Diagnostics, Georgia;* [2]*Foundation for Innovative New Diagnostics, Geneva, Switzerland;* [3]*Georgia National Centers for Disease Control, Georgia;* [4]*Health Research Union, Georgia*
Email: maia.japaridze@finddx.org.

Background and Aims: Georgia, a middle income country with an estimated population of 3.7 million people, is among the world's highest-burden countries, with an HCV prevalence of 6.7% in the general population and a higher burden of disease in high risk populations especially PWID. In 2015, Georgia embarked on an elimination programme, however significant gaps remain in case finding and linkage to care. In particular, although screening programs have largely been decentralised for high risk groups, viremic testing remains a bottleneck for PWID accessing care. Here we describe two novel models of viremic testing that aim to address these weaknesses in the care cascade.
Method: A cluster, non-randomized intervention study where HRS are assigned to one of three arms Arm1: 4 HRS, viremia testing (GeneXpert) on-site, Arm 2: 2 HRS, blood draw on site, confirmatory testing (cAg) at a centralized laboratory, Arm 3 2 HRS, standard of care patients referred for testing at the treatment centre. Participants are eligible for the study if they tested anti-HCV positive on the same day and did not have prior confirmed diagnosis. The proportion of participants who completed each step in the HCV care cascade were compared across the three arms as well as the turn-around time of test results.
Results: Between May 2018 and November 2019, 1671 participants were enrolled (621 in Arm 1, 486 in Arm 2; 565 in Arm 3). Participants were predominantly male (95.4%), mean age was 44.0 (19–88) years and 79.1% were currently injecting drugs. 95% participants reported having taken an HIV test and of these 14 (0.84%) self-reported being HIV-positive. To date, 1517 participants have had a confirmatory viremia test done: 621 (100%) in Arm 1, 483 (99.4%) in Arm 2; 438 (77.5%) in Arm 3. Of those confirmed positive, treatment was initiated for 450 (87.0%) in Arm 1, 273 (70.9%) in Arm 2 and 345 (98.0%) in Arm 3. On average participants received their results the same day (<3 hours) in Arm 1, 21.5 days in Arm 2 and 18.6 days in Arm 3 from the time they had blood drawn for testing.
Conclusion: Confirmatory testing or blood draw on site at HRS showed improved retention of patients in the care cascade compared to referral of patients for blood collection. Moreover, the turnaround time was shortest when confirmatory testing was performed on site. These findings will facilitate scale up of decentralized HCV care for PWID in Georgia and globally.

SAT375

HBeAg seroconversion during treatment with peginterferon-alfa2a (PEG-IFN) is preceded by selection of hepatitis B virus basal core promoter and pre-core variants which are associated with decreased HBV replication

Maria Pfefferkorn[1], Carolin Hahn[1], Karen Rother[1], Danilo Deichsel[1], Cynthia Wat[2], Thomas Berg[1], Florian van Bömmel[1]. [1]*Division of Hepatology, University Clinic Leipzig, Clinic and Policlinic for Gastroenterology, Hepatology, Infectiology, and Pneumology, Leipzig, Germany;* [2]*Roche Products Ltd. Welwyn, United Kingdom*
Email: Maria.pfefferkorn@medizin.uni-leipzig.de.

Background and Aims: Variants in the basal core promoter (BCP, nt1743-1849) of the HBV genome (the mutations A1762T and G1764A [BCP++]) and a stop mutation at position 1896 (PC) in precore-region have been described to be associated with response to treatment with PEG-IFN. We have investigated the development of BCP++/PC variants during treatment with PEG-IFN.
Method: A total of 31 HBeAg positive(+) patients with (n = 19) or without (w/o, n = 12) subsequent HBeAg seroconversion (SC) matched by age, HBsAg levels and HBV genotype, who received PEG-IFN (180 μg/week) for 48 weeks in a prospective randomized study (Roche, WV16241), were retrospectively analyzed. In serum samples derived from baseline (BL), weeks 12, 24, 48 and 72 the HBV markers HBeAg, HBsAg, HBV DNA and HBV RNA were quantified. BCP and PC-stop regions were analyzed at all time points by direct sequencing of the region nt1690-2337 on either HBV DNA, or if HBV DNA was unavailable, on HBV RNA basis.
Results: At BL, 10/19 (52%) patients with subsequent HBeAg SC showed a BCP++ or PC stop mutation. Until the end of treatment all patients with HBeAg SC developed a mutation in the BCP/PC region. In contrast, only 2/12 (16%) patients w/o HBeAg SC showed a mutation before treatment, whereas additionally 5 patients developed a BCP/PC mutation during treatment (58%, $p = 0.003$). Analysis of the different HBV marker kinetics revealed a strong association of the occurrence of BCP or PC mutations and decreasing HBV RNA and HBeAg, but not HBsAg and HBV DNA levels during treatment. Thus, median HBV RNA levels decreased from 6.1 (0–8) log cp/mL before treatment to 3.3 (0–6.0) log cp/mL after 12 weeks of treatment and became (in median) subsequently undetectable in patients with HBeAg SC. Interestingly, in a few patients with persisting wildtype BCP/PC sequences (n = 3), HBV RNA levels remained unchanged in this patient group. Accordingly, patients w/o HBeAg SC who developed a BCP or PC mutation during treatment (n = 3/5), showed a strong decrease of HBV RNA levels from 7.6 (7.7–8.6) log cp/mL before treatment to 0.0 (0–4.3) log cp/mL after 48 weeks.
Conclusion: BCP and PC variants are being selected during PEG-IFN treatment, especially in patients with subsequent HBeAg SC. Irrespective of HBeAg SC, the occurrence of these variants leads to a decrease in HBV replication as measured by HBV RNA. The role of BCP/PC mutations in the process of HBeAg SC needs to be studied and our results to be confirmed in a larger population.

Targeting hepatitis B virus with CRISPR/Cas9 approach

Maria Guadalupe Martinez[1], Aurore Inchauspe[1,2], Elodie Delberghe[1], Fleur Chapus[1], Gregory Neveu[2], Antoine Alam[2], Kara Carter[2], Barbara Testoni[1], Fabien Zoulim[1,3,4,5]. Email: maria-guadalupe.martinez@inserm.fr.

Background and Aims: CHB infections persists mostly due to the lack of therapies that can effectively target the stable HBV covalently closed circular DNA (cccDNA) minichromosome. We used a CRISPR/Cas9 approach to target HBV genome and studied the fate of cccDNA after CRISPR/Cas9 gene editing.
Method: We set up a ribonucleoprotein (RNP) delivery system in de novo HBV infected HepG2 cells expressing the HBV receptor NTCP. RNP complex was delivered after infection was established to ensure targeting of cccDNA. HBV extracellular and intracellular parameters after Cas9 editing were analyzed. Southern blot analysis were performed to determine the presence of cccDNA and RNA-sequencing to determine if mutated cccDNA is transcriptionally active.
Results: Screening of different HBV-specific gRNAs, single or in combinations, showed that CRISPR/Cas9 can efficiently affect HBV replication. Depending on the target in the HBV genome, CRISPR/Cas9 led to degradation or mutations in total HBV DNA, both resulting in reduced viral transcripts. Besides a mild decrease in the amount of cccDNA, potentially due to degradation, we consistently observed the appearance of a smaller cccDNA species, by PCR, southern blot and RNA-seq indicating that this specie is transcriptionally active. Our results suggest that this "small cccDNA" is the product of double stranded breaks induced by Cas9 simultaneously in both target sites followed by repair of the bigger fragment. Following suppression of

HBV DNA replicative intermediate production by Nucleoside analogs (NAs) administrations, the addition of RNPs decreased cccDNA levels, suggesting that cccDNA is indeed directly targeted by the CRISPR/Cas9 complex.
Conclusion: Taken together, our results suggest that targeting HBV with CRISPR/Cas9 leads to mutation, cleavage and repair of cccDNA, and an effective synergy between NAs and CRISPR/Cas9 approaches. Notably, effects induced by Cas9 were sustainable indicating permanent changes in the HBV genome. Regardless of the truncation induced by a combination of gRNAs, the "small cccDNA" was still transcriptionally active and could potentially produce HBsAg. Further and longer-term in vivo studies would be necessary to determine efficient and irreversible gene editing.

SAT378
The correlations between HBV markers and HBV cccDNA in the patients during Na treatment

Matsui Takeshi[1], Kang Jong-Hon[1], Kazunari Tanaka[1], Ryosuke Minami[1], Tsuji Kunihiko[1], Yasuhito Tanaka[2]. [1]*Teine Keijinkai Hospital, Center for Gastroenterology, Sapporo, Japan;* [2]*Nagoya City University Graduate School of Medical Sciences, Department of Virology & Liver unit, Nagoya, Japan*
Email: mtake0402@gmail.com.

Background and Aims: It is well known that HBV markers (HBV DNA, HBcrAg and HBsAg) in sera are linked to quantified HBV covalently closed circular (ccc) DNA in liver tissue. However, it remains unknown as to whether similar correlation exists in the patients during Nucleic acid analog (NA) treatment. The correlation between the HBV ccc DNA in liver tissue and serum HBV marker in the patients during NA treatment was investigated.
Method: 90 patients were included in this study. Intrahepatic HBV ccc DNA was quantified using specimen obtained by liver biopsy or from excised liver tissue in all patients between January 2012 and June 2018 (non-treatment 57, treatment 33). 1. Correlation between the HBV ccc DNA and serum HBV marker was investigated in all patients. 2. Correlation was investigated in 33 patients during NA treatment.
Results: A total of 90 patients were enrolled in this study. The median age was 57 year old. The median HBV ccc DNA levels was 3.4 log copies/μg (<1.7–5.3). The median levels of HBV markers in sera, namely HBV DNA, HBcrAg and HBsAg were 4.1 log copies/ml, 4.3 logU/ml and 3.23 logIU/ml, respectively. Ten cirrhotic cases were included and 19 patients had Gt B, 62 had HBV Gt C and 9 were unknown. 1. HBV markers were related to HBV ccc DNA in all patients. The correlation between HBcrAg and HBV ccc DNA was low in HBeAg negative patients (HBsAg, $r = 0.3989$, $p = 0.0012$; HBV DNA, $r = 0.7010$, $p < 0.001$; HBcrAg, $r = 0.6451$, $p < 0.001$). 2. The HBV markers related to HBV ccc DNA in the patients during NA treatment (HBsAg, $r = 0.4708$, $p = 0.0100$; HBV DNA, $r = 0.5052$, $p = 0.0052$; HBcrAg, $r = 0.6106$, $p < 0.001$). However, HBcrAg and HBsAg were not related to HBV ccc DNA in HBeAg negative (HBsAg, $r = 0.2892$, $p = 0.1917$; HBV DNA, $r = 0.1123$, $p = 0.6189$; HBcrAg, $r = 0.1418$, $p < 0.5290$) or HBV DNA negative patients during NA treatment (HBsAg, $r = 0.3223$, $p = 0.1435$; HBcrAg, $r = 0.2825$, $p = 0.2027$).
Conclusion: HBV DNA was related to HBV ccc DNA in the patients during NA treatment. However, no HBV marker in sera was related in HBeAg negative patients or HBV DNA negative patients in during NA treatment.

SAT379
Delineating HBV transcripts from integrated viral DNA using target enrichment and long read sequencing

Nicholas Van Buuren[1], Ricardo Ramirez[1], Simin Xu[1], Lindsay Gamelin[1], Robert Muench[1], Hongmei Mo[1], Li Li[1], Becket Feierbach[1]. [1]*Gilead Sciences, Inc., Foster City, United States*
Email: nick.vanbuuren@gilead.com.

Background and Aims: Integration of Hepatitis B virus (HBV) DNA into the host genome is associated with the development hepatocellular carcinoma (HCC). Short read sequence analysis is limited to chimeric-read detection. To understand architecture, burden, and transcriptional activity of integrated HBV we developed a target enrichment assay for long-read sequencing. With this method, we can resolve full length integrations and differentiate transcripts from cccDNA or specific HBV integrations.
Method: DNA from 3 HCC cell lines PLC/PRF/5, HuH-1 and Hep3B was sheared to 7 kb fragments. Additionally, RNA from these cell lines and *in vitro* infected primary human hepatocytes (PHHs) was reverse transcribed to full length cDNA. DNA and cDNA libraries were barcoded for multiplexing, enriched using biotinylated 120 bp probes specific for HBV, then sequenced on a Pacific Biosciences Sequel II (PacBio).
Results: Target enrichment increased the frequency of HBV-aligning reads by >1000-fold. DNA sequencing captured entire integration events and, in several cases, greater than 1 kb of flanking host DNA in single reads. Many integrations only include portions of the HBV genome and appear transcriptionally silent. PLC/PRF/5 and HuH-1 cells both contain multiple integrations that intersect host chromosomal translocations. These chromosomal translocations are supported by spectral karyoptying.
Hep3B cells have a single transcriptionally active integration, but HuH-1 and PLC/PRF/5 cells produce three classes of HBV transcripts that: 1) fuse to host genes (e.g. *MVK*, *SNX15*), 2) read-through into the host genome distal to any known gene, or 3) exclude host sequences and terminate near the direct repeat region of HBV. Most transcripts start at Pre-S2 or S open reading frames. Class 1 and 2 transcripts appear to use the host poly(A) signal UAUAAA, while Class 3 transcripts are associated with a cryptic signal CAUAAA found in HBV. Many Class 3 transcripts in HuH-1 cells appear to be the same length, but single nucleotide polymorphism profiles show the transcripts come from two distinct integrations. Class 3 transcripts differ from all of the overlapping cccDNA-derived transcripts in PHHs which use a canonical 3′ end.
Conclusion: HBV-targeted long-read sequencing can distinguish three classes of HBV transcripts and assign HBV transcripts to specific integrations. This tool can provide a more accurate description of the burden and transcriptional activity of integrated HBV in patients.

SAT380
Prospective study of hepatitis B virus infection and its genotypes in the north-eastern India region

Premashis Kar[1], Bhabadev Goswami[2], Jagdish Mahanta[3], Thongam Bhimo[4], Anup Kumar Das[5], Manab Deka[6], Kyrshanlang G Lynrah[7], Mool Raj Kotwal[8], Pradip Bhaumik[9], Moji Jini[10], Rahul Karna[1], Vijaya Kumar Karra[1]. [1]*Maulana Azad Medical College (MAMC), New Delhi, India;* [2]*Guwahati Medical College Hospital, Guwahati, India;* [3]*Regional Medical Research Center, Dibrugarh, India;* [4]*Regional Institute of Medical Sciences, Imphal, India;* [5]*Assam Medical College & Hospital, Dibrugarh, Dibrugarh, India;* [6]*Gauhati University, Guwahati, India;* [7]*North Eastern Indira Gandhi Regional Institute of Health & Medical Sciences, Shillong, India;* [8]*STNM Hospital, Gangtok, India;* [9]*Agartala Government Medical College & Govind Ballabh Pant Hospital, Agartala, India;* [10]*General Hospital, Naharlagun*
Email: premashishkar@gmail.com.

Background and Aims: India has large burden of Hepatitis B virus infection with approximately 2–8% population being HBsAg positive, placing it intermediate HBV endemic zone. Hepatitis B virus genotypes have been associated with severity of liver disease, response to treatment and may conform to a geographical distribution. However, there is little information about HBV genotypes from North East India, which is host to the most indigenous tribes and a higher rate of drug abuse and HIV infection.
The aim of the study was to characterize HBV genotypes across various spectrums of liver diseases viz. acute viral hepatitis (AVH),

Fulminant hepatic failure (FHF), and chronic active hepatitis (CAH), Cirrhosis and hepatocellular carcinoma (HCC) prevailing in the North eastern states of India. We also tried to look for HBV mutants (Precore mutants, surface mutants, and X-gene mutants).

Method: The study was a prospective multicentric study based out of seven designated centers in six North East states of India from 2012 to 2015. 7464 different types of liver disease cases, 7432 prospective blood donors and 650 health care workers were screened for Hepatitis B virus infection. HBV DNA positive patients were genotyped and subjected to surface protein, precore and core mutation analysis and phylogenetic analysis was done.

Results: The prevalence of hepatitis B virus infection from all the centers was 9.9% (1550/15546). 48.9% (768/1550) cases were found to be HBV DNA positive. The most common genotype in north eastern region was found to be genotype D 74.2% (570/768) followed by genotype C 6.5% (50/768) followed by genotype A 4.4% (34/768) and genotype I 0.9% (7/768).

Conclusion: The study demonstrates the presence of multiple genotypes of HBV in the north-eastern states of India viz. genotypes A, C, D and I. However, genotype D has closest evolutionary distance with genotypes from the same region as well as from other parts of India while genotype C shows close evolutionary relatedness with previous sequences from the same region, Vietnam, Polynesia, South Korea and Philippines. Though the phylogenetic evolutionary study is incomplete due to use of limited numbers of reference sequences from other parts of the world, the overall scenario points towards a diverse mix-up and presence of multiple genotypes of HBV in the north eastern states.

SAT381

Hepatitis D virus entry, replication and assembly in stem cell-derived hepatocytes

Bingqian Qu[1], Rebecca Fu[1], Florian Lempp[1], Charlotte Decker[1], Dao Thi Viet Loan[1,2], Stephan Urban[1,3]. [1]*University Hospital Heidelberg, Department of Infectious Diseases, Heidelberg, Germany;* [2]*University Hospital Heidelberg, Schaller Research Group, Heidelberg, Germany;* [3]*German Centre for Infection Research (DZIF), Partner Site Heidelberg, Heidelberg, Germany*
Email: qubingqian@gmail.com.

Background and Aims: The most physiological model for hepatitis D virus (HDV) infection is the primary human hepatocyte (PHH), yet their application is restricted by donor-to-donor variability and rapid ex vivo dedifferentiation. Reconstituting the HBV/HDV receptor, human sodium taurocholate cotransporting polypeptide (NTCP) renders hepatoma cells permissive for HDV infection but they partially resemble hepatocytes due to their transformed nature. Since stem-cell derived hepatocytes have recently been proposed as a cell culture model for HBV, we aimed at characterizing HDV infection in this new model.

Method: Hepatocyte-like cells (HLCs) were differentiated from human embryonic stem cell H9 line in 16 days using a modified protocol, and maintained in culture medium supplemented with oncostatin M and 1.5% dimethyl sulfoxide (DMSO). Differentiated HLCs were transduced with adeno-associated virus serotype 8 (AAV8) encoding NTCP or lentivirus encoding HBV envelope proteins, respectively. After HDV infection, the level of intracellular HDV RNA and antigen (HDAg) was measured by quantitative PCR and immunofluorescence. NTCP was stained by a validated antibody. Upon expression of HBV surface proteins, secreted HDV level was titrated, and its infectivity was determined by a reinfection assay.

Results: The HLCs expressed NTCP albeit at lower levels than NTCP-overexpressing hepatoma cells and allowed HDV permissiveness. HDV could be completely blocked by entry inhibitor Myrcludex B, suggesting NTCP-dependent entry. Upon AAV8-NTCP transduction, NTCP overexpression did not profoundly enhance HDV replication, indicating that NTCP induction was not a limiting factor. We observed increasing numbers of HDAg-positive cells in an inoculum-dependent manner in both HLCs and PHHs, although HDV replication was 10~20 fold weaker in HLCs compared to PHHs ($HDAg^+$ cells: 2.2% versus 21.1% in HLCs versus PHHs). HDV replication induced dozens- to hundreds-fold increase of multiple interferon-stimulated genes in PHHs, however low-replicating HDV in HLCs upregulated levels of only IFI27 and IFL44 genes by 3-fold, suggesting interferon-independent host restriction on HDV in HLCs. In long-term infection, we observed HDV replication up to 23 days and assembly in HLCs transduced with lentivirus expressing HBV envelopes. Although expression of genotype D secreted 2-fold less HBsAg compared to genotype B, both genotypes enveloped comparable amounts of HDV virions. The virions enveloped with genotype D led to more HDAg positive cells in the reinfection.

Conclusion: Altogether HLCs permit HDV entry, replication, and assembly in the presence of HBV envelopes, which provides an additional culture model in HDV study.

SAT382

Crispr/cas9-tailored hepatitis B-x protein knockdown inhibits cellular hyperplasia, invasion and tumorigenicity of HBV-infected hepatoma cells.

Preety Rawal[1], Dinesh Mani Tripathi[2], Vikrant Nain[1], Savneet Kaur[2]. [1]*Gautam Buddha University, School of Biotechnology, Greater Noida, India;* [2]*Institute of Liver and Biliary Sciences, Department of Molecular and Cellular Medicine (MCM), New Delhi, India*
Email: savykaur@gmail.com.

Background and Aims: We have demonstrated previously, that Hepatitis B-X protein (HBx), a transactivator protein encoded in HBV genome plays a crucial role in inducing cancer stemness, invasion, metastasis and cellular transition. In this study, our aim was to design a novel HBx gene specific single guide RNA (sgRNA) with CRISPR/Cas9 system to evaluated its knock-down effects on HBx induced tumorigenic and functional properties of hepatoma cell *in vitro*.

Method: *In silico*, we designed sgRNA against HBx by CRISPOR web based tool with minimal off target activity, further cloned in non-viral eSpCas9-2A-Puro(PX459)V2.0 vector (HBx-CRISPR). *In vitro,* HepG2-2.15 (stable hepatoma cell line with a HBV expression) transfected with HBx-CRISPR or control vector (PX459). In another set of experiment, HepG2 cells transfected with pGFP-HBx used as HBx specific +ve control. To assess the effects of HBx knockdown, functional properties of hepatoma cells including proliferation, migration and invasion were studied in all the set of experiments by transwell migration, invasion and wound healing assays. 3D-spheroid culture assays were performed to study cancer stemness-properties in HBx knockdown and control cells.

Results: Our results showed that the HBx knockdown in the hepatoma cell line decreases HBx gene expression significantly (18 folds decreased, $p > 0.001$ Fig 1A). The HBx knockdown cells showed a markedly reduction in cell proliferation in comparison to cells transfected with the control vector (two folds) and pGFP-HBx (five folds). We observed significant decrease in tumorigenic properties - chemotaxis and invasion in the cells treated with HBx-CRISPR as compared to cells treated with control vector (migration $p > 0.05$) while in pGFP-HBx transfected cells, we observed significant augmentation in tumorigenecity (migration $p > 0.01$, invasion $p > 0.05$, Fig 1B-D). 3D spheroid cultures established that cells treated with HBx-CRISPR formed less number ($p > 0.01$, Fig1E,F) and smaller size ($p > 0.001$ Fig1E,G) of spheroids in culture as compared to cells treated with control vector, which confirms HBx-knockdown reduces stemnness property of hepatoma cells.

Conclusion: The study for the first time shows that targeting HBx by novel tailored CRISPR/Cas9 system effectively reduces the proliferation, invasion and stemness characteristics of hepatoma cells. This study represents an effective and evident non-viral therapeutic approach to control HBV-induced tumor progression.

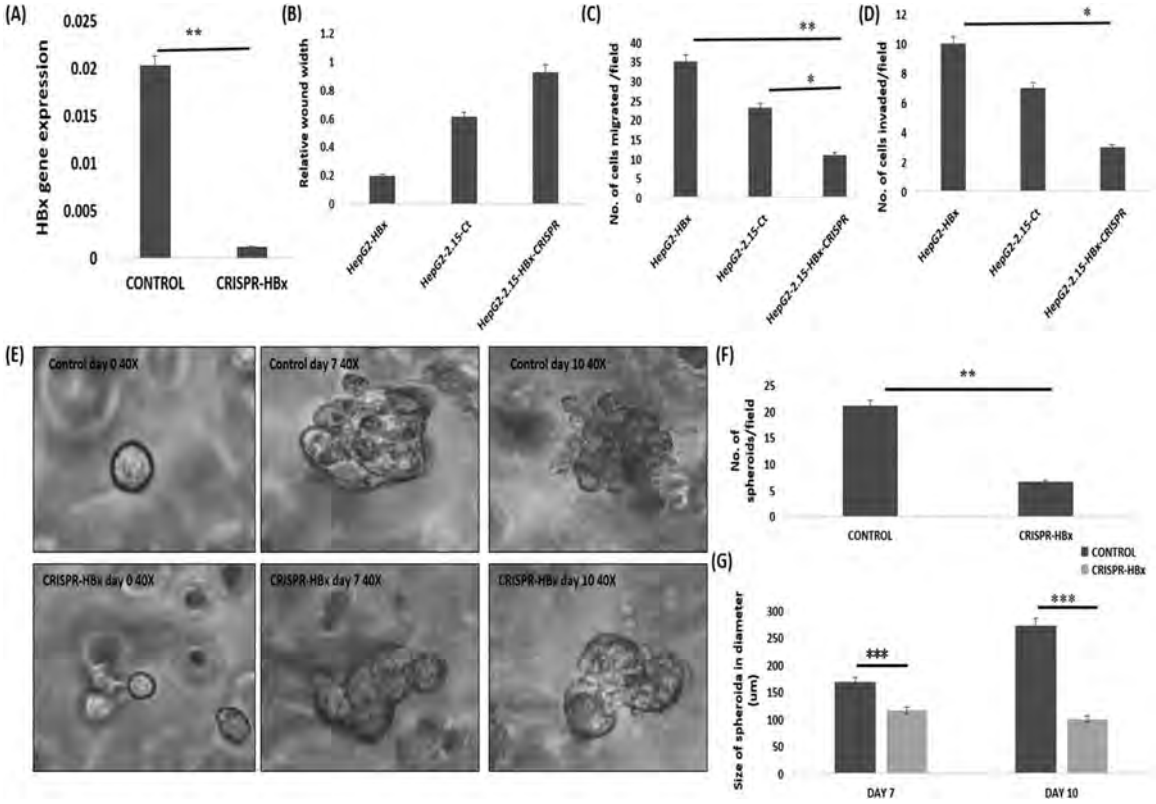

Figure: (abstract: SAT382): (A) Relative gene expression of HBx after transfected with HBx-CRISPR (B) Bar diagram showing relative wound width in HepG2-HBx, HepG2-2.15-Ct and HepG2-2.15-HBx-CRISPR (C,D) Chemotaxis and invasion assays depicting migration of hepatoma cells (E) Phase contrast images of spheroids on day 0, 7 and 10 (F,G) Bar diagram showing number of spheroids and size of spheroids in hepatoma cells. SAT383

Cryptic HBV viremia in anti-HBC positive/HBsAg negative patients with HIV infection is frequently revealed by applying an ultrasensitive droplet digital PCR assay

Romina Salpini[1], Vincenzo Malagnino[2], Mohammad Alkhatib[1], Lorenzo Piermatteo[2], Rossana Scutari[1], Riccardo Chirichiello[2], Tizana Mulas[2], Ada Bertoli[1], Katia Yu La Rosa[1], Marta Brugneti[1], Marco Ciotti[3], Massimo Andreoni[2], Carlo Federico Perno[4], Francesca Ceccherini Silberstein[1], Loredana Sarmati[2], Valentina Svicher[1]. *[1]Tor Vergata University, Department of Experimental Medicine, Rome, Italy; [2]Tor Vergata University, Clinical Infectious Disease, Department of System Medicine, Rome, Italy; [3]Tor Vergata University Hospital, Microbiology and Virology Unit, Rome, Italy; [4]University of Milan, Department of Oncology and Haemato-oncology, Milan, Italy*
Email: rsalpini@yahoo.it.

Background and Aims: Occult HBV infection (OBI) is frequent and associated with poor survival in the setting of HIV infection. Here, we investigate cryptic HBV replication and factors correlated with its detection in anti-HBc positive/HBsAg-negative HIV-infected patients by applying a highly-sensitive (HS) digital droplet (dd) PCR assay for serum HBV-DNA quantification.

Method: This study includes 81 anti-HBc-positive/HBsAg-negative patients with serum HBV-DNA <10 IU/ml by a commercial Real-Time PCR. All patients are HIV-infected, treated with an antiretroviral therapy including ≥1 anti-HBV drug: TAF/FTC (N = 37), TDF/FTC (N = 25), or LMV (N = 19) (median [IQR] duration: 35 [17–61] months). Serum HBV-DNA is quantified by an in-house HS-ddPCR (BioRad) whose linearity, reproducibility and sensitivity are assessed by testing serial dilutions with known concentration of HBV-DNA. Fujirebio assay is used to assess anti-HBc titer (proposed to infer cccDNA amount in the setting of OBI [Caviglia, 2018]). Factors correlated with the detection of cryptic viremia (serum HBV-DNA ≥1 IU/ml) are defined by Fisher exact test.

Results: ddPCR shows excellent linearity in the range of HBV-DNA from 1 to 10,000 IU/ml (R2 = 0.997), good intra- and inter-run reproducibility (coefficient of variation: 7.8% and 18.6%) and high sensitivity (limit of quantification: 1 IU/ml).

Overall, median (IQR) anti-HBc titer is 4.2 (2.4–11.6) COI. 30% of patients are isolated anti-HBc and 70% anti-HBc/anti-HBs positive (median [IQR] anti-HBs titer: 278 [90–957] mIU/ml). Median (IQR) HIV-RNA and CD4+ cell count are <20 (<20–38) copies/ml and 541 (331–727) cells/ul, respectively.

Notably, by ddPCR, cryptic HBV viremia is detected in 29.6% of patients with a median (IQR) HBV-DNA of 4 (1–15) IU/ml. No impact of different anti-HBV drugs on cryptic HBV viremia is observed (percentage of patients with serum HBV-DNA ≥1 IU/ml: 27% for TAF, 28% for TDF and 37% for LMV, p = 0.7). Moreover, a positive correlation is found between HBV-DNA and HIV-RNA (Rho: 0.26, p = 0.02).

By analyzing serological markers, anti-HBs <50 mIU/ml combined with anti-HBc >15 COI is predictive of cryptic HBV viremia (63% of patients with anti-HBs <50 mIU/ml + antiHBc >15 COI has HBV-DNA ≥1 IU/ml vs 26% without this combination, p = 0.046, OR: 4.7 [1.1–21.7]).

Conclusion: ddPCR is a valuable assay for detecting cryptic serum HBV-DNA in the setting of anti-HBc positive/HBsAg-negative patients with HIV infection. The integration of innovative serological and virological markers can help identifying patients with cryptic HBV replication, thus optimizing OBI diagnosis.

SAT384

Osteopontin drives HBV replication and HBV-driven fibrogenesis and represents a novel therapeutic target to achieve functional cure in chronic hepatitis B

Email: s.phillips@researchinliver.org.uk.

Background and Aims: New therapeutic options are urgently needed for chronic Hepatitis B (CHB). We evaluated the host-protein Osteopontin (OPN) as a novel therapeutic target to achieve functional cure in CHB and abrogate HBV-driven fibrogenesis.
Method: Liver biopsies from 91 CHB patients and plasma from 174 treatment (tx)-naïve and nucleos(t)ide analogue (NUC)-treated patients were collected to measure intrahepatic/ plasma OPN by immunohistochemistry/ ELISA. In-vitro, HBV-transfected HuH7 cells and HBV-infected (+) HepaRG were quantified for OPN by real-time (RT)-PCR and immunofluorescence (IF). We also developed an ex-vivo model of acute HBV infection with human precision-cut liver slices (PCLS). HepG2215 cells, HBV+HepaRG and HBV+PCLS were treated with recombinant (r)OPN and blocking OPN-specific aptamer (APT). Intrahepatic and secreted virion-bound HBV DNA, cccDNA and HBsAg were analysed by RT-PCR, digital droplet PCR and ELISA respectively. Primary human stellate cells (pHSCs) were treated with rOPN- and OPN APT-treated HBV+HepaRG culture media (HCM) and fibrosis markers were measured by RT-PCR/ IF.
Results: We observed a positive correlation between OPN levels and fibrosis severity in the liver and plasma of CHB patients ($r = 0.6$, $p < 0.0001$; $r = 0.27$, $p = 0.005$). Tx-naïve CHB patients with no fibrosis (F0) had higher OPN levels than NUC-treated CHB with suppressed viral load and healthy controls. OPN levels positively correlated with HBV viral load and ALT ($r = 0.57$, $p < 0.0001$; $r = 0.39$, $p = 0.0024$). NUC-treated CHB with fibrosis (F1-F4) also had reduced OPN compared to their paired untreated baseline sample. In-vitro, on-going viral replication in HuH7 and HepaRG increased OPN mRNA and protein expression significantly. Infection in PCLS was detected and remained stable for 7 days. Treatment with rOPN increased viral replication/ HBsAg in all 3 models of HBV infection and augmented cccDNA in HepaRG and PCLS. In contrast, viral replication, cccDNA and HBsAg levels were reduced by OPN-APT. Finally, fibrosis markers increased in pHSCs treated with rOPN-HCM and was inhibited by OPN APT-HCM.
Conclusion: This study is the first to report a dual role for OPN and shows its involvement in both HBV-replication and HBV-driven fibrosis. We show that OPN neutralisation can reduce HBsAg and cccDNA in in-vitro and ex-vivo models that recapitulate acute and chronic HBV infection and abrogate fibrogenic processes in human hepatic stellate cells. In summary, we reveal OPN as a new therapeutic strategy for CHB and HBV-driven fibrogenesis.

SAT385

Toll-like receptor 7 and 8 agonists as potent inhibitors of hepatitis delta virus infection

Sandra Westhaus[1], Gömer André[2], Bojkova Denisa[1], Widera Marek[3], Kathrin Sutter[3], Mirko Trilling[3], Anthony Squire[4], Sandra Ciesek[1]. *[1]Institute for Medical Virology, University Hospital, Goethe University Frankfurt am Main, Frankfurt am Main, Germany; [2]Department for Molecular and Medical Virology, Institute for Hygiene und Microbiology, Ruhr-University Bochum, Bochum, Germany; [3]Institute for Virology, University Hospital Essen, University Duisburg-Essen, Essen, Germany; [4]Institut for experimental Immunology and Imaging, University Hospital Essen, University Duisburg-Essen, Essen, Germany*
Email: sandra.westhaus@kgu.de.

Background and Aims: Worldwide an estimate of 257 million people is chronically infected with Hepatitis B virus (HBV) of which 5% are co-infected with the Hepatitis Delta virus (HDV). The course of infection leads to a severe liver inflammation which results in liver cirrhosis and the development of a hepatocellular carcinoma. So far, treatment options are limited to the administration of interferon alpha with response rates between 25 and 50%. Treatment of HBV-infected hepatocytes with Toll-like receptor (TLR) agonists showed a reduction of intracellular HVB DNA and HBeAg secretion. Since HDV is only found in association with an HBV infection it would be important to know if TLR-7 and TRL-8 agonists also affect HDV infection.
Method: Human hepatoma cell lines expressing NTCP (e.g. Huh-7, Hep3B) were infected with cell culture derived HDV and either directly treated with different concentrations of TLR-7 or TLR-8 agonists or indirectly, using supernatant of TLR-7 or TLR-8 stimulated peripheral blood mononuclear cells (PBMCs). The antiviral effect was measured by immunofluorescence staining against HDV or by quantitative RT-PCR. Mechanistically, induction of interferon-stimulated genes (ISGs) as well as secretion of chemokines and cytokines were evaluated by a quantitative SYBR Green based RT-PCR or Luminex Assay, respectively.
Results: Direct treatment of infected hepatoma cells had no effect on viral replication while indirect treatment with stimulated PBMCs supernatant significantly inhibited HDV infectivity. We further

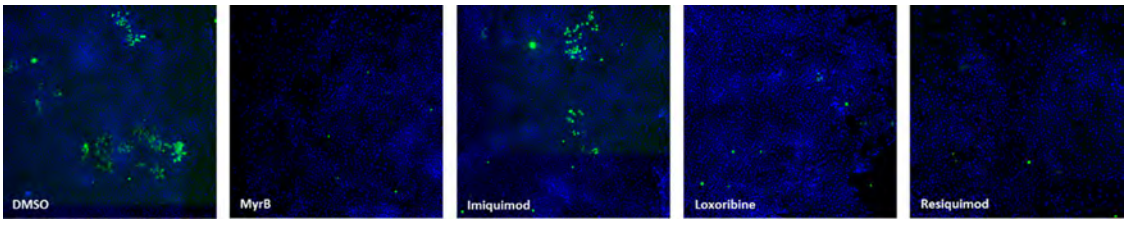

Figure: (abstract: SAT385)

observed that the TLR-7/8 agonist resiquimod was the strongest inhibitor compared to the TLR-7 agonists imiquimod and loxoribine. Furthermore, resiquimod was the most potent inducer of cytokines with IL-6, IL-8 and ITAC-1 significantly increased under TRL treatment. A comparable effect was observed for ISG induction (MDA5, MxA, RSAD2, ISG15, OAS1 and RIG-I). In addition, IFN-α induction was determined and found to be five times more increased by resiquimod than imiquimod or loxoribine. Time kinetic revealed that IFN-α peaked at 4 hours under resiquimod treatment while induction is delayed for imiquimod and loxoribine (peaked at 8 h post treatment).
Conclusion: In conclusion, TLR-7 and TLR-8 agonists showed potent anti-HDV effects in vitro and were able to induce various cytokines in stimulated PBMCs. Together with the induction of type I IFN and ISGs it led to an antiviral state of the cell to control HDV infection.

Email: saviano@unistra.fr.

Background and Aims: Chronic hepatitis B virus (HBV) infection is a major cause of hepatocellular carcinoma (HCC) world-wide. HCC can raise despite low HBV load in non-cirrhotic livers. Molecular mechanisms of virus-cancer interactions and hepatocarcinogenesis are still partially understood. Here, we investigated HBV-host cell interactions in patient-derived HCC using deep single-cell sequencing.
Method: Combining two deep single-cell RNA-sequencing (scRNA-seq) approaches, mCEL-Seq2 and Smart-Seq2, we analyzed HCC cells and tumor microenvironment from patients with low HBV viral load. The Smart-Seq2 protocol allowed for deep full transcript sequencing including the analysis of putative viral integration sites of the host genome.
Results: Computational analyses of gene expression revealed a marked heterogeneity of the HCC. Analyses of virus-induced host responses identified previously undiscovered pathways mediating viral carcinogenesis, including a marked correlation of HBV load and the oncogene SERTAD2. Mapping of fused HBV-host cell transcripts unraveled integration sites in individual cancer cells. The combination of integration analysis and RNA-expression profiles allowed the tracing of cancer development and identification of previously unknown genes implicated in the hepatocarcinogenesis and associated with long-term patients' prognosis. HBV-RNA load was not uniformly distributed across cancer subclones being higher in more differentiated cells and highlighting the fundamental role of HCC in the early phases of carcinogenesis and tumor progression.

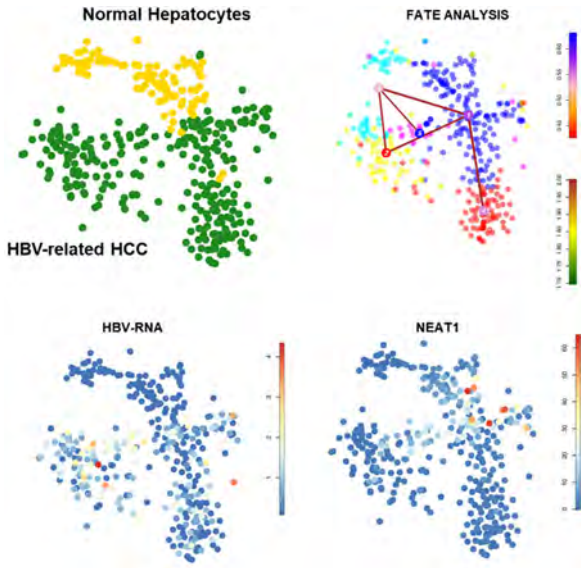

Figure: ScRNA-seq unravels HBV compartmentalization, traces HCC development, dissects the hepatocarcinogenesis and discovers new genes implicated in this process. Data of cancer cells from HBV-induced HCC and normal hepatocytes were integrated and the tumor development was traced (Fate Analysis). HBV-RNA is not uniformly distributed among cancer cells and is higher in more differentiated cells. Gene associated with tumor development such as NEAT1 were also identified.

Conclusion: ScRNA-seq unravels heterogeneity and compartmentalization of both, virus and cancer. The perturbation of gene expression mediating carcinogenesis in cells with low viral RNA levels highlights the importance of curing HBV chronic infection to eliminate both HCC risk and tumor progression. The marked tumor heterogeneity suggests that combination therapies targeting multiple drivers are required for HCC chemotherapeutic approaches.

SAT387

Pangenotypic therapies glecaprevir-pibrentasvir (G-P) and sofosbuvir-velpatasvir-voxilaprevir (S-V-V) after failure with interferon (IFN)-free direct-acting antiviral (DAA) treatment for hepatitis C

Steven Flamm[1], Naoky Tsai[2], Bruce Bacon[3], Michael Curry[4], Scott Milligan[5], Nicole Wick[5], Zobair Younossi[6], Nezam Afdhal[4].

Email: nicole.wick@triohealth.com.

Background and Aims: Despite the remarkable effectiveness of IFN-free DAA treatment in real-world HCV care, treatment failures remain a challenge in disease eradication. Here, we examine outcomes with G-P or S-V-V after DAA failure/relapse.
Method: Inclusion: patients who failed or relapsed following IFN-free DAA therapy and were subsequently treated with G-P (n = 55) or S-V-V (n = 176) between July 2017 and Dec 2018. Data were collected electronically from providers and specialty pharmacies. Variable comparisons were via Exact tests with subsequent z-tests of column proportions. Significantly different variables were used in a logistic regression to generate propensity scores for 1-1 matching without replacement with G-P as the test group. Therapy duration was not included in matching due to sample limitations.
Results: In comparison to S-V-V, the G-P group had a higher percentage of baseline eGFR <30 ml/min (8% v. 1%, p = 0.015), genotype (GT) 2 HCV (9% v 2%, p = 0.040), hypertension (60% v. 42%, p = 0.016), and care at academic centers (42% v. 26%, p = 0.021). G-P

and S-V-V treatment groups were not significantly different for age, gender, insurance, ribavirin, anxiety, depression, diabetes, HCC, HIV, or HBV and had characteristics of GT1 (82% G-P v. 78% S-V-V, p = 0 0.589) and baseline FIB4 >3.25 (37% G-P v. 38% S-V-V, p = 0.651). Therapy duration for G-P was 16 weeks (69%), 12 weeks (16%), and 8 weeks (15%); for S-V-V, 99% patients received 12 weeks (p < 0.001). Prior therapy was mostly ledipasvir-sofosbuvir (L-S) for both G-P (64%) and S-V-V (58%). SVR rates were significantly lower for G-P compared to S-V-V for both intent to treat (ITT, 84% v. 94%, p = 0.017) and per protocol (PP, 85% v. 98%, p < 0.001) populations. After propensity score matching, treatment groups (n = 39 pairs) significantly differed only by therapy duration (G-P 69% 16 weeks, 15% 12 weeks, 15% 8 weeks v. S-V-V 100% 12 weeks, p < 0.001) and had the following characteristics: 95% GT1, 5% GT 3, 100% eGFR>30 ml/min, 33% (G-P) to 36% (S-V-V) FIB4 >3.25,and prior therapy predominantly L-S (80%). In the matched sample, SVR rates were significantly lower for G-P compared to S-V-V for ITT (85% v. 97%, p = 0.048) and PP (85% v. 100%, p = 0.012).

Conclusion: In patients with prior DAA failure/relapse, significantly higher ITT and PP SVR rates were observed with S-V-V compared to G-P both before and after adjustment for clinical differences.

SAT388

A novel intrahepatic restriction factor, HMGA1, contributes to hepatitis B virus (HBV) replication in immune tolerant phase, serving as an anti-HBV target

Zhongliang Shen[1], Jingwen Wu[1], Jing Liu[2,3], Youhua Xie[2,4], Jiming Zhang[1,2]. [1]*Fudan University, Department of Infectious Diseases, Huashan Hospital, Shanghai, China;* [2]*Fudan University, Key Laboratory of Medical Molecular Virology (Ministry of Education/National Health Commission/Chinese Academy of Medical Sciences), Department of Microbiology and Parasitology, School of Basic Medical Sciences, Shanghai Medical College, Shanghai;* [3]*Fudan University, Key Laboratory of Medical Epigenetics and Metabolism, Institutes of Biomedical Sciences, School of Basic Medical Sciences, Shanghai Medical College, Shanghai, China;* [4]*Fudan University, Children's Hospital, Shanghai*
Email: jmzhang@fudan.edu.cn

Background and Aims: In clinic, hepatitis B virus (HBV) replicates at much higher levels in immune tolerant (IT) phase than in inactive carrier (IC) phase. Since the immune responses are similarly comparable between the two phases, intrahepatic host restriction factors (HRFs) are generally accepted to play an important role in HBV gene expression and replication. Previously, we identified a serial of differentially expressed intrahepatic HRFs based on RNA sequencing of liver tissues from the two phases. Identification of functional HRFs contributes to elucidating the virological differences between the two phases, and more importantly, to developing the novel anti-viral candidates for treating chronic hepatitis B (CHB). In this work, we focused on HMGA1, whose mRNA levels are higher in IT phase than in IC phase, and explored the reasons for differential expression of HMGA1, as well as the mechanism by which HMGA1 regulates HBV.
Method: Immunohistochemistry analysis of HMGA1 expression in liver tissues; Serial cell models were used to analyze whether HMGA1 regulates HBV; Co/Chromatin-immunoprecipitation (Co-IP/ChIP) was performed to analyze the interaction between protein/DNA and protein. HBV chronic cccDNA mouse model were used for evaluation of antiviral effects based on gene therapy.
Results: HMGA1 protein levels in IT phase are much higher than in IC phase; HMGA1 promotes HBV gene expression and replication via the activation of HBV core promoter (Cp); The Cp activation depends on the specific binding of transcription complex, in which HMGA1 recruits protein A and B, to a novel cis-element in Cp; Sp1 protein upregulates HMGA1 at transcriptional levels via the recruitment of hepatitis B X (HBx) protein to HMGA1 promoter; Lastly, knockdown of HMGA1 expression significantly cleared HBV persistence in cccDNA mouse model.

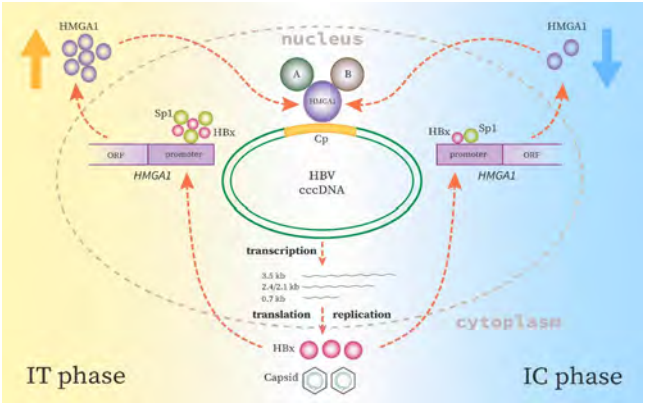

Figure: HMGA1 up-regulates HBV replication via a positive feedback loop. IT: immune tolerant; IC: inactive carrier; Cp: core promoter.

Conclusion: HMGA1 is a key factor to sustain the higher HBV replication in IT phase, and on the other hand, HBx upregulates HMGA1 in a positive feedback manner.

SAT389

Multivariant surface quasispecies in a hepatitis B virus chronically infected individual with concomitant and continually positive surface antigen and anti-HBS biomarkers

[1]*University of Sao Paulo School of Medicine, Gastroenterology, São Paulo, Brazil;* [2]*GATACA, LLC, Blacksburg, United States;* [3]*Center for AIDS Research, Laboratory of Biochemical Pharmacology, Pediatrics, Atlanta, United States;* [4]*ABL SA Group, Luxembourg, Luxembourg*
Email: skon@usp.br

Background and Aims: Coexistence of hepatitis B virus (HBV) surface antigen (HBsAg) and antibodies (anti-HBs) can be found in 2.3–5.2% of chronically HBV infected individuals. Recent reports have indicated that the presence of both biomarkers is associated with high risk of hepatocellular carcinoma (HCC). However, previous studies with clinical samples presenting both biomarkers have demonstrated that the presence of variants in the HBsAg surface (S) gene and anti-HBs subtype-nonspecific can contribute to coexistence of these two biomarkers in chronic HBV infection (CHB).
Method: Herein, we analyzed HBsAg variants in a clinical sample from a 43-years old female CHB individual, with prolonged (>7 years) coexistence of HBsAg and anti-HBs, HBeAg negative, and treatment with TDF. Total DNA was purified from plasma and HBV DNA amplified. We used next generation sequencing (NGS) and a novel HBV-specific assembly/machine-learning tool for quasispecies analysis of the S gene (GATACA Assembly Tool, GAT).
Results: We determined the frequency of 18 site variants in the Surface gene (Table 1). Interestingly, variants Y100S and L127P occurred together in the same haplotypes and eight sites studied presented a variant with stop codon. We found several quasispecies of a same amino acid variation in the variants' pool within this clinical sample. In addition, we demonstrated that defective HBsAg variants can coexist with the wild type and other functional variants. Seven site variants were found in the "a" determinant region of HBsAg that could explain its persistence despite the presence of anti-HBs.

Table 1: Surface gene sites with amino acid identified with GAT

S gene site	Stop codons	AA variants
Y100stop/Y*/N*/S/F/H/C/N	1	7
S114T*/S*/I/P/K/T*/Q	0	6

W196L*/C*/F*/R/G/S/V/STOP	1	8
L216L*/V*/S/STOP*	1	3

*NOTE amino acid with different nucleotides.

Conclusion: Considering that HBsAg S gene is a potential target for antiviral development and HBsAg seroconversion is a potential outcome for functional cure, understanding the dynamics of these variants can help to identify strategies of use for the novel direct-acting antiviral agents.

SAT390

Evaluation of the introduction of hepatitis C core antigen as a routine test to detect viraemia among patients with anti-HCV antibodies

Kevin Pollock[1], Scott McDonald[1], Rory Gunson[2], April Went[1], Allan Mcleod[1], David Goldberg[1], Sharon Hutchinson[1], Stephen Barclay[1,3]. *[1]Glasgow Caledonian University, Department of Life Sciences, Glasgow, United Kingdom; [2]Glasgow Royal Infirmary, West of Scotland Specialist Virology Centre, Glasgow, United Kingdom; [3]Glasgow Royal Infirmary, Gastroenterology, Glasgow, United Kingdom*
Email: stephenbarclay@nhs.net

Background and Aims: Hepatitis C core antigen (Ag) is recommended as an alternative to RNA testing to diagnose current hepatitis C (HCV) infection. Published data has assessed the performance of Ag testing using analysis of cross sectional cohorts. We aimed to assess the performance of Ag testing when introduced as routine to the West of Scotland Specialist Virology Centre.

Method: HCV antibody positive serum samples from June '11, when reflex Ag testing using the Abbott Architect assay became routine, to December '17 were identified from the Scottish HCV test database. Positive Ag results were reported as showing current infection, negative samples as indicating the absence of infection, but recommending an RNA test to confirm. This was either with a further sample, or by request on the index sample. We identified samples where on request RNA testing was performed. Samples with insufficient serum, or for which the Ag test was equivocal, were excluded. For the remainder, the sensitivity and specificity of HCV Ag as a diagnostic tool was assessed using HCV RNA PCR as reference. Multivariate analysis was performed to identify factors associated with a false negative test.

Results: 877/4693 (18.7%) reflex Ag samples had on request PCR testing. 92 samples were excluded (58 insufficient serum, 34 equivocal Ag). 246/775 (31.3%) samples were Ag negative, and 539 (68.7%) positive. Baseline characteristics are shown below. 244/302 samples were RNA and Ag positive (sensitivity 80.8%, 95% CI 76.4–85.2%) whilst 472/473 samples were RNA and Ag negative (specificity 99.8%, 95% CI 99.4–100.2%). The odds of a false negative were raised for genotype 3 (OR = 3.44, 95% CI: 1.15–10.3) and were lowered with older age (OR = 0.93, 95% CI: 0.88–0.98 per year) and viral load (OR = 0.12, 95% CI: 0.07–0.21 per log10 IU/ml2). For samples with known genotype, all (11/11) false negative results with a viral load >3000 iu/ml occurred in genotype 3 infection.

Baseline characteristics	Number (%)
Male	503 (64%)
Female	282 (36%)
Median Age	44 (range 21–90)
Ethnicity	
Unknown	40 (5.1%)
Non-UK indigenous	63 (8.5%)
White	682 (86.9%)
HCV genotype	
Untested	5 (0.6%)
Unknown	489 (62.3%)
1	107 (13.6%)
2	10 (1.3%)
3	173 (22.0%)
4	<5
Co-infection	
HBV	60 (7.6%)
HIV	42 (5.3%)
Cirrhosis	
Yes	97 (12.3%)
No	682 (87.7%)
Methadone	
Unknown	491 (62.5%)
Yes	172 (21.9%)
No	122 (15.5%)
Transmission route	
Unknown	505 (64.3%)
Person who injects drugs (PWID)	249 (31.7%)
Contaminated blood	18 (2.3%)
Other	13 (1.6%)
HCV RNA (log_{10} IU/mL)	4.24 (1.08–7.01)
HCV Ag	
Positive	246 (31.3%)
Negative	539 (68.7%)

Conclusion: In routine use reflex Ag testing is highly specific, but lacks adequate sensitivity. In addition to known limitations at detecting low level viraemia, the Ag assay failed to detect higher level viraemia amongst a number of genotype 3 samples. These findings have implications for the routine introduction of Ag testing, particularly where genotype 3 is prevalent.

SAT391

Virologic causes for DAA treatment failure of chronic hepatitis C

Email: peijerchen@ntu.edu.tw

Background and Aims: Chronic hepatitis C (CHC) is common in Taiwan, as about 4% of population are positive for anti-HCV Ab. Among them, around 70% carry HCV RNA, therefore about 500,000 cases are CHC patients. The Bureau of National Health Insurance has started to reimburse DAAs (direct-acting antiviral agents) since 2017. Preliminary data from Hepatitis C Flagship Project Office showed an HCV cure rate of 97%, meaning that there are still 2–3% of patients who fail to clear HCV despite completing the treatment. In order to understand the causes of treatment failure in Taiwan, it is essential to conduct a clinical and virologic study of these DAA failure patients.
Method: Through collaboration with several hospitals and clinics nationwide, we recruited 40 DAA failure patients. These patients received at least four-week treatment of DAA therapy. Clinical information as well as serum samples were obtained after informed consent. We established polymerase chain reaction (PCR) platform for NS3/4A, NS5A and NS5B, and then identified mutated RAS (resistance-associated substitution) by population sequencing.
Results: In these 40 patients, only one patient did not complete treatment due to hyperbilirubinemia. Sixteen patients had genotype 1b infection, twelve had genotype 2, and two had genotype 3.
Till now, we completed RAS (resistance associated substitution) analysis for 21 patients among these 40 patients. Eight cases were found to have no known RAS according to its genotype and DAA regimen, and the rest 13 cases were found to have at least one mutated RAS. Y93 in NS5A was the most RAS, and its frequency of mutation (91%) was significantly higher than that in HCV database (14%). The frequency of mutation of Y56 in NS3 and L31 in NS5A were also higher than those in HCV database. On the other hand, the frequency of mutation of D168 in NS3 and L159 as well as C316 in NS5B were not higher than those in HCV database. Furthermore, two cases were noted with post-DAA HCV genotypes that were different from the baseline genotypes, suggesting initial mixed infections or a reinfection.
Conclusion: Our study suggests that known RASs are the major virologic cause for treatment failure. Those without known RASs warrant further investigation in order to propose appropriate rescue therapies.

SAT392

Impact of direct antiviral agents (DAAs) on the HBV virologic profile in HCV+ but HBsAg– and HBcAb+ patients

Régine Truchi[1], Laurence Ollier[2], Eve Gelsi[1], Rodolphe Anty[1], Albert Tran[1]. [1]*CHU de Nice Hôpital L'Archet 2, Hepatology, NICE, France;* [2]*CHU de Nice Hôpital L'Archet 2, Virology, NICE, France*
Email: truchi.r@chu-nice.fr

Background and Aims: We have published a case of HBV viral reactivation during DAA treatment in an HIV/HCV+ and HBsAg- patient (1). Few data are available in patients with a cured hepatitis B profile. The purpose of this study was to evaluate the impact of DAAs treatment on the HBV profile in this category of patients.
Method: From March 2015 to October 2016, 60 HCV + patients (44 M, 16 F), median age 58 years, including 21 cirrhotic patients were treated with DAAs. All of these patients were HBsAg- and HBcAb+. 25 patients were also anti HBsAb +. Before treatment, 2 patients had a detectable but unquantifiable HBV viral load (VL). One patient was co-infected with HIV/HCV. The combinations of DAAs used were SOF + DCV, SOF + LDV, SOF + SMV, 2D, 3D, ±ribavirin. The duration of the treatments was between 12 and 24 weeks according to the recommendations. A virological assessment of HCV and HBV was performed every month for 3 months, then at the end of treatment, 3 months and 6 months later.
Results: A patient was lost of follow up at week 8. In ITT, the SVR12 was 98.3%, and 100% in per protocol. Six patients (10%) had HBV quantifiable VL during follow-up. The following table summarizes the evolution of HBV viral loads during the study.
Among the 6 patients who had their HBV VL detectable, transaminases remained in the normal values in 4 patients. In 2 patients, there was a slight elevation of transaminases at the time of HBV VL detection: ASAT at 1.3 times the upper normal limit for one and ALAT at 1.6 times the upper normal limit for the second. The level of HBsAb increased in 2 of 6 patients at the end of follow-up.
Conclusion: The detection of HBV VL in HCV+ patients with HBsAg-, but HBcAb+ is frequent (10%) during DAAs treatment. However, the elevation of HBV VL remains low, with no clinico-biological consequences. Virological HBV monitoring is advised at the end of treatment.

Email: victor.jbeltran@hotmail.com

Background and Aims: The diagnosis of acute hepatitis E (AHE) is based in the presence of RNA-HEV, with or without antiHEV-IgM. However, due to the short duration of viremia, antiHEV-IgM presence in a patient with acute hepatitis (AH) is used as diagnostic criteria, despite its limitations. Aim: To know the HEVAg behaviour in a series of patients with AH.
Method: HEVAg was determined in 27 patients diagnosed of AHE (antiHEV-IgM positive), in 10 patients with acute hepatitis A (AHA), antiHAV-IgM positive, and in 10 patients with AH of probable toxic

Table: (abstract: SAT392)

		Follow up (FU) of HBV viral load (UI/ml)					
Patients	HBsAb (UI/l) Baseline	Baseline	Week 4	Week 8	End of treament (Week 12 or week 24)	FU week 12	FU week 24
1	15	Undetectable	<10	<10	<10	18	<10
2	Negative	<10	14	25	25	Undetectable	<10
3	Negative	Undetectable	Undetectable	Undetectable	Undetectable	25	ND
4	Negative	Undetectable	ND	ND	18	<10	15
5	Negative	<10	32	53	<10	<10	22
6	Negative	Undetectable	Undetectable	Undetectable	16	Undetectable	Undetectable

<10: detectable but unquantifiable, ND: not done.

origin (TAH). The determination was made in the basal serum in all cases and 3 months later in 14 patients from the AHE group. The diagnosis of AH was based in ALT >5× ULN. HEVAg was determined by ELISA (Wantai, China), as well as antiHEV-IgM (DiaPro, Italy). RNA-HEV determination was made by RT-PCR.
Results: Among patients with AHE, 89% men, age 57 years (47–65), 7 (26%) had been transplanted. Hepatitis was icteric in 52%, severe in 18%, ALT 1.294 IU/ml (554–2967), bilirrubin 4,2 mg/dl (1,6–10,6) and 5 (18%), all transplanted, evolved to chronicity,. RNA-HEV was positive in 15/27 (55,5%) and HEVAg in 24/27 (89%). All samples RNA-HEV positive were HEVAg positive. In transplanted patients RNA-HEV was positive in 57% and HEVAg in 100%. The 3 antiHEV-IgM positive/HEVAg negative patients had lower ALT levels than those HEVAg positive (582 vs 1526) and more days from symptoms beginning to the analysis (6 vs 2). In the sample obtained 3 months after diagnosis, antiHEV-IgM was positive in 16/17 (94%) cases and HEVAg in 3/14 (21%), all evolved to chronicity. Positivity at 3 months in patients with self-limited infection was 99% for antiHEV-IgM and 0% for HEVAg. Patients with AHA were all men, 45 years (28–48), all icteric, ALT 2806 IU/ml (1936–2806) and bilirrubin 6,3 mg/dl (4,8–11). HEVAg was negative in all of them. Patients with TAH were 70% women, 55 years (45–63), 60% icteric, ALT 1754 IU/ml (900–1555) and bilirrubin 6,3 mg/dl (0,7–8,4). All were HEVAg negative.
Conclusion: HEVAg is present at diagnosis of AHE antiHEV-IgM positive in a much higher proportion than RHA-HEV, and in all RNA-HEV positive cases, so it should replace RNA-HEV in the AHE diagnosis. Antigenemia duration is lower than antiHEV-IgM; it provides advantages in the diagnosis of acute infection but could also lead to some miss diagnostic cases. Accordingly, HEVAg should be incorporated together with antiHEV-IgM to the serological profile for the etiological diagnosis of acute hepatitis.

SAT394

Hepatitis V virus (HBV) cccDNA mini-chromosome transposase-accessible chromatin by atac-sec in infected primary human hepatocytes (PHHs)

Oceane Floriot[1], Vincenzo Alfano[1], Giuseppe Rubens Pascucci[2], Matteo Pallocca[3], Francesca De Nicola[4], Rivoire Michel[5], Marie-Laure Plissonnier[1], Mirjam Zeisel[1], Massimo Levrero[1,6], Francesca Guerrieri[1]. *[1]Cancer Research Center of Lyon, UMR Inserm 1052 – CNRS 5286 – Mixte CLB – UCBL1, Lyon, France; [2]Istituto Italiano di Tecnologia (ITT), Center for Life Nano Science, Rome, Italy; [3]Regina Elena National Cancer Institute, UOSD SAFU, Rome, Italy; [4]Regina Elena Natioanl Cancer Institute, Oncogenomic and Epigenetic Unit, Rome, Italy; [5]Centre de lutte contre le cancer Léon Bérard (CLB), Lyon, France; [6]Hospices Civils de Lyon, Service d'Hépatogastroentérologie, Hôpital Croix Rousse, Lyon, France*
Email: massimo.levrero@inserm.fr

Background and Aims: Transcriptional activation in eukaryotic cells has been tightly linked with disruption of nucleosome organization at open or accessible genomic sites of remodeled chromatin. Increasing evidence indicate that epigenetic modifications (cccDNA-bound histones post-translational modifications and cccDNA CPG islands methylation) determine the chromatin accessibility and the transcriptional activity of the cccDNA. Recent studies, using cccDNA CHIP-seq on HBV in-vitro infection models and liver biopsies, have confirmed that the acetylation of cccDNA-bound histones and the histone mark H3K4me3 are associated with high viral replication while the hypoacetylation and the repressive mark H3K4me3 translate into lower cccDNA transcription levels.
Methods: We used ATAC-seq (assay for transposase-accessible chromatin followed by high throughput sequencing) to probe open chromatin and detect early changes in cccDNA chromatin accessibility in HBV-infected human primary hepatocytes (PHHs). ATAC-Sec reads are aligned to the HBV genotype D genome (NCBI Reference: NC_003977.2) to generate cccDNA ATAC-seq profiles in HBV-infected PHHs 2 hours, 24 hours and 72 hours post-infection.
Results: We have previously shown that after HBV infection an increasing number of genomic sites change their chromatin accessibility over time with a prevalence of more open, potentially transcriptionally active regions, indicating that HBV infection impacts on host cells chromatin landscape and transcription. The alignment of ATAC-seq and RNA-seq reads to the HBV genome showed that cccDNA chromatin accessibility increases over time after infection with a well-defined profile 72 hours post-infection, when cccDNA is fully transcribed and pgRNA and preC 3.5 kb RNA species are detected in the RNA-seq. The ATAC-seq profile at 72 hours post-infection shows 2 major regions of high chromatin accessibility (CA1 and CA2). The CA1 region overlap a peak of Pol2 recruitment and nucleosomes with highly acetylated H3K27 that are reflected in the accessibility profile of CA1.
Discussion: Altogether these results show that the cccDNA ATAC-Seq allows to study the dynamics of cccDNA chromatin accessibility. cccDNA ATAC-seq may represent a new, rapid and potentially down-scalable, tool to evaluate cccDNA chromatin accessibility, how it relates to cccDNA transcription and how is modified by cytokines, immune responses, HBV direct antiviral agents (DAAs) and host targeting agents (HTAs).

SAT395

Resistance monitoring data from treatment-naive chronic HBV infected patients treated for 28 days with a new class a core protein allosteric modulator RO7049389 monotherapy

Xue Zhou[1], Rémi Kazma[2], Dominik Meinel[2], Yuan Zhou[1], Man-Fung Yuen[3], Edward Gane[4], Christian Schwabe[4], Tawesak Tanwandee[5], Lingzhi Cao[1], Julian Zhou[6], Qingyan Bo[1]. *[1]Roche Innovation Center Shanghai, Shanghai, China; [2]Roche Innovation Center Basel, Basel, Switzerland; [3]The University of Hong Kong, Hongkong, China; [4]Auckland Clinical Studies, Auckland, New Zealand; [5]Mahidol University, Bangkok, Thailand; [6]Roche Product Development, Shanghai, China*
Email: qingyan.bo@roche.com

Background and Aims: RO7049389 is a small molecule, Class A HBV core protein allosteric modulator being developed for the treatment of chronic hepatitis B. In a Phase Ib clinical study (NCT02952924), treatment-naive chronic HBV infected HBeAg-positive and -negative patients received 4 weeks oral administration of RO7049389 or placebo (200 mg to 1000 mg daily). Potent antiviral effects were observed and no subject experienced virologic breakthrough. Here, we present the resistance monitoring data of this study.
Methods: A near full-length HBV genome was amplified and underwent next generation sequencing using HBV DNA extracted from the baseline samples of all 37 patients and from the end of treatment (EoT, day 28) and subsequent last follow-up visit (LFU) samples of all 22 patients who had a quantifiable HBV DNA (>20 IU/mL) at EoT. The mutations in each sample were determined by comparing with the HBV reference sequence (HBV genotype A, NCBI ID X02763). The analyses focused on amino acid substitutions in the core protein, especially the 24 positions located within the putative compound-binding pocket suggested by cocrystal structures. The impact of mutations on the susceptibility to RO7049389 was assessed in a transient transfection assay using corresponding point-mutants.
Results: A total of 71 samples, 34 baseline (28 active: 6 placebo), 16 EoT (11 active: 5 placebo), and 21 LFU (17 active: 4 placebo), were successfully amplified and sequenced. Among them, only 5 samples from 3 patients contained amino acid substitutions of >5% frequency in any of the 24 amino acids of the putative compound-binding pocket. One patient (active) harbored 99.9% T109C at baseline, which decreased to 67.8% at LFU. The second patient (placebo) harbored 15.8% T109M at baseline, which increased to 99.8% at EoT. The LFU sample of this patient failed amplification. The third patient (active) harbored 8.0% I105 V at baseline and HBV DNA went below 20 IU/mL at EoT. In vitro assays with the corresponding point-mutants showed that T109C and I105 V did not confer resistance to RO7049389, while

T109M led to reduced susceptibility to RO7049389 (5.4 fold change in EC50), at the cost of reduced replication capacity (22% of the wild type). The reason why T109M was enriched during placebo treatment remains unclear.

Conclusions: In this study, a low occurrence of polymorphisms within the 24 amino acids in the putative binding pocket of RO7049389 was observed in all sequenced samples. Baseline polymorphisms known to reduce RO7049389 activity were observed in only 1 of the 34 (3%) patients with baseline sequence data, as this was a placebo-treated patient, no conclusion on reduced in vivo susceptibility can be drawn. No mutations known to reduce RO7049389 activity in vitro emerged or were enriched after 28 days of treatment, which is consistent with the robust decline in plasma HBV DNA among all patients who received RO7049389 monotherapy.

SAT396

Developing a sensitive HBV genotyping assay for HBV DNA suppressed patients using both DNA and RNA sequencing

Yang Liu[1], Lindsey May[1], Xinan Liu[1], Ross Martin[1], Evguenia S Svarovskaia[1], Anuj Gaggar[1], Hongmei Mo[1], Becket Feierbach[1]. [1]*Gilead Sciences, Inc., Foster City, United States*
Email: yang.liu@gilead.com

Background and Aims: Hepatitis B virus (HBV) genotypes impact treatment outcomes and disease progression. Due to limitations of current genotyping methods in patients with low HBV viral load, here we have developed a more sensitive assay for determining HBV genotype in HBV DNA suppressed patients using DNA and RNA sequencing followed by phylogenetic analysis.

Table 1: Success rate for amplification and genotyping of samples

Genotype[a]	Success rate for amplification and genotyping, n/N (%)
A	8/8 (100%)
B	8/8 (100%)
C	7/8 (87.5%)
D	8/8 (100%)
E	7/7 (100%)
F	9/10 (90%)
G	1/1 (100%)
H	5/5 (100%)
Total	53/55 (96.4%)

[a]Historical genotype was determined by INNO-LiPA or RT sequence (1–344 aa) from baseline sample.

Method: Fifty-five serum samples from 55 chronic hepatitis B patients (HBeAg–, n = 20; HBeAg+, n = 35) across genotypes A to H with long-term tenofovir alafenamide (TAF) or tenofovir disoproxil fumarate (TDF) treatment from Gilead clinical studies were collected. All samples had undetectable HBV DNA (HBV DNA <29 IU/mL by COBAS TaqMan Assay). Total nucleic acid was extracted and a 341 bp amplicon located at HBV S gene overlapping with reverse transcriptase domain of polymerase (RT/pol) was amplified from both viral DNA and RNA via RT-nested PCR followed by population sequencing. HBV genotype was determined by phylogenetic analysis.

Results: The assay successfully amplified HBV S/RT gene from 53 of 55 (96.4%; HBeAg-, n = 19; HBeAg+, n = 34) patient serum samples with HBV DNA <29 IU/mL across GT A to H using both DNA and RNA sequencing. Phylogenetic analysis demonstrated the genotypes of all the 53 PCR positive samples matched the historical genotypes determined by INNO-LiPA or RT sequence (1–344 amino acid) from the corresponding baseline samples (Table 1). The majority of the samples (61%) were from patients that had been on suppressive therapy for 3 years. In two cases, we were able to genotype patients that maintained HBV DNA undetectable status for >4.5 years.

Conclusion: A sensitive genotyping assay for HBV DNA suppressed patients using both HBV DNA and RNA sequencing and phylogenetic analysis can accurately determine HBV genotype irrespective of baseline genotype, HBeAg status, or duration of viral suppression. The ability to determine genotype in virally-suppressed patients may facilitate the evaluation of novel treatment agents for HBV in this patient population.

SAT398

Impact of antiviral therapy for blocking mother-to-child transmission on virus quasispecies in pregnant women with chronic HBV infection

Zhihua Liu[1], Huijie Guo[2], Yunfei Gao[3], Xueru Yin[4], Jing Hu[5]. [1]*Nanfang Hospital, Southern Medical University, Department of Infectious Diseases, Guangzhou, China;* [2]*Shool of Public Health, Southern Medical University, Department of Epidemiology, Guangzhou, China;* [3]*Nanfang Hospital, Southern Medical University, Department of Obstetrics and Gynecology, Guangzhou, China;* [4]*Nanfang Hospital, Southern Medical University, Department of Infectious Diseases, Guangzhou, China;* [5]*School of Public Health, Southern Medical University, Department Epidemiology, Guangzhou, China*
Email: zhihualiu@126.com

Background and Aims: To explore the effect of short-course antiviral therapy for blocking mother-to-child transmission (MTCT) of HBV during pregnancy on the quasispecies heterogeneity of the HBV reverse transcriptase (RT) region and the correlation between the evolution of viral quasispecies in the HBV RT region during pregnancy and postpartum abnormal alanine aminotransferase (ALT).

Method: Twenty-one chronic HBV infection pregnant women were included in this study. They received tenofovir disoproxil fumarate (TDF) or telbivudine (LdT) since the 28 ± 4th week of gestation for blocking MTCT of HBV and discontinued the therapy at delivery. Blood samples were taken at the baseline, 4 weeks of antiviral treatment, and 4–8 weeks after delivery. The next generation sequencing technique combined with bioinformatic methods were used to study the characteristics of quasispecies in the HBV RT region, and the dynamic changes of viral quasispecies heterogeneity during the treatment of and after the discontinuation of antiviral therapy were compared.

Results: During the treatment and after the discontinuation of antiviral drugs in pregnant women with chronic HBV infection, no significant changes were noticed in the quasispecies complexity and diversity of HBV RT region. The main effect between the time points, the main effect between the two groups did not reach statistical significance ($p > 0.05$) in the value of the shannon entropy (Sn) or the Hamming distance. Resistance associated variants (RAVs) (Frequency ≥0.1%) could be detected in all patients in both the TDF group and LdT group. Apart from a patient in the TDF group who had a mutation frequency of 1.32% in A181 T at 4 weeks postpartum (this value was 0.79% before treatment), all RAVs were detected at low frequency (<1.0%). The quasispecies complexity of HBV RT during pregnancy in the postpartum ALT abnormal group was significantly higher than that of the postpartum ALT normal group. Baseline quasispecies complexity (Sn) of HBV RT could predict the postpartum ALT abnormality, and the area under the ROC curve was 0.897 (95% CI, 0.749~1.000, $p = 0.007$).

Conclusion: 1. Short duration treatment of antiviral therapy during pregnancy had no significant effect on quasispecies heterogeneity in HBV RT region, with low potential risk of drug-resistant mutations. 2. The baseline (28 ± 4 week of gestation) HBV RT quasispecies complexity could predict the postpartum ALT abnormality in pregnant woman with chronic HBV infection.

Viral hepatitis A/E: Clinical aspects

SAT399

Significant compartment-specific impact of the RNA extraction and quantification method on the sensitivity of hepatitis E virus detection: implications for clinical care?

Patrick Behrendt[1,2,3], Birgit Bremer[1], Karin Rottengatter[4], Daniel Todt[5], Eike Steinmann[5], Markus Cornberg[1,3,6], Michael P. Manns[1,3,6], Benjamin Maasoumy[1,3,6]. [1]*Department of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany;* [2]*Twincore, Centre for Experimental and Clinical Infection Research, Institute of Experimental Virology, Hannover, Germany;* [3]*German Centre for Infection Research (DZIF), partner-site Hannover-Braunschweig, Germany;* [4]*Altona Diagnsotics GmbH, Germany;* [5]*Ruhr-University Bochum, Department of Molecular and Medical Virology, Germany, Germany;* [6]*Centre for Individualised Infection Medicine (CIIM), Hannover, Germany*
Email: maasoumy.benjamin@mh-hannover.de

Background and Aims: The hepatitis E virus (HEV) is the most common cause of acute viral hepatitis worldwide and may lead to chronic infection in immunocompromised hosts. RNA detection in plasma/stool is the gold-standard for diagnosis and required to determine efficacy of antiviral treatment. The impact of different viral extraction and quantification methods on reported HEV RNA results is poorly investigated.

Method: We evaluated the performance of the RealStar HEV2.0 kit (Altona Diagnostics, RS) utilizing three different RNA extraction methods (MagNA Pure 96 DNA and Viral NA SV Kit, MgP; QIAamp Viral RNA mini Kit Qiagen; VRK; COBAS Ampliprep TNAi, TNAi). The WHO standard (plasma) and patient samples (stool) were used to determine the lower limit of detection (LLOD). The best performing extraction method was evaluated in a total of 307 longitudinally samples (stool and plasma) of patients with acute (n = 18) or chronic (n = 36) HEV infection and compared to results with the former diagnostic standard of our center (TNAi/FastTrack Diagnostic Kit FTD-67.1; FTD).

Results: In plasma, the LLOD was 49, 95 and 329 IU/ml for extraction with MgP, VRK and TNAi, respectively. The sensitivity in stool samples were best with extraction by TNAi (LLOD 21IU/ml) followed by the VRK (LLOD 528 IU/ml), and lowest with MgP. In longitudinal plasma samples (n = 252) of HEV infected patients, the combination of MgP/RS had a good agreement with TNAi/FTD ($r^2 = 0.82$). Due to better sensitivity in low viremic patients, MgP/RS could reveal 54 (35.1%) HEV RNA positive samples in all samples tested negative with TNAi/FTD (n = 145). In stool, utilization of TNAi/RS showed an r^2 of 0.82 compared to TNAi/FTD. Of all HEV negative samples tested with TNAi/FTD (n = 36), 15 (41.6%) were positive when analysed with TNAi/RS. In our cohort, plasma samples at end of ribavirin treatment (EOT) could be re-analysed with TNAi/RS in 26 chronically infected individuals. Strikingly, out of 13 patients who had a viral relapse after treatment, 2 patients were HEV RNA positive at EOT when tested with our former diagnostic standard (TNAi/FTD), while re-testing with MgP/RS revealed HEV RNA in 8 of 13. In patients with sustained virological response, all except of one patient with low viremia (21IU/ml, MgP/RS) were HEV RNA negative at EOT.

Conclusion: Different methods for RNA extraction and quantification have a significant, compartment-specific impact on the sensitivity of HEV detection. Knowledge about the favourable combinations of extraction and quantification has important implications in particular for the identification of patients at risk for viral relapse after treatment.

SAT400

Effectiveness of hepatitis A vaccination in human immunodeficiency virus-infected men who have sex with men during an outbreak of hepatitis A in Osaka, Japan

Hiroki Bessho[1], Satoshi Tanaka[1], Akio Ishihara[1], Dai Watanabe[2], Tomoko Uehira[2], Hisashi Ishida[1], Takuma Shirasaka[2], Eiji Mita[1]. [1]*National Hospital Organization Osaka National Hospital, Department of Gastroenterology and Hepatology, Osaka, Japan;* [2]*National Hospital Organization Osaka National Hospital, Department of Infectious Diseases, Osaka, Japan*
Email: tanakasatoshi-onh@umin.ac.jp

Background and Aims: The number of notified cases of hepatitis A among men who have sex with men (MSM) has rapidly increased in Japan since 2018. In our recent paper, sequence analysis has shown that hepatitis A virus (HAV) isolated from patients' serum or stool samples were identical to the EuroPride strain (RIVM-HAV16-090), one of the major HAV strains identified from the European outbreaks since 2016, suggesting that the current outbreak HAV strain was imported from Europe via sexual contact among MSM. The hepatitis A outbreak among MSM is still ongoing in Japan. In order to control this outbreak among MSM and to prevent further outbreaks spreading into the general population, we are encouraging MSM patients to receive vaccination for hepatitis A. In this study, we examined the effectiveness of hepatitis A vaccination in HIV-infected MSM.

Method: This is a retrospective study at our hospital in Osaka, Japan. A total of 212 HAV-seronegative and human immunodeficiency virus (HIV)-positive MSM patients who received hepatitis A vaccination between January 2011 and June 2019 were included. Patients received three doses of HAV vaccine (Aimmugen, Kaketsuken, Japan; the only licensed inactivated hepatitis A vaccine in Japan) at week 0, 4, and 24. Anti-HAV IgG antibody was determined between week 28 and 36. Predictive factors for HAV seroconversion were assessed by univariate and multivariate logistic regression analysis.

Results: The baseline characteristics of all patients at initial vaccination were as follows (continuous variables are expressed as median): age, 44 years old; sex (male/female), 212/0 and CD4 lymphocyte count, 497/μL. All patients received antiretroviral therapy and viral suppression (HIV-RNA <50 copies/mL) was maintained in 195 patients. Anti-HAV IgG antibody titers after vaccination ranged from 0.17 to 16.10 signal-to-cutoff ratios, and HAV seroconversion occurred in 203 patients (95.8%). Both univariate and multivariate analysis showed that high initial CD4 lymphocyte count (odds ratio = 5.38, 95% confidence interval [1.37–21.1], P = 0.016) was found to be statistically significant predictive factors for HAV seroconversion.

Conclusion: This study indicated that three doses of Aimmugen achieved good immune response against HAV in HIV-infected MSM patients and that high initial CD4 lymphocyte count can be a predictive factor for HAV seroconversion.

SAT401

Histopathology of hepatitis E is associated with patients' immune status and preexisting liver condition

Background and Aims: Infection with the hepatitis E virus (HEV), a leading cause of acute hepatitis, represents a significant global disease burden. Given that, hepatitis E histopathology is hitherto relatively poorly characterized, and it is unknown what causes its remarkable variability. Thus, we aimed at a systematic analysis of hepatitis E histology and its association with clinical parameters.
Method: Fifty-two liver tissue samples (48 biopsies and 4 resection specimens) from 41 patients with molecularly proven hepatitis E (27 HEV genotype (gt) 3, three gt 1, one gt 4 and 10 undetermined gt infections) were systematically analysed for 33 histopathologic features. Findings were subjected to hierarchical clustering and resulting clusters analysed for their association with clinical parameters.
Results: Twenty-three of the 41 (56%) patients were immunocompromised, whereas 18 (44%) had no evidence of immunosuppression. Five patients (12%) had preexisting liver disease (LD). The histopathologic spectrum ranged from nearly normal over acute, chronic, and steatohepatitis to subtotal necrosis patterns of injury. Hierarchical clustering identified three main histopathologic clusters (C1-C3) which segregated along the patients' immune status and preexisting LD: C1 comprised mostly patients with preexisting LD; histology mainly reflecting the preexisting LD did not point to hepatitis E. C2 comprised mainly immunocompromised patients; histology displayed little active inflammation. C3 comprised almost all immunocompetent patients; histology displayed more active inflammation. Accordingly, the three clusters differed markedly with respect to their clinical and histopathologic differential diagnoses.
Conclusion: Hierarchical clustering unraveled three main groups of hepatitis E with distinct histopathologies, suggesting that these reflect biologically different manifestations of the disease. The association of histopathologic changes with the patient's immune status and preexisting liver condition might explain the diversity of hepatitis E histopathology and suggests that these factors are the key underlying determinants. Our results may help to improve patient management by guiding the clinico-pathological diagnosis of hepatitis E.

Epidemiology of fulminant hepatitis A cases in Vienna - an informative case series

David JM Bauer[1,2], Stephan Aberle[3], Anna Farthofer[1], David Chromy[2,4], Benedikt Simbrunner[1,2], Dr. Lisa Steininger[1,2], Mattias Mandorfer[1,2], Ralf Schmidt[5], Michael Trauner[1], Robert Strassl[5], Florian Mayer[5], Heidemarie Holzmann[3], Thomas Reiberger[1,2]. *[1]Medical University of Vienna, Department of Medicine III, Division of Gastroenterology and Hepatology, Wien, Austria; [2]Medical University of Vienna, Vienna HIV & Liver Study Group, Wien, Austria; [3]Medical University of Vienna, Department of Virology, Wien, Austria; [4]Medical University of Vienna, Department of Dermatology, Wien, Austria; [5]Medical University of Vienna, Institute of Clinical Virology, Wien, Austria*
Email: david.bauer@meduniwien.ac.at

Background and Aims: Hepatitis A virus (HAV) may lead to severe hepatitis with a fulminant course. Recent reports suggest a rising incidence of severe HAV cases in certain risk groups.
Method: We retrospectively identified patients with HAV-IgM (+) serology and/or confirmed viremia (HAV-RNA+) between Q1/2008 and Q3/2018. We defined severe HAV cases as an ALT/AST elevation >5×ULN and fulminant HAV cases as HAV patients with ALT/AST>5×ULN presenting with one of the following: (i)hepatic encephalopathy (HE) or ammonia levels>100 μmol/L, (ii)coagulopathy with INR>1.5 or (iii)jaundice with bilirubin >5 mg/dL.
Results: 579 HAV-IgM/RNA (+) patients were identified (44% male, age: 60 [IQR: 33] years) including 62 (11%) with HAV-RNA (+). HAV genotype was available in 25 patients (1A: 16; 1B: 6; 3A: 3). 69 (11.9%) patients showed severe HAV infection – including 39 (6.7%) patients with a fulminant HAV course. Sexual transmission was suspected in 3 (4%) in MSM patients with severe/fulminant HAV.
Most common symptoms of severe acute HAV infection were nausea/vomiting (63%), fatigue/malaise (52%), abdominalgia (47%), fever (43%), jaundice (39%), dark urine (30%), diarrhea (20%), hepatomegaly (19%). 37 (53.6%) patients with severe HAV were hospitalized, and 6 (9%) required ICU support. The number of HAV-IgM (+)/year was 101.5, 59, and 20.7 for the periods before 2010, 2010–2015, and 2015–08/2018, while the proportion of fulminant HAV cases increased from 6% and 3% to 21%, respectively.
Peak transaminases were higher in fulminant (AST: 1523 ± 2243.5, ALT: 2806 ± 2330 IU/mL) than in severe cases (AST: 468 [1396.5] $p < 0.001$, ALT: 535 [1617.5] IU/mL, $p < 0.001$).
In severe/fulminant HAV cases, the peak of bilirubin levels and INR occurred after a median of 3 [5] and 0 [1] days after peak ALT, respectively.
Patients with severe/fulminant HAV were younger (33 vs. 61 years) and more often male (50.7% vs. 43%), as compared to non-severe HAV cases. Genotypes in fulminant cases were: (1A: 12; 1B: 2). One patient (2.6%) with fulminant HAV required LTX. In severe/fulminant cases 30-day mortality after HAV diagnosis was 1/69 (1.6%).

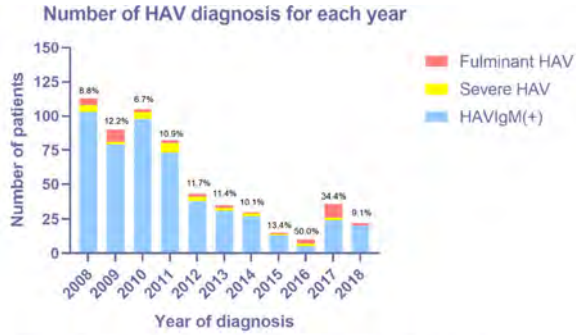

Fig.1- Yearly incidence of HAV IgM/RNA (+) with non-severe, severe and fulminant disease course, with yearly percentages of severe/fulminant disease course

Conclusion: In recent years, we observed a relative increase in the rate of fulminant HAV cases at the General Hospital in Vienna. Unvaccinated MSM might represent an emerging risk group for HAV infection. One fulminant HAV case required LTX. 30-day mortality after HAV diagnosis in severe/fulminant disease course was 1.6%.

SAT403
Epidemiology of fulminant hepatitis E cases in Vienna - an informative case series

David JM Bauer[1,2], Stephan Aberle[3], Anna Farthofer[1], David Chromy[2,4], Benedikt Simbrunner[1,2], Dr. Lisa Steininger[1,2], Mattias Mandorfer[1,2], Ralf Schmidt[5], Michael Trauner[1], Robert Strassl[5], Florian Mayer[5], Heidemarie Holzmann[3], Thomas Reiberger[1,2]. *[1]Medical University of Vienna, Division of Gastroenterology and Hepatology, Department of Medicine III, Wien, Austria; [2]Medical University of Vienna, Vienna HIV & Liver Study Group, Wien, Austria; [3]Medical University of Vienna, Center for Virology, Wien, Austria; [4]Medical University of Vienna, Department of Dermatology, Wien, Austria; [5]Medical University of Vienna, Institute of Clinical Virology, Wien, Austria*
Email: david.bauer@meduniwien.ac.at

Background and Aims: While the role of hepatitis E virus (HEV) infection in immunocompromised and organ transplant recipients is recognized, it is also important to increase knowledge on clinical symptomatic cases in immune competent patients.

Method: The electronic records of the Vienna General Hospital were systematically screened for HEV-IgM (+) and/or HEV-RNA (+) results detected between Q1/2008-Q3/2018. Severe HEV cases were defined as ALT >5×ULN, while a fulminant course of HEV was defined as ALT>5×ULN plus one of the following criteria: (i) encephalopathy or ammonia levels >100 μmol/L, (ii) coagulopathy with INR>1.5 or (iii) jaundice with bilirubin>5 mg/dL.

Results: We identified 216 patients with HEV infection, of which 67 (31.9%) and 25 (11,6%) patients showed a severe and fulminant course, respectively. Previous travels to high-HEV endemic countries were recorded in 16 (23.9%) severe and in 10 (45.5%) fulminant cases. HEV-RNA was tested in 149/216 (69.0%) patients; but only, 19/149 (12.8%) were PCR+.

While the median age was 45 [IQR:31] in acute HEV it was 45 [IQR:31] and 36 [IQR:27.25] years in severe and fulminant HEV. The most common symptoms of severe/fulminant HEV were abdominalgia 70.2%, Icterus 32.9%, fever 26.9%, dark urine 23.9%, fatigue 23.9%, 20.1%.

Patients with severe/fulminant HEV were hospitalized in 32/67 (49.2%) cases and admitted to intensive care in 2/67 (3.0%) cases.

The incidence rates of HEV in the periods Q1/2008–2010, 2011–2015, and 2015-Q3/2018 were 21, 39.5, and 0.5, while the annual incidence of severe/fulminant courses of HEV was 3.5, 11.5, and 3.5, respectively. Peak levels of ALT (2347.5 [1975.25] vs. 307.5 [400.1] IU/mL, p < 0,001) and bilirubin (10.7 [7.9] vs. 1.08 [1.038], p < 0.001) were higher in fulminant HAV than in severe HAV cases. In fulminant HEV cases, peak bilirubin and INR occurred in a median 1 [2] day and 1 [10] days, respectively, after peak ALT.

Compared to all non-severe acute HEV cases, patients with severe/fulminant HEV were younger (48.5 vs. 23 years), more often male (54.6% vs 58.2%; p = 0.013). Patients with fulminant HEV more often had ascites (22.7% vs. 2.4%) and hepatic encephalopathy (18.2% vs. 2.4%). Liver transplantation was scheduled in 4 (5.9%) of severe/fulminant HEV cases but was ultimately never required. The overall 30-day mortality after diagnosis of severe /fulminant HEV was n = 1 (3.4%).

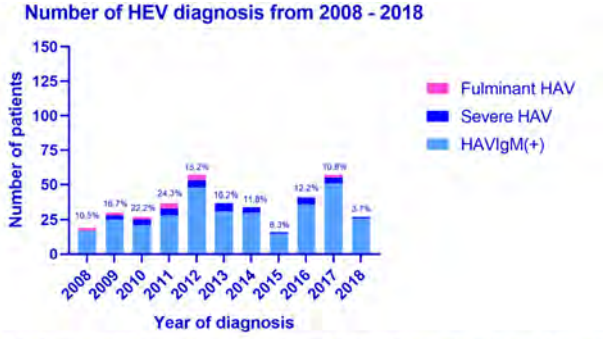

Fig.1 - Number of HEV diagosis per year form Q1/2008 to 3Q/2018, percentage of severe/fulminant disease courses for each year are given above the corresponding bar

Conclusion: Over the last 10 years we observed a stable annual rate of patients presenting with acute HEV at the Vienna General Hospital. Patients with severe and fulminant courses of HEV infection had most often recent travels to high HEV endemic countries. Cases with a chronic course of HEV infections remain to be identified.

Impact of acute kidney injury in patients with acute hepatitis A

Ahmad Khan[1], Kamesh Gupta[2], Raseen Tariq[3], Nasir Saleem[4], Shailendra Singh[5]. *[1]University of Charleston, Charleston, United States; [2]Baystate Medical Center, Springfield, United States; [3]Rochester General Hospital, Rochester, United States; [4]University of Tennessee Health Science Center - Health Sciences Library, Memphis, United States; [5]CAMC Memorial Hospital, Charleston, United States*
Email: drahmadk83@gmail.com

Background and Aims: Patients with acute hepatitis A (hep-A) are at risk of developing acute kidney injury (AKI) due to intolerance to oral intake. Few small studies have suggested worse outcomes of patients with hep-A and AKI. We aimed to investigate the impact of AKI on hospital related outcomes in these patients through a large database analysis.

Method: We queried the National Inpatient Sample (NIS) from 2004 to 2014 to identify the hep-A related hospitalizations with coexisting AKI through ICD-9CM codes. Primary outcomes included prevalence of AKI in patients with hep-A with secondary outcomes as in-hospital mortality, length of stay (LOS) and inflation adjusted total hospitalization charges and cost. We used univariate and multivariate regression analysis to adjust for confounding factors to predict for mortality and increased resource utilization.

Results: We recorded a total of 10,005 of hep-A hospitalizations with 502 (5.02%) having AKI between 2004–2014. Patients in AKI group were older, mean age 61 vs 45 years old, 41% were females and 54.20% had government insurance. A total of 150 patients died within the hospital and 74 (49.34%) had AKI. Mean LOS (6.8 vs. 4.10 days), mean total hospitalization charges (62,436$ vs.27,073$) and mean total hospitalization cost (17,216$ vs. 8,326$) were recorded in AKI group. AKI was found to be an independent predictor of mortality (adjOR: 13.56, p < 0.01) after adjusting for confounders.

Table: Demographics and outcomes related to acute hepatitis A hospitalizations with and without AKI

	Acute Hep A with AKI *n* or *(%)*	Acute Hep A without AKI *n* or *(%)*	*p* value
No. of patients	502 (5.02%)	9503 (94.8%)	
Patient Characteristics			
Female	206 (41%)	4919 (51.76%)	<0.001
Age in years (Mean)	60.37	56.64	<0.001
Race			P = 0.43
White	68.84	56.74	
Black	5.15	8.36	
Hispanic	18.38	22.65	
Other			
Hospital Characteristics:			
Hospital Teaching Status			P = 0.95
Teaching	2.52	48.44	
Non-Teaching	2.46	46.58	
Hospital size			P = 0.63
Small	9.97	11.97	
Medium	22.53	25.36	
Large	67.5	62.68	
Hospital Location			<0.001
Rural	1.16	9.79	
Urban	112.59	76.46	
Hospital Region			P = 0.65
Northeast	28.38	27.42	
Midwest	17.29	19.74	
South	30.48	33.68	
West	23.85	19.16	
Primary and Secondary Outcomes			
Mortality	74	150	
Length of Stay (days)	6.8	4.1	
Total Hospitalization Charges (USD)	62,436$	27,073$	
Total Hospitalization Cost (USD)	17,216$	8,326$	

Conclusion: Our study shows that AKI leads to worse outcomes in hospitalized patients with acute hep-A. However, it is preventable with replenishing fluid loss in an effective manner in these patients.

SAT405

Are we aligned with WHO international strategy to eliminate hepatitis C by 2030: real-world data from Khyber Pakhtunkhwa, Pakistan

Bakht Biland[1], Mohsin Haq[2], Momina Haq[2], Najib Haq[2]. [1]*Peshawar Medical College, Peshawar, Khayber Pakhtunkhaw, Pakistan, Gastroenterology Department, Pakistan;* [2]*Peshawar Medical College, Peshawar, Khayber Pakhtunkhaw, Pakistan, Gastroenterology Department, Peshawar, Pakistan*
Email: dr.mohsinahaq@gmail.com

Background and Aims: Pakistan has the second highest prevalence and burdens of hepatitis C virus (HCV) in the world. According to a meta-analysis, it is believed to chronically infect approximately 6.2% of the Pakistani population. Most of these cases are as a result of syringe reuse and unscreened blood product transfusions. G3-HCV represents 79% of all HCV infections in Pakistan. It is vitally important to treat the current epidemic unfolding in Pakistan in a cost-effective way. This study aimed to investigate the epidemiology of HCV genotypes in sixteen large districts of KPK. We also look at the recurrence rate and factors associated with poor response to DAAs which could impact WHO goal to eradicate HCV from the world by 2030.
Method: We looked at the HCV database held at Peshawar Medical College Teaching Hospital between January 2017 to April 2019. The HCV transmission via possible routs was evaluated by detailed questionnaire.
Results: Total of 1547 cases of active ECV infection were identified. The most prevalent genotype of HCV was recorded 3a (61.73%), followed by un typable (18.62%), 1a (16.16%), mixed genotypes (2.52%), 1b (0.71%), 3b (0.19%) and 2a (0.06%). Majority of the HCV patients in the KPK population acquire HCV due to the uses of unsafe injections (60.70%). Genotype 3a and 1a were seen more frequently in patients with past history of dental or medical surgery and blood-transfusion, respectively. Total 39 mixed genotypes patients were observed. In these 39 patients' genotypes 3a-1a were found in 32 individuals (82.05%) whereas the 3a-2a genotype was observed in 3 patients (7.69%), 4a-3a 2 patients (5.13%), 3a-1b in 1 patient (2.56%) and 2a-1a in 1 patient (2.56%). All eligible patients were treated with Sofosbuvir based regimens and overall SVR of 92% was achieved. Poor response rate was observed in mixed and un typeable genotypes. Relapse/reinfections were due to unsafe use of injectable needles.
Conclusion: Current study identified the major risk factor of HCV as the unsafe medical practices which transmit the HCV in the KPK population. Intravenous injections, unsafe dental and medical surgeries and visits to unhygienic barbers' shops were the main culprit. Mixed and un typeable genotypes were regarded as the major group with inadequate SVR. We are not aligned with WHO international strategy in Pakistan at present and therefore urgently need to focus our attention on the health care professional's awareness and public especially in rural areas to avoid the uses of unsafe injections/needles to control the further transmission of HCV infections.

SAT406

Hepatitis E seroprevalence and rate of viremia in immunocompromised patients - a systematic review and meta-analysis

Gustav Buescher[1], Ann-Kathrin Ozga[2], Marylyn Addo[1,3], Sven Pischke[1,3], Thomas Horvatits[1,3]. [1]*University Medical Center Hamburg-Eppendorf, I. Department of Medicine, Hamburg, Germany;* [2]*University Medical Center Hamburg-Eppendorf, Institute of Medical Biometry and Epidemiology, Hamburg, Germany;* [3]*German Center for Infection Research (DZIF), Hamburg-Lübeck-Borstel-Riems and Heidelberg, Hamburg, Germany*
Email: t.horvatits@uke.de

Background and Aims: Immunocompromised patients are at higher risk for acquisition of hepatitis E virus (HEV) infections. Chronification of hepatitis E may lead to life-threatening liver cirrhosis. However, prevalence of HEV infections in different cohorts of immunocompromised individuals remains conflicting. Aim of the study was to estimate the anti-HEV seroprevalence and the rate of HEV-RNA positivity among transplant recipients and patients with HIV infection.
Method: For this systematic review and meta-analysis we performed a literature search (PubMed) from 1996–2019 assessing studies reporting anti-HEV seroprevalence and HEV-RNA positivity. Data were stratified by assay, patient cohort (nature of transplantation, HIV-1) and methodological quality (according to JBI). Studies reporting on patients with elevated liver enzymes were analyzed separately. Datasets were pooled and analyzed using a linear mixed-effects meta regression model, which estimated seroprevalence rates based on pooled studies.
Results: 119 studies reporting the anti-HEV IgG seroprevalence and 78 studies reporting rate of HEV-RNA positivity were included in the final analysis. In 14.629 transplant recipients seroprevalence (range: 6%–29%) did not differ significantly compared to 23.692 HIV-1 positive patients (range: 4%–19%), p = n.s. HEV-RNA positivity was significantly higher in transplant recipients than in patients with HIV (1.16% vs. 0.4%; $p < 0.05$; Fig. 1). Subgroup analysis showed highest rates of HEV-RNA positivity in lung transplant recipients (2.1%) and lowest in liver transplant recipients (0.9%). Focusing on immunosuppressed individuals with elevated liver enzymes rates of HEV-RNA were significantly higher in transplant recipients compared to HIV positive patients (2.1% vs. 0.4%; OR 5.2, $p < 0.05$).

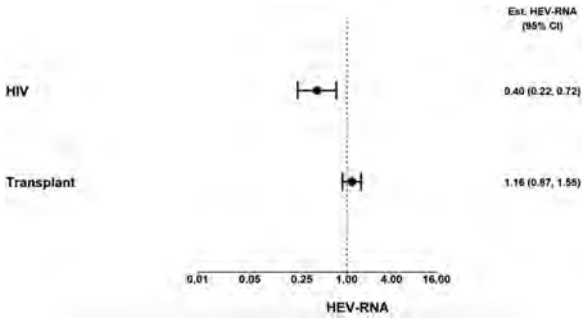

Figure 1: HEV-RNA positivity in two patient cohorts (HIV, Transplant) with normal liver values in percent ($p < 0.05$).

Conclusion: HEV infections are common among immunocompromised individuals. Interestingly, rates of HEV-RNA positivity, indicating ongoing infection, were significantly higher in transplant recipients compared to those with HIV-1. In a subgroup with elevated liver enzymes HEV-RNA detection was 5 times higher in transplant recipients compared to HIV patients. These findings support the assumption that transplant patients are at higher risk of chronic HEV infection than HIV patients at comparable exposure rates.

SAT407

Therapeutic window for ribavirin therapy in transplant recipients with chronic hepatitis E virus infection

Midas Mulder[1], Robert De Man[2], Nassim Kamar[3], Gülcan Durmaz[1], Joep de Bruijne[4], Thomas Vanwolleghem[5], Annemiek Van der Eijk[6], Teun Van Gelder[1,7], Dennis Hesselink[7], Brenda De Winter[1]. Email: m.b.mulder@erasmusmc.nl

Figure: (abstract: SAT407): Ribavirin steady-state plasma concentration and dose versus response and non-response in patients with a chronic HEV infection.

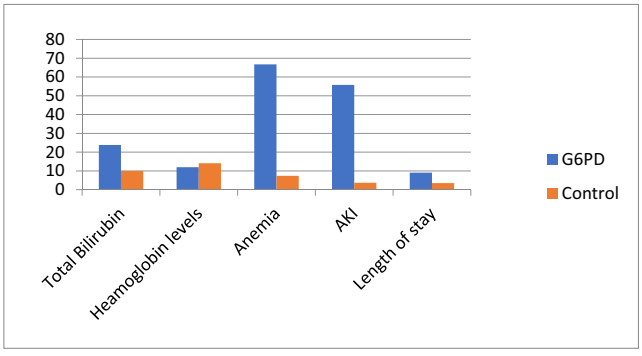
Background and Aims: The optimal dose, target concentration and duration of ribavirin (RBV) therapy in solid organ transplant (SOT) and hematopoietic stem cell transplant (HSCT) recipients with chronic hepatitis E virus (HEV) infection are unknown. The aim of this study was to investigate the association between RBV plasma concentrations and virologic response and anemia. Consequently, define the therapeutic window for RBV in SOT and HSCT recipients with a chronic HEV infection.
Method: In this retrospective, multicenter, cohort study, data of adult SOT and HSCT recipients with chronic HEV infection, who had been treated with RBV monotherapy between 2008 and 2018 were included. Data were collected in four European university hospitals. A sustained virologic response (SVR) was defined as an undetectable level of HEV RNA in serum at least 6 months after completion of RBV therapy. A clinically relevant response to RBV was defined as a decrease of the HEV RNA load after the initiation of RBV therapy with at least a factor 2. No response was defined as a rise in the HEV load. Receiver operating characteristic curve analyses were performed and the half-maximal effective concentration was calculated to determine a representative therapeutic window. Factors associated with a SVR were investigated using multiple binary logistic regression analysis.
Results: A total of 96 patients with 300 RBV plasma determinations (RBV concentration range 0.10–7.40 mg/L) were included. RBV monotherapy for a median of three months resulted in a SVR in 62.5% of the patients and 88.5% of the patients developed anemia. RBV plasma concentrations at steady-state were significantly higher in the response group compared to the non-response group: median 1.96 (IQR 1.81–2.70) versus 0.49 (IQR 0.45–0.73) mg/L, p = 0.0004. RBV caused dose-dependent hemoglobin reduction with higher RBV plasma concentrations resulting in more hemoglobin reduction.
Conclusion: RBV monotherapy resulted in a SVR in 62.5% of the patients. RBV plasma concentrations at steady-state were significantly higher in the group with a virologic response. The therapeutic window for RBV for treating a chronic HEV infection in SOT and HSCT recipients ranges between 1.8 and 3.0 mg/L.

SAT408

Does glucose-6-phosphate dehydrogenase deficiency affects morbidity in acute viral hepatitis? A case control study from a tertiary care hospital in Karachi, Pakistan

Om Parkash[1], Mahrukh Ali[1], Zara Ghos[1], Omair Ayaz[1]. [1]*Aga Khan University Hospital, Pakistan, Medicine, Karachi, Pakistan*
Email: om.parkash@aku.edu

Background and Aims: Viral hepatitis is known to be one of the significant causes of morbidity and mortality globally. In patients with glucose 6 phosphate dehydrogenase deficiency (G6PD), acute viral hepatitis may be associated with complications such as severe anemia, hemolysis, renal failure, hepatic encephalopathy and even death. In this study we will compare the parameters of morbidity and outcomes in patients of acute hepatitis with and without co-existing G6PD deficiency.
Method: Nine male patients with acute viral hepatitis and diagnosed G6PD deficiency were compared with 27 matched control patients presented with acute viral hepatitis, from January 2012 to December 2018.
Results: The patients with G6PD deficiency had a significantly raised mean total bilirubin levels as compared to controls (23.8 ± 17.4 vs 10.0 ± 8.8 mg/dl, respectively, p < 0.01), Direct and indirect bilirubin levels were also significantly raised in patients with G6PD deficiency. Mean Hemoglobin levels were low in G6PD patients in comparison to the control group (12.0 ± 2.6 vs 14.07 ± 2.6 g/dl, respectively, p = 0.05). Hemolysis was seen in 22.2% of G6PD group. Anemia was more prevalent in G6PD patients as compared to controls (66.7% vs 7.4%, respectively, p < 0.02). Acute kidney injury in G6PD group was significantly high as compared to control group (55.8% vs 3.7%, respectively, p < 0.02). Only one patient in each group required hemodialysis. The most common etiology was hepatitis A in both group (66.7% vs 44.4%) followed by hepatitis E. The average duration of stay was prolonged in G6PD patients (9.1 ± 12.2 vs 3.5 ± 1.5 days, respectively, p < 0.05). No significant difference was seen in symptoms, prothrombin time, liver enzymes and outcome in both groups i.e. recovery was seen in both groups.



Conclusion: Acute viral hepatitis in patients with G6PD has a more severe clinical course due to complications leading to prolonged hospital stay but no difference was seen on overall clinical outcome of patients.

Email: Michael.Peeters@sciensano.be

Background and Aims: Except for immunosuppression, male gender, age >50 and chronic liver disease, no correlators with clinical outcomes of a Hepatitis E Virus (HEV) genotype (gt) 3 infection have been identified. In Belgium, diagnosis of HEV is centralized at the National Reference Center (NRC) for Viral Hepatitis, Sciensano. We analyzed virological factors and clinical outcomes in a nationwide cohort of HEV patients.

Method: Demographic, clinical and biochemical parameters of HEV infections documented at the NRC were collected between 2010–2018. Serum HEV –IgM, –IgG and HEV RNA were determined by ELISA and RT qPCR. HEV was subtyped by Sanger sequencing of an ORF2 fragment. Odds ratios (OR), risk ratios (RR) and 95% confidence intervals (95% CI) were calculated using STATA.

Results: 402 cases were identified. Among 300 cases with clinical data, the median age was 57 years and 69% were males. HEV viremia was detected in 211 patients with an available genotype in 177. HEV gt3 infections largely predominate (93% [165/177]) with subtypes 3c (38% [67/177]) and 3f (44% [78/177]) almost equally represented. The percent of immunocompromised patients (30% vs 16%; OR3c = 2.2 [1.0–4.7] p = 0.045) was higher for patients infected with a virus from the clade of gt3c (achi), compared to a virus from the clade of gt3f (efg), while a similar but non-significant trend was observed for pre-existing liver cirrhosis (9.9% vs 3.4%; OR3c = 3.1 [0.8–12.5]). Patients with a HEV gt3f infection had higher peak values of ALT (mean of 2199 vs 1528 U/L; p = 0.005) and bilirubin (mean of 8.6 vs 4.1 mg/dl; p = 0.001) compared to a HEV gt3c infection. In addition, HEV gt3c infections were treated more in ambulatory settings, while the percent of patients admitted to the hospital was higher for HEV gt3f cases (36% for 3c; 61% for 3f; RR3f = 1.7 [1.2–2.4] p = 0.003). There were no differences between the subtypes in intensive care unit admissions (5.7%), in hospitalization durations (median of 4.0 weeks), in chronicity (18% vs 14%, RR3f = 0.8 [0.4–2.0]) nor in deaths (1.4% vs 4.8%; RR3f = 3.4 [0.4–30]).

Conclusion: A similar number of HEV gt3c and gt3f infections have been diagnosed in Belgium. Despite more pre-existing comorbidity in patients infected with HEV gt3c, HEV gt3f infections are associated with a more severe disease course according to laboratory values and hospitalization rates. Our nationwide analysis is the first to identify a correlation between HEV gt3 subtype and clinical outcomes.

Hepatitis E virus infection in liver transplant recipients in Sweden

Miriam Karlsson[1,2], Catarina Skoglund[3], Maria Castedal[3], Marie Karlsson[1], Martin Lagging[1,4], Heléne Norder[1,4]. *[1]Institute of Biomedicine, Sahlgrenska Academy, University of Gothenburg, Department of Infectious Diseases/Virology, Gothenburg, Sweden; [2]Region Västra Götaland, South Älvsborg Hospital, Department of Infectious Diseases, Borås, Sweden; [3]Sahlgrenska University Hospital, Sahlgrenska Academy, University of Gothenburg, Transplant Institute, Gothenburg, Sweden; [4]Region Västra Götaland, Sahlgrenska University Hospital, Department of Clinical Microbiology, Gothenburg, Sweden*
Email: Miriam.ec.karlsson@vgregion.se

Background and Aims: Liver-transplanted patients with acute hepatitis E virus (HEV) infection are at risk developing a chronic infection, which may rapidly progress to severe liver damage if not treated. However, the prevalence of HEV infection after liver transplantation remains largely unclear and likely varies geographically. Thus the aim of this study was to investigate the prevalence of acute and chronic HEV infection among liver transplant recipients in an HEV endemic region.

Method: During 2013–2018, 116 liver-transplant recipients were prospectively enrolled. They were evaluated for anti-HEV IgM and IgG antibodies as well as HEV RNA at the time of liver transplantation, and 6 and 12 months post transplantation. Additionally, medical records were reviewed.

Results: Seven (6%) had detectable HEV RNA, of whom six acquired their infection post-transplantation and one had detectable HEV RNA prior to transplantation. Additionally, 4 (3%) patients had serological markers indicative of HEV infection without detectable HEV RNA. Signs and symptoms of HEV infection were subtle, none were diagnosed in routine clinical care, and none developed a chronic HEV infection. Furthermore 15 patients (13%) had reactive anti-HEV IgG serologies in pre-transplant samples.

Conclusion: A substantial proportion of liver transplant recipients in Sweden are at risk of acquiring acute HEV infection, but surprisingly, no chronic HEV infection were detected in the present study. As HEV infections are often discrete and not diagnosed by current clinical practise, and as ribavirin therapy is available, the introduction of routine prospective HEV RNA screening of liver transplant recipients may be warranted.

Email: t.horvatits@uke.de

Background and Aims: Various viruses have been reported to be present in semen and possibly outlast the duration of viremia indicating replication beyond the blood-testis barrier. Acute and chronic hepatitis E virus (HEV) genotype 3 infections have been associated with extrahepatic manifestations, but replication in the testis has never been documented. Thus, we studied presence of HEV in semen of patients with acute or chronic HEV infection.

Method: Three chronically HEV infected (2 heart transplant recipients, 1 lymphoma patient) and 5 immunocompetent patients with acute HEV infection were included in the study – in all patients semen, urine, stool and blood were screened for HEV PCR positivity. In addition, HEV presence in testis, was analyzed in 12 experimentally HEV-infected (genotype 3) male pigs (using dilutions of the inoculum from 10^{-4} to 10^{-8}, corresponding to a dosage of up to 14.746 IU/dose) by PCR. The study has been approved by the local ethics board.

Results: 2/3 chronically HEV infected patients (one genotype 3i, two genotype 3c) tested positive for HEV in semen with concentrations 3–4 log higher than viral load in serum. Under treatment with ribavirin HEV viremia disappeared in both patients. In one of them high HEV level in semen outlasted the duration of viremia for >12 weeks (see Figure 1), while viral load in semen in the second patient strongly decreased but remained positive for 20 weeks longer than viremia. In contrast none of 5 semen samples from immunocompetent patients with acute, self-limited HEV infection (viremia range from 24 to 160.442 IU/ml) tested positive for HEV. Furthermore, in none of the 12 experimentally HEV infected immunocompetent pigs HEV could be found in the testes, while 8/12 tested positive for HEV in their livers, 7/12 in various lymph node localisations, 6/12 in their gallbladders, 5/12 in their spleens and 8/12 in the feces.

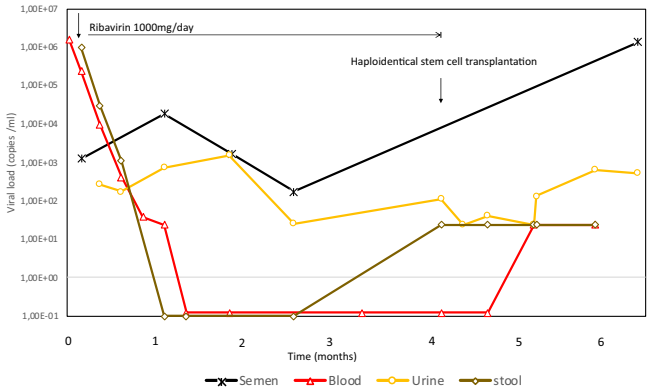

Figure: HEV viral load in semen, blood, urine and stool in a 66-year old patient with chronic hepatitis E under condition of a B-cell lymphoma, undergoing subsequent allogenic stem cell transplantation.

Conclusion: HEV can persist in semen of patients with chronic but not acute infection >5 months longer than viremia. These results imply the testes to be a niche of HEV replication without an adequate access of the immune system. Larger studies are warranted to elucidate whether chronic HEV infection could potentially be transmitted through sexual activity.

Email: junqiniu@aliyun.com

Background and Aims: Pradefovir is a liver-targeting oral prodrug of adefovir, a nucleotide analog with antiviral activity against HBV DNA polymerase. The phase 2 study is to evaluate the safety and tolerability of multiple oral doses of pradefovir 30 mg, 45 mg, 60 mg, and 75 mg, compared to tenofovir disoproxil fumarate (TDF) 300 mg.

Method: Treatment-naïve and experienced (not on treatment period greater than 6 months) patients including those with advanced fibrosis (F3) or compensated cirrhosis (F4) (≤10%). The primary objective was to evaluate the safety and tolerability of multiple oral doses of pradefovir 30, 45, 60, 75 mg, compared to TDF 300 mg once daily for 24 weeks and to identify the most appropriate dose of pradefovir for the forthcoming Phase 3 study.

Results: A total of 240 subjects were randomized and treated in the study. Approximately 48 patients in each group. All patients received >1 dose (ITT). Patient were 100% Chinese; 76% male with average age of 35.5 (±9.8) years. Around 80% were HBeAg positive and about 10% had liver cirrhosis. The demographics of each treatment groups were similar to the study population as a whole. Mean baseline HBV DNA was 7.24 (±1.33) log10 IU/ml. and mean baseline ALT was 156.5 (±79.3) U/L. The majority of patients had previously received antivirals or IFN. Reductions from baseline in HBV DNA at week 24 were 5.40, 5.34, 0.5.33, 5.40 log10 IU/ml for pradefovir 30, 45, 60, 75 mg respectively vs 5.12 log10 IU/ml for TDF group. The proportion of patients with HBV DNA <169 copies/ml were 27.1, 54.2, 47.9, and 58.3% for pradefovir 30, 45, 60, 75 mg group respectively and 41.7% for TDF group (Figure A and B). A dose response relationship was demonstrated for the pradefovir treatment group. The proportion of patients with HBeAg loss at 24 weeks were 2.86%, 12.12%, 6.45%, 9.09% for pradefovir 30, 45, 60, 75 mg group respectively and 3.03%% for TDF group. The more significant changes of serum creatinine in TDF group compared to pradefovir 30 or 45 mg groups from baseline to 24 weeks and serum phosphorous were comparable between all pradefovir groups and TDF (Figure C and D). Most frequently reported AEs included cholinesterase decreased (45%), creatine kinase MB increased (31%), Hypophosphatemia (8%). Most of AEs were mild (grade I). There were no treatment related SAEs were reported. Overall AEs and laboratory abnormality were comparable to TDF 300 mg group.

Conclusion: The reductions in HBV DNA with pradefovir treatment groups demonstrated comparable/or superior to the control TDF once daily group. A higher rate of HBeAg loss in receiving pradefovir treatment groups were observed comparing to the TDF 300 mg treatment group.

Combination of NA, PEG-IFN alpha-2b and GM-CSF enhanced hbsab production in NA experienced CHB patients (the anchor a study): an interim analysis

Di Wu[1], Weiming Yan[1], Deming Tan Tan[2], Shifang Peng[3], Yongping Chen[4], Jiaji Jiang[5], Xin-Yue Chen[6], Xiaoguang Dou[7], Ke Ma[1], Peng Wang[1], Ping Yin[8], Li Sun[9], Meifang Han[1], Qin Ning[1]. *[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Infectious Diseases, Wuhan, China; [2]Xiangya Hospital, Central South University, Department of Infectious Diseases, China; [3]Xiangya Hospital, Central South University, Department of Infectious Diseases, China; [4]The First Affiliated Hospital of Wenzhou Medical University, Department of Infectious Diseases, China; [5]First Affiliated Hospital of Fujian Medical University, Liver Research Center, China; [6]Beijing Youan Hospital, Capital Medical University, International Medical Department, China; [7]Shengjing Hospital of China Medical University, Department of Infectious Diseases, China; [8]Tongji Medical College, Huazhong University of Science and Technology, Department of Epidemiology and Biostatistics, School of Public Health, China; [9]Xiamen Amoytop Biotech Co., Ltd, China*
Email: 183194468@qq.com

Background and Aims: Granulocyte-macrophage colony stimulating factor (GMCSF) has various effects on immune responses and has previously been used as an adjuvant to HBV vaccine to enhance the antibody response. This multicenter, randomized controlled trial (NCT02327416) was to evaluate whether combination of NA, peginterferon alfa-2b (Peg-IFN α-2b) and GMCSF could induce HBsAg loss/seroconversion in patients undergoing long-term NA.

Method: 249 CHB patients who had received NA>1 year, with HBsAg <3000 IU/ml and HBV DNA ⩽1000 copies/ml, were randomized 1:1:1 to receive ETV for 96 weeks (Group I) or ETV for 48 weeks and Peg-IFN a-2b (180 μg/week) for 96 weeks (Group II) or ETV and intermittent GMCSF (75 μg/day, first 5 days each month) for 48 weeks plus Peg-IFNα-2b for 96 weeks (Group III). Interim data on 249 patients (81 in Group I, 83 in Group II and 85 in Group III) were analyzed.

Results: Baseline characteristics were comparable among treatment groups. At week 96, patients receiving triple combination therapy (NA+ Peg-IFN+ GMCSF) and patients receiving dual combination therapy (NA+ Peg-IFN) achieved higher rates of HBsAg loss than those continuing NA treatment (19.40%, 31.34% and 0%, respectively, $p < 0.001$ for all comparisons vs Group I). There was no significant difference in HBsAg loss rate between Group III and Group II ($p = 0.527$). Rates of HBsAb ≥ 10IU/ml were significantly higher in Group III (32.76%) and Group II (34.43%) than Group I (0%, $p < 0.001$ for all comparisons vs Group I). HBsAg seroconversion was only observed in Group III (20.69%) and Group II (27.87%) ($p = 0.3619$). At week 12 after initiating Peg-IFN, 58 patients in Group III and 47 in Group II had normal or mild elevated ALT levels (<2 × ULN), among these subgroup of patients, triple combination therapy induced significantly higher HBsAb positivity rates than dual combination therapy (48.28% vs 29.79%) at week 96. The difference between the two groups and the 95% CI was 18.49% (0.15% to 36.83%), which was statistically significant. Moreover, numerically higher rates of HBsAb>100IU/L were observed in Group III than in Group II at week 96 (17.24% vs 8.51%, $p = 0.19$). Both dual and triple combination therapy regimens were generally well-tolerated.

Conclusion: For patients with virological suppression by NA, a combination of ETV and Peg-IFN α-2b therapy with or without GMCSF significantly increases rates of HBsAg loss/seroconversion. GMCSF may enhance the therapeutic effect of Peg-IFN α-2b in terms of HBsAb positivity in those with normal or mild elevated on-treatment ALT levels.

SAT414

Efficacy and safety of treatment interruption in patients with HBeAg negative chronic hepatitis B

Teresa Broquetas[1], Miquel Mico[2], Montserrat Garcia-Retortillo[1], Nuria Cañete Hidalgo[1], Marc Puigvehí[1], Susanna Coll[1], Marc Batlle[1], Ana Viu[1], Esther Garrido[1], Judit Romero[1], Juan Jose Hernandez[2], Xavier Bessa[1], Jose A. Carrión[1]. *[1]Liver Section, Gastroenterology Department, Hospital del Mar, IMIM (Institut Hospital del Mar d'Investigacions Mèdiques), UAB, Barcelona, Spain; [2]Laboratori de Referència de Catalunya, El Prat de Llobregat, Spain*
Email: 60578@parcdesalutmar.cat

Background and Aims: in patients with HBeAg negative chronic hepatitis B (CHB), HBsAg loss rarely occurs during nucleos(t)ids analogues (NUC) therapy (<1% yearly). Recent studies show that NUC discontinuation may increase HBsAg loss rates and in the EASL Guidelines it is suggested that this therapeutic strategy can be considered. The aims of this study were to determine the rates of HBsAg loss after NUC discontinuation and its predictive factors. As a secondary aim we evaluated the safety of this therapeutic strategy.

Method: prospective open study of non-cirrhotic patients with CHB HBeAg negative, with at least 3 years of NUC therapy. HBsAg levels (IU/ml), DNA (IU/ml), anti-HBs and transaminases were determined at weeks 0, 4, 12, 24, 36, 48 and subsequently, every 6 months. HBcrAg (log/ml) was determined at week 0. Retreatment criteria were defined as acute hepatits (ALT >10 UNL confirmed at 2 weeks or ALT 5–10 UNL confirmed at 4 weeks) and persistent hepatitis as ALT 2–5 UNL and DNA >2000 IU/ml for at least 6 months.

Results: from From December 2017 to October 2019, NUC was interrupted in 57 patients. The median (range) age was 52 (29–80) years, 74% were male. The pre-treatment time with NUC was 8.5 (3.2–17.3) years; tenofovir in 37 (64.9%), entecavir in 17 (29.8%), lamivudine in 2 (3.5%) and telbivudine in 1 (1.7%). Baseline HBcrAg levels were 2.5 (<2.0–4.1) and HBsAg levels of 687 (0.2–14637). After a median follow-up of 51 (4–99) weeks, 5 (8.8%) patients lost the HBsAg: one patient at week 4, two at week 24 and two at week 36. Patients who lost HBsAg showed a longer treatment duration (median: 14 years) and lower values of HBsAg (19.8) than patients who did not eliminate HBsAg, 8 years ($p = 0.002$) and 827 IU/mL ($p = 0.003$) respectively. HBsAg loss was achieved in 5 (15.2%) of 33 patients with HBsAg <1000 ($p < 0.046$). All patients who lost HBsAg ($n = 5$) had received a minimum of 9 years of NUC ($n = 24$) ($p = 0.006$). There were no differences between groups in terms of age, gender, ethnicity, type of NUC or HBcrAg levels. During the follow-up, only 2 (3.5%) patients have required to restart the NUC due to acute hepatitis, with excellent response to treatment while 96.5% of patients remain without retreatment criteria.

Conclusion: Treatment discontinuation in patients with chronic hepatitis B HBeAg negative increases the rate of HBsAg loss and is a safe strategy. All the patients that lost HBsAg had levels <1000 IU/ml and had a minimum of 9 years of treatment prior to the interruption. After one year of follow-up, 96.5% of patients remain without antiviral treatment.

SAT415

Pegylated interferon beta strongly reduces all serological and intrahepatic hepatitis B virus parameters in immunodeficient humanized mice

Email: a.pirosu@uke.de

Background and Aims: Pegylated interferon-alpha (peg-IFN-alpha) remains a valuable finite therapy for chronic hepatitis B (CHB) infection because it provides higher rates of HBsAg seroclearance compared to treatment with polymerase inhibitors. Peg-IFN-beta, which is used in multiple sclerosis treatment, acts on the same cellular receptor. While IFN-alpha promotes cccDNA epigenetic suppression and destabilisation, knowledge of IFN-beta antiviral activity towards HBV is limited. Aim of this study was to investigate the efficacy of peg-IFN-beta, in comparison to peg-IFN-alpha, to lower viremia, levels of circulating viral antigens and intrahepatic viral loads in vivo, in a system lacking adaptive immune response.
Method: Human liver chimeric uPA/SCID/IL-R2γ (USG) mice stably infected with HBV (GT-D) received either peg-IFN-beta or peg-IFN-alpha (Plegridy® or Pegasys® 25 ng/gr, twice/week) for 6 weeks while a group of infected mice remained untreated. Serological and intrahepatic virological changes were determined by qRT-PCR, ELISA and IHC. HBx protein was determined by WB and ChIP-qPCR was performed to assess SMC6 interaction with the cccDNA.
Results: Expression of human interferon stimulated genes (ISGs) strongly and similarly increased in both treated groups (e.g. peg-IFN-beta: ISG15 = +2.6Log, MXA = +2.4Log, OAS = +1.8Log), compared to the untreated controls. Compared to baseline, median HBV DNA viremia declined 2.6Log and 1.2Log after peg-IFN-beta and peg-IFN-alpha treatment, respectively. Notably, median reduction of circulating HBsAg levels appeared stronger upon peg-IFN-beta administration (−1.1Log), compared to peg-IFN-alpha (−0.4Log). Median HBeAg reduction was 1.5Log and 0.54Log in mice receiving peg-IFN-beta or peg-IFN-alpha, respectively. Intrahepatically, peg-IFN-beta appeared superior to peg-IFN-alpha in reducing total HBV DNA/cell (−1.4Log vs −1Log), total HBV RNA (−1.1Log vs −0.5Log) and pgRNA (−1.6Log vs −0.6Log). HBcAg staining was markedly reduced in both treated groups, while SMC6 staining reappeared in nuclei of human hepatocytes. Moreover, IFN treatment reduced HBx in both groups and SMC6 was found associated to the cccDNA, despite overall cccDNA reduction.
Conclusion: Administration of peg-IFN-beta promoted more profound direct antiviral effects in vivo than peg-IFN-alpha in immunodeficient humanized mice, leading to a strong decline of all viral markers, including HBx and SMC6-associated epigenetic silencing of the persisting cccDNA.

hzVSF, a novel HBV therapeutic candidate, shows WHsAg loss in woodchuck hepatitis model and safety in phase I clinical study

Byoung Ahn[1], Byong Cheol Lee[1], Hyun-Jun Kim[1], Sungman Park[1], Yena Lee[1], Yunjin Choi[1], Han Earl Kim[1], Yoon-Won Kim[2].
[1]ImmuneMed, Inc, Research Institute, Chuncheon, Korea, Rep. of South; [2]Hallym University, College of Medicine, Microbiology, Chuncheon, Korea, Rep. of South
Email: smpark@immunemed.co.kr

Background and Aims: hzVSF, humanized immunoglobulin G4 targeting membrane-bound vimentin of virus0infected cells, exhibited anti-replicative and anti-inflammatory effect in HBV-infected human hepatocytes. The purpose of the current studies was to evaluate antiviral effect of hzVSF in acute and chronic woodchuck hepatitis virus (WHV)-infection models. Furthermore, we examined the safety of the hzVSF and pharmacokinetics (PK) profile in healthy volunteers.
Method: 1) To evaluate the efficacy of hzVSF in acute WHV-infected woodchucks, we examined the viral titer, serum transaminases, bilirubin, and liver hepatopathology after hzVSF treatment. 2) In chronic WHV infection model, the efficacy of hzVSF monotherapy and combination therapy with tenofovir alafenamide fumarate (TAF) was assessed. 3) Phase I clinical study of intravenous (iv) single ascending dose of hzVSF up to 1200 mg was conducted to elucidate the safety and pharmacokinetics in healthy volunteers.
Results: 1) In acute WHV woodchuck model, hzVSF treatment attenuated clinical symptoms of acute infection, including body weight loss, the elevation of alanine aminotransferase (ALT), aspartate aminotransferase (AST), and bilirubin level, and immune cell infiltration into the liver tissue. 2) In chronic woodchuck model, monotherapy of hzVSF showed the suppression of WHV DNA and WHsAg in 25% of animals, no rebound was observed after cessation of hzVSF treatment. Fifty percent of WHV-infected animals in the combination treatment group (hzVSF+TAF) showed the reduction of WHV DNA and WHsAg to baseline (LLOQ) and no relapse after the cessation of treatment. 3) In phase I study, single iv dose of hzVSF showed tolerability and safety with no serious adverse effects up to top dose and dose-proportional PK profile.
Conclusion: hzVSF exhibits anti-viral and anti-inflammatory effects in WHV-infection models and safety in phase I study. This potential novel HBV treatment warrant further clinical studies in chronic HBV infection patients.

Email: ale.loglio@gmail.com

Background and Aims: Administration of entry inhibitor Bulevirtide (BLV) 10 mg/day + TDF has been shown to be effective and safe in HDV hepatitis. However, its effectiveness and safety beyond 48 weeks and the kinetics of virological and clinical relapse after discontinuation have never been demonstrated in a real-life setting.
Method: Three patients with compensated HDV cirrhosis and contraindication to Peg-IFN were treated with BLV 10 mg/day + TDF for up to 76 weeks (Case 1: 69 years, female, HDV RNA 23,600 IU/mL, ALT 140 U/L; Case 2: 51 years, male, concomitant autoimmune hepatitis, HDV RNA 392,000 IU/mL, ALT 232 U/L; Case 3: 58 years, female, autoimmune thrombocytopenia, HDV RNA 5,900,000 cp/mL, ALT 244 U/L). Liver function tests, total bile acids, and HBV/HDV markers were monitored. HDV RNA was quantified by RoboGene (LOD <6 IU/mL) or by in-house RT PCR (LOD <100 cp/mL).
Results: In Case 1, HDV RNA became undetectable by week 36 and ALT normalized by week 20, both markers remained negative up to week 52 when BLV was withdrawn. After BLV discontinuation, HDV RNA became detectable after 2 weeks (24 IU/mL), progressively increased up to week 16 (13,655 IU/mL) and then declined to 431 IU/mL at week 38 post-treatment. A similar pattern was observed for ALT levels that progressively increased >ULN from week 14 to week 30 (41→333 U/L), and then declined, without any signs of lab/clinical decompensation. At last available sample, 38 weeks after BLV

discontinuation: HDV RNA 431 IU/mL, ALT 70 U/L. HBsAg progressively declined from 22 IU/mL at EOT to 0.20 IU/mL at last sampling. In Case 2 and Case 3, BLV treatment was continued for 76 weeks. Both patients achieved and maintained a biochemical and virological response through week 76 with no evidence of virologic breakthrough or biochemical elevations. At week 76, HDV RNA was <6 IU/mL and 150 cp/mL, and ALT 33 and 35 U/L, respectively while no significant changes of HBsAg were observed during treatment. In Case 2, a significant improvement in portal hypertension features and liver function tests were documented, as well as a reduction of plasma cell infiltration and histological activity in the liver biopsy performed at week 72.
BLV was well tolerated in all 3 patients, without any clinical drug-related adverse events except for an asymptomatic increase in bile acids.
Conclusion: Up to 76 weeks of Bulevirtide 10 mg/day monotherapy is safe and effective in patients with HDV related compensated cirrhosis.

SAT418

Correlation between HBV core-related antigen and the new quantitative IGG anti-core in treated caucasian HBeAg-negative patients and inactive carriers with and without a functional cure

Alessandro Loglio[1], Floriana Facchetti[1], Elisa Farina[1], Nicoletta Nandi[1], Alberto Perego[2], Riccardo Perbellini[1], Sara Colonia Uceda Renteria[3], Marta Borghi[1], Roberta Soffredini[1], Corinna Orsini[2], Giovanna Lunghi[3], Ferruccio Ceriotti[3], Pietro Lampertico[1].

Migliavacca" Certer for Liver Disease, Division of Gastroenterology and Hepatology, Milan, Italy; [2]Fujirebio Italia S.r.l., Pomezia, Italy; [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Virology Unit, Milan, Italy
Email: pietro.lampertico@unimi.it

Background and Aims: Hepatitis B core-related antigen (HBcrAg) and the quantitative assessment of IgG antibodies against HBV core antigen (qAnti-HBc IgG) are new HBV biomarkers that however have not been compared. The study aimed to assess their relationship in HBsAg positive and negative patients, with and without oral therapy.
Method: This cross-sectional/longitudinal retrospective study evaluated 411 sera from 4 groups of Caucasian patients: Group 1: 189 HBsAg-positive, HBeAg-negative patients under long-term TDF/ETV; Group 2: 28 patients who cleared HBsAg during NUC therapy; Group 3: 87 inactive carriers; Group 4: 22 inactive carriers who cleared HBsAg. qAnti-HBc IgG (Fujirebio) were quantified as cut-off index (COI), and HBcrAg levels (Fujirebio) were expressed as LogU/mL (LLD<2.5 Log U/mL, quantification range 3.0–7.0).
Results: In 189 Group 1 patients [age 66, 47% cirrhosis CPT A, 95% gt D, 65% NUC-experienced, TDF/ETV treated for 100 months, undetectable HBV DNA for 118 months, HBsAg 517 (1–11,781) IU/mL], median qAnti-HBc IgG was 127 (6–282) COI, while HBcrAg 3.0 (2.5–5.3; 56% <LLD) LogU/mL. At multivariate analysis, low qAnti-HBc IgG were associated only with longer HBV DNA suppression (OR 1.02, $p < 0.001$) while low HBcrAg only with lower qHBsAg. All the 105 HBcrAg negative patients tested positive for qAntiHBc IgG [123 (2–282) COI]. In samples collected after one year, qAnti-HBc declined from 107 to 85 COI, qHBsAg from 250 to 202 IU/mL, while HBcrAg remained stable (2.8 vs 3.0 LogU/mL; 50%<LLD).
The 28 Group 2 patients who cleared HBsAg during NUC [age 59, 36% cirrhosis CPT A] were divided into two subgroups, according to NUC indication (CHB vs recent HBV infection): qAnti-HBc was lower in the former than in the second subgroup [58 (14–222) vs 209 (59–285) COI ($p = 0.010$)] and HBcrAg 3.0 (2.5–4.1) vs 3.2 (2.6–4.5) LogU/mL, but 59% vs 18% <LLD ($p = 0.033$), respectively.
In Group 3 [age 53, qHBsAg 321 (0.12–52,000) IU/mL], qAnti-HBc were 267 (75–299) COI and HBcrAg 2.7 (2.5–3.9; 76%<LLD); patients with <267 COI had lower qHBsAg and HBV DNA, however only the latter significant (OR 1.00, $p = 0.028$). In Group 4 (age 64, 27% with anti-HBs) qAnti-HBc were 226 (138–277) COI and HBcrAg 2.8 (95% <LLD). Overall, patients under NUC have both lower qAnti-HBc and HBcrAg level ($p < 0.0001$).
Conclusion: Anti-HBc IgG and HBcrAg levels are reduced by NUC treatment but have different kinetics, thus representing additional useful markers for the management of HBV patients.

SAT419

The establishment of hepatitis B care and treatment clinics with viral load testing capacity in the United Republic of Tanzania: a demonstration project following WHO guidelines, Zanzibar, 2017–2019

Ali Salim[1], Sanaa Said[1], Shaun Shadaker[2], Geoff Beckett[2], Noele P. Nelson[2], Brian McMahon[3,4], Aaron Harris[2]. *[1]Mnazi Mmoja Hospital, Zanzibar, Tanzania; [2]Centers for Disease Control and Prevention, Division of Viral Hepatitis, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Atlanta, United States; [3]Alaska Native Tribal Health Consortium, Anchorage, United States; [4]CDC – Arctic Investigations Program, Anchorage, United States*
Email: ieo9@cdc.gov

Background and Aims: In 2015 about 257 million persons were living with chronic hepatitis B worldwide and about 887,000 related deaths occurred. Zanzibar is a low-resource semi-autonomous nation with a hepatitis B prevalence of about 2%. To mitigate this burden, in 2015 the World Health Organization (WHO) issued hepatitis B care and treatment guidelines. We report early results of the implementation of hepatitis B care and treatment programs in Zanzibar.
Method: A five-year demonstration project was launched December 2016 at Mnazi Mmoja Hospital in Zanzibar. Clinical and laboratory staff at each site received training on the delivery of hepatitis B-directed care and laboratory testing. Participants were recruited from Zanzibar's National Blood Donation Program where donors are systematically screened for HIV, hepatitis C antibody (anti-HCV), syphilis, and hepatitis B surface antigen (HBsAg). Participants were invited to participate in the program if they tested negative for HIV and anti-HCV, and were HBsAg-positive. Participants were examined for clinical signs of liver disease and received hepatitis B-related laboratory testing every 6–12 months for assessment of treatment eligibility. Specimens were sent to a lab in Dar es Salaam for hepatitis B virus (HBV) DNA testing. Tenofovir disoproxil fumarate (TDF) was provided for participants meeting WHO guidelines eligibility. Clinical and laboratory data were collected for programmatic evaluation purposes.
Results: After 34 months, 587 participants enrolled: 360 with complete laboratory results, 154 with two clinic visits, and 70 with ≥3 clinic visits. Of those with complete lab results, the median age was 34 years (IQR 28–41), 218 (61%) male. Of these, 26 patients were started on TDF: 17 who met the criteria for liver cirrhosis, and/or 15 with APRI >1.5, 3 met WHO criteria by HBV DNA and ALT; 1 discontinued due to intolerance from fatigue. ALT values decreased among those treated, from a median of 98.5 (IQR 44–246) to 34.5 (IQR 25–62) ($p = 0.06$). Of enrolled patients, 1 was diagnosed with hepatocellular carcinoma and 5 patients died due to complications from HBV-associated liver disease. Challenges included patients presenting with advanced liver disease.
Conclusion: Hepatitis B care and treatment is feasible in low-resource settings. While challenges remain, testing and linkage to care is critical to decrease the global burden of hepatitis B.

SAT420

Nucleos(t)ide analogue therapy decreases the HBeAg loss rate in HBeAg positive chronic hepatitis B patients with hepatitis flare: a propensity score matching study

Chien-Wei Peng[1,2], Rachel Wen-Juei Jeng[1,2], Yi-Cheng Chen[1,2,3], Rong-Nan Chien[1,2,3], Yun-Fan Liaw[2,3]. *[1]Chang Gung Memorial Hospital, Linkou branch, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan; [2]Chang Gung University, College of Medicine, Taoyuan,*

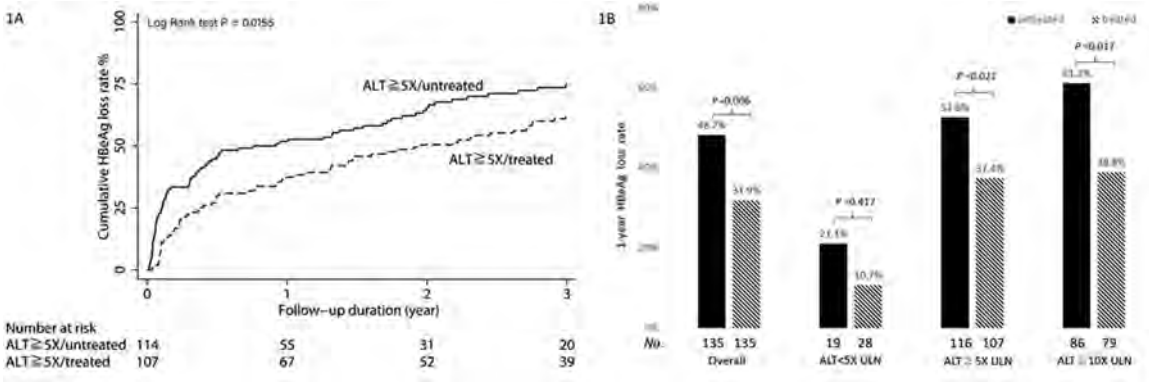

Figure: (abstract: SAT420): Kaplan-Meier curve of hepatitis flare patients with or without treatment after PSM; 1B:1-year HBeAg loss rate between treated and untreated HBeAg positive patients after PSM.

Taiwan; [3]Chang Gung Memorial Hospital, Linkou branch, Liver research unit, Taoyuan, Taiwan
Email: liveryfl@gmail.com

Background and Aims: Asian pacific guidelines have recommended that HBeAg positive patients with hepatitis flare deserve 3 months close monitoring for spontaneous HBeAg loss if there is no concerns for hepatic decompensation (Liaw YF et al. Hepat Int 2012). In contrast to earlier findings during lamivudine therapy (56%/62 vs. 25%/28, Perrillo RP et al, Hepatology 2002), a recent study involving 51 patients showed lower HBeAg loss rate after immediate nucleos(t)ide analogue (Nuc) therapy (30% vs. 47%) than that of the untreated patients with ALT >10X upper ULN (Brahmania M et al CGH 2019). These controversial findings from 2 studies with small number of patients require larger studies to clarify.
Method: HBeAg positive CHB patients received Entecavir or Tenofovir monotherapy during 2006–2017 were recruited as treated cohort (Study group) while those without anti-viral treatment during 1980–2000 were enrolled as untreated cohort (Control group). Patients without proper monitor of ALT level, co-existence of other liver diseases and follow-up less than one year were excluded. Propensity score matching (PSM) was performed to adjust the difference between the Study and Control groups including age, gender, genotype, cirrhosis, ALT level and alfa-fetoprotein (AFP) level with 1:1 ratio. Logistic regression was performed to investigate predictors for 1-year HBeAg loss.
Results: A total of 270 patients were analyzed with 135 patients in each arm after PSM. No differences of age, gender, genotype, cirrhosis, ALT level and AFP level were noted between two groups. The overall one-year HBeAg loss rate was lower in the study than in the control group (31.9% vs. 48.2%, P = 0.006) especially when patients encountering hepatitis flare (ALT ≥ 5X ULN) (Figure). In multivariate analysis, ALT level ≥ 10X ULN (<5X as referent, adjusted OR: 5.44, P < 0.001) and Nuc treatment (untreated as referent, adjusted OR: 0.52 (0.31–0.88), P = 0.015) were independent predictors for HBeAg loss by 1 year.
Conclusion: Nuc therapy resulted in lower HBeAg loss rate. Endogenous host immune driving toward HBeAg loss may be halted by Nuc therapy especially in those with hepatitis flare. The results add support to the recommendation of Asian-Pacific guidelines.

SAT421

Long-term risk of primary liver cancers in tenofovir versus entecavir treatment for chronic hepatitis B

Chao-Hung Hung[1], Yao-Hsu Yang[2], Sheng-Nan Lu[3]. *[1]Chiayi Chang Gung Memorial Hospital, Division of Hepatogastroenterology, Department of Internal Medicine, Chiayi, Taiwan; [2]Chiayi Chang Gung Memorial Hospital, Department of Traditional Chinese Medicine, Chia-Yi, Taiwan; [3]Chiayi Chang Gung Memorial Hospital, Division of Hepatogastroenterology, Department of Internal Medicine, Chia-Yi, Taiwan*
Email: chh4366@yahoo.com.tw

Background and Aims: It remains controversial whether tenofovir disoproxil fumarate (TDF) and entecavir (ETV) treatment is associated with different clinical outcomes for chronic hepatitis B (CHB). We compared the long-term risk of TDF versus ETV on primary liver cancers including hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (CCC) in CHB patients from a large multi-institutional database in Taiwan.
Method: From 2011 to 2018, a total of 21,222 CHB patients who had received TDF or ETV in seven medical institutes constituting the Chang Gung Memorial Hospitals were screened for eligibility. Patients with coinfection, preexisting cancer, missing data and less than 6 months of follow-up were excluded. Finally, 7,248 patients (5,348 and 1,900 in the TDF and ETV groups, respectively) were linked to the National Cancer Registry database for the development of HCC or CCC. Propensity score matching (PSM) (1:2) analysis was used to adjust for baseline differences.

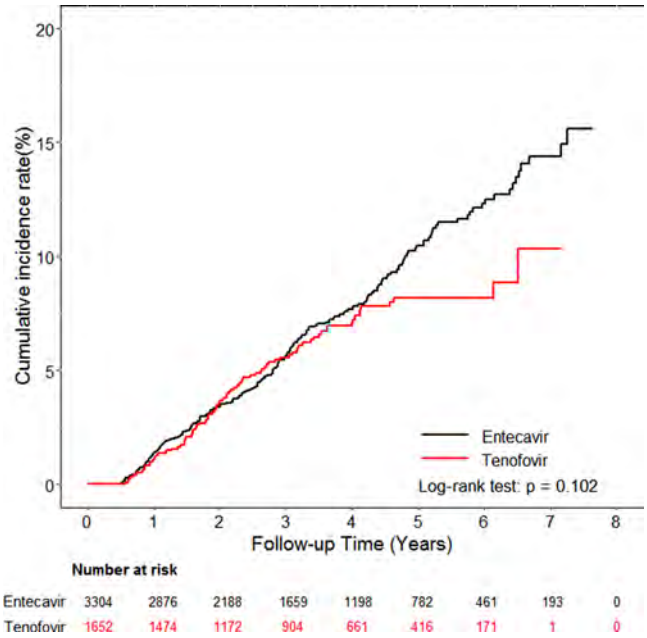

Figure: Cumulative incidence of HCC in PSM population.

Results: The incidence rate of HCC was not different in the entire population (hazard ratio [HR] 0.89; 95% confidence interval [CI] 0.71 to 1.12, p = 0.315) and in the PSM population (HR 0.87; 95% CI 0.69 to

1.11, p = 0.274) after adjusting baseline factors. In the subgroup analysis, TDF treatment was associated with a lower risk of HCC than ETV treatment (HR 0.54; 95% CI 0.30 to 0.98, p = 0.043, PSM model) among decompensated cirrhotic patients. There was no difference between TDF and ETV groups in the incidence rate of CCC (HR 1.84; 95% CI 0.54 to 6.29, p = 0.330 in the entire population and HR 1.04; 95% CI 0.31 to 3.52, p = 0.954 in the PSM population, respectively).

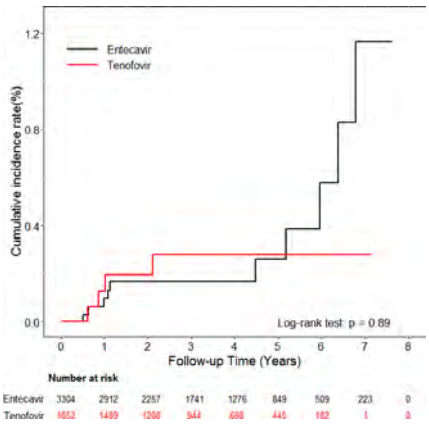

Figure: Cumulative incidence of CCC in PSM population.

Conclusion: Treatment with TDF and ETV showed a comparable long-term risk of HCC and CCC in CHB patients, whereas TDF appeared to be a lower risk of HCC than ETV in decompensated cirrhotic patients.

SAT422

ATI-2173, a novel phosphoramidate nucleoside prodrug for HBV cure regimens

Douglas Mayers[1], Katherine Squires[1], Roger Rush[2], Abel De La Rosa[1]. [1]*Antios Therapeutics, Atlanta, GA, United States;* [2]*Allon Preclinical Consulting, LLC, Concord, MA, United States*
Email: dlmayers007@gmail.com

Background and Aims: ATI-2173 is a liver-targeted phosphoramidate prodrug of clevudine (CLV) designed to deliver the 5′-monophosphate of CLV to the liver, decreasing systemic exposure to CLV and potentially enhancing anti-HBV activity. Unlike chain terminating nucleos(t)ide analogues, the active 5′-triphosphate of ATI-2173/CLV has unique antiviral properties as a non-competitive, non-chain terminating HBV polymerase inhibitor. CLV produced extended post-exposure reductions of HBV DNA in the woodchuck HBV model and in man but clinical development was stopped when reversible proximal skeletal myopathy was observed with exposures of >8 months (median 18 mo.).
Methods: *In vitro* studies are ongoing in primary human hepatocytes and liver cell lines. Hepatic extraction was measured in portal/jugular vein cannulated cynomolgus monkeys dosed IV and orally.
Results: ATI-2173 has an anti-HBV EC_{50} of 1.71 µM with a CC_{50} >100 µM in HepG2.2.15 cells. The EC_{50} dropped 1000-fold to 1.31 nM in primary human hepatocytes without evidence of cytotoxicity. ATI-2173 has low serum protein binding with low fold-change in EC_{50} *in vitro* in the presence of increasing concentrations of human serum. *In vitro* combination studies of ATI-2173 activity against HBV in primary human hepatocytes demonstrated additive antiviral activity with TDF, lamivudine, and GLS4 (CAM inhibitor); and synergistic activity with entecavir (ETV), adefovir and interferon. *In vitro* drug resistance studies confirm mutational cross resistance with lamivudine, telbivudine, and ETV but not HBV capsid inhibitors or TDF. ATI-2173 had no *in vitro* genotoxicity and a negative hERG assay. ATI-2173 liver-targeting was confirmed in the rat and cynomolgus monkey with an 82% hepatic extraction ratio after an oral dose in the monkey.
Conclusions: ATI-2173 is a potent liver-targeted molecule that delivers the 5′-monophosphate of clevudine, enhancing the anti-HBV activity while significantly reducing systemic exposure to clevudine in the rat and monkey. ATI-2173 combined with TDF, ETV or other direct acting antivirals, could become an integral part of combination HBV cure regimens.

SAT424

Impact of ESC+ technology on the hepatic safety profile of GalNAc-delivered, HBV-targeting RNAi therapeutics

Edward Gane[1], Christian Schwabe[2], Jorg Taubel[3], Anna Bakardjiev[4], Stephen Huang[5], Xiao Ding[4], Lynn Connolly[4], Phil Pang[4], Pushkal Garg[5], Vasant Jadhav[5]. [1]*University of Auckland, Auckland, New Zealand;* [2]*Auckland Clinical Studies, Auckland, New Zealand;* [3]*Richmond Pharmacology, London, United Kingdom;* [4]*Vir Biotechnology, Inc, San Francisco, United States;* [5]*Alnylam Pharmaceuticals, Cambridge, United States*
Email: abakardjiev@vir.bio

Background and Aims: Ribonucleic acid interference (RNAi) therapies are a promising option for functional cure of chronic hepatitis B virus (HBV) infection and must have an acceptable safety profile in a patient population with underlying liver disease. Enhanced Stabilization Chemistry Plus (ESC+) RNAi design retains enhanced metabolic stability needed for in vivo potency while reducing sequence matched off-target effects. This improved specificity is hypothesized to result in better liver safety – the target organ of GalNAc-RNAi. To test the ability of ESC+ technology to improve hepatic safety profile in the clinic, we evaluated ALN-HBV and VIR-2218, two investigational HBV RNAi therapeutics designed to target all HBV transcripts. VIR-2218 was derived from ALN-HBV using ESC+ technology.
Method: RNA-Seq analysis was used to evaluate differential gene expression in human liver cells transfected with ALN-HBV or VIR-2218. Relative hepatotoxicity was assessed in a humanized mouse model in which the liver is populated with human hepatocytes. In separate clinical studies, normal healthy volunteer cohorts (randomized 3:1 active:placebo) received single subcutaneous doses of 0.1, 0.3, 1 and 3 mg/kg of ALN-HBV (Study ALN-HBV-001) or 50, 100, 200, 400, 600 or 900 mg of VIR-2218 (Study VIR-2218–1001).
Results: RNA-Seq analysis in human liver cells showed reduced off-target effects with VIR-2218 compared with ALN-HBV, as expected with ESC+ design. In addition, human ALT1 levels were notably lower in a humanized liver mouse model with VIR-2218 compared to ALN-HBV, consistent with the improved specificity of VIR-2218. In humans, transient ALT elevations were observed with ALN-HBV in 1/6 (17%) and 4/6 (67%) subjects after a single dose of 1 and 3 mg/kg, respectively. These elevations were asymptomatic and not accompanied by hyperbilirubinemia. In contrast, no ALT elevations potentially related to VIR-2218 were observed with single doses of VIR-2218 ranging from 50 to 600 mg (~0.8 to 10 mg/kg). At 900 mg (~15 mg/kg), mild ALT changes have been observed in a subset of subjects.
Conclusion: ESC+ design appears to improve the hepatic safety profile of HBV-targeting RNAi, an important consideration in this patient population, especially in those with advanced liver disease. Evaluation of VIR-2218 in chronic HBV patients is ongoing.

SAT425

A once-per-week or every-two-week dosing regimen is more efficacious for the TIR7 agonist JNJ-64794964 (JNJ-4964) to induce an anti-hepatitis B virus (HBV) effect and HBV-specific immune responses in AAV-HBV mice

Florence Herschke[1], Chris Li[2,3], Ren Zhu[2], Quinglin Han[2], Qun Wu[2], Qing Lu[2], Tse-i Lin[3,4], An De Creus[1]. [1]*Janssen Pharmaceutica NV, Beerse, Belgium;* [2]*Asia Pacific Centre of Excellence of Translational Science, Shanghai, China;* [3]*No longer with Janssen;* [4]*Janssen South San Francisco, San Francisco, United States*
Email: fherschk@its.jnj.com

Background and Aims: JNJ-64794964 (JNJ-4964/ AL-034/ TQ-A3334), is a novel, selective, oral Toll-like receptor 7 (TLR7) agonist currently in phase 1 clinical development for chronic hepatitis B (CHB) treatment. The aim of the present study was to investigate the effects of dosage and dosing frequency on the efficacy and safety of JNJ-4964 in an adeno-associated virus vector expressing HBV (AAV-HBV) mouse model.
Method: C57BL/6 mice infected with rAAV8-1.3HBV (genotype D) were treated orally with JNJ-4964 at doses ranging from 2 to 20 mg/kg and dosing frequencies of twice-per-week (BIW), once-per-week (QW), once-every-2-weeks (Q2W) or once-per-month (Q4W) (n = 8–10/group). After 12 weeks of dosing, mice were followed up for 4 weeks. The anti-HBV activity of JNJ-4964 was assessed on plasma HBV viral load, HBV surface-antigen (HBsAg) expression and anti-HBs antibodies, and liver HBsAg and HBV core antigen expression (HBcAg). The capacity of JNJ-4964 to induce plasma cytokine production and splenic HBV-specific immune responses were evaluated by ELISA and T- and B-cell ELISpot assays.
Results: Anti-HBV activity of JNJ-4964 increased in a dose-dependent manner, from 6 mg/kg onwards. At the same dose, declines in plasma HBV viral load, plasma HBsAg, liver HBsAg and HBcAg expression were more pronounced with higher dosing frequency. Plasma HBsAg levels became undetectable with the following regimens: from 6 mg/kg and above BIW, from 14 mg/kg and above QW, at 18 mg/kg Q2W. CXCL10, IFN-alpha, IL-12p40 and IFN-gamma were upregulated at all frequencies tested in a dose-dependent manner, however peak levels tended to decrease and not completely return to baseline upon repeated dosing with the BIW and QW dosing frequencies. QW dosing appeared more effective versus the other dosing frequencies tested for the induction of adaptive immune responses, e.g., increase in plasma anti-HBs antibodies and the induction of spleen anti-HBs IgG-producing B cells and of spleen HBs-specific IFN-gamma-producing T cells. No clinical signs or relevant changes in body weight gain were observed throughout the study.
Conclusion: JNJ-4964 dosing frequency impacted the extent of immune stimulation and anti-HBV effect that JNJ-4964 may trigger in AAV-HBV mice. To trigger adaptive immune responses, as well as an indirect anti-HBV effect, the QW dosing frequency was overall more efficient than the BIW, Q2W and Q4W dosing frequencies. Dosing frequency did not impact safety in AAV-HBV mice.

SAT426

In vitro and in vivo characterization of VIR-2218, an investigational RNAi therapeutic targeting hepatitis B virus

Yesseinia Anglero-Rodriguez[1], Florian Lempp[2], Abigail Liebow[1], Tuyen Nguyen[1], Sarah LeBlanc[1], Charalambos Kaittanis[1], Joseph Barry[1], Adam Castoreno[1], Jonathan Gall[2], Hannah Kaiser[2], Christy Hebner[2], Stuart Milstein[1], Vasant Jadhav[1], Anna Bakardjiev[2].
[1]Alnylam Pharmaceuticals; [2]Vir Biotechnology
Email: chebner@vir.bio

Background and Aims: An RNAi therapeutic targeting HBV RNAs has the potential to contribute to functional cure with finite treatment by decreasing expression of viral antigens, including tolerogenic HBsAg. VIR-2218 is an investigational, N-acetylgalactosamine (GalNAc)-conjugated RNAi therapeutic created using Enhanced Stabilization Chemistry Plus (ESC+) chemistry that targets within the HBV X gene region shared by all HBV transcripts. VIR-2218 is currently in Phase 2 clinical development.
Method: In vitro activity and specificity of VIR-2218 were measured after transfection-mediated delivery of VIR-2218 in multiple cell-based systems. Pan-genotypic activity was determined using luciferase readout in a psiCHECK2-plasmid incorporating the HBx gene in Cos7 cells. HBV mRNA, HBsAg and HBeAg levels were measured in the HBV-expressing HepG2.2.15 cell line. The effects of VIR-2218 on HBsAg and HBeAg levels were also measured in HBV-infected HepG2-NTCP cells. In vivo, HBsAg levels were examined following single or multiple subcutaneous (SC) injections of VIR-2218 in mice transduced with AAV8-HBV encoding HBV genotype D.
Results: Evaluation of in vitro VIR-2218 activity at 50 nM in cells transfected with a psiCHECK2-HBV plasmid encoding sequences representing HBV genotypes A-J demonstrated X mRNA knock-down against all 10 genotypes (22.4% to 51.4% remaining). In HepG2.2.15 cells, VIR-2218 inhibited HBV mRNA in a dose-dependent manner, with an IC_{50} of 766 pM, 2.21 nM, and 499 pM for HBsAg mRNA, HBeAg and HBsAg, respectively. This potent inhibition was confirmed in an authentic infection model in HBV infected HepG2-NTCP cells. In the AAV-HBV mouse model, single SC doses of VIR–2218 at 0.3, 1, and 3 mg/kg resulted in sustained and dose-dependent– reduction of serum HBsAg (34%, 72%, and 92% maximum reduction, respectively). Additionally, mice receiving 1 and 3 mg/kg doses every other week × 6 or monthly × 3, or a single dose at 9 mg/kg, exhibited dose-responsive serum HBsAg reduction, with a maximum of 2.7- to 2.8–log reduction in the highest dose group.
Conclusion: VIR-2218 targets a highly conserved region of the HBV genome and demonstrates pan genotypic effects against HBV in vitro. In vivo, VIR-2218 demonstrates potent, sustained anti-viral activity in the AAV-HBV mouse model. These data support development of VIR-2218 for treatment of patients with HBV.

Email: gepapath@med.uoa.gr

Background and Aims: In the registrational trials 108/110, tenofovir alafenamide (TAF) compared to tenofovir disoproxil fumarate (TDF) was shown to have similar efficacy and improved safety in renal function and bone mineral density (BMD) parameters. However, those trials did not include chronic hepatitis B (CHB) patients with significant renal and/or bone disorders. In Greece, TAF has been reimbursed since February 2018 mostly for patients with impaired renal function [estimated glomerular filtration rate (eGFR) <60 ml/min or serum phosphate <2.5 mg/dl] and/or osteoporosis (T-score < −2.5). Thus, the aim of this study was to assess the characteristics of

CHB patients who started TAF based on the Greek reimbursement criteria and eventually the effectiveness and safety of TAF in such patients.

Method: Adult (≥18 years old) CHB patients who started TAF between 02/2018–10/2019 at 13 clinics participating in the HERACLIS-TAF registry were included. Main exclusion criteria were coinfection with hepatitis D virus, active malignancy and biphosphates use in the last 6 months. Demographic, clinical and laboratory characteristics as well as reason for TAF use were recorded. MDRD formula was used for eGFR estimation. PAGE-B score was calculated at TAF onset.

Results: In total, TAF therapy was initiated in 176 patients (71% males; age: 64 ± 12 years, 64% >60 years old): 11 (6%) nucleos(t)ide analogue (NA) naive and 165 (94%) NA experienced; 157/176 (89%) were directly switched to TAF from other NA(s) (138 from TDF) and 8 (5%) had discontinued NA(s) for >2 months (TDF: 6). The main reason for TAF use was renal in 96 (54%), BMD in 61 (35%) (osteoporosis 44, osteopenia 17) and both renal and BMD disorders/risks in 19 (11%) patients. At TAF onset, 56 (32%) and 24 (13.6%) patients had eGFR <50 and 50–59 ml/min and 19 (11%) patients had phosphate <2.5 mg/dL. Common comorbidities were: hypertension 50%, diabetes 24%, hemodialysis 6%, transplantation 4%. PAGE-B score was low (<10) in 13 (7.4%), moderate (10–17) in 67 (38%) and high (>17) in 60 (34%) patients.

Conclusion: CHB patients who receive TAF in Greece are different than those included in the registrational trials, as all patients have significant renal and/or bone disorders/risks and most patients are old (>60 years), NA(s) experienced with comorbidities usually have moderate/high HCC risk. Future research is expected to evaluate the effectiveness and safety of TAF in this real-world clinical setting.

SAT428

Early PEG-interferon-related ALT flares of high magnitude lead to HBsAg decline and loss. A study of 639 chronic hepatitis B patients

Hannah S.J. Choi[1,2], Mina Farag[1], Willem Pieter Brouwer[3], Milan Sonneveld[3], Jordan Feld[1], Robert De Man[3], Bettina Hansen[1,4], Harry Janssen[1]. *[1]University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]University of Toronto, Institute of Medical Science, Toronto, Canada; [3]Erasmus University Medical Center, Department of Gastroenterology and Hepatology, Rotterdam, Netherlands; [4]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada*
Email: w.p.brouwer@erasmusmc.nl

Background and Aims: Serum alanine aminotransferase (ALT) flares play an important role in assessing nucleos(t)ide analogues (NA) discontinuation and during treatment with novel compounds aiming for functional cure (HBsAg loss). Flares can be a double-edged sword in chronic hepatitis B (CHB), as they may result in accelerated serological response but could also lead to liver failure.

Method: A post hoc analysis of four international randomized trials (HBV-99-01, PARC, ARES, PEGON) involving pegylated interferon (PEG-IFN-α-2a or α-2b)-based therapy was conducted to characterize ALT flares in CHB patients. Patients received PEG-IFN monotherapy (n = 260), de novo PEG-IFN+NA combination therapy (n = 128), PEG-IFN add-on to NA pretreatment (n = 123), or NA monotherapy (n = 128). A flare was defined as an episode of ALT elevation ≥5×ULN after start of therapy, with those occurring within the first 24 weeks considered 'early', and after 24 weeks, 'late'. Patients with NA withdrawal flares were excluded. Logistic regressions were performed to describe the association between flares and serum HBsAg levels.

Results: During a median follow-up of 72 weeks, 111/639(17%) patients experienced at least one flare. The median timing of the first flare was 12 weeks (IQR 4–60) and the median magnitude was 6.6xULN (IQR 5.5–8.6). The flare group was older (36 vs 33 yrs), mostly Caucasian (79% vs 55%), largely genotype A/D (40%/50% vs 22%/38%), with higher baseline ALT (3.5 vs 1.5×ULN), HBV DNA (7.8 vs 5.0 logIU/mL), and HBsAg levels (4.3 vs 3.9 logIU/mL), all p ≤0 .01. Almost all flares (99%) were found in patients who received PEG-IFN-based therapy. Flares were observed in 38/251(15%) patients with PEG-IFN added on NA vs 72/260(28%) with PEG-IFN monotherapy (p < 0.01). Among patients who received combination therapy, more flares were observed in the de novo PEG-IFN+NA therapy group compared to PEG-IFN add-on (36/128(28%) vs 2/123(2%), p < 0.01). In total, 131 patients achieved ≥1log decrease in HBsAg. In univariable analysis, early flare was significantly associated with ≥1 log decline in HBsAg (odds ratio (OR) (95% CI): 3.8 (2.3–6.2), p < 0.01), as were male sex and increasing magnitude and number of flares. In multivariable analysis, compared to having no flare, early flares were independently associated with ≥1log decline in HBsAg (OR: 4.0 (2.2–7.3), p < 0.01). Early ALT elevations ≥5×ULN had a significant effect on serum HBsAg decline (Figure; p < 0.01). Of the 22 patients who achieved HBsAg loss, 16(73%) had at least one flare, which all occurred early during treatment (p < 0.01). Neither decompensation nor death was observed with flares.

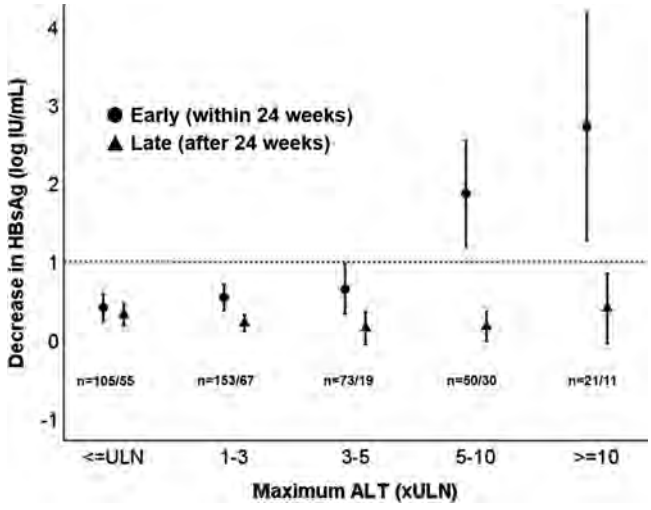

Figure: Association between of maximum serum ALT level and HBsAg decline, occurring early during treatment or late.

Conclusion: Early on-treatment flares were significantly associated with a greater decrease in serum HBsAg and with HBsAg loss compared to late flares or no flares.

Background and Aims: Switching to TAF, a novel tenofovir prodrug, has shown maintenance of viral suppression with stable or improved bone and renal safety at Wk 24 in CHB patients with moderate to severe renal impairment (eGFR by Cockcroft-Gault [$eGFR_{CG}$] <60 mL/min) and ESRD patients on HD. We evaluated the safety and efficacy in these virally suppressed patients with renal impairment 1 year after switching to TAF in a Phase 2 study.

Method: CHB patients with renal impairment receiving TDF and/or other OAVs for ≥48 weeks and virally suppressed for ≥6 months with HBV DNA <20 IU/mL at screening were enrolled into 2 cohorts: 1) moderate-severe renal impairment (eGFRCG 15 to <60 mL/min) and 2) ESRD (eGFRCG <15 mL/min) on chronic HD. All patients were switched to TAF 25 mg QD for 96 weeks (given post-HD on days of dialysis for ESRD patients). Safety assessments including changes in bone (hip and spine BMD) and renal (CrCl by Cockcroft-Gault [$eGFR_{CG}$], serum creatinine) parameters, viral suppression, and biochemical responses were assessed in all patients at Week 48.

Results: 93 patients (mod-severe impairment 78; ESRD 15) were enrolled from 26 sites in 8 countries; 89% of patients remained on study at Week 48. At baseline, 74% were male, 77% Asian, 68% ≥60 y, 83% HBeAg-negative and median ALT was 17 U/L. Up to 25% overall (both cohorts) had osteoporosis at hip and/or spine, and a high proportion had comorbidities (60% HTN, 24% DM). Key efficacy/safety results at Week 48 are summarized in the Table. Efficacy (HBV DNA<20 IU/mL) was maintained in nearly all patients on treatment at Week 48 and a high proportion had normal ALT levels. Five patients discontinued study drug early (withdrew consent) with last available HBV DNA <20 U/mL; 1 patient had HBV DNA ≥20 IU/mL and 1 patient died. Relative to baseline levels, switching to TAF resulted in stable hip/spine BMD in moderate to severe renal impairment patients, with a slight decrease in hip BMD in ESRD patients. Slight improvements were observed in renal parameters including $eGFR_{CG}$ and markers of renal tubular function in moderate to severely impaired patients. TAF was well tolerated, with no Grade 3/4 or serious adverse events related to study drug.

Conclusion: In renally-impaired CHB patients, including ESRD patients on HD, viral suppression was well maintained, and the bone and renal safety were stable or improved 48 weeks after switching to TAF.

Table. Efficacy and safety results at Week 48

n/N (%) or median (Q1, Q3)	Moderate-Severe RI[a] n=78	ESRD on HD[b] n=15
Efficacy		
HBV DNA <20 IU/mL	72/78 (92)[c]	14/15 (93)[d]
ALT normal (2018 AASLD criteria)	68/78 (87)	12/15 (80)
ALT normalization (2018 AASLD criteria)	3/5 (60)	NA

Background and Aims: Treatment of hepatitis D virus (HDV) infection with pegylated interferon alfa (PEG-IFNa) is currently considered the standard of care (SOC). Previous studies demonstrated off-treatment HDV RNA responses in 25–31% of cases. Virological responses regarding HDV RNA were determined with in-house assays with rather high limits of detection. We here aimed to investigate the frequency and impact of low and very low HDV RNA viremia detectable with highly sensitive assays only (LV).
Method: We re-analyzed HDV RNA in samples collected in the HIDIT-2 trial (Wedemeyer et al., Lancet Infectious Diseases 2019) with the Robogene assay (RA; Jena Analytics). In the HIDIT-2 study, patients were treated with PEG-IFN-2a alone or in combination with tenofovir dipivoxil for 96 weeks. Complete samples were available for 93 patients at baseline, week 48, week 96 and follow-up week 24 (week 120). HDV RNA was extracted by manual extraction according to the package insert. The lower limit of detection (LOD) of Robogene assay is 14 IU/ml, quantitative results were here reported above 100 IU/ml only. Data were compared with the previously reported, less sensitive in house assay (IA; Mederacke et al., J Clin Microbiol. 2010;48, 2022–9).
Results: HDV RNA was undetectable by both, the sensitive RA and the IA in 25 (27%), 29 (31%) and 22(24%) patients at treatment weeks 48 and 96 and FU week 24, respectively. Low viremia (IA undetectable/RA positive) was detected in 15 (16%), 13 (15%) and 7 (8%) patients at these time points with very low viremia below 100 IU/ml in most cases. Low HDV viremia detectable at week 48 or week 96 was associated with a high risk for post-treatment relapse (positivity in both assays at FU week 24 in 10/15 (67%) for week 48 LV samples and 10/13 (77%) for week 96 LV samples). In contrast, the post-treatment relapse rate was lower in patients with undetectable HDV RNA in both assays during treatment (6/25 (24%) for week 48 undetectable samples and 6/29 (21%) for week 96 undetectable samples). Low HDV viremia post treatment at week 120 was not associated with biochemical hepatitis in most cases as only 2/7 patients had elevated ALT levels, one of those with a viremia of 416 IU/ml.
Conclusion: Re-testing of HIDIT-2 samples with a very sensitive commercial HDV RNA assay identified that one quarter to one third of samples being previously classified as undetectable were actually HDV RNA positive. Detection of low HDV viremia at week 48 or end of treatment was associated with a high risk for post-treatment virological relapse. Thus, future trials should use sensitive assays to determine treatment response. The clinical meaning of off-treatment low viremia requires further investigation.

Email: htan@aligos.com

Background and Aims: Current standard of care for chronic hepatitis B (CHB) can effectively inhibit viral DNA replication but fails to reduce HBsAg that suppresses the human immune system. Previously, we have identified S-antigen Transport-inhibiting Oligonucleotide Polymers (STOPs) that share structural similarity with Nucleic Acid Polymers (NAPs) but contain several novel chemical features. STOPs can reduce HBsAg secretion by potentially affecting protein trafficking from the infected cell resulting in intracellular degradation of HBsAg. In this study, inhibition of HBV DNA or HBsAg secretion by STOPs was examined in pairwise or triple combinations with nucleos(t)ides, core assembly modulators (CAMs), and HBV-specific antisense oligonucleotides (ASOs).
Method: STOPs were synthesized on ABI 394 and Expedite 8909 synthesizers using standard phosphoramidite chemistry. In vitro combination studies were performed using the HepG2-derived HBV-producing stable cell line, HepG2.2.15. STOPs and ASO's were administered by transfection using RNAiMAX. Compounds were added to cells in a checkerboard fashion and inhibition of HBV replication measured by HBV DNA or HBsAg release assays 6 days after compound addition. Data were analyzed using the Bliss-Independence model using Pritchard's MacSynergy II.
Results: In HepG2.2.15 cells STOPs exhibit potent anti-HBsAg activity with EC_{50} values in the low nanomolar range. When tested in pairwise combinations with other inhibitors, STOPs demonstrated significant synergy (synergy volume of >100 uM^2%), synergy (25–100 uM^2%) or additivity (0–25 uM^2%); no antagonistic effects were observed. Combination of STOPs and ASOs exhibited the greatest potential for synergy with compound-dependent synergy volumes ranging from 343.05 uM^2% (ALG-010133and ALG-020002) to 3.87 uM^2% (ALG-010093 and ALG-020205). Anti-HBV DNA activity was tested in STOP pairwise combinations with nucleos(t)ides and CAMs. STOPs demonstrated minor synergy with nucleos(t)ides (synergy volumes of 25.91 uM^2% and 29.01 uM^2%) and additive interactions with CAMs (1.35 uM^2%). No antagonistic effects were observed.
Conclusion: Future functional cure for CHB will require a combination of compounds with different mechanisms of action. STOPs demonstrate an in vitro antiviral profile that suggests they may become an important component of functional cure combination therapy. To this end, our STOP compounds are currently advancing towards combination clinical trials in CHB.

Bile acid derivatives inhibit hepatitis B virus infection in vitro and in vivo

Kiyoaki Ito[1], Akinori Okumura[1], Koichi Watashi[2], Masashi Yoneda[1]. [1]*Aichi Medical University, Department of Gastroenterology, Nagakute, Japan;* [2]*National Institute of Infectious Diseases, Department of Virology II, Tokyo, Japan*
Email: itokiyo@hotmail.co.jp

Background and Aims: Chronic hepatitis B virus (HBV) infection remains a major health problem worldwide. Currently, the first-line treatment for HBV is nucleos(t)ide analogs or interferon (IFN); however, efficient therapeutic approaches to achieving a cure are lacking. Therefore, novel anti-HBV agents with different mechanisms from current drugs are needed. Recently, sodium taurocholate cotransporting polypeptide (NTCP) was identified as an HBV receptor, and it is strongly and negatively regulated by bile acid (BA)-activated FXR via induction of small heterodimer partner (SHP). We hypothesized that BA derivatives, which are FXR agonists, would block HBV entry efficiently by inhibiting NTCP.
Method: HepG2-hNTCP-C4 cells in which NTCP was forcibly expressed in cell lines and fresh human hepatocytes (PXB-cells) collected from chimeric mice were used to examine the efficacies of BA derivatives against HBV as *in vitro* study. HepG2.2.15 cells which were stable HBV expression cells were also used to evaluate the mechanisms of strong inhibitory effect against HBV by FXR/TGR5 dual agonist (dual agonist). We also employed uPA/SCID mice with humanized liver (PXB mice) to examine the efficacy of dual agonist against HBV infection *in vivo*.
Results: In the infection experiments of HBV with HepG2-hNTCP-C4 and PXB-cells, dual agonist showed a strong dose-dependent inhibitory effect against HBV. On the other hand, dual agonist did not show any inhibitory effect against HBV in HepG2.2.15 cells. In the binding assay between TAMRA fluorescently labeled HBV preS1 protein and NTCP on the liver cell membrane, dual agonist showed strong inhibitory effect. Dual agonist severely prolonged the initial rise of hepatitis B surface antigen (HBsAg) and hepatitis B-e antigen (HBeAg), and significantly suppressed the HBV DNA during administration in PXB mice.
Conclusion: Our results suggest that BA derivatives are prospective candidate anti-HBV agents. By analyzing in detail the mechanism of dual agonist's strong anti-HBV effects, it leads to the development of more effective and safer anti-HBV agents.

Early on-treatment ALT normalization in patients with chronic hepatitis B is associated with lower risk of hepatocelluar carcinoma development

Jong Eun Yeon[1], Sehwa Kim[1], Min-jin Lee[1], Young-Sun Lee[1], Ji Hoon Kim[1], Yeon Seok Seo[2], Hyung Joon Yim[3], Soon Ho Um[2], Kwan Soo Byun[1]. [1]*Seoul, Department of Internal Medicine, Korea University College of Medicine, Seoul, Korea, Rep. of South;* [2]*Seoul, Department of Internal Medicine, Korea University College of Medicine, Seoul, Korea, Rep. of South;* [3]*Gyeonggi-do, Department of Internal Medicine, Korea University College of Medicine, Seoul, Korea, Rep. of South*
Email: jeyyeon@hotmail.com

Background and Aims: Recently, the use of potent antiviral agents has made it possible to effectively reduce liver disease related events such as hepatic encephalopathy, variceal bleeding, ascites, and HCC in patients with chronic hepatitis B. The aim of this study was to determine whether there is a relationship between normalized ALT resulting from the use of antiviral agents and the occurrence of liver disease related events.
Method: From 2007 to 2018, we studied 427 patients treated with entecavir or tenofovir at Korea University Guro Medical Center. The patients divided into ALT normal group and ALT abnormal group after 1 year of antiviral treatment. The ALT normal level is 34 for men, 30 for women in the KASL standard, and 35 for men and 25 for women in the AASLD standard. Liver related disease included HCC, hepatic encephalopathy, variceal bleeding, and ascites.
Results: The baseline characteristics of 427 patients median age was 50 (IQR 42~57), median value of AST was 78 (IQR 47~135), ALT was 88 (IQR 45~178), HBV DNA(IU) was 2,190,000 (IQR 170,000~36,815,316IU), and AFP was 7.05(IQR 3.325~26.025). 67% of all patients were male and 33% were female. 61.4% of patients used entecavir and 46.4% of patients used tenofovir. The people who used both drugs sequentially were 7.5%. Patients with HBeAg-positive were 54.8% and patients with anti-HBe Ab positive were 50.8%. Overall survival in ALT abnormal group was lower than ALT normal group after 1 year of antiviral treatment without statistical significance (Log rank test, $P = 0.201$ in the KASL standard and $P = 0.265$ in the AASLD standard). The cumulative incidence of HCC in normal ALT group was significantly lower than abnormal ALT group (Log rank test, $P < 0.001$ in both the KASL and AASLD standard). The incidence of Liver disease related events in the two group was not significant. (Log rank test, $P = 0.333$ in the KASL and $P = 0.428$ in AASLD standard).
Conclusion: ALT normalization after 1 year of entecavir and tenofovir treatment is correlated with reduction of development for HCC, but not overall survival and development of liver disease related events. Patients who failed to normalize ALT after 1 year of entecavir and tenofovir treatment should be observed more carefully for development of HCC.

Best in class hepatitis B virus anti-sense oligonucleotides: next generation bridged nucleic acid chemistries significantly improve the therapeutic index by reducing hepatotoxicity and increasing in vivo efficacy in a mouse model

Jin Hong[1], Rajendra Pandey[1], Vivek Rajwanshi[1], Dinah Misner[1], Hua Tan[1], John Cortez[1], Yuchun Nie[1], Suping Ren[1], Dana Cho[1], Laxman Eltepu[1], Tilani De Costa[1], Priya Mishra[1], Kang Hyunsoon[1], Aneerban Bhattacharya[1], Sushmita Chanda[1], David Smith[1], Julian Symons[1], Lawrence Blatt[1], Leonid Beigelman[1]. [1]*Aligos Therapeutics, Inc., South San Francisco, United States*
Email: jhong@aligos.com

Background and Aims: Reducing hepatitis B virus (HBV) S antigen (HBsAg) is key to achieving functional cure in chronic hepatitis B (CHB) patients. Antisense oligonucleotides (ASOs) are effective in reducing HBsAg in animal models, and CHB patients. However, hepatotoxicity is a major side effect of ASOs and is exacerbated with high affinity more active Locked-Nucleic Acid (LNA) modified ASOs. Next generation Bridged Nucleic Acid (BNA) and nucleobase modified monomers can reduce hepatotoxicity while maintaining efficacy. We have therefore applied these chemistries in our LNA-containing HBV targeting ASOs.
Method: ASOs with LNA and BNA chemistries were synthesized on ABI 394 and Expedite 8909 synthesizers using standard phosphoramidite chemistry. In vitro screening of LNA ASOs was carried out in HepG2.2.15 cells using a HBsAg release assay. Potent LNA-containing ASOs were chosen for N-Acetylgalactosamine (GalNac) conjugation and tested at 3 × 10 mg/kg every 3 days in the adeno-associated virus (AAV)-HBV mouse model. BNA wing and nucleobase gap modifications were applied per an in-house algorithm and compared to its all-LNA ASO.
Results: The structure activity relationship (SAR) of BNA wing and nucleobase gap modifications were explored across a set of diverse LNA ASOs. For ALG-020089, an LNA-containing ASO in the HBx region, targeting all HBV transcripts including HBx, a single replacement of a 5-methyl LNA C in the wing with 5-methyl spirocyclopropyl C improved the nadir for HBsAg by 0.5 $\log_{10}$ IU/ml while reducing serum alanine aminotransferase (ALT) by 3-fold. In ALG-020090, another HBx region LNA ASO, a single replacement of deoxy-T in the gap with 2-thio T reduced serum ALT by 30-fold to normal levels while maintaining in vivo activity. Interestingly, these

modified ASOs demonstrate equal potency to an ASO (SSO-2) currently in clinical development but eliminated the ALT elevations in mice associated with the compound. Furthermore, combination of HBsAg and HBx region ASOs demonstrated additive to synergistic antiviral activity in vitro.
Conclusion: We demonstrated that applying next generation BNA and nucleobase chemistries in LNA ASO gapmers can significantly improve the in vivo therapeutic index. A combination of HBsAg and HBx region ASOs demonstrated that these novel nucleotide chemistries could lead to best in class anti-HBV ASOs. Currently, these novel ASO therapeutics are being advanced into clinical trials for CHB.

Background and Aims: About 257 million persons are living with chronic hepatitis B virus (HBV) infection worldwide, which is responsible for 887,000 annual deaths. The African region has a HBV prevalence of 6.1%. To mitigate this burden, the World Health Organization (WHO) issued HBV care and treatment guidelines in 2015 for low resource countries. We report early results of the implementation of HBV care and treatment programs in Tanzania following WHO guidelines with HBV DNA testing capacity.
Method: A five year demonstration project was launched in December 2016 at Muhimbili National Hospital in Dar es Salaam. Clinical and laboratory staff at each site received training regarding the delivery of HBV-directed care and HBV-related laboratory testing. Participants were recruited from Tanzania's National Blood Donation Program where donors are systematically screened for HIV, hepatitis C, syphilis, and hepatitis B surface antigen (HBsAg). Participants were invited to participate in the program if they tested negative for HIV and HCV, and were HBsAg-positive. Participants were examined for clinical signs of liver disease and received HBV-related laboratory testing every 6–12 months for assessment of antiviral treatment eligibility by WHO criteria. Tenofovir disoproxil fumarate (TDF) was provided for treatment-eligible participants.
Results: After 34 months, 1,465 participants were enrolled: 905 with complete laboratory results, 298 with two clinic visits, and 28 with three clinic visits. Median age for patients with complete lab results was 34 years (IQR 28–42), 874 (68%) male. Of these, 144 were treatment eligible by WHO guidelines, and 81 were started on TDF. Among those treated HBV DNA values decreased significantly from a median of 28,694 (IQR 52–691,983) to 22 (IQR 20–394), $p = 0.003$, and remained stable for those not treated ($p = 0.96$); median ALT values also decreased significantly from 44 (26–116) to 27 (18–41) ($p = 0.001$). Of enrolled patients, 22 were diagnosed with hepatocellular carcinoma. Challenges included drug licensure, patient affordability of HBV-related testing, and overwhelming demand for HBV services.
Conclusion: HBV care and treatment is feasible in low-resources settings, however testing and linkage to care is critical to decrease the global burden of hepatitis B. Most persons who were treatment eligible had advanced liver disease indicating the need for HBV management in Sub-Saharan Africa.

SAT438
Solving the cold chain problem - development of a heat-stable therapeutic vaccine to combat chronic hepatitis B

Julia Sacherl[1], Anna Kosinska[1], Katrin Singethan[1], Kristina Kemter[2], Martin Kaechele[1], Lisa Wolff[1], Sandra Essbauer[3], Sabine Hauck[2], Ulrike Protzer[1]. *[1]Institute of Virology, School of Medicine, Technische Universität München/Helmholtz Zentrum München, Munich, Germany; [2]LEUKOCARE AG, Martinsried, Germany; [3]Bundeswehr Institute of Microbiology, Virology and Intracellular Agents, Munich, Germany*
Email: protzer@tum.de

Background and Aims: The simultaneous induction of B- as well as virus-specific effector T-cell responses seems to play an important role for an effective therapeutic vaccine against chronic hepatitis B. Therefore, we developed a heterologous protein prime, modified vaccinia virus Ankara (MVA)-boost therapeutic vaccine which proved to break immune tolerance in various chronic hepatitis B mouse models. A major challenge of worldwide vaccine application is that the vaccine components require appropriate cooling during transport and storage to maintain efficacy. This is an important logistic and financial challenge in particular in low- and middle-income countries and areas with high outdoor temperatures. To prevent loss of vaccine efficacy due to thermal instability, we aimed to develop a new, lyophilized, heat-stable vaccine containing hepatitis B virus (HBV) surface (HBsAg) and core antigen (HBcAg), as well as an MVA vector expressing core and S protein (MVA-S/C).
Method: Vaccine components were formulated with stabilization and protection solutions (SPS®) platform technology. Integrity of the antigens after thermal stressing was analyzed by ELISA, Western Blot (WB), native agarose gel electrophoresis (NAGE), dynamic light scattering (DLS) and transmission electron microscopy (TEM). MVA-S/C infectivity was evaluated by $TCID_{50}$. Immunogenicity and safety of our vaccine were validated in wild-type (WT) and adeno associated virus (AAV)-HBV-transduced mice.
Results: Our *in vitro* results demonstrated a very good thermostability of the SPS®-formulated vaccine components. These stabilized components maintained antigen integrity, stability and quality as well as viral infectivity, even after a 40 °C temperature challenge for one month or a 25 °C challenge for 12 months. *In vivo* experiments in WT-mice showed that all stabilized vaccine components were very well tolerated and induced strong HBsAg-specific and HBcAg-specific $CD8^+$ T-cell response as well as high-titer HBV-specific antibodies despite the temperature stressing. Even after 12 months storage at 25 °C we could show that our stabilized vaccine was safe, able to suppress antigen levels and HBV-replication in AAV-HBV-transduced mice as well as capable of breaking immune tolerance.
Conclusion: Our results demonstrate that SPS®-formulation allows to generate a highly functional and heat-stable vaccine to combat chronic hepatitis B worldwide, especially in countries without functional cooling chains.

SAT439
Multicistronic DNA-based therapeutic vaccine as a promising candidate to treat chronic hepatitis B virus (HBV) infection

Helene Kerth[1,2], Anna Kosinska[1,2], Martin Kaechele[1], Andreas Oswald[3], Jinpeng Su[1], Percy A. Knolle[2,4], Ulrike Protzer[1,2]. *[1]Institute of Virology, Technical University / Helmholtz Centrum Munich, Germany; [2]Center for Infection Research (DZIF), Munich Partner site; [3]Institute of Virology, Technical University Munich, Munich, Germany; [4]Institute of Molecular Immunology and Experimental Oncology, Technical University Munich, Munich , Germany*
Email: kerthhelene@gmail.com

Background and Aims: Induction of HBV-specific immune responses by therapeutic vaccination represents promising novel therapy to cure chronic HBV infection. We have developed a clinical candidate therapeutic hepatitis B vaccine (*TherVacB*), based on two protein immunizations with recombinant surface and core antigens (HBsAg, HBcAg) and a boost with Modified Vaccinia virus Ankara vector

(MVA) expressing HBV antigens. Disadvantages of very complicated and expensive purification of the recombinant proteins for clinical use could be overcome by DNA-based vaccines which lead to production of the antigens of interest directly *in vivo*. Therefore, we aimed to generate DNA vaccine covering the most common HBV genotypes and serotypes to broaden and improve B- and T-cell immune responses elicited by *TherVacB*.

Methods: Therapeutic DNA based vaccine (DNA-HBVac), encoding HBV small and large envelope proteins of genotypes A and B/C, core protein of genotypes B/C and D and HBV reverse transcriptase (RT) domain was generated. Western blotting and ELISA were used to examine stability and integrity of the expressed antigens *in vitro*. Immunogenicity of DNA-HBVac was assessed in C57BL/6 mice and AAV-HBV mouse model reflecting persistent HBV infection. HBV-specific B- and T -cell responses were determined by ELISA and flow cytometry.

Results: *In vitro* analysis showed that all DNA-HBVac-encoded HBV proteins were properly expressed. Immunization of C57BL/6 mice with DNA-HBVac prime and MVA-HBVac boost proved to be safe and well tolerated. The regimen resulted in very strong HBV-specific CD8 and CD4 T-cell responses as compared to previous immunization strategies, but as expected low anti-HBs response. Employing persistent HBV infection model, AAV-HBV-transduced mice, we could demonstrate that priming with DNA-HBVac elicited strong core-, envelope-, and RT-specific CD8 T-cell response in the livers of the mice. Moreover, we have observed significant serum ALT elevation during DNA-HBVac vaccination, suggesting increased cytotoxic T cell activity in the liver. These vigorous HBV-specific CD8 T cell responses resulted in a significant serum HBsAg and HBeAg reduction and even HBV clearance in some mice.

Conclusion: Our results show that DNA-HBVac may be a promising alternative for the classical recombinant protein priming for *TherVacB* regimen, without the need for labor intensive and expensive recombinant protein purification.

EDP-514, a novel pangenotypic class II hepatitis B virus core inhibitor: preliminary results of a phase 1 study in healthy adult subjects

Kajal Larson[1], Alaa Ahmad[1], Eoin Coakley[1], Jingwen Chai[1], Daniel Dickerson[2], Nathalie Adda[1]. *[1]Enanta Pharmaceuticals, Inc, Watertown, United States; [2]PRA Health Sciences, Lenexa, Lenexa, United States*
Email: bruscar94114@gmail.com

Background and Aims: Chronic hepatitis B (CHB) is a global public health challenge with an unmet medical need for curative therapy, i.e., a finite treatment which yields a sustained post-treatment response. EDP-514 is a potent inhibitor of HBV replication with an *in vitro* EC_{50} of 18, 27 and 17 nM in HepAD38, HepDE19, and HepG2.2.15 cells, respectively, and a >4-log viral load reduction in HBV-infected chimeric mice with human liver cells. Here, we present preliminary pharmacokinetic (PK) and safety results of single ascending doses (SAD) of EDP-514 from an ongoing SAD and multiple ascending dose (MAD) phase 1 study in healthy subjects (HS).

Method: A randomized, double-blind, placebo (PBO)-controlled study is being conducted to characterize the safety and PK profile of SAD and MAD, and food effect (FE) in HS. Fifty subjects (EDP-514 [n = 38] or PBO [n = 12]) were enrolled into 6 SAD cohorts (Table 1); in the MAD phase, 32 subjects are planned to receive either EDP-514 (n = 24) or PBO (n = 8).

Results: The blinded safety data demonstrate that adverse events (AEs) were infrequent, mild in intensity, and with no severe or serious AEs, and no AEs that led to study drug discontinuation. Only the event of mild headache was observed in 4 subjects and resolved in follow-up. No clinically significant laboratory test abnormalities or pattern of abnormalities was observed.

Based on preliminary PK results, EDP-514 exposure increased with increasing single doses in an approximately dose-proportional manner, up to 600 mg (Table 1). The mean plasma concentration at 24 hr ranged from 2.4- to 10.7-fold higher than the *in vitro* serum protein adjusted EC_{50} of 71 ng/mL.

Conclusion: In the SAD phase, EDP-514/PBO was generally safe and well-tolerated, with favourable PK exposures supporting once daily dosing. Further data from MAD cohorts in HS will be presented.

SAT441

Novel cell culture 3D model for HBV/HIV co-infection and antiviral evaluation

Leda Bassit[1], Christina Gavegnano[1], Kiran Verma[1], Ruby Kleinbard[1], James Kohler[1], Jan Mead[1], Raymond F Schinazi[1]. *[1]Emory University School of Medicine , Center for AIDS Research, Laboratory of Biochemical Pharmacology, Department of Pediatrics, Atlanta, United States*
Email: lbassit@emory.edu

Background and Aims: The impact of prior HIV-1 infection on the development of chronic hepatitis B infection accelerates progression of HBV-related liver disease, increases persistent infection, risk of hepatocellular carcinoma, and liver-related mortality; It also increases HBV DNA levels and lowers HBeAg loss and $CD4^+$T cells. A relevant *in vitro* model should be able to quantify these effects as well as the impact of novel antivirals on these events. Our objective was to develop a 3D model that mimics native tissue environment, allowing co-culture and maintenance of phenotype and function.

Method: Using magnetized cells with nanoshuttle bioprinting solution, we built organoids with HepAD38 or HepG2-NTCP cells with or without $CD4^+$T cells. Cells were infected with HBV (for HepG2-NTCP) or HIV-1 (for $CD4^+$ T cells). We measured p24 antigen (ELISA) and HIV-1 RNA (RT-PCR) for HIV-1, and HBeAg (ELISA) and HBV DNA and cccDNA (qPCR) for HBV. We assessed a panel of antiviral drugs including tenofovir alafenamide (TAF), entecavir (ETV) and our HBV capsid assembly modulator (GLP-26 – AAC, PMID: 31712213, 2019) in this organoid system.

Results: Novel 3D co-cultured organoids were created and permissive to HBV/HIV-1 infection. Immunofluorescence confirmed the presence of HIV-1 (p24 antigen) and/or HBV (core antigen) in these organoids (Fig.1). No apparent cytotoxicity was observed on both cell types when they were co-cultured with or without HIV-1. HepG2-NTCP plus $CD4^+$T cells secreted HIV-1 p24 antigen and were positive for HIV-1 RNA. Presence of HIV-1 in co-cultured organoids did not

Table: (abstract: SAT440): Preliminary PK results of EDP-514 in the SAD phase

Dose (mg)	$AUC_{0\text{-inf}}$ (ng/mL*hr)	C_{max} (ng/mL)	C_{24} (ng/mL)	T_{max} (hr)	$T_{1/2}$ (hr)
50	10588 (30.2)	559 (18.2)	171 (37.3)	3 (1–5)	17.2 (9.1)
100	16388 (26.1)	876 (41.8)	239 (32.5)	3 (1–5)	25.2 (39.6)
200	19962 (18.6)	1030 (20.3)	338 (28.9)	3.5 (2–4)	15.6 (15.9)
400	34194 (36.6)	2244 (45.4)	490 (38.4)	3 (2–4)	18.3 (39.3)

Data presented as mean (%CV) except for T_{max} (median [range]); Doses were given fasted except as indicated.

increase levels of HBV DNA or cccDNA. TAF or ETV inhibited HIV-1 RNA replication in co-cultured and coinfected cells. TAF, ETV or GLP-26 similarly inhibited HBV DNA replication in HepAD38 cells mono- or -cocultured with $CD4^+$T cells, with or without HIV-1. GLP-26 in the presence or absence of HIV-1 inhibited HBV DNA replication more potently than TAF or ETV, with EC_{90} values 3- to 7-fold lower for GLP-26 *versus* TAF or ETV.

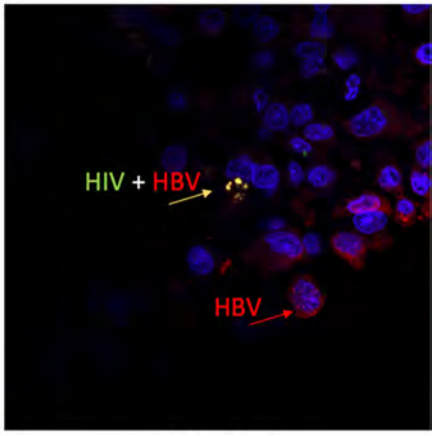

Figure 1: Immunofluorescence image of 3D co-cultured HepAD38 plus $CD4^+$T cells co-infected with HIV-1.

Conclusions: Organoids contained HBV (HepAD38 or HepG2-NTCP) and HIV-1 ($CD4^+$T) permissive cells supported productive HBV and/or HIV-1 replication. This novel model was reproducible and provided multiple and simultaneous modalities to quantify HIV-1 and HBV replication; this system can be used to measure key cellular events that drive pathogenesis of HIV-1/HBV in co-infected individuals, and can also be used to identify novel agents that block these events in the context of a relevant cellular system of co-infection. More importantly, we validated this novel organoid system of co-infection as a model for HBV infection and antiviral evaluation.

SAT442

Safety and efficacy of switching to tenofovir alafenamide (TAF) in virally suppressed chronic hepatitis B (CHB) patients with hepatic impairment: week 48 results from a phase 2 open label study

Email: limys@amc.seoul.kr

Background and Aims: Switching to TAF, a novel tenofovir prodrug, has shown maintenance of viral suppression with stable or improved bone and renal safety at Wk 24 in CHB patients with impaired hepatic function. Here we evaluated the efficacy and safety 48 weeks after CHB patients with hepatic decompensation were switched to TAF.
Method: In this Phase 2 study (NCT03180619) patients with CHB having a Child–Turcotte–Pugh (CTP) score ≥7 and ≤12 at screening, or by documented history, receiving TDF and/or other OAVs for ≥48 weeks, with HBV DNA <LLOQ for ≥24 weeks and <20 IU/mL at screening were eligible to participate. All patients were switched to TAF 25 mg QD and were to be treated for 96 weeks. Safety assessments including changes in bone (hip and spine BMD) and renal (CrCl by Cockcroft-Gault [$eGFR_{CG}$], serum creatinine) parameters, viral suppression, and biochemical responses were assessed at Week 48.
Results: 31 patients were enrolled at 18 sites in 7 countries and 90% completed 48 weeks of treatment. At baseline, 74% were ≥50 y, 68% male, 81% Asian, 90% HBeAg-negative, with median fibrotest (FT) score 0.81, median CTP and MELD scores of 6 and 10, respectively, median $eGFR_{CG}$ 98 mL/min, and 19% and had osteoporosis by T score at spine. Prior use of TDF and entecavir was reported by 68% and 45%, respectively. Key efficacy/safety results at Week 48 are summarized in the Table. By missing equals failure analysis, 31 patients (100%) had HBV DNA <20 IU/mL, 81% had normal ALT and CTP/MELD scores were stable. After switching to TAF in this population with liver impairment, CTP, MELD, and FT scores were unchanged while bone and renal parameters were stable. TAF was well tolerated with few having Grade 3 or 4 AEs (4 patients); no serious AEs related to study drug, and 1 patient who discontinued for worsening renal function unrelated to TAF.
Conclusion: CHB patients with hepatic impairment who were switched to TAF from TDF or other OAV showed high rates of viral suppression, normal ALT and bone and renal safety were stable at Week 48.

SAT443

Prospective evaluation of qHBsAg decline in patients affected by chronic hepatitis B, E genotype, treated with entecavir or tenofovir

Lucio Boglione[1], Ilaria De Benedetto[1], Tommaso Lupia[1], Giuseppe Cariti[2], Giovanni Di Perri[3]. *[1]University of Turin, Medical Sciences, Italy; [2]Amedeo di Savoia Hospital, Medical Sciences, Turin, Italy; [3]University of Turin, Medical Sciences, Turin, Italy*
Email: lucio.boglione@unito.it

Background and Aims: European clinical practice guidelines (EASL) on chronic hepatitis B recently recognized the importance of migration flows in changing the prevalence and incidence of hepatitis B infection in low endemic European countries such as Italy and Germany. Phylogenetic analyses have shown that genotype E, which is mainly diffused in West Africa, is relatively recent. No data were available about a different serological or virological response in naïve patients affected by chronic hepatitis B (CHB), E genotype treated with tenofovir (TDF) or ETV. The aim of this study was the prospective evaluation of serological and virological response in a cohort of CHB patients with E genotype treated with TDF or ETV and followed for at least 5 years.
Method: we prospectively evaluated qHBsAg decline in chronic hepatitis B, HBeAg-negative, E genotype, treated with tenofovir 245 mg (TDF) or ETV 0.5 mg from 2008 to 2014. Inclusion criteria were: naïve patients with active chronic hepatitis B (CHB) without other viral co-infection. qHBsAg test was performed with ARCHITECT HBsAg (Abbott Diagnostics, Ireland). Serum HBV-DNA levels were quantified by the Real Time PCR COBAS AmpliPrep/COBAS TaqMan HBV Test 2.0 (Roche Molecular Systems, NJ, USA).
Results: sixty-five patients (89.2% males) were enrolled. Median age was 29 years [IQR 22–36] and the most prevalent route of transmission was familiar (25; 38.5%). Median liver stiffness was 7.4 kPa [IQR 4.5–9.3], ALT 65 U/L [IQR 31–122], HBV-DNA 3.4Log IU/ml [IQR 2.8–4.5], qHBsAg3.4Log UI/ml [IQR 2.8–4.5]. According to clinical evaluation, 40 patients (61.5%) started ETV whereas 25

Table. Efficacy and Safety Results at Week 48

n/N (%), or median (Q1, Q3)	TAF (N=31)
Efficacy

Figure: (abstract: SAT442)

patients (38.5%) TDF. The qHBsAg decline was significantly higher in patients treated with TDF at any time-points and after 5 years the median decline with ETV was 0.31 LogIU/mL and 0.68 LogIU/mL with TDF. At the same time-points higher response rate in HBV-DNA suppression were observed in patients receiving TDF. In the absence of resistance-associated mutations, in 20% of ETV-patients HBV-DNA persisted detectable at 5 years. In univariate analysis for qHBsAg decline the following factors were considered: age, sex, qHBsAg and HBV-DNA at baseline, liver stiffness, type of therapy. In the multivariate analysis the only predictive factor for qHBsAg decline is the treatment with TDF ($\beta = -0.119$; DS = 0.025; $p < 0.001$).
Figure: qHBsAg decline after 5 years of therapy in patients affected by CHB and treated with ETV or TDF.
Conclusion: in E genotype the patients treated with TDF showed greater qHBsAg decrease after 5 years than ETV; virological response was higher in TDF than ETV groups. The reason of this finding was unknown and further studies are required to explain this aspect. According to our results, however, TDF could represent the optimal choice in this setting of patients.

SAT444

Low HBcrAg and HBsAg levels identify patients most likely to achieve sustained response after nucleos(t)ide analogue cessation: results from a global individual patient data meta-analysis (create study)

Email: m.j.sonneveld@erasmusmc.nl

Background and Aims: Sustained response is observed in a limited number of patients after cessation of nucleo(s)tide analogue (NA) therapy. We aimed to study the relationship between serum levels of hepatitis B core related antigen (HBcrAg) and HBsAg at treatment

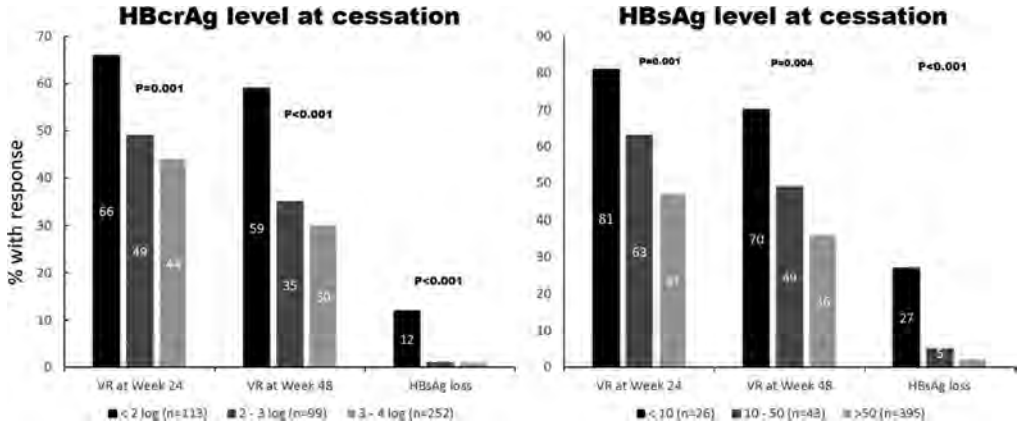

Figure: (abstract: SAT444): Observed response rates across HBcrAg and HBsAg level at treatment cessation. VR: virological response.

cessation and subsequent sustained virological response and HBsAg loss.

Method: We performed an individual patient data meta-analysis of patients who discontinued NA therapy in compliance with EASL criteria. Patient data was acquired from 9 cohorts from Asia and Europe. HBcrAg and HBsAg were measured at treatment cessation. Studied endpoints included virological response (VR, defined as HBV DNA <2,000 IU/mL) and HBsAg loss at 24 and 48 weeks off-treatment. Retreatment was based on HBV DNA and ALT criteria, and retreated patients were considered non-responders.

Results: We analysed 464 patients, of whom 317 (68%) were male and 75 (16%) were HBeAg positive at the time of treatment initiation. Median treatment duration was 294 weeks (IQR: 196–428), and median duration of consolidation therapy was 102 weeks (IQR: 56–165). Patients were treated with ETV/TDF/other in 61%/27%/12%. VR was observed in 234/464 (50%) at week 24 and 155/401 (39%) at week 48 post-treatment. HBsAg loss was observed in 17 (4%) patients. 216 patients were retreated during the follow-up period, with HBV DNA elevation (76%) and ALT flare (21%) the main indications. All resolved without sequelae after retreatment. VR at week 24 was observed in 74/113 (66%) of patients with HBcrAg <2 log at treatment cessation, compared to 44% in patients with HBcrAg >3 log (p = 0.001; figure 1). Similar results were observed at post-treatment week 48. HBsAg loss was observed in 12% of patients with HBcrAg <2 log at treatment cessation, versus 1% in patients with HBcrAg >3 log (p < 0.001). Similarly, VR at week 24 was observed in 21/26 (81%) of patients with HBsAg <10 IU/mL, versus 47% in patients with HBsAg >50 IU/mL (p = 0.001) at treatment cessation. Similar results were obtained when response was assessed at post-treatment week 48. HBsAg loss was observed in 27% of patients with HBsAg <10 IU/mL at treatment cessation, versus 2% in patients with HBsAg >50 IU/mL (p < 0.001). Findings were consistent when limited to the subset of patients who were HBeAg-negative at start of NA therapy.

Conclusion: In this global individual patient data meta-analysis of patients who discontinued NA therapy, low HBcrAg (<2 log) and low HBsAg levels (<50 IU/mL) at treatment cessation were associated with highest rates of VR and HBsAg loss. These cut-offs could be used for an improved selection of patients for NA cessation.

Email: maria.cortese@vhir.org

Background and Aims: A low but relevant percentage of successfully treated patients with chronic Hepatitis B develop hepatocellular carcinoma due to the continuous intrahepatic expression of viral proteins. A therapy based on gene silencing could be a useful approach in these cases, and the X gene (HBX), thanks to its co-terminal localization, could be an optimal target. Here we presented a new system of gene silencing based on antisense locked nucleic acid (LNA) Gapmer that targets some hyper-conserved regions of HBX.

Method: HepG2-NTCPs were treated with DMSO 2.5% at least 14 days. They were infected with Hepatitis B virus (HBV) at multiplicities of genome equivalents of 250–500 by 1 hour (h) of spinoculation at 37°C followed by a maximum of 24 h of incubation. At 48 h post infection cells were transfected, using TransIT-X2, with 4 different antisense LNA Gapmers (GP1 to 4) from 12.5 to 100nM. Cells and supernatants were collected at 72 h post treatment. Extracellular HBV e antigen (HBeAg) and s antigen (HBsAg) were quantified using a chemiluminescent immunoassay (CLIA). Intracellular RNA was extracted using RNeasy micro kit and pregenomic RNA (pgRNA) was quantified by RT-qPCR using Taqman probe. A scrambled control Gapmer was included in each experiment.

Results: At the lowest concentration tested, GP1 and GP4 efficiently inhibited HBeAg expression (respectively 68.6 and 54.8% of inhibition related to the mock-untreated). At 50nM the reduction related to the scramble was 68.9 and 53% for HBeAg and 76.8 and 62% for HBsAg. The association of GP1+GP4 and GP2+GP3 did not increase the inhibition of viral protein expression (respectively 60.5 and 24.4% for HBeAg and 65.4 and 28.1% for HBsAg). Mock-untreated HBV infected cells actively produced pgRNA reaching an amount of 4 log of copies/ng of total RNA. GP treatment induced a reduction of pgRNA, related to the scramble, of 76.2, 69.3, 66.3 and 31.4% in presence of GP1, GP4, GP1+4 and GP2+3 respectively (from 1 to 0.6 log less related to the mock-untreated). Of note, pgRNA and HBeAg production strongly correlated (p < 0.001, rho = 0.9).

Conclusion: HBeAg could to be an optimal *in vitro* marker of productive HBV replication. LNA Gapmers efficiently inhibit the viral expression. Considering their ability to entry into cellular nucleus, they could be a new valuable therapeutic strategy to control the intracellular expression of HBV. Further experiments are required to confirm these preliminary data and improve Gapmer efficiency.

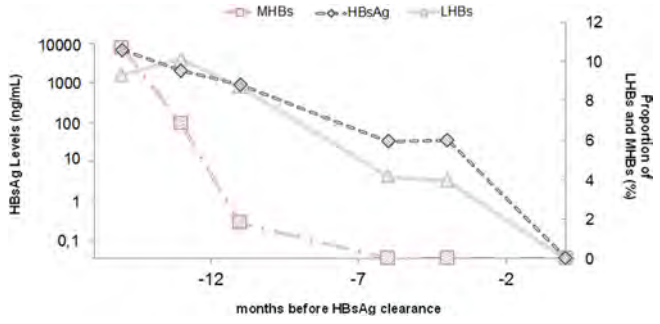
The composition of HBsAg during peginterferon-alfa2a treatment can predict treatment response in HBV/HDV-coinfection

Maria Pfefferkorn[1], Drechsel Luise[1], Karen Rother[1], Sara Sopena Santisteve[2], Heyne Renate[3], Maria Buti[2], Pietro Lampertico[4], Dieter Glebe[5], Thomas Berg[1], Florian van Bömmel[1]. *[1]Division of Hepatology, University Clinic Leipzig, Clinic and Policlinic for Gastroenterology, Hepatology, Infectiology, and Pneumology, Leipzig, Germany; [2]Internal Medicine, Hepatology Section, Hospital Vall Hebron, CIBERehd, Universitat Autónoma de Barcelona, Barcelona, Spain; [3]Liver and Study Center Checkpoint, Berlin, Germany; [4]CRC "A. M. and A. Migliavacca" Center for Liver Disease, Division of Gastroenterology and Hepatology, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milan, Italy; [5]Institute for Medical Virology, National Reference Centre for Hepatitis B and D viruses, Institute for Medical Virology, Justus-Liebig University Giessen*
Email: Maria.pfefferkorn@medizin.uni-leipzig.de

Background and Aims: Treatment with pegylated interferon alpha-2a (PEG-IFN) is currently considered the standard of care for patients with HBV/HDV-coinfection, and clearance of HBsAg provides the optimal treatment end point. The proportion of the different HBsAg components (large (L), middle (M) and small (S)HBs) was shown to predict HBsAg loss in patients with HBV mono infection. Aim of this retrospective study was to assess whether the HBsAg composition before and during treatment may also be associated with HBsAg clearance in patients with HBV/HDV-coinfection.

Method: A total of 26 Patients received 180 mg PEG-IFN per week for a mean time of 40.7 (9–100) months. HBV biomarkers including HDV RNA, HBV DNA, HBV RNA and HBsAg components were measured in available serum samples.

Results: During treatment, 4/26 patients showed HDV RNA loss and HBsAg clearance whereas 22/26 patients showed no serological response (NR), from whom 6/22 achieved undetectable HDV RNA levels. HDV RNA (mean 5.9 vs 7.8 log cp/mL; $p = 0.506$), HBV DNA (mean 3.7 vs. 3.1 log IU/mL); $p = 0.350$); HBsAg (mean 4.3 vs 4.4 log ng/mL; $p = 0.521$) and HBsAg components (mean percentages 6.6 vs 5.9 LHBs %, $p = 0.800$; MHBs 8.9 vs 13.4 %, $p = 0.521$) at baseline showed no significant difference across responders and non-responders. HDV RNA became undetectable in patients with subsequent HBsAg loss after 12 (4–24) months but showed no significant decline in the NR group. HBV DNA became undetectable in both groups. HBV RNA was undetectable in all patients and samples before and during treatment. In patients with HBsAg loss, total HBsAg levels and ratios of LHBs showed a significant decrease by month 6 and 12 treatment in comparison to the NR group (p = 0.02 and p = 0.01). Median proportions of MHBs strongly decreased during treatment (from 10.7% [15 months before HBsAg loss] to 1.8% [11 months before HBsAg loss]) and became undetectable 6 months before the loss of LHBs and total HBsAg (see Figure). In contrast, the ratios of LHBs and MHBs showed no significant difference in the NR group during the entire observation time.



Conclusion: LHBs and MHBs might be suitable markers for monitoring the efficacy of PEG-IFN treatment and response prediction in HBV/HDV-coinfected patients. Our results need to be validated in a larger patient cohort.

All-cause mortality and liver-related death following entecavir, tenofovir disoproxil fumarate or lamivudine therapy among treatment-naive chronic hepatitis B patients in British Columbia, Canada

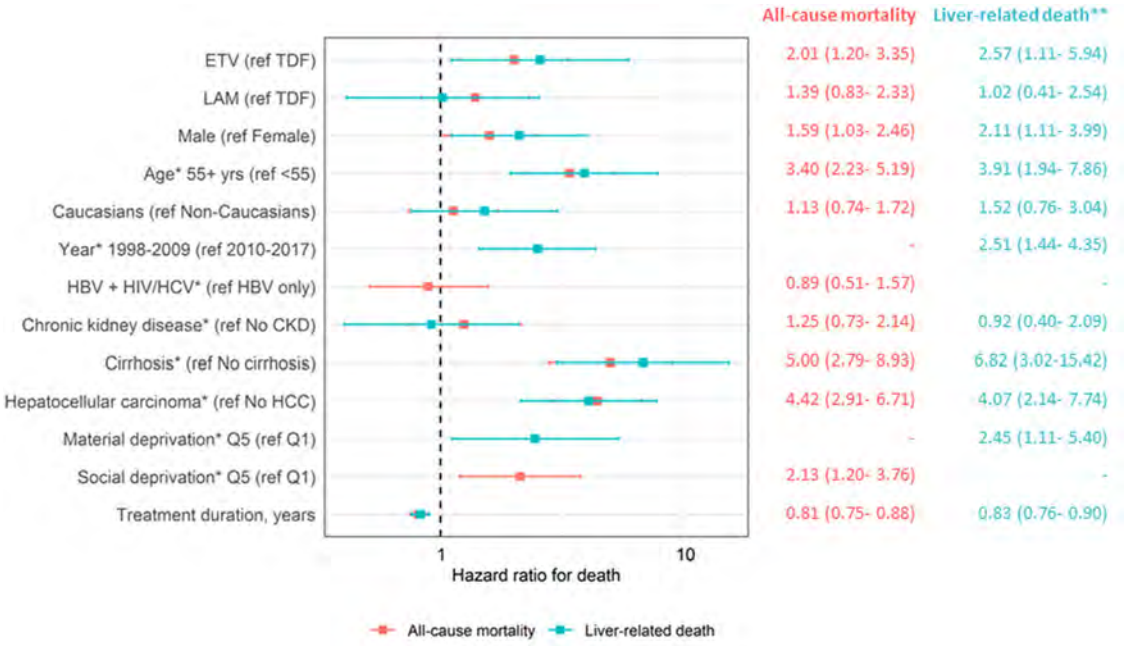
Mawuena Binka[1], Younathan Abdia[1,2], James Wilton[1], Zahid Butt[3], Maryam Darvishian[4], Stanley Wong[1], Amanda Yu[1], Sofia Bartlett[1,2], Dahn Jeong[1,2], Emilia Clementi[1,2], Prince Adu[1,2], Dr. Margo Pearce[1,2], Maria Alvarez[1], Eric Yoshida[2], Alnoor Ramji[2], Dr. Jason Wong[1,2], Mel Krajden[1,2], Naveed Janjua[1,2]. *[1]BC Centre for Disease Control, Vancouver, Canada; [2]University of British Columbia, Vancouver, Canada; [3]University of Waterloo, Waterloo, Canada; [4]BC Cancer Research Centre, Vancouver, Canada*
Email: mawuena.binka@bccdc.ca

Background and Aims: Entecavir (ETV), tenofovir disoproxil fumarate (TDF) and lamivudine (LAM) are publicly-funded options for chronic hepatitis B (HBV) therapy in British Columbia (BC), Canada. Although in use for over a decade, there is conflicting information about their relative impact on long-term survival. We assessed the association between ETV, TDF or LAM therapy and all-cause mortality/liver-related death among treatment-naïve chronic HBV patients within a large population-based cohort in BC.

Method: The BC Hepatitis Testers Cohort (BC-HTC) includes data from all HBV-positive individuals diagnosed in BC from 1990–2015 linked with medical visit, prescription and mortality data. Treatment-naïve HBV-positive individuals within the BC-HTC who initiated ETV, TDF or LAM and received only one of these three drugs on or before Dec 31, 2017 were included in this study. To account for differing profiles at baseline, treatment groups were matched 1:3:3 by common referent propensity score matching with ETV as the reference group. Key matching variables included sex, ethnicity, age group, chronic kidney disease, cirrhosis and hepatocellular carcinoma at treatment start, as well as treatment duration. The relative impact of ETV, TDF, and LAM therapy on all-cause and liver-related mortality from treatment start until Dec 31, 2018 was assessed with multivariable Cox proportional-hazards models, accounting for the competing risk of death from other causes when assessing liver-related death.

Results: 2,464 matched participants initiated ETV (n = 352), TDF (n = 1,056) or LAM (n = 1,056). These individuals were mostly East Asian (63.4%), Caucasian (26.2%) and South Asian (4.4%). Relative to TDF, the ETV treatment group was at greater risk of both all-cause (adjusted hazard ratio[aHR] 2.01, 95% CI: 1.20–3.35) and liver-related mortality (aHR 2.57, 95% CI: 1.11–5.94). Differences in mortality risk for LAM and TDF treatment groups were not statistically significant (aHR: All-cause mortality 1.39, 95% CI: 0.83–2.33; Liver-related death 1.02, 95% CI: 0.41–2.54).

Conclusion: Among treatment-naïve chronic HBV patients, the risk of all-cause mortality and liver-related death post-treatment initiation was higher with ETV relative to TDF and LAM. This finding is noteworthy and warrants further study given the potential implications for HBV therapy and the conflicting findings of similar studies conducted in distinct, more ethnically homogenous, South Korean study populations.



*At HBV treatment initiation; **Competing risk: death from non-liver-related causes; LAM: Lamivudine; ETV: Entecavir; TDF: Tenofovir disoproxil fumarate; CKD: chronic kidney disease; HCC: hepatocellular carcinoma; Q: quintile

Email: kimmi.cox@triohealth.com

Background and Aims: Previously we reported increased HBV suppression, ALT normalization, and improved renal function with TAF treatment. However, certain patients that would potentially benefit from switching to TAF, e.g. with impaired renal function, remained on non-TAF therapies. Here we further examined variables associated with TAF adoption from approval (Nov 2016) to Dec 2018.
Method: Patients enrolled in the TRIO HBV registry from 6 academic and 4 community centers in the US were included in this study. TAF initiation was assessed using Kaplan-Meier methods with subsequent log-rank tests. Overall TAF initiation rates were compared using z-tests.
Results: Study population (n = 1037): predominantly male (599, 58%), Asian (887, 86%), <60 years old (700, 68%), from academic centers (611, 59%), with HBV DNA suppression (951/1035, 92%), and receiving tenofovir disoproxil fumarate (TDF [640, 62%]) at enrollment. A history of HCC (inactive) was present for 2% (25) patients, 4% (44) fatty liver, 10% (103) diabetes, 13% (131) hyperlipidemia, 23% (237) hypertension, and 8% (78) osteopenia/osteoporosis. At enrollment, 5% (48/965) had FIB4 >3.25, 6% (65/1030) had eGFR <60 ml/min, and 29% (304/1035) had elevated ALT (>25 U/L in females or >35 U/L in males). In the study window, 396 (38%) patients initiated TAF. Adoption was significantly higher in patients receiving TDF at enrollment (52% v. 12% non-TDF, $p < 0.001$), at community practices (56% v. 25% academic, $p < 0.001$), and without HCC history (39% v. 8%, $p = 0.005$), fatty liver (39% v. 8%, $p < 0.001$), or hyperlipidemia (39% v. 28%, $p = 0.005$). Adoption was not significantly different by age, insurance type, osteopenia/osteoporosis, eGFR, FIB4, or ALT. [Figure] Reasons for initiating TAF were provided for 365/396 patients: 66% (241/365) indicated safety/side effects, 27% (99/365) physician preference, and 6% (21/365) efficacy.
Conclusion: Safety/side effects was stated as a primary reason for initiating TAF, yet osteopenia/osteoporosis, suboptimal eGFR, ALT, or FIB4 were not associated with significantly higher TAF adoption. These data suggest that prevention, rather than observation of detrimental clinical measures, accounted for most TAF adoption. Most patients with renal or bone disease were not switched to TAF which may be due to access, an issue which will be further explored.

FIGURE: TAF initiation in study population and by select characteristics at enrollment. X axis = months from enrollment (Nov 2016), Y axis = cumulative proportion of patients initiating TAF.

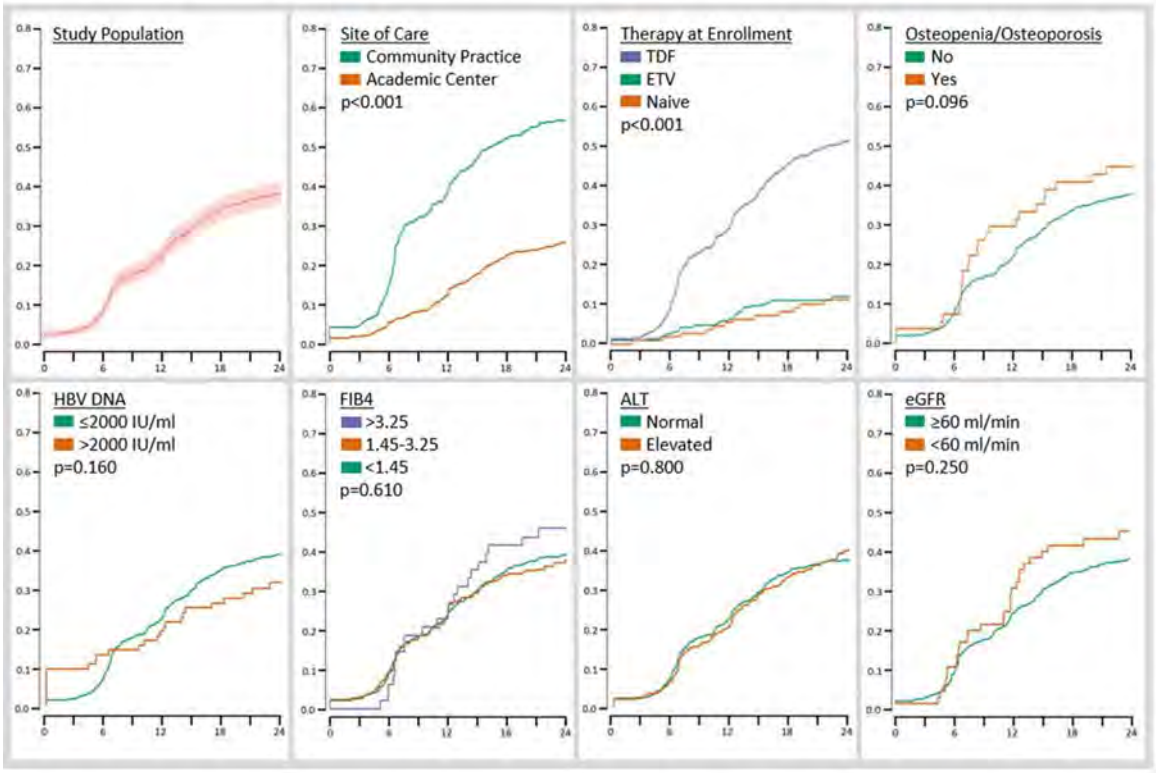

Figure: (abstract: SAT448)

Background and Aims: A functional cure for chronic hepatitis B is unavailable, as current therapeutics lack mechanisms for viral surface antigen (HBsAg) reduction. S-antigen Transport-inhibiting Oligonucleotide Polymers (STOPs) reduce HBsAg in vitro and are structurally similar to nucleic acid polymers (NAPs). Novel chemical properties have imparted 20 to 100-fold improvements in potency over clinical stage NAPs. To identify the mechanism for enhanced potency, we investigated the structural features necessary for STOPs antiviral activity via modifications of sequence, length and chemistry.
Method: To assess STOPs antiviral activity, HBsAg levels were measured in treated and untreated HBV-infected cells. Briefly, STOPs were transfected into HepG2.2.15 and HBV-infected HepG2-NTCP cells. HBsAg levels and cytotoxicity were measured 6 days post transfection via ELISA and CellTiter Glo, respectively.
Results: ALG-010000 was identified as a potent inhibitor of HBsAg secretion in HepG2.2.15 and infected HepG2-NTCP cells with EC50 values of 4.6 and 5.3 nM respectively. Varying the length of STOPs from 18–50 nucleotides (nt) revealed a length dependency on antiviral activity; potency was maintained at lengths >34 nt, and dramatically reduced at lengths <30 nt. Sequence variations in STOPs were also tested for activity. When the AC dinucleotide repeat of ALG-010000 was changed to alternative repeated bases such as AG, the antiviral activity was completely abolished. Similarly, polyA and polyC sequences were inactive, in contrast to the reported activity for NAPs. However, when the base identities were maintained, such as with a CA repeat, activity was similar to ALG-010000. Interestingly, when the optimal length was maintained, polyA stretches replacing 2–5 dinucleotide repeats at the flanks of the oligonucleotide were tolerated while polyC stretches were not. In addition to length and sequence, backbone and sugar chemistry were modified. Potency was improved with site specific incorporation of backbone chemistries such as a stereospecific phosphorothioate bond.
Conclusion: We have demonstrated that STOPs potency is length and sequence dependent, requiring a minimal length of 34 nt and a minimal AC dinucleotide composition of 50%. Chemistries that improve antiviral activity have also been identified. Collectively, these defined structural elements provide a framework for STOPs design and are important for their advancement. Further exploration is ongoing.

SAT450

Low hepatitis B surface antigen at baseline and increased ALT levels during treatment predicts significant HBsAg decline in peginterferon alfa added to long-term nucleus(t)ice analogue. Results from two randomized controlled trials in 165 patients

Mina Farag[1], Hannah S.J. Choi[1,2], Scott Fung[1], Heng Chi[3], Margo J.H. van Campenhout[3], Seng Liem[1,3], Qing Xie[4], Milan Sonneveld[3], David Wong[1], Jordan Feld[1], Karel J. van Erpecum[5], Robert De Man[3], Bettina Hansen[1,6], Harry Janssen[1]. *[1]Toronto General Hospital, University Health Network, Toronto Centre for Liver Disease, Toronto, Canada; [2]Institute of Medical Science, University of Toronto, Toronto, Canada; [3]Erasmus Medical Centre Rotterdam, Department of Gastroenterology & Hepatology, Rotterdam, Netherlands; [4]Ruijin Hospital, Jiaotong University, Department of Infectious Diseases, Shanghai, China; [5]University Medical Center, Department of Gastroenterology, Utrecht, Netherlands; [6]University of Toronto, Institute of Health Policy , Toronto, Canada*
Email: mina.farag@uhn.ca

Background and Aims: Pegylated-interferon (PEG-IFN) treatment has been associated with higher HBsAg decline rates than nucleos(t)ide analogues (NA) and is thus increasingly used in the setting of

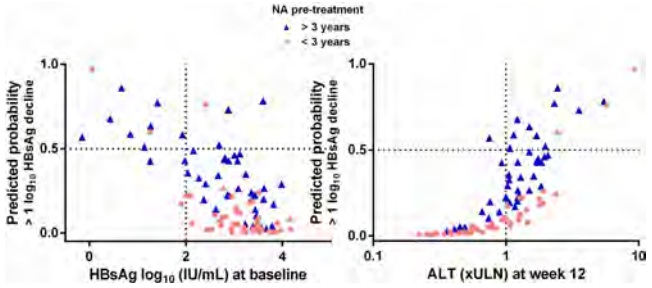
novel combination regimens aiming for functional cure. We investigated in two randomized, controlled trials the factors that influence HBsAg decline in CHB patients pre-treated with nucleos(t)ide analogues (NA) who received PEG-IFN add-on therapy.

Method: HBsAg decline was evaluated in two investigator-initiated randomized controlled trials conducted in Europe, China and Canada (PAS and PEGON studies). HBeAg positive and negative patients with normal ALT at baseline, were pre-treated with NA therapy >12 months and then were allocated to 48 weeks of NA+PEG-IFN add-on, or continued NA monotherapy. To study the factors that influence >1log$_{10}$ HBsAg decline, we performed a logistic regression analysis.

Results: Of the 165 patients, 97 (59%) patients randomized to PEG-IFN add-on, and 68 (41%) to continue NA monotherapy. At baseline, 77 patients were HBeAg positive, and 88 were HBeAg negative. The mean age was 42 years, 82% male, 79% Asian, and 17% Caucasian. The median baseline HBsAg level was 3.1 log$_{10}$ IU/mL. At week 48, 22 (13%) patients achieved HBsAg >1 log$_{10}$ decline in the add-on arm compared to none on NA monotherapy.

By univariable analysis, factors associated with >1log$_{10}$ HBsAg decline were PEG-IFN add-on (odds ratio [OR] 2.1; 95% CI 1.1–4.4; p = 0.03), HBeAg negative (OR 3.3; 95% CI 1.25–10; p = 0.02), lower HBsAg levels at baseline (OR 0.4; 95% CI 0.2–0.7; p = 0.001), longer duration (years) of NA treatment prior to Peg-IFN (OR 1.2; 95% CI 1.02–1.32; p = 0.02), and ALT (>xULN) increase during treatment starting from week 12 (OR 2.6; 95% CI 1.3–5.2; p = 0.008).

In multivariable analysis, lower HBsAg level at baseline (OR 0.3; 95% CI 0.1-0.8; p = 0.02) and ALT increase at week 12 (OR 2.5; 95% CI 1.3-4.8; p = 0.01) remained independently associated with >1log$_{10}$ HBsAg decline in patients treated with 3 years of NA or more (OR 4.2; 95% CI 1.5–12.1; P = 0.007) (figure), when adjusted for PEG-IFN add-on and HBeAg at baseline.



Conclusion: HBsAg decline >1log$_{10}$ after the addition of PEG-IFN to long term NA is significantly associated with lower levels of HBsAg level at baseline and higher ALT at week 12. Longer duration of NA therapy before PEG-IFN increases the probability of HBsAg decline.

Background and Aims: There were insufficient data regarding the treatment strategy for patients who demonstrated a partial or suboptimal response to entecavir (ETV) or tenofovir disoproxil fumarate (TDF). We aim to investigate the effect and safety of tenofovir alafenamide (TAF) switching in chronic hepatitis B (CHB) patients with advanced fibrosis and partial response to other nucleot(s)ide analogue (NUC).

Method: Approximately 80 adult CHB patients with advanced fibrosis (including fibrosis stage 3 and cirrhosis), who are currently on NUC (except TAF) therapy with detectable hepatitis B virus (HBV) DNA after at least 52 weeks of therapy will be considered eligible for this open label, prospective interventional cohort study. Enrolled patients will switch prior NUC to TAF 25 mg/day for 96 weeks. The objectives are to describe the improvement of rate of viral suppression, alanine aminotransferase (ALT) normalization, and the trend in renal function, bone mineral density with TAF.

Results: From Feb. 2019, 24 patients were enrolled. Seven (29.2%) were male with a median age of 53 years old. Liver fibrosis assessment showed a median level of 10.6 kPa. The median ALT level was 23.5 U/L with ALT level within normal limit (40 U/L) in 22 (91.7%) of the patients. The median hepatitis B surface antigen and HBV DNA levels were 2,267 IU/mL and 64 IU/mL, respectively. Ten (41.7%) patients were hepatitis B e antigen positive. Two (8.3%) had YMDD mutation at enrollment. The prior NUCs included ETV in 14 (58.3%), TDF in 9 (37.5%), and lamivudine in 1 (4.2%) of the patients. The median HBV DNA level declined from 64 IU/mL at enrollment to 28.5 IU/mL at 4th week, 21 IU/mL at 12th week, and below low limit of quantification at 24th week, respectively, after TAF switching. Undetectable HBV DNA was achieved in 8/24 (33.3%), 8/18 (44.4%), and 3/4 (75.0%) patients at 4th, 12th, and 24th week, respectively (figure 1A). The rate of ALT normalization was 91.7%, 87.5%, 94.4%, and 100% at enrollment, 4th, 12th, and 24th week, respectively, after TAF switching. There were no significant changes inserum creatinine and eGFR levels from enrollment to 24th week after TAF switching (figure 1B). Only mild degrees of adverse events were found which were considered unrelated to treatment. One patient withdrew at 4th week of enrollment due to personal reason.

Conclusion: The preliminary results demonstrated the efficacy and safety of TAF switching in viral suppression for those patients with advanced fibrosis and partial virologic responses to other NUCs.

Background and Aims: GLS4 is a hepatitis B virus (HBV) capsid assembly modulator that have demonstrated potent antiviral activity as monotherapy, in this study, we evaluate the safety and efficacy of the combination therapy of GLS4/Ritonavir(RTV) with Entecavir(ETV) compared with ETV monotherapy in HBeAg positive CHB patients (pts)(Clinical trial identifier: NCT04147208).

Method: 250 CHB pts will be enrolled into 2 groups. Naïve group : treatment-naïve or patients with no prior exposure to anti-hepatitis B drugs within the last 6 months, n = 125; Virally suppressed group: patients have taken ETV for more than1 year and achieved virus suppression (HBV DNA <50 IU/mL), n = 125). In each group, pts will be randomly allocated 4:1 to receive 120 mg GLS4/100 mg RTV(TID) combined with 0.5 mg ETV(QD) or 0.5 mg ETV(QD) monotherapy for 96 weeks(assigned as cohort A and cohort B in Naïve group; as cohort C and cohort D in Suppressed group).

Results: Currently, 146 patients had been enrolled and 77 pts have received treatment≥12 weeks, available data at 12th week are presented here. Compared to baseline, mean HBV DNA reduction in treatment naïve pts were 5.02 and 3.84 log10 IU/ml, while the decline of pgRNA were 2.63 vs. 0.27 log10 IU/ml in cohort A and cohort B, respectively. For HBsAg, the mean reduction from baseline were 0.43 vs. 0.21 log10 IU/ml, and for HBeAg were 0.49 vs. 0.29 log10 IU/ml respectively in cohort A and cohort B. 28.6% pts (4/14) in cohort A and 5.9% (1/17) in cohort B had HBsAg levels declined ≧0.5log IU/ml. In cohort A, 2 pts (14.3%) had HBsAg declined ≧1.5log IU/ml (81250 dropped to 2490 IU/ml; 55620 dropped to 1760 IU/ml, respectively). In Suppressed group, the mean declines of HBV pgRNA were 1.59 vs. 0.15 log10 IU/ml in cohort C and cohort D, those of HBsAg and HBeAg were 0.11 vs. 0 log10 IU/ml and 0.17 vs. 0.06 log10 IU/ml. The proportion of HBsAg declined ≧0.1log IU/ml from baseline was 62.5% (15/24) vs. 13.6% (3/22) in cohort C and cohort D, respectively. Combination of GLS4/RTV with ETV had been generally safe and well tolerated, the most common adverse events (AEs) were ALT elevation and hypertriglyceridemia. According to CTCAE5.0, ALT elevation ≧grade 3 were 7.1%(3/42) vs. 2.6%(1/39) in GLS4/RTV+ETV combined and ETV monotherapy group, respectively. These patients'ALT level declined after temporary suspension of the drug and symptomatic treatment, and these ALT flares correlated well with more rapid decline in HBsAg and/or HBeAg. Hypertriglyceridemia ≧ grade 3 were 4.8%(2/42) vs. 0 (0/39) in GLS4/RTV+ETV combined and ETV monotherapy group.

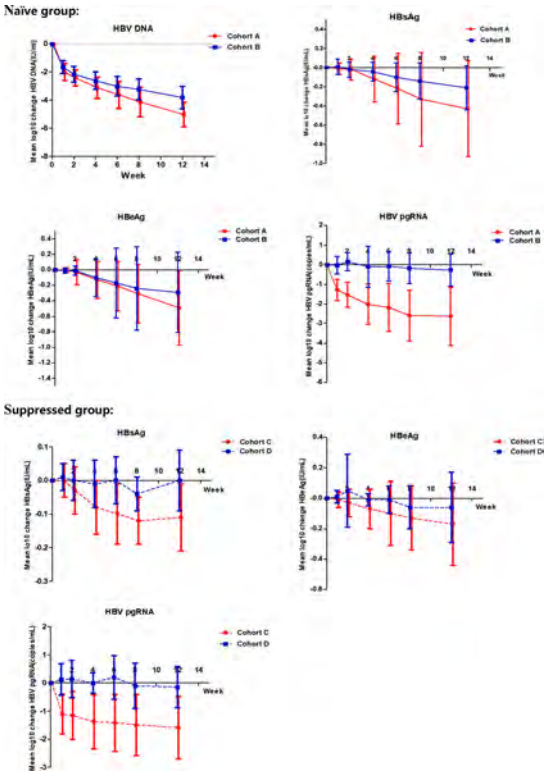

Figure: Comparison of antiviral activities between combination therapy and monotherapy.

Conclusion: Interim results showed that the antiviral efficacy of combination therapy of GLS4/RTV with ETV is remarkably superior to ETV monotherapy, further studies are ongoing to evaluate the safety and efficacy of the combination therapy.

SAT453

Long-term efficacy of generic antiviral drugs (tenofovir and entecavir) in supression of viral replication in chronic hepatitis B

Enrique Práxedes González[1], Marta Casado[1], José López González[1], Isabel Moreno Moraleda[1], Teresa Maria Jordan Madrid[1], Almudena Porcel[1], José Luis Vega Sáenz[1]. [1]*Hospital Universitario Torrecárdenas, Gastroenterology and Hepatology Department, Almería, Spain*
Email: enripraxedes@gmail.com

Background and Aims: The main goal of nucleot(s)ides analogues therapy in chronic hepatitis B, is to achieve sustained suppression of viral replication (VR). Antiviral therapy with Viread® (tenofovir disoproxil fumarate TDF) or Baraclude® (entecavir ETV) suppresses hepatitis B virus (HBV) viremia in most patients. The approval and commercialization of generic drugs of ETV and TDF, has resulted (since April 2017), in a change of antiviral treatment in patients previously treated with Viread® and Baraclude®, who were switched to their respective generic drugs.
The aim of our study was to assess the efficacy in suppression HBV DNA to undetectable levels of the generic antiviral TDF and ETV drugs, in patients with sustained virological response previously obtained with Viread® and Baraclude® and in patients who had been treated with generic antivirals from the beginning.
Methods: We included all chronic hepatitis B patients treated with Viread® or Baraclude® until April/2017, who were switched to generic TDF or ETV (group A) and patients who started treatment with generic antiviral drugs from the beginning, with more than 1-year follow-up (group B). Patients started on Viread® and Baraclude® after October/2016 and those with inadequate follow-up, were excluded. The follow-up protocol included viral load (VL) (HBV DNA) determination and adherence assessment, every six months. Suppression of VR was defined as undetectable HBV DNA levels.
Results: Group A: 73 patients (47 men and 26 women), with an average age of 52 years. Eleven patients were treated with Baraclude® and 62 with Viread®. Thirteen patients had liver cirrhosis and most of them (95%) were HBeAg negative. Long term virological suppression was achieved in 70 patients with Baraclude® and Viread®; after switching to generic antiviral drug, 15 of them (13 TDF, 2 ETV) showed sustained detectable HBV DNA, 4 of them were cirrhotic patients. VL ranged from 13 to 96 IU/mL.
Group B: 18 patients, 12 treated with TDF and 6 with ETV. Virological suppression was achieved in 10 patients and the remaining eight (5 TDF and 3 ETV) showed detectable VL (18–300 IU/mL) after 1-year of treatment despite a correct adherence, 3 of them were cirrhotic patients.
Conclusions: In one out five patients with chronic hepatitis B, the change of treatment from Viread® or Baraclude® to generic TDF and ETV failed to maintain VR suppression, however with viral loads below 100 IU/mL. In almost half of the patients treated with generics antiviral drugs from the beginning, therapy failed to achieve viral load suppression after more than one year of treatment. We do not know the impact of this long term incomplete viral response on the liver disease. However, in patients with cirrhosis, we have to increase the surveillance or to evaluate the use of other antiviral drugs that ensure complete VR suppression.

Guideline change for antiviral therapy reduced the risk of HBV-related HCC development among cirrhotic patients in South Korea

David Kim[1], Jae Seung Lee[1], Ho Soo Chun[1], Hye Won Lee[1], Beom Kyung Kim[1], Jun Yong Park[1], Do Young Kim[1], Kwang-Hyub Han[1], Yu Rim Lee[2], Won Young Tak[2], Young Oh Kweon[2], Sang Hoon Ahn[1], Seung Up Kim[1]. [1]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South;* [2]*Kyungpook National University, Department of Internal Medicine, Daegu, Korea, Rep. of South*
Email: powerof1004@gmail.com

Background and Aims: In September 2015, the guideline of the Korean Association for the Study of Liver (KASL) to start antiviral therapy (AVT) for patients with chronic hepatitis B (CHB)-related cirrhosis was changed from HBV DNA level ≥2,000 IU/L and aminotransferase (AST) or alanine aminotransferase (ALT) levels ≥ upper limit of normal to HBV DNA level ≥ 2,000 IU/L regardless of the AST or ALT level. This study investigated whether the KASL guideline change reduced the risk of CHB-related hepatocellular carcinoma (HCC) development among cirrhotic patients in South Korea.
Method: A total of 429 patients with CHB-related cirrhosis who started AVT between 2014 and 2016 were recruited. The risk of HCC development was compared between patients who started AVT before and after September 2015 (previous [n = 196, 45.7%] vs. the current guideline [n = 233, 54.3%]).
Results: Univariate analysis showed that starting AVT according to previous guidelines (vs. current guideline), older age, and male gender significantly predicted an increased risk of HCC development (all $p < 0.05$). Subsequent multivariate analysis showed that starting AVT according to previous guidelines (vs. current guideline) (HR = 1.833), older age (HR = 1.041), and male gender (HR = 2.719) independently predicted an increased risk of HCC development (all $p < 0.05$). In addition, multivariate analysis showed that starting AVT according to previous guidelines (vs. current guideline) (HR = 2.400) and male gender (HR = 3.058) were independent predictors of mortality ($p < 0.05$). The cumulative incidence of HCC and mortality were significantly higher in patients who started AVT before the guideline change (all $Pp<0.05$ by log-rank test).
Conclusion: The prognosis of patients with CHB-related cirrhosis who started AVT was improved after the change in KASL guidelines.

SAT455

ALG-000184, a prodrug of capsid assembly modulator ALG-001075, demonstrates best-in-class preclinical characteristics for the treatment of chronic hepatitis B

Qingling Zhang[1], Sandrine Vendeville[2], Vladimir Serebryany[1], Michael Welch[1], Jyanwei Liu[1], Caroline Williams[1], Yannick Debing[2], Andreas Jekle[1], Sarah Stevens[1], Jerome Deval[1], Tse-I Lin[2], Dinah Misner[1], Sushmita Chanda[1], Raymond F Schinazi[3], Pierre Raboisson[2], Julian Symons[1], Lawrence Blatt[1], Leonid Beigelman[1], David Smith[1]. [1]*Aligos Therapeutics, Inc., South San Francisco, United States;* [2]*Aligos Belgium BVBA, Leuven, Belgium;* [3]*Emory University, Atlanta, United States*
Email: dsmith@aligos.com

Background and Aims: Capsid assembly modulators (CAMs) represent a clinically validated strategy for inhibiting hepatitis B virus (HBV) RNA encapsidation, leading to reductions in circulating HBV DNA and RNA in infected patients. We recently reported on ALG-001075, a novel class-II (normal, empty capsid formed) CAM with excellent antiviral potency and in vivo efficacy in a mouse adeno-associated virus-HBV model (AASLD, 2019, poster 699). We now advance ALG-000184, a prodrug of ALG-001075, which demonstrates superior pharmacokinetic properties relative to ALG-001075.
Method: Antiviral activity on HBV DNA was determined in HepG2.117 cells using quantitative PCR, with and without 40% human serum. Activity was also assessed in primary human hepatocytes (PHH) infected with HBV. Solubility, stability and permeability of ALG-

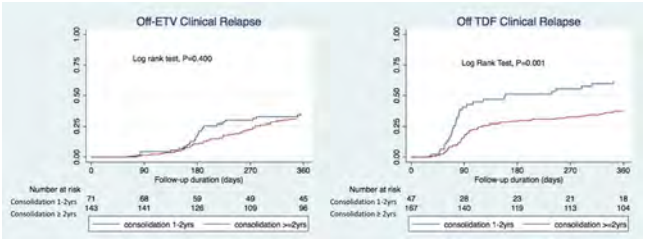
001075 and ALG-000184 were evaluated in vitro. Pharmacokinetic properties of ALG-001075 were evaluated across species following oral dosing of ALG-001075 or ALG-000184 administered as aqueous formulations.
Results: ALG-001075 was found to be a potent inhibitor of HBV DNA production in HepG2.117 cells with EC_{50}/EC_{90} values of 0.63/3.17 nM (n = 12), a 4.2-fold shift was noted in the presence of 40% human serum. When ALG-001075 was added to PHH at the time of infection, reductions in extracellular HBsAg and HBV RNA were noted, indicating inhibition of de novo cccDNA formation. ALG-001075 has low aqueous solubility, whereas ALG-000184 showed excellent aqueous solubility (>120 mg/mL) in phosphate buffered saline (PBS) and was stable in simulated gastric or intestinal fluid ($t_{1/2}$ >12 hrs). Permeability in Caco-2 cells more than doubled and the efflux ratio was significantly reduced for the prodrug as compared to ALG-001075. When ALG-000184 was dosed as an aqueous solution in mouse, rat, monkey and dog, it was rapidly absorbed and conversion to ALG-001075 was efficient. ALG-001075 plasma exposure in rats increased linearly with ALG-000184 dosed up to 300 mg/kg, the highest dose tested.
Conclusion: ALG-001075 is the most potent class-II CAM reported to date, efficiently blocking both HBV genome encapsidation and *de novo* cccDNA formation. ALG-000184 demonstrates excellent solubility and oral absorption with efficient conversion to ALG-001075 in vivo, with pharmacokinetic properties across species predicting once daily dosing in humans. ALG-000184 is currently advancing in development as a potential best-in-class CAM.

SAT456

Longer consolidation duration is required to reduce 1-year clinical relapse rate after stopping tenofovir in HBeAg negative CHB patients

Rachel Wen-Juei Jeng[1,2], Chien-Hung Chen[2,3], Yi-Cheng Chen[1,2], I-Shyan Sheen[1,2], Rong-Nan Chien[1,2,4], Yun-Fan Liaw[2,4]. *[1]Linkou Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan; [2]Chang Gung University, College of Medicine, Taoyuan, Taiwan; [3]Kaohsiung Chang Gung Memorial Hospital, Department of Gastroenterology and Hepatology, Kaohsiung, Taiwan; [4]Linkou Chang Gung Memorial Hospital, Liver Research Unit, Taiwan*
Email: liveryfl@gmail.com

Background and Aims: Our recent report (AASLD 2019) showed no significant difference in 1-year clinical relapse rate among overall 902 Nuc treated HBeAg negative CHB patients with consolidation duration of 1–2, 2–3 and ≥3 years. Comparing with ETV, TDF therapy is associated with much earlier off-therapy relapse. Whether consolidation duration required to be longer in this population remained unknown. Aim: To compare the optimal length of consolidation treatment in terms of 1-year clinical relapse (CR: HBV DNA ≥2000 IU/ml + ALT ≥2X ULN) rate between ETV and TDF treated patients.
Method: HBeAg negative CHB patients from two tertiary medical centres received ETV or TDF and had stopped therapy after demonstration of undetectable HBV DNA for more than 1 year with off-Nuc followed-up ≥1 year were recruited. The 1-year CR rate was compared among patients with consolidation therapy of 1–2 year vs. ≥2 years. Propensity score matching with age, cirrhotic status, prior treatment history, proportion of EOT HBsAg categorized level (≥200, 200–100, <100 IU/ml) at 1:1 ratio was performed to adjust the characteristics between off ETV and off TDF patients. Kaplan-Meir analysis and log rank test was performed to compare the consolidation duration impact on off ETV or TDF 1-year clinical relapse rate.
Results: A total of 428 patients were included, with 214 patients in each groups. Age, EOT age, gender, cirrhotic status, genotype, prior treatment history and proportion in EOT HBsAg ≥200, 100–200, <100 IU/ml were comparable between off ETV and TDF group. In Kaplan Meir analysis, the 1-year CR rate was significantly lower in off-TDF patients with consolidation ≥2 years than those <2 years (37.7% vs. 61.7%, log rank test, P = 0.001) whereas there was no difference (30.8% vs. 35.2%, log rank test, P = 0.400) in off-ETV patients.



Conclusion: The results have demonstrated that consolidation duration in off-TDF patients may require longer period ≥2 years to reduce the off-Nuc 1-year clinical relapse rate.

Longer-term experience with tenofovir alafenamide (TAF) in HBV-infected patients; changes in EGFR, FIB4, ALT, and DNA suppression

Rajender Reddy[1], Michael Curry[2], Ho Bae[3], Douglas Dieterich[4], Victor Ankoma-Sey[5], Calvin Pan[6], Hie-Won Hann[7], Myron Tong[8], W. Ray Kim[9], Paul Kwo[10], Lynn Frazier[11], Kimmi Cox[12], Scott Milligan[12], Nezam Afdhal[2]. *[1]University of Pennsylvania, Philadelphia, United States; [2]Beth Israel Deaconess Medical Center (BIDMC), Boston, United States; [3]St. Vincent Medical Center, Asian Pacific Liver Center, Los Angeles, United States; [4]Icahn School of Medicine at Mount Sinai, New York, United States; [5]Liver Associates of Texas, PA, Houston, United States; [6]NYU Langone Health, NYU School of Medicine, New York, United States; [7]Thomas Jefferson University Hospital, Philadelphia, United States; [8]Huntington Medical Research Institute Liver Center, Pasadena, United States; [9]Stanford University School of Medicine, Stanford, United States; [10]Stanford University School of Medicine, Stanford, United States; [11]Liver Wellness Center, Little Rock, United States; [12]Trio Health Analytics, La Jolla, United States*
Email: kimmi.cox@triohealth.com

Background and Aims: TAF provides similar efficacy to tenofovir disoproxil fumarate (TDF) but with an improved safety profile particularly for bone loss and renal injury. However, continued benefit with longer-term TAF has not been sufficiently studied. Here we evaluate virologic suppression rates, eGFR, fibrosis, and ALT at 48+ weeks of TAF therapy in US clinical practice.
Method: TRIO has developed a national HBV network consisting of 6 academic and 4 community-based centers serving 17 US States to understand real-world HBV treatment. Of the 1037 patients enrolled from Jan 2017, 270 patients initiated TAF and remained on therapy for 48+ weeks as of Jan 2019. Lab measurement data at baseline and at or after (but nearest) 48 weeks of TAF therapy were collected. Elevated ALT was defined as >35 U/L for males and >25 U/L for females, HBV suppression was assigned for HBV DNA measures ≤2000 IU/ml. Comparisons between baseline and 48-week measures were made using McNemar's test (for dichotomous variables), Bowker's test (for multi-level variables) or t-test (for continuous variables). To identify variables associated with elevated ALT, eGFR <60 ml/min, or FIB4 >1.45 at 48 weeks, logistic regressions were conducted with adjustments for multicollinearity of variables.
Results: The study population (n = 270) was mostly male (59%), Asian (89%), and under or normal weight (60%) with a mean age of 53 years. Prior to initiating TAF, 81% of the patients received TDF, 8% entecavir, 6% were treatment naïve, 2% TDF/emtricitabine, 1% lamivudine, and 1% adefovir dipivoxil. As of Jan 2019, mean (median) TAF duration was 508 (512) days and ranged from 338 to 803 days. In paired analyses (Table), statistically significant changes were reduced mean ALT and increased DNA suppression; changes in FIB4 and eGFR were not significantly different between baseline and 48 weeks. Variables

associated with elevated ALT and eGFR <60 ml/min at 48 weeks were baseline elevated ALT (p < 0.001) and baseline eGFR <60 ml/min (p < 0.001), respectively. For FIB4 >1.45 at 48 weeks, significantly associated variables were baseline FIB4 >1.45 (p < 0.001) and Medicare as primary coverage (p = 0.010, collinear with Age ≥50).

Measures	Baseline (those on ≥48 weeks)	At 48 weeks	(% difference)	p
ALT, mean (SD) n	28 (26) n = 259	24 (13) n = 259	−15.1%	0.013
Normalized ALT, n (%)	201/259 (78%)	214/259 (83%)	6.5%	0.053
Suppressed HBV DNA, n (%)	247/256 (96%)	255/256 (100%)	3.2%	0.011
FIB4 >3.25, n (%)	13/237 (5%)	13/237 (5%)	0.0%	0.723
eGFR <60, n (%)	18/242 (7%)	21/242 (9%)	16.7%	0.366

Conclusion: This study of HBV-infected individuals receiving TAF for 48+ weeks found that statistically significant improvements occurred in ALT and HBV DNA suppression. Continued monitoring is ongoing to understand changes in these and other measures with longer term TAF.

SAT458

Immtav, a novel immunotherapy approach to eliminate hepatitis B virus

Ruth Martinez Hague[1], Dominic Hine[1], Joannah Fergusson[1], Zoë Wallace[1], Amanda Woon[1], Daniel Kay[1], Jose Donoso[1], Marcin Dembek[1], Mary Connolly[1], Richard Suckling[1], Sara Crespillo Torreno[1], Wilawan Bunjobpol[1], Andrew Knox[1], Sarah Leonard[1], Bethany Turner[1], Katrin Wiederhold[1], Mala Maini[2], Stephen Megit[1], Lucy Dorrell[1]. Email: ruth.martinez-hague@immunocore.com

Background and Aims: Treatment with nucleos(t)ide analogues, the current SOC for chronic HBV, effectively controls viral replication but does not sufficiently overcome immune exhaustion and whilst some agents in development are showing promise, they also require a long treatment duration. We have developed a potent bispecific molecule that redirects polyclonal T cells regardless of antigen specificity to eliminate HBV infected hepatocytes with the aim of delivering a rapid functional cure. ImmTAV molecules are bispecific fusion proteins, combining a high affinity TCR and an anti-CD3 (scFv) T cell activating moiety which are capable of specifically targeting HBV derived peptides presented by HLA on the surface of infected cells. The aim of this study was to demonstrate that ImmTAV molecules can potently, rapidly and specifically eliminate cells containing either integrated HBV DNA or those infected with HBV.
Method: Potency and specificity of ImmTAV molecules targeting the HBV envelope were tested against antigen positive (PLC/PRF/5 A2B2M, with integrated HBV DNA) and negative (HepG2 A2B2M) cell lines, as well as in a HepG2-NTCP *in vitro* infection system. Elimination of HBV envelope-positive cells was assessed using the Opera Phenix and the IncuCyte® Live cell systems, and the Primeflow RNA assay. Nucleos(t)ide analogues were added to the assay to look at the effect on T cell activation in the presence of ImmTAV molecules. T cells from peripheral blood of healthy donors were used as effectors in all experiments.
Results: In each of the formats tested, ImmTAV molecules mediated the specific elimination of cells containing integrated HBV DNA and the elimination of HBV-infected cells in an *in vitro* infection model (Figure), without killing antigen negative cells. The addition of nucleos(t)ide analogues to the assay did not change the potency of the ImmTAV.
Conclusion: ImmTAV molecules can potently and specifically eliminate HBV-infected cells, even in the presence of SOC nucleos (t)ide analogues. Our lead ImmTAV molecule IMC-I109 V has now gone through preclinical development to support first-in-human trials. These data provide evidence of a novel immunotherapeutic strategy that aims to achieve a rapid functional cure for people living with chronic HBV.

SAT459

HBV RNA decline without concomitant HBsAg decrease is associated with a low probability of sustained response and HBsAg loss

Sylvia Brakenhoff[1], Robert De Man[1], Andre Boonstra[1], Margo J.H. van Campenhout[1], Robert De Knegt[1], Florian van Bömmel[2], Annemiek Van der Eijk[3], Thomas Berg[2], Bettina Hansen[4,5], Harry Janssen[4], Milan Sonneveld[1]. Email: s.brakenhoff@erasmusmc.nl

Background and Aims: HBV RNA is a novel biomarker that may reflect intrahepatic HBV replication. Novel compounds have shown potent HBV RNA declines without concomitant HBsAg decrease. How this relates to long-term off-treatment response is yet unclear. We therefore aimed to study the degree of on-treatment HBsAg decline among patients with pronounced HBV RNA decrease in relation to off-treatment sustained response and HBsAg loss.
Method: We quantified HBV RNA (log copies/mL) and HBsAg (log IU/mL) in chronic hepatitis B patients who participated in two global randomized controlled trials (the 99–01 and PARC studies). In the 99-

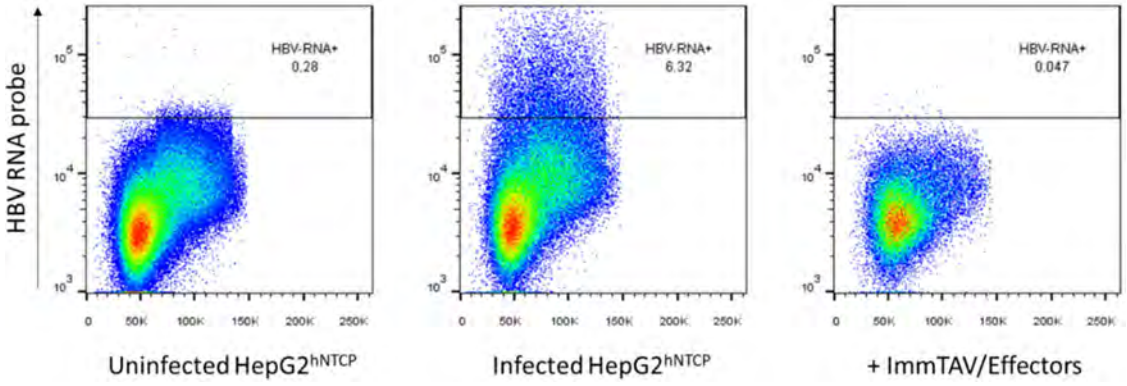

Figure: (abstract: SAT458): Elimination of HBV-infected cells by T cells when re-directed by HBV-specific ImmTAV.

01 study, HBeAg positive patients were randomized to peginterferon (PEG-IFN) ± lamivudine for one year; in the PARC study HBeAg negative patients were treated with PEG-IFN ± ribavirin for one year. Primary study endpoints were sustained response (SR), defined as HBV DNA < 2,000 IU/ml 6 months after end of treatment, and HBsAg loss.

Results: 279 patients were enrolled; 176 HBeAg positive, 103 HBeAg negative. SR was achieved in 57 (20.4%) patients and HBsAg loss in 18 (6.5%) patients. At week 24 of treatment, more pronounced HBV RNA decline was associated with higher rates of SR (13.6% with <1 log decline, 26.7% with >2 log decline) and HBsAg loss (1.2% with <1 log decline, 9.9% with >2 log decline; figure 1) at 6 months post-treatment. However, among 99 patients with at least 2 log HBV RNA decline at on-treatment week 24, 50 (50.5%) did not experience at least 0.5 log HBsAg decline at the same time point. Off-treatment sustained response rates were low in the absence of concomitant HBsAg decrease. Among patients with >2 log HBV RNA decline at week 24, SR was achieved in 15/34 (44.1%) of those with HBsAg decline >1 log, versus 8/50 (16.0%) patients without HBsAg decline (p < 0.001, figure 1). Similar observations were made for HBsAg loss; 10/34 (29.4%) with >1 log HBsAg decline at week 24, versus 0/50 (0.0%) in the absence of an HBsAg decline (p < 0.001, figure 1). Findings were consistent across other HBV RNA cut-offs, and at different time points (on-treatment week 12 and end-of-treatment).

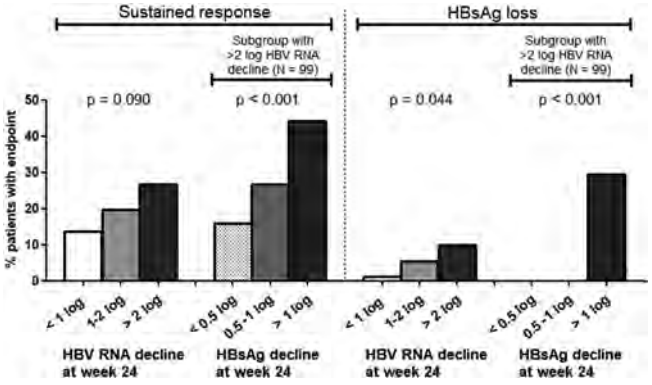

Figure 1: Rates of sustained response and HBsAg loss according to HBV RNA decline at week on-treatment 24, overall and stratified by HBsAg decline at week 24.

Conclusion: In this cohort, many patients with HBV RNA decline during PEG-IFN treatment did not experience HBsAg decrease. Absence of concomitant on-treatment HBsAg decline was associated with low rates of off-treatment sustained response and HBsAg loss. Future treatment trials should therefore consider kinetics of both biomarkers to adequately assess antiviral efficacy.

SAT460

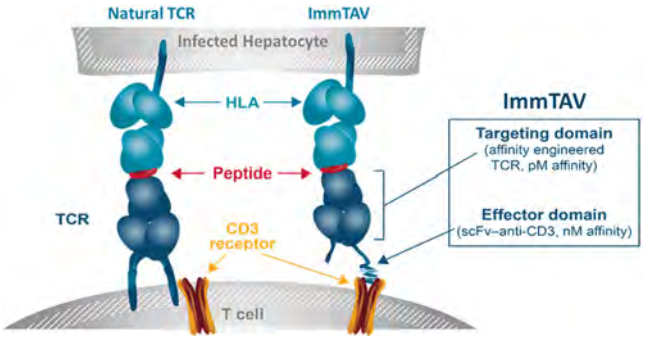
HBV specific ImmTAV induce a broad immune response enabling the elimination of HBV positive cells

Sarah Leonard[1], Rachel Paterson[1], Mauro Monteiro[1], Joannah Fergusson[1], David Depoil[1], Mary Connolly[1], Sara Crespillo Torreno[1], Marcin Dembek[1], Jose Donoso[1], Tressan Grant[1], Dominic Hine[1], Richard Suckling[1], Zoë Wallace[1], Andrew Knox[1], Ruth Martinez Hague[1], Bethany Turner[1], Katrin Wiederhold[1], Stephen Megit[1], Lucy Dorrell[1]. [1]*Immunocore Limited, Milton, United Kingdom*
Email: sarah.leonard@immunocore.com

Background and Aims: It is widely acknowledged that an effective immune response is required to resolve chronic HBV. We have therefore, developed a potent bispecific molecule that redirects polyfunctional T cells regardless of antigen specificity to eliminate HBV infected hepatocytes with the aim of delivering a rapid functional cure. Current approaches show promise at blocking the viral lifecycle but the slow elimination of infected cells by hepatocyte turnover and exhausted virus specific T cells suggests that long treatment durations will be required to deliver a functional cure. The ImmTAX™ platform has the potential to dramatically accelerate the elimination of infected cells by engaging and redirecting non-HBV specific T cells. The potential of this approach is demonstrated clinically through tebentafusp, an ImmTAC® demonstrating single agent activity in metastatic melanoma. To test whether a HBV specific ImmTAV can redirect T cells and drive a polyclonal T cell response in a manner comparable to that of ImmTAC molecules (Figure 1), we examined the T cell subsets, cytokine and chemokine responses observed following *in vitro* exposure of HBV$^+$ cells to a HBV specific ImmTAV.

Method: Effector CD8$^+$, CD4$^+$, natural killer, MAIT and gamma delta T cells from healthy donor peripheral blood were isolated using magnetic bead separation or antibody-based cell sorting. ImmTAV mediated apoptosis of HBV$^+$ cell lines was measured with each subpopulation using Incucyte killing assays. Cytokine and chemokine release were measured over 5 days using the Luminex MagPix assay.

Results: Our data indicates that HBV specific ImmTAV molecules induce apoptosis of HBV$^+$ cell lines through redirection of multiple T cell subpopulations, including both CD8$^+$ and CD4$^+$ T cells. We show that each T cell subpopulation produces a broad range of cytokines and chemokines in response to ImmTAV-mediated stimulation. Detection of cell surface HLA presented HBV peptide by mass-spectrometry and quantification through binding of labelled TCR indicates that the commonly used cell line PLC/PRF/5 displays ~20 copies of antigen per cell, which is comparable to that required for tebentafusp mediated activity.



Conclusion: Preliminary results demonstrate that HBV specific ImmTAV molecules stimulate a broad cytokine and chemokine response, comparable to those observed clinically for tebentafusp, suggesting that ImmTAV molecules have the potential to accelerate elimination of infected HBV cells. This data supports the development of our lead HBV ImmTAV which has gone through preclinical development to support first-in-human trials.

Background and Aims: Recent studies demonstrate that the population with CHB is aging. Tenofovir alafenamide (TAF) is a first-line treatment for chronic hepatitis B virus infection (CHB), particularly in those at risk for TDF-associated bone and renal effects, including patients with advanced age. We reviewed our experience in the subset of geriatric CHB patients participating in ongoing TAF clinical trials.
Method: Included were patients age ≥65 y treated with TAF in 3 large Phase 3 trials (pooled analysis of viremic patients naïve to TAF in Studies 108 and 110, and suppressed patients switched from TDF to TAF [vs continued TDF] in Study 4018), and data from a single arm Phase 2 study in virally suppressed patients with renal and/or hepatic impairment switched to TAF from TDF and/or other antivirals (Study 4035). Efficacy (HBV DNA <29 or <20 IU/mL) and safety (adverse events [AEs], serious AEs, changes in hip and spine bone mineral density [BMD] and changes in creatinine clearance [$eGFR_{CG}$]) were

Table. TAF Efficacy and Safety in Geriatric vs Non-Geriatric CHB Patients

Study 4035 (renal impairment)[b]	+1.48 (-0.40, 3.16)	+1.21 (-1.25, +2.32)	NA
Study 4035 (hepatic impairment)[b]	+1.97 (+0.37, +3.36)	+1.53 (-0.18, +2.27)	NA

All efficacy results are missing=failure; bone and renal safety are observed data. $eGFR_{CG}$ is creatinine clearance (Cockcroft-Gault method). BMD is bone mineral density.
[a]For Studies 108/110 results are for HBV DNA <29 IU/mL. [b]Study 4035 results are at Week 24. [c]End-stage renal disease patients are not included in this analysis.

Figure: (abstract: SAT461)

assessed for older (≥65 y) vs younger (<65 y) patients. In Studies108, 110, and 4018, results for TDF in patients ≥65 y were also determined for comparison.
Results: A total of 124 patients ≥65 y were included, representing 6.5% of all enrolled patients. Other than age, decreases in renal/bone parameters, and increased comorbidities, the older and younger groups were generally similar. Efficacy and safety results are summarized in the Table. Rates of virologic suppression was comparable in geriatric vs non-geriatric patients treated with TAF. Overall, AEs and SAEs were similar between older vs younger patients; there were no Grade 3/4 AEs related to study drug in patients ≥65 y. Compared with younger patients, declines in $eGFR_{CG}$ and hip/spine BMD were greater in viremic older patients; however, the decreases were less than in older patients on TDF. In suppressed patients, $eGFR_{CG}$ increases were greater in younger vs older patients receiving TAF, while changes in hip and spine BMD were similar; TDF treatment resulted in declines in BMD and $eGFR_{CG}$.
Conclusion: The efficacy and safety of TAF in geriatric CHB patients were generally similar to younger patients. Small improvements in renal and bone parameters can be seen in older patients switched from TDF to TAF.

Pharmacokinetics of VIR-2218, an RNAi therapeutic for the treatment of HBV infection, in healthy volunteers

Sneha V. Gupta[1], Marie C. Fanget[1], Anna Bakardjiev[1], Gabriel I. Robbie[2], Varun Goel[2], Erik Mogalian[1]. [1]*Vir Biotechnology, Inc., San Francisco, United States;* [2]*Alnylam Pharmaceuticals, Inc., Cambridge, United States*
Email: emogalian@vir.bio

Background and Aims: VIR-2218 is an investigational N-acetylgalactosamine (GalNAc)-conjugated ribonucleic acid interference (RNAi) therapeutic in development for functional cure of chronic hepatitis B virus infection (CHB). VIR-2218 was created using Enhanced Stabilization Chemistry Plus (ESC+), which retains enhanced metabolic stability needed for in vivo potency while reducing sequence matched off-target effects. VIR-2218 is designed to silence all HBV transcripts, from both cccDNA and integrated DNA, across all 10 HBV genotypes. Preliminary pharmacokinetic (PK) data from the first-in-human Phase 1 randomized, blinded, placebo-controlled, dose ranging study of VIR-2218 in healthy volunteers are reported herein.
Method: Six single ascending dose cohorts of eight subjects (6:2 active:placebo) received a single subcutaneous (SC) dose of VIR-2218 ranging from 50 to 900 mg. Plasma samples were assessed to determine PK of VIR-2218 and active metabolite.
Results: VIR-2218 was absorbed after SC injection with median T_{max} of 4–8 hours. VIR-2218 was not measurable in plasma after 48 hours for any subject, consistent with rapid GalNAc-mediated liver uptake; the median apparent elimination half-life ($t_{1/2}$) ranged from 2.85–5.71 hours. Following single SC dose of 50 to 900 mg, plasma area under the curve (AUC_{last}) and mean-maximum concentrations (C_{max}) increased with dose with mean exposures ranging between 786 to 74,700 ng*hr/mL and 77.8 to 6010 ng/mL, respectively. Interpatient variability in VIR-2218 plasma PK parameters was generally low (~30%). In preclinical species, the most prevalent active metabolite (~12%), AS(N-1)3′ VIR-2218, is equally potent as parent VIR-2218. AS (N-1)3′ VIR-2218 was detectable in plasma in 0/6 subjects at 50 mg, 3/6 subjects at 100 mg and in all subjects at 200, 400, 600 and 900 mg. The PK profile of the metabolite was similar to VIR-2218 with AUC_{last} and C_{max} values of AS(N-1)3′ VIR-2218 in plasma ≤10% of VIR-2218.
Conclusion: VIR-2218 demonstrated favorable PK properties in healthy volunteers supportive of SC dosing and continued development. Evaluation of VIR-2218 in patients with HBV is ongoing.

SAT463

Characterization of IL-21-expressing recombinant hepatitis B virus (HBV) as a therapeutic agent targeting persisting HBV infection

Zhongliang Shen[1], Jingwen Wu[1], Jing Liu[2,3], Youhua Xie[2,4], Jiming Zhang[1,2]. [1]*Fudan University, Department of Infectious Diseases, Huashan Hospital, Shanghai, China;* [2]*Fudan University, Key Laboratory of Medical Molecular Virology (Ministry of Education/National Health Commission/Chinese Academy of Medical Sciences), Department of Microbiology and Parasitology, School of Basic Medical Sciences, Shanghai Medical College, Shanghai;* [3]*Fudan University, Key Laboratory of Medical Epigenetics and Metabolism, Institutes of Biomedical Sciences, School of Basic Medical Sciences, Shanghai Medical College, Shanghai, China;* [4]*Fudan University, Children's Hospital, Shanghai*
Email: jmzhang@fudan.edu.cn

Background and Aims: Gene therapy based on adeno-associated virus (AAV) has been used for treatments in chronic hepatitis B virus (HBV) mouse model and achieved promising therapeutic effects. However, the nonspecific transduction of AAV and the integration of cargo gene into host genome could pose potential risks. Novel therapeutic vectors need to be developed. The hepatocyte tropism of HBV, as well as the accessibility of virions, makes HBV an ideal candidate for the development of hepatocyte-targeting therapeutic vector. We have generated a highly replicative HBV replicon plasmid, named 5c3c, with a maximized in-frame deletion within the functionally non-critical spacer region of polymerase, where cargo gene sequences can be inserted in-frame with the overlapping preS1-preS2-S open reading frame(ORF). Meanwhile, IL-21 has been reported to be positively associated with the outcome of HBV treatments in clinic and mouse models, which makes it a therapeutic gene for HBV.
Method: We cloned human or murine IL-21 gene into 5c3c to create recombinant HBV (rHBV) replicon (hIL-21-5c3c and mIL-21-5c3c, respectively). rHBV replicon plasmids were transfected into hepatoma Huh7 cells or injected into mice to collect rHBV virions. The infection and super-infection ability of virions was confirmed in HepG2 cells stably expressing NTCP (HepG2-NTCP) and human liver chimeric mice. Lastly, we assessed the anti-viral effects of rHBV replicon in chronic HBV mouse model.
Results: A large amount of rHBV virions carrying hIL-21 or mIL-21 could be obtained from in vitro and in vivo. These virions could infect HepG2-NTCP cells to initiate HBV gene expression (including IL-21) and replication. Most importantly, these virions possessed super-infection ability in both HepG2-NTCP cells and human liver chimeric mice. Lastly, we found rHBV replicon could clear HBV serum markers and intrahepatic HBV DNA (including rHBV DNA) with long-lasting HBV specific memory responses.

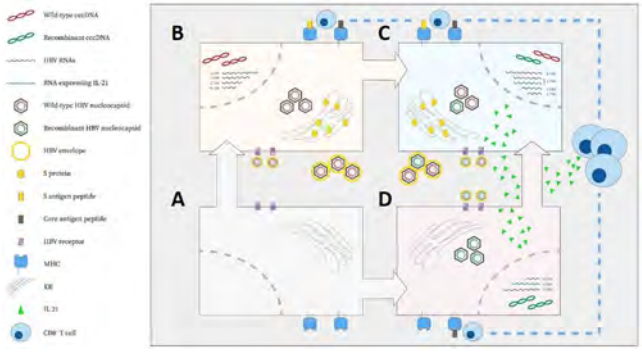

Figure: **Application of therapeutic rHBV virions to chronic hepatitis B treatments.** (A) HBV-free hepatocytes. (B) Wild-type HBV virions infect hepatocytes and then secretes progeny HBV. (C) rHBV virions super-infect hepatocytes. (D) rHBV virions infect HBV-free hepatocytes.

Conclusion: These results demonstrated rHBV virions carrying IL-21 gene could provide a novel vehicle for chronic HBV treatments.

SAT464

Optimising delivery of therapeutic hepatitis B vaccines to induce resident memory T cells in the liver

Tamsin Cargill[1], Sanjana Narayan[1], Senthil Kumar Chinnakannan[1], Lian Ni Lee[1], Claire Hutchings[1], Paul Klenerman[1], Eleanor Barnes[1].
[1]*University of Oxford, NDM, Peter Medawar Building, Oxford, United Kingdom*
Email: tamsin.cargill@bnc.ox.ac.uk

Background and Aims: We have previously developed viral vectors (chimapanzee adenoviral [ChAdOx1] and modified vaccinia Ankara [MVA]) encoding hepatitis B virus (HBV) antigens for the therapy of chronic HBV infection. Used in heterologous prime-boost strategies, they generate high magnitude, polyfunctional T cell responses in mouse splenocytes. Since HBV is exclusively hepatotropic, the aim of this study was to evaluate the characteristics of vaccine induced intrahepatic T cells and target them to the liver by optimising vaccine delivery.
Method: C57BL6 mice were vaccinated with 5×10^7 infectious units (iu) ChAdOx1-HBV (prime, week 0) followed by 2×10^6 plaque forming units (pfu) MVA-HBV (boost, week 4). After intramuscular (i.m) ChAdOx1-HBV prime, MVA-HBV boost was delivered either i.m or intravenously (i.v) to assess its effect on intrahepatic T cell responses. Mice were sacrificed 14 or >60 days after MVA-HBV. Lymphocytes were isolated via mechanical dissociation and were surface stained using fluorochrome-labelled antibodies and a pentamer specific for the H2Kb restricted epitope VWLSVIWM. Cells were acquired on an LSRII flow cytometer (BD) and analysed by FlowJo v10 (BD). Statistical analysis was performed on PRISM v8 (GraphPad).
Results: Vaccine induced VWLSVIWM specific CD8 T cells in the blood and liver are predominantly CD44+CX3CR1+CD62L-. Liver T cells express higher CD69 (median fluorescence intensity [MFI] 13154 vs 2315, $p < 0.0001$) and CXCR6 (54.3% vs 16.1%, $p = 0.0008$) than in the blood at day 14 after boost vaccination. The magnitude of VWLSVIWM T cells is increased in the liver after i.v as compared to i.m MVA-HBV boost vaccination at day 14 (3.00% vs 4.90% of all CD8 T cells, $p = 0.04$) but not at >60 days after boost vaccination (3.11% vs 3.98%, $p > 0.05$).
Conclusion: Therapeutic HBV vaccination induces long lived T cells with a CD69+ tissue residency phenotype in the liver. Although the magnitude of vaccine induced T cells in the liver at day 14 after boost MVA-HBV vaccination can be increased by i.v rather than i.m administration, this was not sustained out to day 60. This transient increase of intrahepatic T cells after i.v. boost MVA vaccination may be sufficient to enable immunological control of HBV in chronic infection.

Email: gaozl@mail.sysu.edu.cn

Background and Aims: HBsAg loss is regarded as functional cure and considered as an optimal treatment endpoint for chronic hepatitis B. In order to explore a better strategy to achieve functional cure and confirm the HBsAg loss rate of previous clinical studies in the real world, Chinese Foundation for Hepatitis Prevention and Control launched the multicenter real-world study that focused on functional cure, named Everest Project. (NCT04035837).
Method: The Everest Project plans to recruit 30,000 CHB patients from over 260 hospitals in China who had experienced effective NA therapy for more than one year, presented as HBV DNA<100 IU/ml, HBeAg negative and HBsAg<1500 IU/mL, between April 2018 and December 2021. Peg-IFNα "add-on" or "switch to" treatment for 48 to 96 weeks was selected by patients. The primary endpoints were HBsAg loss and seroconversion rates at 48 and 96 weeks.
Results: Up to now, 2673 eligible patients were recruited. 1427 patients who have completed 24 weeks of treatment and 516 patients who have completed 48 weeks of treatment were analyzed. 82.3%

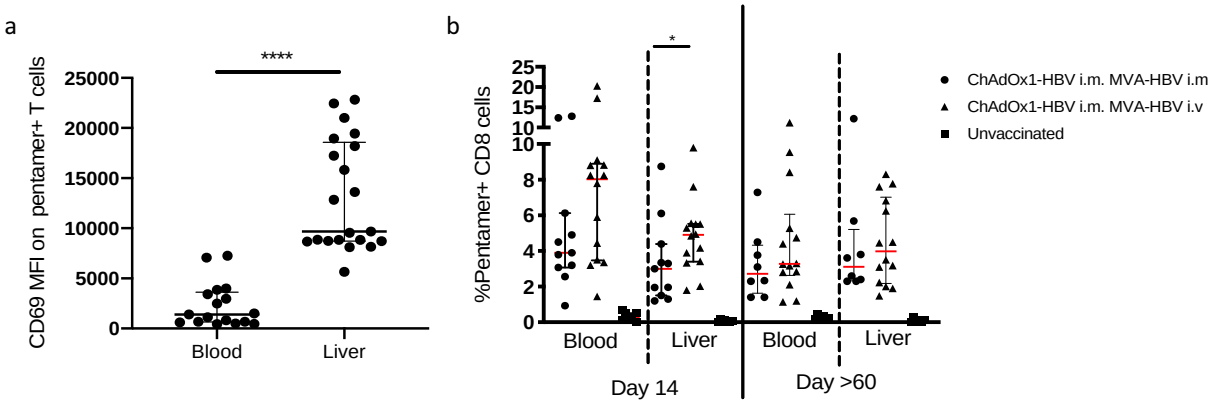

Figure: (abstract: SAT464): (a) MFI of CD69 in VWLSVIWM T cells (pentamer+) in the blood and liver and (b) percentage of VWLSVIWM T cells (pentamer +) in the blood and liver day 14 and day >60 after i.m or i.v MVA-HBV boost vaccination.

patients were male with a mean HBsAg baseline of 388.4 IU/ml. The overall rate of HBsAg loss for patients treated ≥12, ≥24, ≥36 and ≥48 weeks was 13.00%, 16.06%, 20.49% and 23.01%. Subgroup analysis based on baseline HBsAg stratification (0.05–100, 100–500, 500–1000, 1000–1500 IU/mL) found that the HBsAg loss rate was highest in patients with baseline HBsAg between 0.05 and 100 IU/mL (34.93% for patients treated ≥48 weeks).

Fig 1: Interim data of HBsAg loss of Everest Project in China. *The mean baseline of HBsAg was 388.4 IU/ml.

Conclusion: Functional cure can be well achieved in NA suppressed CHB patients by pegIFNα "add-on" or "switch to" strategies, especially for those with lower HBsAg baseline. Patients who complete the full course of treatment have the highest chance to functional cure. The rate of HBsAg loss in this large-scale real-world study is consistent with previous clinical research.

SAT467

Occurence of hepatocellular carcinoma in chronic hepatitis B patients undergoing entecavir or tenofovir treatment: a multicenter study in Taiwan

Email: yhhuang@vghtpe.gov.tw

Background and Aims: Nucleos(t)ide analogues (NUCs) treatment, including entecavir (ETV) or tenofovir (TDF), had been demonstrated to reduce the risk of hepatocellular carcinoma (HCC) development in patients with chronic hepatitis B (CHB). However, some studies reported an even lower risk of HCC occurrence by TDF as compared with ETV. We performed a multi-center study to compare the incidence of HCC between the two NUCs among lamivudine-naive CHB patients by collecting data from ten medical centers in Taiwan.
Method: From 2007, 5131 CHB patients had been received ETV or TDF treatment in this multicenter data cohort. Among them, 816 patients were excluded due to HCV coinfection, underlying HCC or malignancy, less than 6 months of treatment, lamivudine-experienced or resistance. Finally, 4315 patients were recruited in this study, including 3124 on ETV and 1191 on TDF treatment. Factors associated with HCC occurrence were evaluated.
Results: Of the 4315 patients, 1106 had underlying liver cirrhosis. As of the end of 2018, 192 patients developed HCC, with the incidence of 0.009 per person-year for ETV and 0.008 per person-year for TDF. Factors associated with HCC occurrence were age >55 y/o (HR = 2.717, 95% CI = 2.017–3.661, $p < 0.001$), male gender (HR = 1.441, 95% CI = 1.029–2.017, $p = 0.033$), and presence of cirrhosis (HR = 5.705, 95% CI = 4.162–7.821, $p < 0.001$) in multivariate analysis. There was no statistical difference in the risk of HCC occurrence between ETV or TDF treatment. In subgroup patients with cirrhosis, the incidence of HCC was 0.021 per person-year for ETV, and 0.025 per person-year for TDF. Again, TDF, as compared with ETV, did not further reduce the risk of HCC in univariate analysis. Only male gender and age >55 y/o were the significant factors related to HCC development in cirrhotic patients.
Conclusion: The statistical difference of the HCC risk between TDF and ETV was not reached in this multicenter, large cohort study, even in subgroup patients with liver cirrhosis.

SAT468

Anti-HBS induction and HBsAg reduction by nasal administration of a therapeutic vaccine containing HBsAg and HBcAg (NASVAC) in patients with chronic HBV infection

Osamu Yoshida[1], Akbar Sheikh Mohammad Fazle[2], Takahiro Sanada[3], Michinori Kohara[3], Kyoko Tsukiyama-Kohara[4], Takashi Miyazaki[5], Taizo Kamishita[5], Mamun Al-Mahtab[6], Aguilar Julio[7], Gerardo Guillen[7], Yoichi Hiasa[1]. *[1]Ehime University Graduate School of Medicine, Department of Gastroenterology and Metabology, Toon, Japan; [2]Ehime University Graduate School of Medicine, Department of Pathology , Toon, Japan; [3]Tokyo Metropolitan institute of Medical Science, Department of Microbiology and Cell Biology, Japan; [4]Kagoshima University, Joint Faculty of Veterinary Medicine, Kagoshima, Jersey; [5]TOKO YAKUHIN KOGYO CO., LTD, Osaka, Japan; [6]Bangabandhu Sheikh Mujib Medical University, Department of Hepatology, Dhaka, Bangladesh; [7]Center for Genetic Engineering and Biotechnology, Biomedical Research Department, Havana, Cuba*
Email: yoshidao@m.ehime-u.ac.jp

Background and Aims: HBs antigen (HBsAg) loss is termed functional cure and recognized as an ideal treatment goal for the patients with chronic hepatitis B virus (HBV) infection. However, it is difficult to achieve functional cure by nucleos(t)ide analogs (NAs) or interferon. Thus NAs require long-term treatment. Further, chronic HBV infection without hepatitis, not recommended for anti-HBV therapy by current guidelines, needs suitable drugs for achieving functional cure, because these patients owe a risk for hepatic flare and hepatocellular carcinoma. This study was aimed to assess the efficacy of nasal administrative therapeutic vaccine, NASVAC, containing both HBsAg and HBcAg, on kinetics of HBsAg in CHB patient under NAs and chronic HBV infection without hepatitis.
Method: CHB patient with NAs and HBV carrier enrolled in an open-label clinical trial at Ehime University Hospital, Japan, after obtaining written consent and permission from institutional review board and enrollment of study to the clinical trial authority of Japan

(IRB#18EC003; registered to jRCT (#jRCTs061180100). NASVAC was emulsified in carboxyl vinyl polymer to increase the viscosity, then administrated for 10 times, once in every 2 weeks, by a special device designed for durable existence of NASVAC in nasal mucosa. Data were analyzed at 6 months after end of treatment (EOT).
Results: Twenty nine HBV patients under NAs treatment (NA group: age: 49–66 years, ALT: 16–28 U/L, HBsAg: 93–1942 IU/mL) and forty two chronic HBV infection without hepatitis (w/o NA group: age: 44–64 years, ALT: 16–29 U/L, HBsAg: 311–3706 IU/mL) were enrolled. 75% of NA and 74.3% of w/o NA displayed HBsAg reduction, the mean HBsAg reduction was 16.7% in NA and 18.3% in w/o NA at 6 months after EOT. 37.9% in NA and 58.5% in w/o NA developed anti-HBs. HBV-DNA reduction was observed in 68.2% of w/o NA and 3 patients showed sustained HBV-DNA negativity. 4 patients, two in NA and two in w/o NA, achieved functional cure.
Conclusion: NASVAC induced anti-HBs, and reduced HBsAg in CHB with NAs and chronic HBV infection. Overall 4 patients achieved functional cure by NASVAC. NASVAC could be a novel immune therapy for achieving functional cure in HBV infected patients.

SAT469
The development and application of a prognosis prediction model for children with chronic hepatitis B

Email: zhongyanwei@126.com

Background and Aims: Serum hepatitis B surface antigen quantification(qHBsAg) was considered to be a reliable marker to predict antiviral treatment outcome. However, whether qHBsAg could predict HBsAg seroclearance in children with chronic hepatitis B (CHB) remains unclear. The aim of the study was to develop a prognosis prediction model for children patients with CHB treated with interferon(IFN).
Method: 195 children patients aged 1–17 years with CHB were enrolled from January 2010 to February 2015 in 302 hospital, who were treated with IFN alpha 48 weeks, and the end of treatment following up at least 6 months. Lasso regression model was used for features selection. Multivariable logistic regression analysis was used to develop the predicting models. The performance of these models was assessed with respect to its calibration, discrimination, and clinical usefulness. Internal validation was assessed by internal validation cohort with 82 children patients with CHB, and data was gathered from March 2015 to October 2016. An independent validation cohort contained 111 consecutive children patients from January 2015 to March 2016 in 4 other hospitals.
Results: Predictors contained in two models: predictive model before treatment(the BT model) and predictive model after 12–24 weeks treatment(the AT model) included age, baseline qHBsAg, qHBsAg at week 24, the decreasing percentage of qHBsAg at week 24, HBeAg and CD4. The BT model showed good discrimination, with an AUC of 0.8415(AUC, 0.8340 and 0.8203 through internal validation and independent validation), and good calibration. The AT model showed good discrimination, with an AUC of 0.9038(AUC, 0.8816 and 0.8598 through internal validation and independent validation), and good calibration. Decision curve analysis demonstrated that two models were clinically useful. Analysis of key clinic features showed: at the end of 48 weeks IFN treatment, the incidence rates of HBsAg seroclearance was 54.05% (100/185) among the patients with under 4.88 years old. The incidence rates of HBsAg seroclearance was 82.76% (24/29) among the patients with qHBsAg ≤666.95 IU/ml before treatment. Among the patients with qHBsAg levels ≤386.05 IU/ml at week 24, incidence rates of HBsAg seroclearance was 84.55% (104/123). In addition, the decreasing percentage of qHBsAg was over 92.7% at week 24, the incidence rates of HBsAg seroclearance was 77.37% (106/137), which indicated that baseline HBsAg levels, or HBsAg levels at week 24 and the decreasing percentage of qHBsAg at week 24 were the strong predictors of HBsAg seroclearance. All of them are independent prognostic factors.
Conclusion: AT and BT models can be conveniently used to facilitate the individualized prediction of children with CHB before antiviral therapy, which were very important and clinically useful for prediction of HBsAg seroclearance in children with CHB treated with IFN.

Pre-operative gamma-glutamyltransferase to lymphocyte ratio predicts long-term outcomes for intrahepatic cholangiocarcinoma following hepatic resection

Jinju Wang[1], Hui Li[2], Lin Xu[2], Jiaxin Li[1], Yong Zeng[1]. [1]*West China Hospital, Liver Surgery & Liver Transplantation Center, Chengdu, China;* [2]*West China Hospital, Laboratory of Liver Surgery, Chengdu, China*
Email: 1448944361@qq.com

Background and Aims: Intrahepatic cholangiocarcinoma (ICC) is a heterogeneous hepatobiliary cancer with limited treatment options. A number of studies have illuminated the relationship between inflammation-based prognostic scores and outcomes in patients with ICC. However, reliable and personalized prognostic algorithm in ICC after resection is pending. To appraise the prognosis value of gamma-glutamyltransferase (GGT) to lymphocyte ratio (GLR) in ICC patients following curative resection.
Method: ICC patients following resection with curation intent (2009–2018) were divided into two cohorts: derivation cohort and validation cohort. The derivation cohort was used to explore an optimal cutoff value and the validation cohort was used to further evaluate the score. Overall survival (OS) and recurrence - free survival (RFS) were analyzed and predictors of OS and RFS were determined.
Results: 527 ICC patients were included and randomly divided into the derivation cohort (264 patients) and the validation cohort (263 patients). The two patient cohorts had comparable baseline characteristics. The optimal cutoff was 33.7. Kaplan-Meier curves showed worse OS and RFS in the GLR>33.7 group compared with GLR≤33.7 group in both cohorts. Univariate and multivariate analyses demonstrated GLR as an independent prognostic factor for OS (derivation cohort: hazard ratio (HR) = 1.457, 95% confidence interval (CI): 1.027–2.067, $P = 0.035$; validation cohort: HR = 1.562, 95%CI: 1.078–2.263, $P = 0.018$) and RFS (derivation cohort: HR = 1.465, 95%CI: 1.027–2.092, $P = 0.035$; validation cohort: HR = 1.564, 95%CI: 1.129–2.166, $P = 0.007$).
Conclusion: Preoperative GLR is an independent prognostic factor for ICC patients following curative resection. Higher GLR is associated with worse OS and RFS.

SAT474
LXR agonism potentiates sorafenib sensitivity in HCC by activating microRNA-378a transcription

Zhongjie Lin[1], Lin Ji[1], Shi Jiang[1], Junjie Xu[1], Yu Pan[1], Di Wu[1], Xiujun Cai[1]. [1]*Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Department of General Surgery, Hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: Sorafenib is the first-line treatment for advanced hepatocellular carcinoma (HCC), but the clinical response to sorafenib is seriously limited by drug resistance. Dysregulation of

microRNA play a critical roles in sorafenib resistance. Our studies have a better understanding of the dysfunction of microRNA in the sorafenib resistance and identify novel druggable targets for use in combination with sorafenib to increase its efficacy. in HCC cells.

Method: MicroRNA (miRNA) sequencing was performed to screen for potential miRNA candidates. Treatment with sorafenib resulted in sorafenib-resistant HCCs that were significantly depleted in miRNA-378a-3p, suggusting that miRNA-378a-3p play a crucial role in sorafenib resistance. We used RNA pulldown, western blots, immunohistochemistry, luciferase assays and immunoblotting to study the role of miR-378a in sorafenib resistance cell. To examine LXRa agonism in combination with sorafenib treatment, we added varying concentrations of sorafenib and LXRa agonist drugs to HCC cell lines. Patient-derived xenografts and cell-derived xenografts were used to study the functions of microRNA-378a and LXRa agonism.

Results: Our miRNA microarray data indicate that MicroRNAs (miRNA) were mostly downregulated in sorafenib resistance cell, such as microRNA-378a. There was a significant uncoupling of primer microRNA and pre-miRNAs levels in sorafenib-resistant cells. Down-regulation of xpo5 caused the precursor-microRNA-378 exporting nucleus limitation and restrained the maturation of microRNA, which reduced microRNA-378a expression conferring sorafenib resistance to hepatocellular carcinoma cells by activating IGF-1R to regulate RAS/RAF/ERK signaling pathways. LXRα (Liver X receptor alpha) functioned as a transcription activator of microRNA-378a and made sorafenib-resistance cells and model sensitive to sorafenib.

Conclusion: Attenuated XPO5-mediated export of precursor-miRNA limitation conferred sorafenib resistance in HCC. LXR agonist (GW3965) in combination with sorafenib represents a novel therapeutic strategy for HCC treatment.

Ivermectin inhibits cholangiocarcinoma proliferation via induction of endoplasmic reticulum stress in vitro and vivo

Zhe Wan[1], Dong Cen[1], Lin Ji[1], Junjie Xu[1], Haoqi Pan[1], Xiujun Cai[1].
[1]*Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, Department of General Surgery, HangZhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: Cholangiocarcinoma (CCA) is the second most common type of liver cancer, and is highly aggressive with very poor prognosis because of insensitivity to most of antitumor drugs. To reduce the mortality of cholangiocarcinoma and increase the possibility of cure, it is urgent and necessary to find effective and relatively safe drugs for the treatment of cholangiocarcinoma.

Method: In this study, we performed high-throughput drug screening, and found the river blindness drug Ivermectin (IVM) can inhibit Cholangiocarcinoma Proliferation in vitro and in vivo. RNA sequencing for ivermectin treated CCA cells prompted ER-Stress may play a vital role in inhibiting CCA cells proliferation. And thus, we studied the mechanism of induction of ER-Stress by ivermectin in CCA cell lines.

Results: Ivermectin inhibits CCA cell lines proliferation significantly via evaluating cell viability with Cell Counting Kit-8 after treated with 10 μM IVM dissolved with DMSO, while HIBEC cell (Human Intrahepatic Biliary Epithelial Cells) is not sensitive to IVM. The CCA cells treated with IVM are arrested in G1 phase. The results of colony formation assay demonstrate IVM can inhibit CCA cells proliferation.

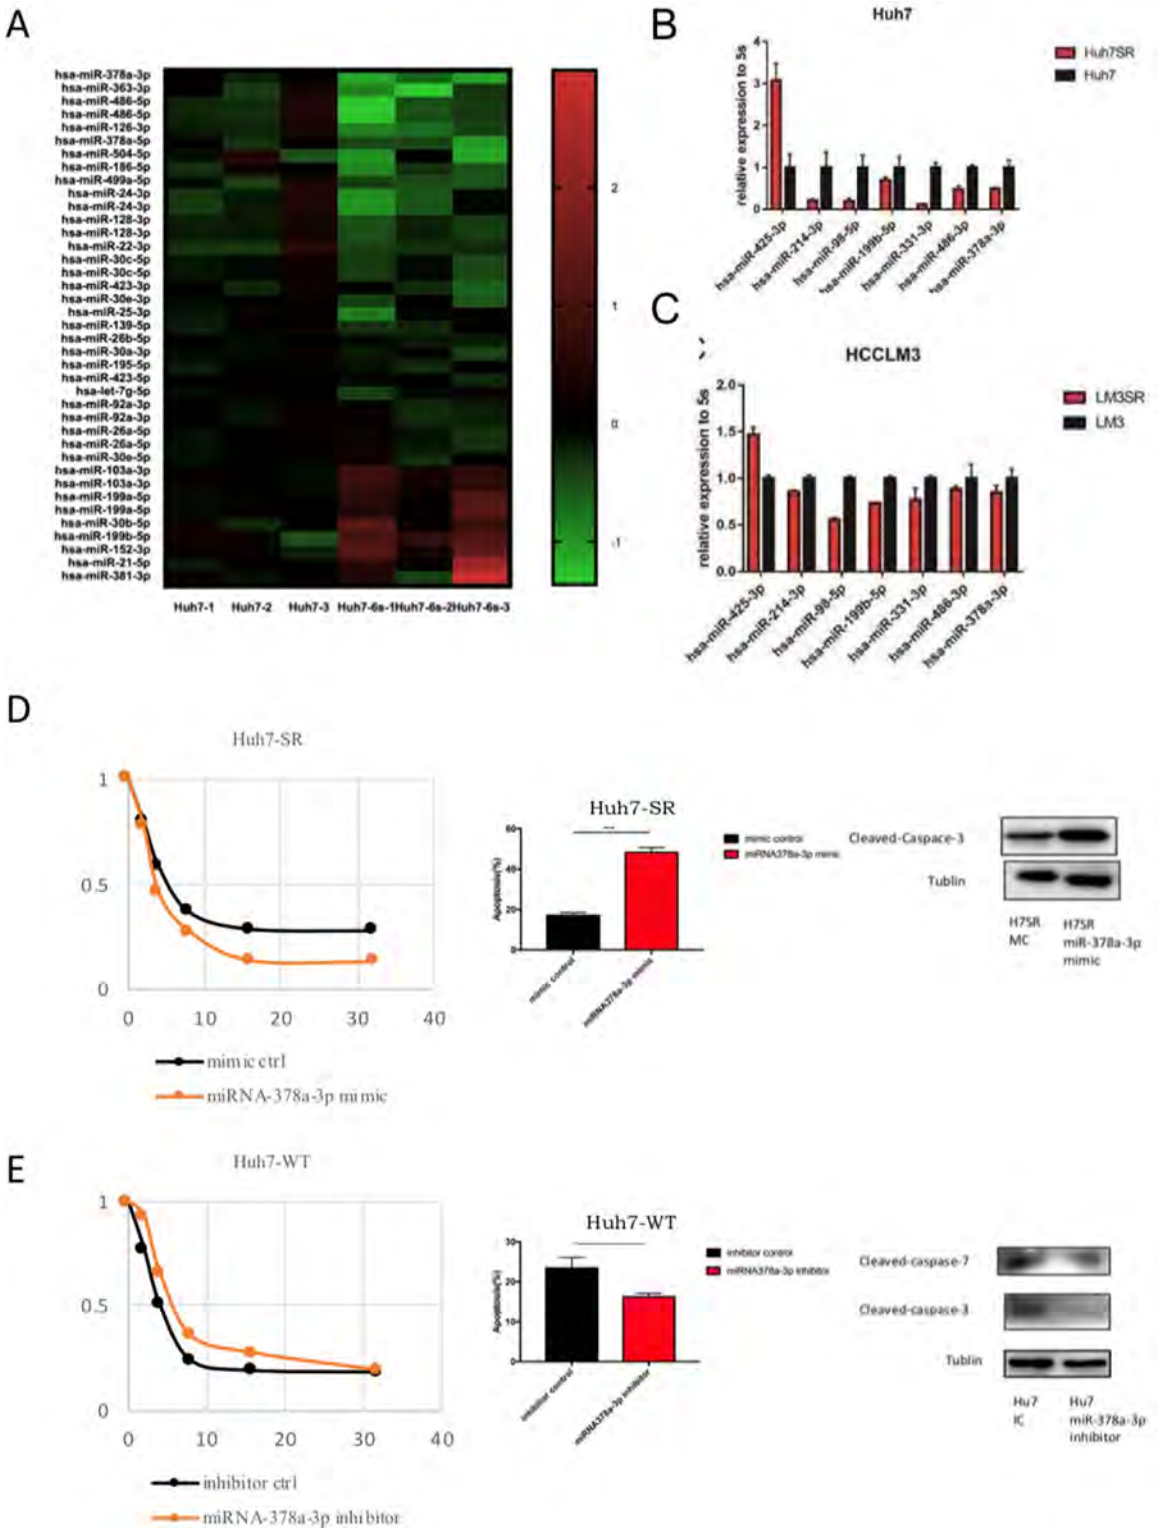

Figure: (abstract: SAT474)

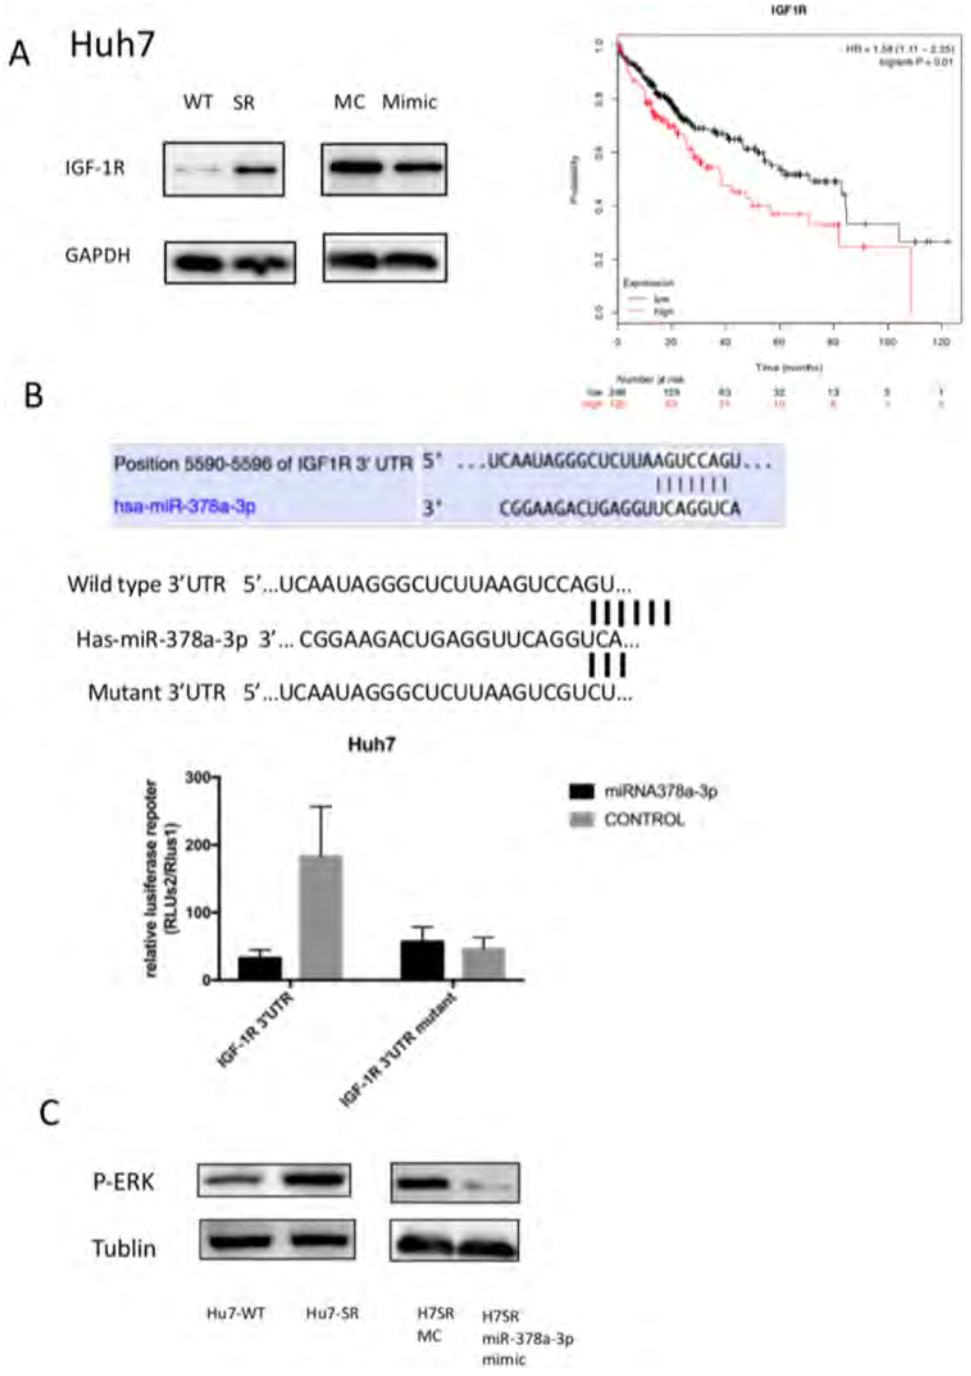

Figure: (abstract: SAT474)

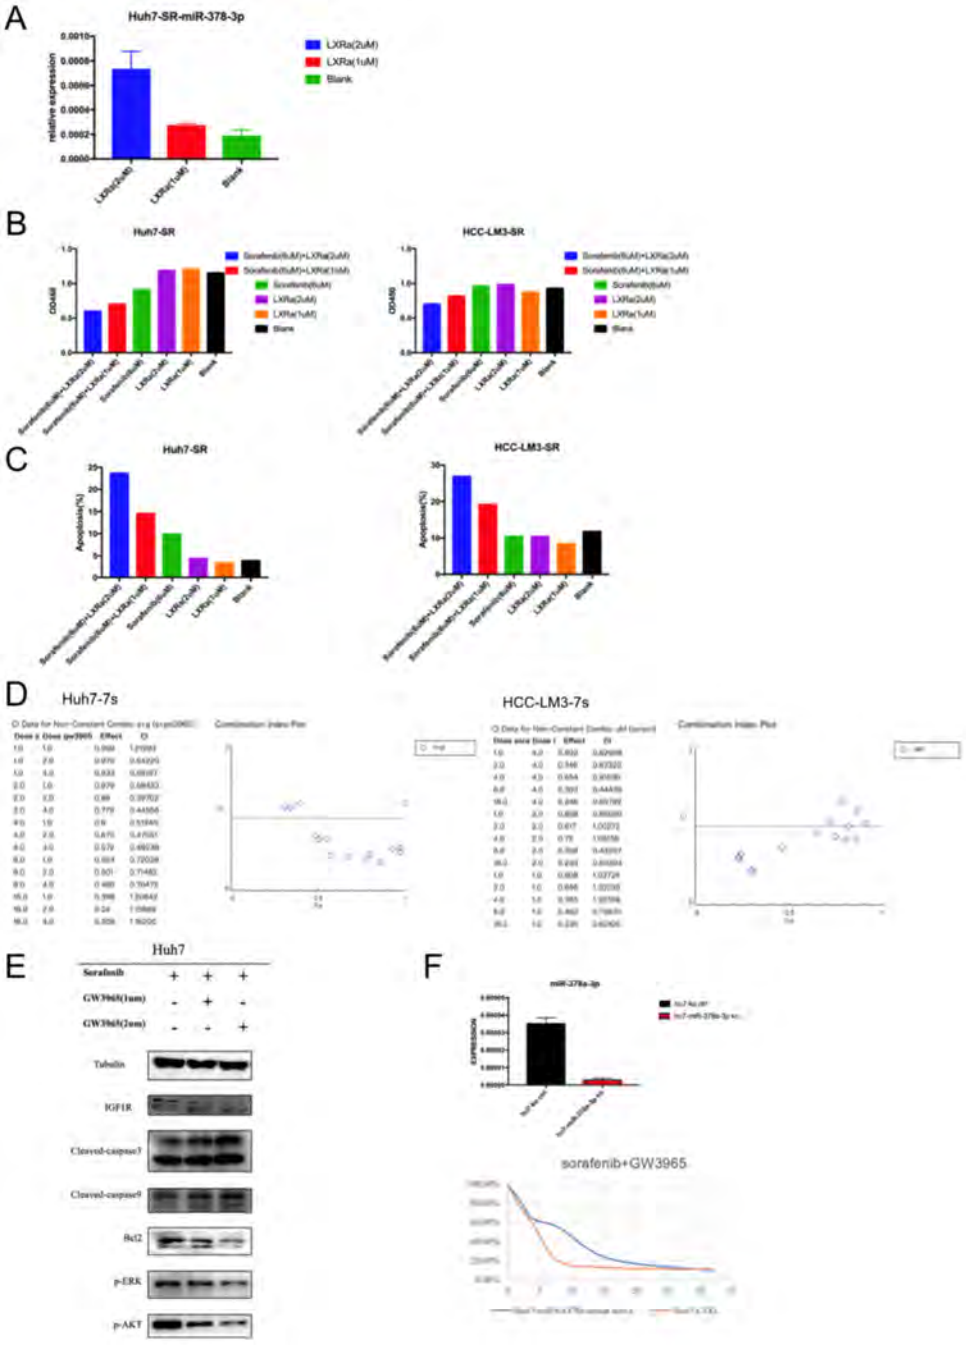

Figure: (abstract: SAT474)

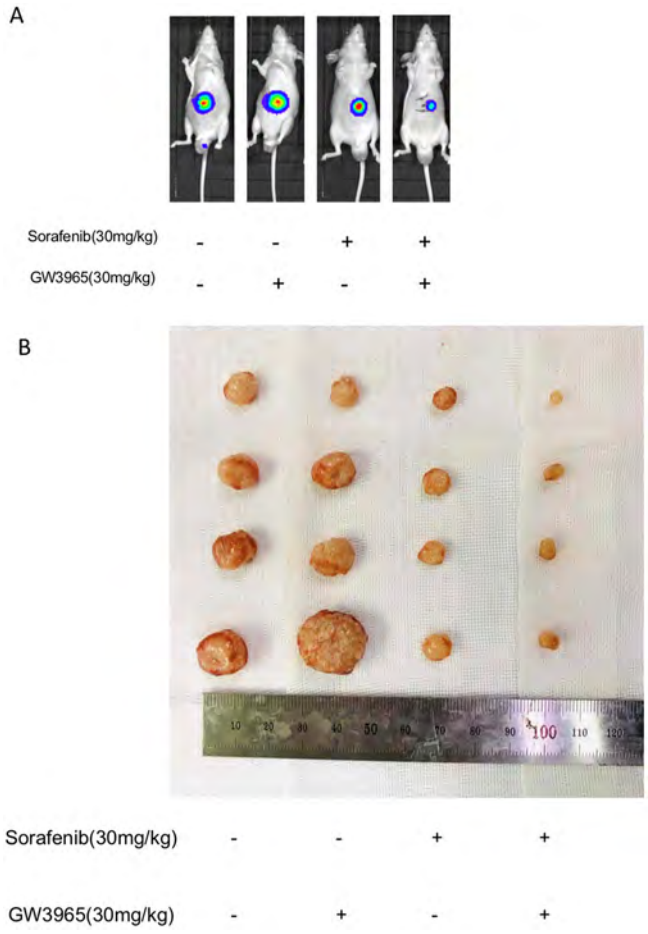

Figure: (abstract: SAT474)

Analysis of RNA sequencing to cells treated with IVM indicates induction of ER-Stress is potential mechanism of anti-tumor. Western-Blot experiments confirm ER-Stress play a vital role in this anti-tumor process. By constructing Patient-Derived tumor Xenograft (PDX) and Cell-Derived tumor Xenograft (CDX) subcutaneously in nude mice, IVM can inhibit CCA proliferation and have significant anti-tumor effect in vivo.
Conclusion: Ivermectin can inhibit cholangiocarcinoma cells proliferation in vivo and vitro via induction of ER-Stress and would be a promising drug therapy for cholangiocarcinoma, which provides novel treatment methods for CCA.

SAT476
Percutaneous microwave ablation versus open surgical resection for colorectal cancer liver metastasis

Lei Chen[1], Qinxian Zhao[2]. [1]*PLA General Hospital, Department of Otolaryngology, Beijing, China;* [2]*PLA General Hospital, Beijing, China*
Email: 646966182@qq.com

Background and Aims: To compare the therapeutic outcomes between open surgical resection (OSR) and percutaneous microwave ablation (PMWA) for colorectal liver metastasis (CRLM) ≤3 cm.
Method: In this retrospective study, 200 consecutive patients with 306 CRLMs were reviewed. Overall survival (OS), disease-free survival (DFS), local tumour progression (LTP), intrahepatic distant recurrence, and extrahepatic metastasis were analysed to compare the therapeutic efficacy. Cox proportional hazards regression analysis was used to identify the prognostic factors for OS and DFS. Major complications and postoperative hospital stay were also assessed.
Results: The 1-, 3-, and 5-year OS rates were 91.6%, 64.1%, and 46.3%, respectively, in the PMWA group and 89.7%, 62.4% and 44.7%, respectively, in the OSR group (P = 0.839). The 1-, 3-, and 5-year DFS rates were 61.9%, 44.8%, and 41.3%, respectively, in the PMWA group and 58.1%, 24.4%, and 18.3%, respectively, in the OSR group (P = 0.066). The two groups had comparable 5-year cumulative rates of intrahepatic distant recurrence (P = 0.627) and extrahepatic metastasis (P = 0.884). The 5-year cumulative LTP rate was lower in the OSR group than in the PMWA group (P = 0.023). The rate of major complications was higher in the OSR group than in the PMWA group (P = 0.025), and the length of hospital stay after treatment was shorter in the PMWA group (P < 0.001).

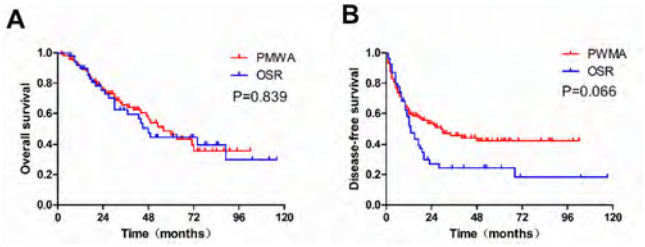

Figure: A: Graph shows cumulative overall survival rates after each treatment. The 1-, 3-, and 5-year overall survival rates were, respectively, 91.6%, 64.1%, and 46.3% in the PMWA group and 89.7%, 62.4%, and 44.7% in the OSR group. B: Graph shows cumulative disease-free survival rates after each treatment. The 1-, 3-, and 5-year disease survival rates of the PMWA group were, respectively, 61.9%, 44.8%, and 41.3% in the PMWA group and58.1%, 24.4%, and 18.3% in the OSR group. PMWA = percutaneous microwave ablation; OSR = open surgical resection.

Conclusion: There were no significant differences in OS or DFS between the two groups. PMWA was associated with increased LTP, fewer postoperative days and fewer major complications

Email: nadira.delhem@ibl.cnrs.fr

Background and Aims: Photodynamic Therapy (PDT) is a local anti-tumoral modality relying on systemic administration of a non-toxic dye, called Photosensitizer (PS), followed by illumination to elicit tumor cell death. Using 5-Aminolevulinic acid (5-ALA), the FDA-approved oral pro-drug of Protoporphyrin IX, the actual PS, we investigated the in-vitro impact of PDT over Hepatocellular Carcinoma (HCC) cell lines, and over healthy and tumoral liver cells obtained from surgical specimen of patients with HCC.

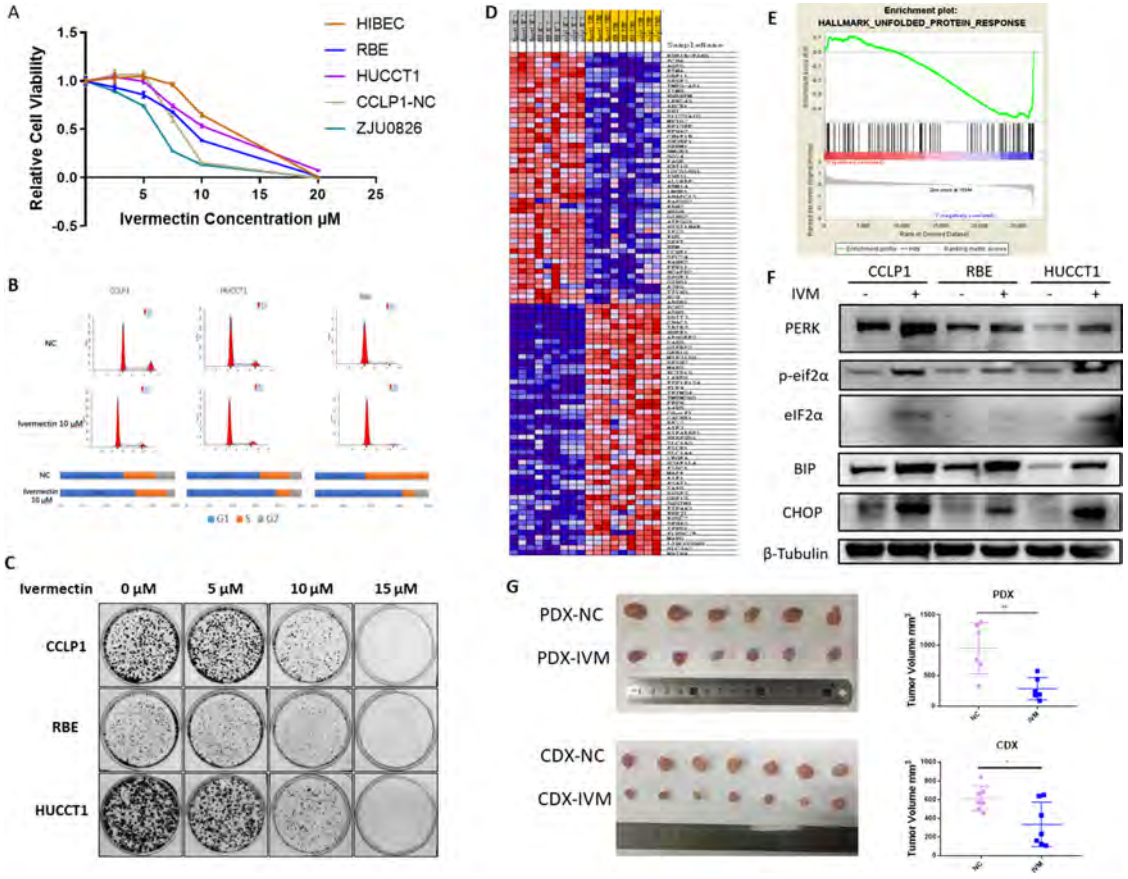

Figure: (abstract: SAT475)

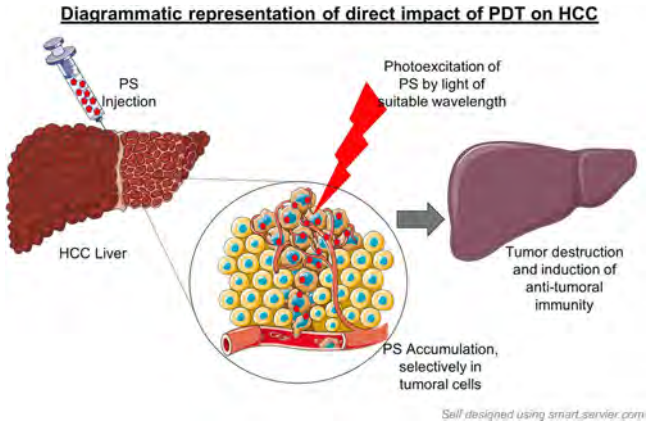


Method: Optimal 5-ALA PDT dosage was determined on three HCC cell lines; by testing different 5-ALA concentrations and illumination dosages. The efficacy was evaluated by analyzing viability, cellular proliferation and cytotoxicity, 24 hours post illumination. To examine safety of the therapy, primary healthy donor hepatocytes and liver myofibroblasts were treated by the optimal PDT dose, to measure their viability 24hr post illumination. Markers of fibrosis were analyzed by qPCR and ELISA, to observe fibroblast activation by 5-ALA PDT. To validate our findings, we investigated the viability of tumoral and healthy hepatocytes obtained from the same patient, till 12 days post illumination.

Results: In HCC cell lines, 5-ALA PDT induced a dose-dependent decrease of cellular viability; the optimal dose exhibiting IC50, thereafter, induced decreased cellular proliferation and increased cytotoxicity with respect to non-treated control. The viability of primary hepatocytes from a healthy donor treated with 5-ALA PDT decreased roughly 3 folds. Myofibroblasts treated by 5-ALA PDT did not exhibit any change in viability along with no change in mRNA expression levels of fibrosis markers. i.e. collagen-1, HSP47, αSMA, TIMP1, MMP2 together with no change in collagen secretion levels. When tested on tumoral and healthy hepatocytes from the same HCC patient, viability with respect to Non-Treated control decreased continuously up to 4 folds in both.

Conclusion: While having a negative effect on healthy hepatocytes, which might be due to the central role of the liver in heme-biosynthesis, the 5-ALA pathway for Protoporphyrin IX synthesis, our results still suggest that a non-targeted 5-ALA PDT can be effective to induce HCC cytotoxicity. Further studies are expected to develop targeted PS, which could localize selectively to the tumor core, along with surgical devices allowing targeted illumination of the tumor bedside intraoperatively, as an adjuvant to surgical resection.

SAT479

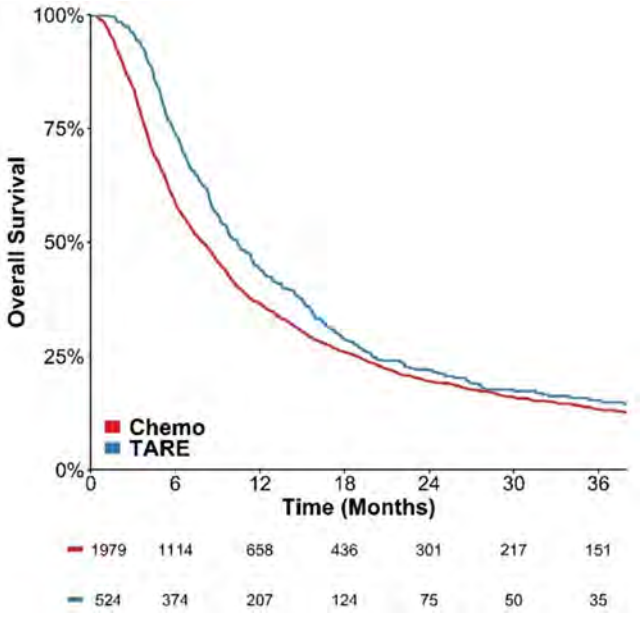
Transarterial radioembolization versus systemic treatment for the management of hepatocellular carcinoma with vascular invasion: analysis of the US national cancer database

Joseph Ahn[1], Michael Luu[2], Mazen Noureddin[3], Walid Ayoub[3], Alexander Kuo[3], Vinay Sundaram[3], Andrew Klein[2], Todd Brennan[2], Irene Kim[2], Tsuyoshi Todo[2], Georgios Voidonikolas[2], Marc Friedman[4], Jonathan Steinberger[4], H. Gabriel Lipshutz[4], Andrew Hendifar[5], Jun Gong[5], Kambiz Kosari[2], Shelly C. Lu[3], Nicholas Nissen[2], Ju Dong Yang[3]. *[1]Mayo Clinic, Gastroenterology and Hepatology, Rochester, United States; [2]Cedars-Sinai Medical Center, Comprehensive Transplant Center, Los Angeles, United States; [3]Cedars-Sinai Medical Center, Division of Digestive and Liver Diseases, Los Angeles, United States; [4]Cedars-Sinai Medical Center, Interventional Radiology, Los Angeles, United States; [5]Cedars-Sinai Medical Center, Division of Medical Oncology, Los Angeles, United States*
Email: judong.yang@cshs.org

Background and Aims: For hepatocellular carcinoma (HCC) with vascular invasion, systemic treatment is recommended but transarterial radioembolization (TARE) is often used in clinical practice. The aim of this study was to investigate the outcome of patients who received TARE as a first-line treatment for HCC with vascular invasion in the United States (US).

Method: We performed a retrospective cohort analysis of the National Cancer Database (NCDB), which represents more than 70 percent of newly diagnosed cancer cases nationwide. All HCC patients diagnosed between 2010 and 2015 with the tumor stage of T3BN0M0 according to the 7th edition of the American Joint Committee on Cancer TNM staging system (tumor involving a major branch of a large vein of the liver without lymph nodes or extrahepatic metastasis) and received TARE or systemic treatment as a first-line treatment were included. Cox proportional hazard regression analysis was performed to identify factors associated with overall survival. Propensity score matching and inverse probability of treatment weighting adjusted analysis were performed to compare the outcome between TARE and systemic treatment.

Results: A total of 1979 patients who received systemic treatment and 524 patients who received TARE were included. The proportion of patients receiving TARE increased from 15.7% in 2010 to 31.4% in 2015. The median tumor size of the largest lesion was comparable (7.1 cm for systemic treatment vs. 7.0 cm for TARE, P = 0.43). In terms of overall survival, treatment at a community cancer program (hazard ratio [HR]: 1.43, 95% confidence interval [CI]: 1.12–1.82, p = 0.004) or comprehensive community cancer program (HR: 1.16, 95% CI: 1.03–1.29, p = 0.014) vs. academic cancer program, receiving care at the Midwest vs. Northeast region of the US (HR: 1.22, 95%: CI 1.06–1.41, p = 0.006), Charlson comorbidity index ≥3 vs. 0 (HR: 1.38, 95% CI 1.21–1.57, p < 0.001), larger tumor size (HR per cm: 1.04, 95% CI: 1.03–1.05, p < 0.001), elevated alpha-fetoprotein [AFP] vs. normal AFP (HR: 1.49, 95% CI 1.29–1.72, p < 0.001) were independently associated with shorter overall survival. With systemic treatment as a reference group, TARE was independently associated with improved overall survival (HR 0.80, 95% CI 0.72–90, p < 0.001).(Figure) Propensity score matching analysis (HR 0.81, 95% CI: 0.69–0.94, p < 0.001) and inversed proportion of treatment weight-adjusted analysis (HR 0.83, 95% CI: 0.78–0.89, p < 0.001) did not change the results.



Conclusion: Type and location of medical facilities, medical comorbidities, tumor size, elevated AFP, and type of HCC treatment were associated with overall survival in HCC patients with vascular invasion. Patients who received TARE had a longer survival compared to those who received systemic treatment. The role of TARE in combination with systemic treatment should be further investigated in HCC with vascular invasion.

SAT480

ALBI grade is a good predictive parameter for prognosis in advanced HCC patients with nivolumab therapy

Wei Teng[1], Chen-Chun Lin[1], Shi-Ming Lin[1], Ming-Mo Ho[2], Kar-Wai Lui[3], Chao-Wei Hsu[1]. *[1]Linkou Chang Gung Memorial Hospital, Gastroenterology and Hepatology, Taoyuan, Taiwan; [2]Linkou Chang Gung Memorial Hospital, Medical Oncology, Taiwan; [3]Linkou Chang Gung Memorial Hospital, Radiology, Taiwan*
Email: lincc53@gmail.com

Background and Aims: The Albumin-Bilirubin (ALBI) grade is a new index for liver function evaluation using only albumin and total bilirubin level. This study aimed to investigate the application of ALBI grade after nivolumab therapy for prognosis prediction in advanced HCC patients.

Method: One hundred and eight patients who had advanced HCC experienced nivolumab were retrospectively reviewed between August 2015 and December 2018 in Chang Gung Memorial Hospital, Linkou Medical Center. Six patients were excluded due to Child-Pugh class C and a total of 102 patients were enrolled for analysis. Image response was reviewed by an independent radiologist according to RECIST v1.1. The Cox regression model was used to identify independent predictors of progression-free survival (PFS) and overall survival (OS).

Results: The median age was 61 (range 26–86) years old and most was male gender (78%). Chronic hepatitis B virus infection accounted for most etiology (67%) and 42% patients were ALBI grade I at baseline. Forty-two (41%) patients had no any systemic treatment experience before. Objective response after first course of nivolumab treatment occurred in 21% patients and 28 patients could occur best objective response during median follow-up duration 10.7 (range 3.5–49.1) months. The median PFS and OS were 4.7 and 12.2 months, respectively. By Cox regression analysis, AFP response (a >20% decline in serum AFP levels from baseline) at 12 weeks (aHR = 0.61, 95%CI = 0.34–0.97, P = 0.044), ALBI grade I (aHR = 0.48, 95%CI = 0.26–0.87, P = 0.015) and first objective response (aHR = 0.41, 95%CI = 0.17–0.97, P =

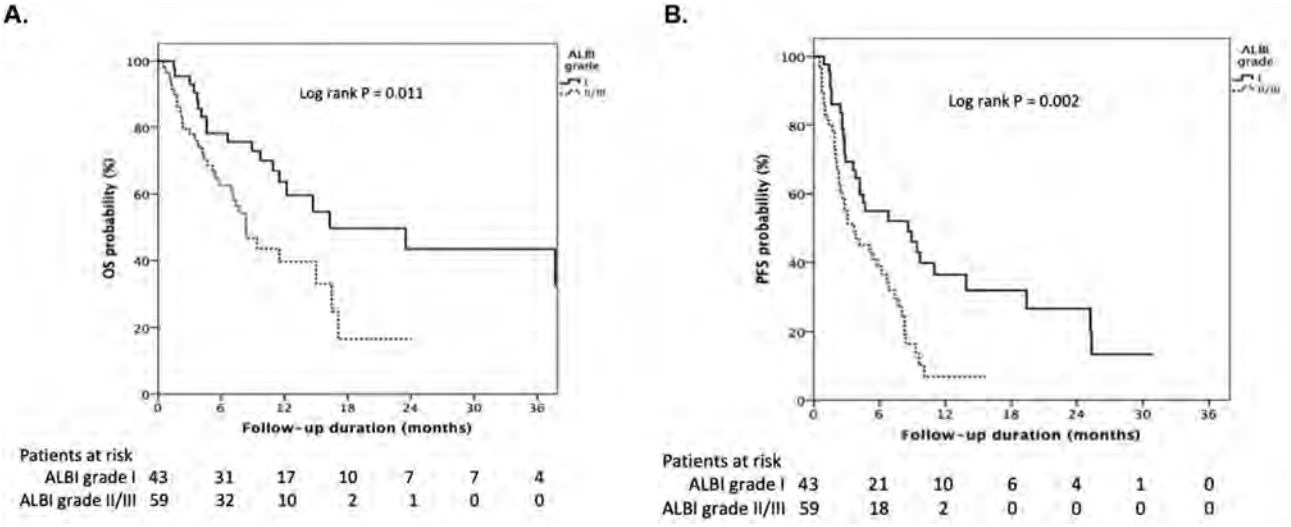


Figure: (abstract: SAT480)

0.043) were protective factors of OS while AFP response at 12 weeks (aHR = 0.38, 95%CI = 0.12–0.78, P = 0.043), ALBI grade I (aHR = 0.51, 95%CI = 0.28–0.94, P = 0.030) and AFP < 400 ng/ml (aHR = 0.37, 95%CI = 0.19–0.72, P = 0.003) were protective factors of PFS. Baseline ALBI grade I exhibited significantly longer OS (median 16.3 vs. 8.3 months, log rank P = 0.011) (Figure A) and PFS (median 8.6 vs. 3.7 months, log rank P = 0.002) (Figure B) compared with ALBI grade II/III.
Conclusion: ALBI grade was a good parameter to predict OS and PFS after nivolumab therapy in advanced HCC patients.

SAT481
Early changes in circulating FGF19 and ANG-2 levels as a possible predictive biomarker for lenvatinib therapy in hepatocellular carcinoma

Makoto Chuma[1], Haruki Uojima[2], Kazushi Numata[1], Hisash Hidaka[2], Hidenori Toyoda[3], Atsushi Hiraoka[4], Toshifumi Tada[3], Shunji Hirose[5], Takashi Nakazawa[2], Masanori Atsukawa[6], Norio Itokawa[7], Taeang Arai[6], Manabu Morimoto[8], Katsuaki Ogushi[1], Akito Nozaki[1], Tatehiro Kagawa[5], Takashi Kumada[3], Shin Maeda[9]. *[1]Yokohama City University Medical Center, Gastroenterological Center, Yokohama, Japan; [2]Kitasato University School of Medicine, Department of Gastroenterology, Internal Medicine, Sagamihara, Japan; [3]Ogaki Municipal Hospital, Department of Gastroenterology and Hepatology, Ogaki, Japan; [4]Ehime Prefectural Central Hospital, Gastroenterology Center, Matsuyama, Japan; [5]Tokai University School of Medicine, Division of Gastroenterology, Department of Internal Medicine, Isehara, Japan; [6]Nippon Medical School Hospital, Division of Gastroenterology, Department of Internal Medicine, Tokyo, Japan; [7]Nippon Medical School Chiba Hokusoh Hospital, Division of Gastroenterology, Department of Internal Medicine, Inzai, Japan; [8]Kanagawa Cancer Center Hospital, Hepatobiliary and Pancreatic Medical Oncology, Yokohama; [9]Yokohama City University Hospital, Department of Gastroenterology, Yokohama*
Email: chumamakoto@gmail.com

Background and Aims: Lenvatinib has become available as first-line therapy for patients with unresectable hepatocellular carcinoma (HCC). However, predictive biomarkers for the response to lenvatinib therapy have not yet been clarified. The aim of this study was to identify clinically significant biomarkers of lenvatinib therapy, to target strategies against HCC.
Method: Levels of circulating angiogenic factor (CAF) were analyzed in blood samples collected at baseline and at two, four, and eight weeks after introducing lenvatinib, from 74 Child-Pugh class A HCC patients who received lenvatinib. As CAF biomarkers, serum vascular endothelial growth factor (VEGF), fibroblast growth factor 19 (FGF19), FGF23, and angiopoietin-2 (Ang-2) were measured using enzyme-linked immunosorbent assays. The modified Response Evaluation Criteria in Solid Tumors were used to assess tumor response.
Results: When the analysis was stratified according to whether patients were lenvatinib responders (complete response or partial response) or non-responders (stable disease or progressive disease), significantly increased FGF19 levels (FGF19-i) and decreased Ang-2 (Ang-2-d) levels were seen on day 28 in lenvatinib responders as compared to non-responders (ratio of FGF19 level on day 28/baseline: responders vs. non-responders: 2.09 vs. 1.23, respectively, $P < 0.001$; ratio of Ang-2 level on day 28/baseline: 0.584 vs. 0.810, respectively, $P < 0.001$). Increases in FGF23 levels or VEGF on day 28 were not significantly different in responders versus non-responders. FGF19-i and Ang-2-d showed receiver-operating characteristic curve areas of 0.732 and 0.743, with specificity and sensitivity in discriminating responders from non-responders of 68.6% and 66.7%, respectively. In multivariate analysis, a combination of serum FGF19-i and Ang-2-d was the most independent predictive factor for lenvatinib response (HR, 8.283; 95%CI, 2.281–30.082; $P = 0.0013$). Progression-free survival (PFS) was significantly longer in the FGF19-i and Ang-2-d group (6-month PFS, 87.5%) than either the FGF19-i alone or Ang-2-d alone group (67.9%), or neither the FGF19-i nor low Ang-2-d group (33.0%, $P = 0.007$). Furthermore, the biomarker combination of serum FGF19-i and Ang-2-d showed the greatest independent association with PFS (HR, 0.298; 95%CI, 0.119–0.747; $P = 0.0098$) in multivariate analysis.
Conclusion: Early changes in circulating FGF19 and Ang-2 levels might be useful for predicting clinical response and PFS in HCC patients on lenvatinib therapy.

SAT482
The volume of enhancement of disease (VED) predicts the early response to treatment and overall survival in patients with advanced hepatocellular carcinoma treated with sorafenib

Claudia Campani[1], Stefano Colagrande[1], Linda Calistri[1], Chiara Lorini[1], Alessandro Castellani[1], Fabio Marra[1]. *[1]University of Florence*
Email: claudiacampani.cc@gmail.com

Background and Aims: The response of patients with advanced HCC treated with sorafenib is still unpredictable. We analysed the predictive value of the Volume of Enhancement of Disease (VED), a new radiologic parameter based on the arterial enhancement coefficient (ΔArt%) in computed tomography, in the early evaluation of the response to sorafenib in patients with advanced HCC.

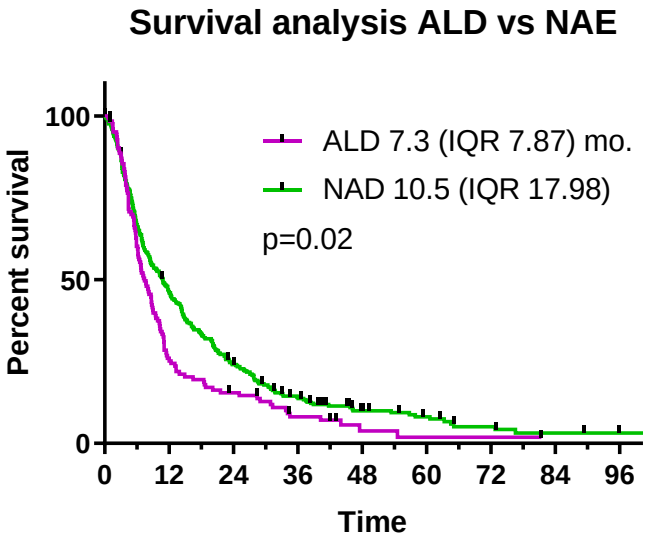
Method: We included patients with advanced hepatocellular carcinoma (HCC) who underwent a multiphase enhanced CT (multi-detector Somatom Sensation 64 CT scan) before (T0) and after 60–70 days of therapy with sorafenib (T1), enrolled between 2012–2016. The same target lesions utilised for the assessment of response were used for the calculation of size and for the calculation of VED (volume lesion × Δart%/volume lesion). We compared these values at T0 and T1 in patients with a clinical benefit (CB, the composite of complete response, partial response and stable disease) from therapy or with progressive disease (PD). Survival probability was evaluated in the study population and in the different subgroups of patients, based on tumor size and VED, but also on ancillary imaging findings and blood chemistries.
Results: Thirty-two patients with advanced HCC treated with sorafenib (25 men, 7 women, mean age 65.8 years) were selected. At T1 8 patients had CB (1 partial response, 7 stable disease) and 24 had PD. VEDT0 was >70% in 8/8 CB patients compared to only 12/24 patients in the PD group (P = 0.011). In CB patients, but not in PD, VEDT1 values were significantly lower than those at T0 (p = 0.018). No significant differences in the ancillary imaging findings were found between the two time points. Patients with VEDT0 >70% showed a significantly higher median survival than those with lower VEDT0 (506 vs. 266 days, p = 0.032). Patients with VEDT0 >70% and alpha-fetoproteinT0 ≤400 ng/ml had a significantly longer survival than all other combinations of the two biomarkers (median survival: 582 days vs. 208–213 days for the other combinations of the two biomarkers).
Conclusion: In patients with advanced HCC treated with sorafenib, VED is a novel and simple radiologic parameter obtained by contrast-enhanced CT, which could be helpful in selecting patients who are more likely to respond to sorafenib therapy, and with a longer survival. Patients with baseline VED value >70% and alpha-fetoprotein ≤ 400 ng/ml showed longer survival.

SAT483

Alcoholic liver disease is associated with a poorer survival after radioembolisation for hepatocellular carcinoma

Clemens Schotten[1], Amr El Fouly[2], Paul Peter Manka[1], Alexander Dechêne[1,3], Lars Peter Bechmann[1,4,5], Sonia Radunz[6], Maren Schulze[6], Ali Canbay[1,4,5], Jens Theysohn[7], Guido Gerken[1], Ken Herrmann[8], Heiner Wedemeyer[1], Jan Best[1,4]. *[1]Essen University Hospital, Department of Gastroenterology and Hepatology, Essen, Germany; [2]Faculty of Medicine - Helwan University, Endemic Medicine Dept., Egypt; [3]Paracelsus Medizinische Privatuniversität Nürnberg, Department of Internal Medicine 6, Nürnberg, Germany; [4]University Hospital Magdeburg, Department of Gastroenterology, Hepatology and Infectiology, Magdeburg, Germany; [5]University Hospital Knappschaftskrankenhaus Bochum GmbH, Medizinische Klinik, Bochum, Germany; [6]Essen University Hospital, Department of General Surgery and Transplantation, Essen, Germany; [7]Essen University Hospital, Department of Radiology, Essen, Germany; [8]Essen University Hospital, Department of Nuclear Medicine, Essen, Germany*
Email: clemens.schotten@uk-essen.de

Background and Aims: Alcoholic liver disease (ALD) is a frequent predisposing risk factor for liver cirrhosis and hepatocellular carcinoma (HCC) in the Western World. Radioembolisation (RE) represents a safe and effective locoregional treatment option for advanced stage HCC in the absence of extrahepatic tumor burden. However, overall survival (OS) after RE shows heterogeneous outcomes, even within comparable BCLC stages. To address this, we aimed to identify independent risk factors that might be attributed to poorer OS after RE in a large monocenter cohort study.
Method: We performed a retrospective analysis of 453 patients with HCC who received RE between January 2006 and May 2014. ALD was defined as alcohol consumption of seven or more drinks weekly prior diagnosis of liver cirrhosis or HCC. Patients who did not fulfill these criteria were defined as non-alcoholic liver disease group (NAD). The main causes of HCC in the NAD group were 80 (24%) hepatitis C, 66 (20%) HBV infection and 97 (30%) NAFLD. All subjects were not amenable to surgical, systemic or alternative locoregional treatments and did not exhibit prognostically relevant extrahepatic metastasis.
Results: A total of 125 patients (27.6%) were diagnosed with ALD. Tumor burden and extension according to TNM classification and frequency of extrahepatic comorbidities did not differ between groups. Pretreatment with other modalities was more common in NAD (43 vs 26%; p < 0.01). ALD patients showed an inferior performance status due to hepatic morbidity (p < 0.01). Advanced liver disease was more common in ALD and an inferior Child Pugh and BCLC stage was evident (p < 0,05). However, toxicity determined by ALBI Score did not differ between the two groups (p = 0.42). Of note, ALD showed an inferior median overall survival 7.3 (IQR 7.87) months vs 10.5 (IQR 17.98) p < 0.02. However, after stratification for BCLC stage no difference was evident (Stage A p = 0.82, Stage B p = 0.22, Stage C p = 0.11).



Conclusion: ALD patients had a poorer overall survival in this large single center cohort. Therefore, we postulate, that history of alcohol abuse should be considered as relevant risk factor in the evaluation process for RE.

SAT484

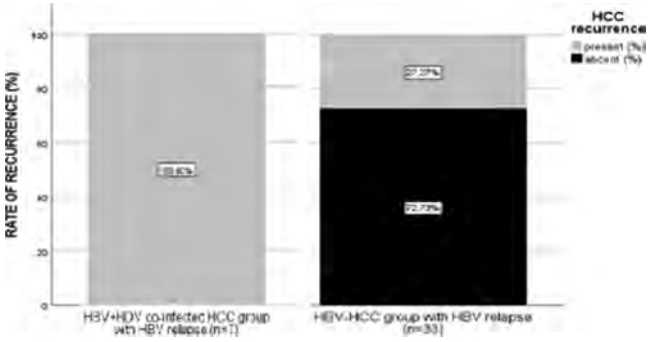
HBsAg relapse after living donor liver transplantation in hepatocelluler carcinoma patients with hepatitis D virus infection may result in hepatocellular carcinoma relapse

Adil Baskiran[1], Tevfik Tolga Sahin[1], Volkan Ince[1], Serdar Karakas[1], Fatih Ozdemir[1], Ipek Balikci Cicek[2], Kendal Yalcin[1], Brian Carr[1], Sezai Yilmaz[1]. *[1]Liver Transplantation Institute of Inonu University, Surgery, Malatya, Turkey; [2]Statistics Department of Inönü University, Statistics Department, Malatya, Turkey*
Email: dr.adil.baskiran@gmail.com

Background and Aims: Most frequent etiology of hepatocellular carcinoma (HCC) is viral hepatitis related liver cirrhosis. In the present study, we aimed to evaluate HCC recurrence following living donor liver transplantation (LDLT) patterns in patients with HBV and HDV infection.
Method: HBV related (n = 163 [84%]) or HBV+HDV co-infected (n = 31, [16%]) HCC that received LDLT were included in the study. Demographic data, Milan criteria, disease free survival (DFS), HCC and HBV recurrence was evaluated. The first year following the liver transplantation monthly routine laboratory evaluation including liver function tests, complete blood count and alpha-feto protein (AFP) together with abdominal ultrasound (USG) were performed.

Abdominal computerized tomography (CT) or magnetic resonance imaging (MRI) was obtained every three months for the first year. Postoperative Hepatitis B recurrence was considered as hepatitis B surface antigen positivity determined after the postoperative third month.

Results: The median age of the patients was 55 (23–72) years. The two groups were similar in terms of demographic characteristics except body mass index was lower in HBV+HDV co-infected HCC group ($p < 0.05$). There was no statistically significant difference among the study groups in terms of tumor recurrence ($p > 0.05$). HBV +HDV co-infection significantly increased the HCC recurrence rates of the patients with tumors beyond the Milan criteria ($p < 0.05$). DFS was similar among the both groups ($p > 0.05$). HBV recurrence in HBV +HDV co-infected individuals showed 100% HCC recurrence ($p < 0.05$).



Conclusion: HDV enhances the tumor progression and causes recurrence in tumors beyond the Milan criteria following LDLT. Additionally, HBsAg relapse after LDLT with HBV and HBV+HDV co-infection means HCC relapse. In HBV+HDV co-infected HCC group HCC recurrence ocurred 100% if the patients have HBV recurrence. HBV recurrence in the postoperative period seems to be risk factor for HCC recurrence in both HBV-HCC and HBV+HDV co-infected HCC groups. So we made some changes regarding our approach to patients with HDV related HCC cases which includes a more strict surveillance program regarding the antiviral therapy and increased HBIg doses in our protocol.

SAT485

13C-methacetine breath test for the prediction of liver damage caused by transarterial chemoembolization in patients with hepatocellular carcinoma

Stella Wellhöner[1], Florian Gerhardt[1], Albrecht Boehlig[1], Rami Al-Sayegh[1], Rhea Veelken[1], Bettina Maiwald[2], Steffen Strocka[2], Tim-Ole Petersen[2], Timm Denecke[2], Thomas Berg[1], Florian van Bömmel[2]. *[1]University Hospital Leipzig, Division of Hepatology, Clinic and Polyclinic for Gastroenterology, Hepatology, Infectiology, and Pneumology, Leipzig, Germany; [2]University Hospital Leipzig, Clinic and Polyclinic for Diagnostic and Interventional Radiology, Leipzig, Germany*
Email: florian.vanboemmel@medizin.uni-leipzig.de

Background and Aims: Transarterial chemoembolization (TACE) can lead to deterioration of liver function during the treatment of hepatocellular carcinoma. The LiMAx (maximum liver function capacity test) is a real-time breath test for liver function capacity. The aim of our study was to investigate the relationship between hepatic side effects of a TACE and the LiMAx result.

Method: 70 patients (55 male, 66 with liver cirrhosis) with HCC and planned TACE were prospectively included in the study. In all patients, a LiMAx test was performed 0–7 days before TACE. Before TACE, the average body mass index was 30+/−6 (22–42) and the MELD score 10 ± 3 (6–18) points. The Child-Pugh-Score (CPS) was A in 60 and B in 10 patients. Side effects (NW) after TACE were recorded according to CTCAE classification. LiMAx values as well as classical parameters of liver function were compared with the occurrence of NW.

Results: Within 4 weeks after TACE, 30/70 patients had reported side effects including 7 patients with side effects grade II-III. Severe side effects included development or worsening of ascites in 6 and hepatic encephalopathy in 1 patient. In 5 patients there was an increase in the CPS score resulting in 5 patients switching from Child A to B, whereas no patient changed to CPS C. Side effects >grade II occurred only in patients with LiMAx value of 250 before TACE. Patients with CPS A before TACE which experienced severe side effects had initially LiMAX test results >180. The LiMAx test (AUC = 0.83) allowed a stronger prediction for the occurrence of side effects compared to albumin (AUC = 0.38), CPS (AUC = 0.68), ALT (AUC = 0.62), MELD score (AUC = 0.71) or bilirubin (AUC = 0.69) in the ROC curve analysis.

Conclusion: Measuring liver function using a 13C methacetine breath test is a helpful method for early identification of patients at risk of liver function deterioration by TACE.

SAT486

Influence of acute kidney injury on the prognosis of patients receiving transarterial transembolisation for hepatocellular carcinoma: based on ICA-AKI criteria

Won Sohn[1], Hong Joo Kim[1], Yong Kyun Cho[1], Byung Ik Kim[1]. *[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Internal Medicine, Seoul, Korea, Rep. of South*
Email: hand0827@naver.com

Background and aim: Hepatocellular carcinoma (HCC) commonly develops in patients with liver cirrhosis. Acute kidney injury (AKI) is an independent prognostic factor for overall survival in patients with cirrhosis. In recent years, the new AKI criterion (International Club of Ascites, ICA-AKI) has been introduced in patients with cirrhosis to assess the early change of renal function and classify the status of AKI. This study aimed to investigate the influence of AKI on the prognosis of HCC patients receiving transarterial chemoembolisation (TACE).

Method: A total of 347 HCC patients with Child-Pugh class A and pre-TACE serum creatinine (SCr) ≤1.5 mg/dL receiving TACE as an initial therapy between 2000 and 2014 were analyzed. Overall survival with related risk factors in patients with HCC underwent TACE including AKI was investigated. We assessed AKI using SCr at 2 days, 2 months, and 4 months after TACE. The AKI stage after TACE is defined considering ICA-AKI criteria: stage 0, no increase of SCr or an increase of SCr <0.3 mg/dl; stage 1, an increase of SCr≥0.3 mg/dl or SCr≥1.5–2 times from baseline; stage 2, an increase of SCr≥2- 3 times from baseline; stage 3, an increase of SCr≥3times from baseline, or SCr≥4.0 mg/dl with an acute increase of ≥0.3 mg/dl, or an initiation of renal replacement therapy.

Results: The mean age was 60.9 years. Of 347 patients, death was observed in 109 patients (31%) and the median time of overall survival was 81 months. The mean SCr levels at pre-TACE, 2 days, 2 months, and 4 months after TACE were 0.9, 0.9, 0.9, and 1.1 mg/dL, respectively. The AKI within 4 months after TACE developed in 37 patients (11%). The AKI stages were stage 0 in 310 (89%), stage 1 in 10 (3%), stage 2 in 10 (3%), and stage 3 in 17 patients (5%). The multivariable analysis demonstrated that the risk factors for overall survival were serum albumin ≤3.5 g/dL (hazard ratio [HR] 1.56, $p = 0.031$), pre-TACE alpha-fetoprotein ≥100 ng/mL (HR 1.60, $p = 0.023$), BCLC stage B or C (HR 2.73, $p < 0.001$), bilobar location of HCC (HR 1.86, $p = 0.005$), AKI stage 1 (HR 7.45, $p < 0.001$), AKI stage 2 (HR 7.61, $p < 0.001$), and AKI stage 3 (HR 17.10, $p < 0.001$).

Conclusion: AKI is an independent prognostic factor for overall survival in patients receiving TACE for HCC. The AKI and its stage based on ICA-AKI criteria may be helpful to evaluate the prognosis of HCC patients treated with TACE.

SAT487

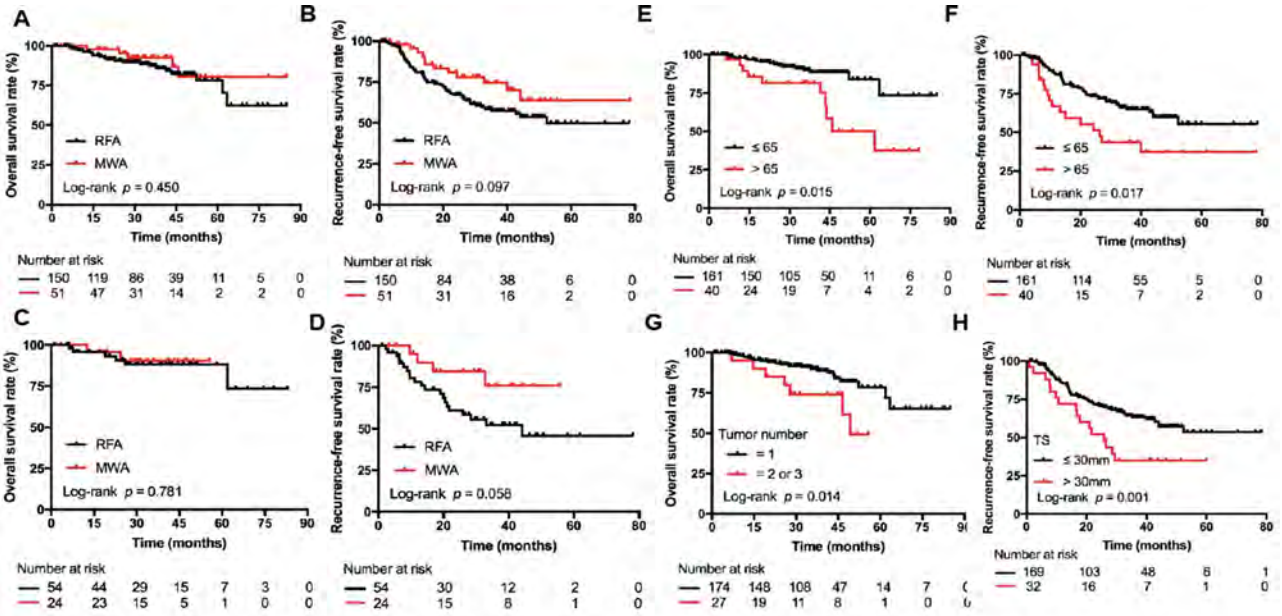
Radiofrequency versus microwave ablation for hepatocellular carcinoma within the Milan criteria in challenging locations: a retrospective controlled study

Xue Han[1], Jiayan Ni[1], Jinhua Huang[2]. [1]*Sun Yat-sen University Cancer Center, Department of Minimally Invasive Interventional Radiology, Guangzhou, China;* [2]*Sun Yat-sen University Cancer Center, Department of Minimally Invasive Interventional Radiology, Guangzhou, China*
Email: huangjh@sysucc.org.cn

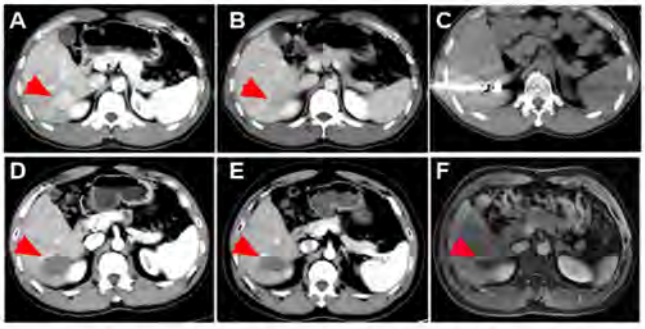
Background and Aims: As local ablation therapies, radiofrequency ablation (RFA) and microwave ablation (MWA) are two most often performed procedures for treatment of patients with hepatocellular carcinoma (HCC). The anatomical location of liver tumor has been validated as a significant prognostic factor associating with local efficacy and treatment-related complication after percutaneous thermal ablation. The purpose of this study was to compare the safety and efficacy of RFA with those of MWA for patients with the Milan criteria HCC in challenging locations.

Method: We retrospectively investigated 201 consecutive patients with the Milan criteria HCCs who underwent RFA (RFA group, n = 150) or MWA (MWA group, n = 51) between January 2012 and December 2016. Overall survival (OS), recurrence-free survival (RFS), local tumor control, and complications related to the treatments were compared between the two groups. Prognostic factors were analyzed by the Cox proportional hazard regression model.

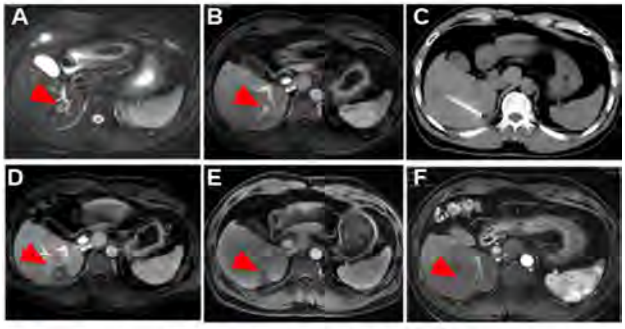
Results: Median follow-up duration was 36.7 months (range: 6.2–64.0 months). Cumulative 1-, 3-, and 5-year OS rates were 97.9%, 92.3%, and 80.6% in the MWA group and 96.4%, 87.4%, and 78.2% in the RFA group, respectively (P = 0.450). Cumulative RFS rates at 1, 3, and 5 years were 93.2%, 74.4%, and 63.7% in the MWA group and 80.3%, 57.3%, and 49.6% in the RFA group, respectively (P = 0.097). Multivariate analyses showed that patient age above 65 years (P = 0.004) and tumor number more one (P = 0.004) were associated with overall mortality, and patient age above 65 years (P = 0.048) and tumor size greater than 3 cm (P = 0.009) were associated with inferior RFS. The incidences of major complications were not significantly different between the two 46 groups (3.3% vs 3.9%, P = 0.843).



Kaplan-Meier curves of overall survival (A) and recurrence-free survival (B) in all 201 patients with the Milan criteria HCCs after RF A and MWA.
Kaplan-Meier curves of overall survival (C) and recurrence-free survival (D) in patients with subcapsular HCCs after RF A and MWA.
Kaplan-Meier curves of overall survival (E) and recurrence-free survival (F) in patients with an age of above 65 years.
Kaplan-Meier curves of overall survival (G) in patients with a tumor number of more than 1 and recurrence-free survival (H) in patients with an age of above 65 years.



Representative pictures of patient with the Milan criteria HCC in challenging location after RFA. A&B: Pre-RFA CT images (A: arterial-phase CT; B: portal-phase CT; the red arrow shows the location of HCC); C: A plain CT scan during the RFA procedure shows the well location of RFA electrode probe; D-E: Post-RFA arterial-phase CT images at 3-month (D) and 1-year (E); F: Post-RFA contrast-enhanced T1WI image at 5-year.



Representative pictures of patient with the Milan criteria HCC in challenging location after MWA. A&B: Pre-MWA MRI images (A: contrast-enhanced T1WI; B:T2WI; the red arrows show the location of HCC); C: A plain CT scan during the MWA procedure shows the well location of MWA electrode probe; D-G: Post-MWA MRI images (contrast-enhanced T1WI) at 3-month (D), 1-year (E) and 5-year (F), respectively.

Figure: (abstract: SAT487)

Conclusion: For patients with the Milan criteria HCCs in challenging locations, RFA and MWA were both safe and effective treatments that appeared comparable safety, local tumor control, and long-term survival.

SAT488

Effectiveness of sorafenib dose modifications on treatment outcome of hepatocellular carcinoma: analysis in real-life settings

Jeong Won Jang[1], Kwon Yong Tak[1], Heechul Nam[1], Jong Young Choi[1], Seung Kew Yoon[1], Si Hyun Bae[2], Chang Wook Kim[3], Jin Mo Yang[4], Sung Won Lee[5]. [1]*Seoul St. Mary's Hospital, Hepatology, Seoul, Korea, Rep. of South;* [2]*Eunpyeong-gu, St. Paul's Hospital, Hepatology, Seoul, Korea, Rep. of South;* [3]*Uijeongbu St. Mary's Hospital, The Catholic University, Hepatology, Euijeongbu, Korea, Rep. of South;* [4]*St. Vincent's Hospital, Hepatology, Suwon-si, Korea, Rep. of South;* [5]*St. Mary's Hospital, The Catholic University of Korea Bucheon, Hepatology, Bucheon, Korea, Rep. of South*
Email: garden@catholic.ac.kr

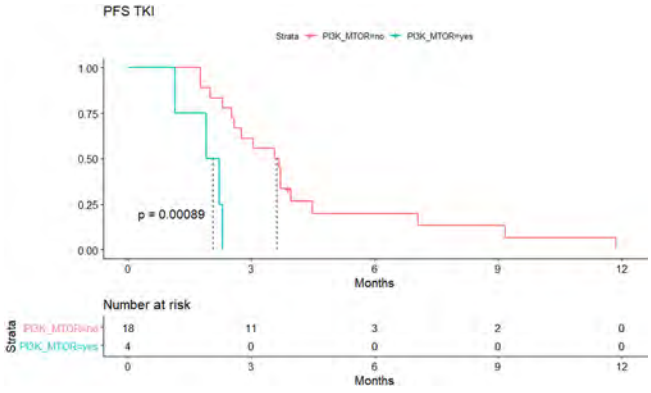
Background and Aims: Controlling adverse events through dose reduction can enhance drug adherence and treatment response. Currently, there is no guide for sorafenib dosing. The aim of this multicenter, retrospective, real-life, cohort study was to evaluate whether sorafenib dosing could affect treatment outcomes.
Method: A total of 782 hepatocellular carcinoma (HCC) patients treated with sorafenib between 2008 and 2018 were evaluated for sorafenib dosing and its modifications via medical records at baseline and regular followed-up. Study outcomes included progression-free survival (PFS), overall survival (OS), sorafenib duration, cumulative dose, adverse events (AEs), and drug discontinuation.
Results: The median patient survival was 5.2 months. Overall, 242 (30.9%) patients underwent dose reduction and 121 (17.5%) discontinued sorafenib due to AEs. In multivariate analysis, dose reduction was identified to be independently predictive of PFS and OS. Dose reduction from 800-to-400 mg/d provided significantly better PFS than dose maintained at 800 mg/d or dose reduction from 800-to-600 mg/d. Likewise, dose reduction from 800-to-400 mg/d resulted in a significantly better OS than other dosing. However, dose reduction to 200 mg/d led to significantly worse PFS and OS. Hand-foot skin reaction and drug discontinuation due to AEs were higher in the 800-to-600 mg/d group than 800-to-400 mg/d group. The 800-to-400 mg/d group had significantly longer treatment duration and higher cumulative dose than the 800 mg/d-maintained group.
Conclusion: Sorafenib dose reduction can improve HCC survival and increase patient tolerance and adherence coupled with longer duration and higher cumulative dose. Dose reduction from 800 mg/d to 400 mg/d than to 600 mg/d is recommended when clinically warranted. However, dose reduction to 200 mg/d is not recommended.

SAT490

Mutations in circulating tumor DNA predict primary resistance to systemic therapies in patients with advanced hepatocellular carcinoma

Johann von Felden[1,2], Amanda J. Craig[2], Ismail Labgaa[2], Teresa Garcia-Lezana[2], Delia D'Avola[2], Amon Asgharpour[2], Douglas Dieterich[2], Antoinette Bonaccorso[2], Miguel Torres-Martin[2], Daniela Sia[2], Max Sung[2], Parissa Tabrizian[2], Myron Schwartz[2], Josep Llovet[2], Augusto Villanueva[2]. [1]*University Medical Center Hamburg Eppendorf;* [2]*Icahn School of Medicine at Mount Sinai*
Email: j.von-felden@uke.de

Background and Aims: Despite our understanding of the key molecular alterations of early stage hepatocellular carcinoma (HCC), little is known about the mutational landscape of advanced HCC. Predictive biomarkers of response to systemic treatment are also lacking. Mutations detected in HCC tissue affecting the WNT/b-catenin and PI3 K pathways have been associated to primary resistance to immune checkpoint blockade (CPI) and tyrosine kinase inhibitors (TKI), respectively(Harding et al. Clinical Cancer Res. 2019). We aimed at describing the mutational landscape of advanced HCC and identifying predictors of primary resistance to CPI or TKI using liquid biopsy, specifically circulating tumor DNA (ctDNA).
Method: We prospectively enrolled patients with HCC at advanced stages receiving systemic therapies between October 2015 and January 2019. We conducted mutation analysis of ctDNA from plasma, including a composite approach of targeted ultra-deep sequencing (n = 25 key HCC genes) incorporating unique molecular barcodes, and Digital Droplet PCR (DDPCR) of the *TERT* Promoter mutation C228 T. Primary endpoint was progression-free survival (PFS) stratified by mutation profiles in ctDNA. Secondary endpoints were overall survival and objective response rate.
Results: We included a total of 121 patients. The most frequent mutations in advanced HCC (n = 85) were TERT promoter (51%), TP53 (32%), CTNNB1 (17%), PTEN (8%), AXIN1, ARID2, KMT2D, and TSC2 (each 6%). TP53 and CTNNB1 mutations were mutually exclusive. Patients with mutations in the PI3 K/MTOR pathway had significantly shorter PFS than those without these mutations after TKI (2.1 versus 3.7 months, p < 0.001, HR for progression or death: 6.7 in multivariate Cox regression, p = 0.01, n = 22), but not after CPI (n = 32). WNT pathway mutations were not associated with PFS, overall survival, or objective response in patients with and without mutations after CPI (n = 32). Serial profiling of ctDNA correlates with treatment response (n = 8).



Conclusion: Mutation calling from ctDNA in advanced HCC detects similar frequencies of mutations compared to those reported in early stages, except lower rates in CTNNB1. Mutations in the PI3 K/MAPK pathway correlate with worse PFS in patients receiving TKIs. We did not find a correlation between WNT/b-catenin pathway mutations and response to CPI, however, our findings need to be further validated in large and prospective investigations.

SAT491

Diagnostic value of brush cytology alone and in combination with tumor marker in malignant biliary stricture

Jaseem Ansari[1], Praveen Mathew[2], Prashant Y Kanni[3]. [1]*Vydehi Institute of Medical Sciences and Research Centre, Medical Gastroenterology, Bengaluru, India;* [2]*Vydehi Institute of Medical Sciences and Research Centre, Medical Gastroenterology, Bengaluru, India;* [3]*Vydehi Institute of Medical Sciences and Research Centre, Medical Gastroenterology, Bengaluru, India*
Email: jaseem10ansari@gmail.com

Background and Aims: Differentiating malignant from benign lesions is an important step in the management of patients with biliary stricture. This makes tissue diagnosis the key step in the evaluation of such patients. Endoscopic retrograde cholangio-pancreaticography (ERCP) based brush cytology sampling is a useful tool in the tissue diagnosis of biliary strictures. The aim of

our study is to determine the yield of brush cytology alone and in combination with tumor maker in patients with suspected malignant stricture.
Method: 68 patients with suspected malignant biliary obstruction based on clinical presentation with altered liver function tests in a cholestatic pattern and evidence of biliary obstruction in the form of stricture or pancreatic/biliary mass on imaging (contrast computerised tomography) underwent ERCP & brush cytology with onsite cytology analysis . The final diagnosis was approved based on the histological examination of the tissue taken surgically or by endoscopic – fine needle aspiration.
Results: A total of 68 cytological specimens were included. The mean age of the patients was (52.03 ± 10.47) years and (51.5%)were males. (52.9%) of the patients had distal CBD stricture. Out of the 52 patients with malignant stricture confirmed with histology , 46 patients had positive brush cytology. The sensitivity and specificity of brush cytology with on site analysis in diagnosing malignant stricture in our study was (80.77%) and 75 % respectively ($p < 0.001$). The sensitivity of brush cytology in diagnosis of malignancy in distal CBD stricture was (92.31%). The sensitivity and specificity of brush cytology in combination with Ca19.9 was (96.2%) and (62.5%) respectively($p < 0.001$).
Conclusion: Brush cytology has high sensitivity and specificity when performed with good technique and with on site analysis of the sample . The accuracy of the test is further enhanced while used in combination with tumor markers. Thus making the notion that brush cytology with on site analysis and in combination with tumor marker is a reliable method of diagnosing malignant biliary strictures

SAT492

miR-486-3p mediates sorafenib resistance through targeting FGFR4 and EGFR in hepatocellular carcinoma

Lin Ji[1], Zhongjie Lin[1], Zhe Wan[1], Shunjie Xia[1], Shi Jiang[1], Dong Cen[1], Liuxin Cai[1], Junjie Xu[1], Xiujun Cai[1]. *[1]Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, Department of General Surgery, hangzhou, China*
Email: srrsh_cxj@zju.edu.cn

Background and Aims: HCC is a common malignancy worldwide and surgery or reginal treatments are deemed insufficient for advanced-stage disease. Sorafenib is an inhibitor of many kinases and was shown to benefit advanced HCC patients. However, resistance emerges soon after initial treatment, limiting the clinical benefit of sorafenib and the mechanisms still remain elusive. Thus, this study aims to investigate the mechanisms of sorafenib resistance and to provide possible targets for combination therapies.
Method: Sorafenib resistant cell lines were established by sustained treatment of small dose of sorafenib. qRT-PCR and western blotting were used to measure microRNA and protein levels. Effects of sorafenib was valued by cell viability analysis using Cell Counting Kit-8 assay or real-time cellular analysis. MicroRNA manipulation was performed using RNAi transfection or CRISPR-CAS9 technique. Cell apoptosis analysis was carried out using flowcytometry and TUNEL assay. Cell cycle analysis was conducted using flowcytometry. Binding between microRNA and 3′UTR was verified by Luciferase reporter assay. Over-expressing miR-486-3p in sorafenib resistant animal model was conducted using lentivirus.
Results: Through miRNA sequencing, we found miR-486-3p was downregulated in sorafenib resistant HCC cell lines. The finding was confirmed via qRT-PCR analysis. Cell viability experiments showed increasing miR-486-3p expression could induce cell apoptosis while miR-486-3p knockdown by CRISPR-CAS9 technique could reduce cell apoptosis under sorafenib treatment. Mechanism dissections showed that miR-486-3p mediated sorafenib resistance through targeting FGFR4 and EGFR, which was predicted by online database miRWALK2.0 and verified using luciferase reporter assay. Importantly, FGFR4 or EGFR selective inhibitor could enhance sorafenib efficacy in resistant cells. Clinical data also indicated that miR-486-3p level was downregulated in tumor tissue compared with adjacent normal tissue in HCC patients. Analysis using online database KM-plotter indicated that patients with high expression of miR-486-3p had significantly worse overall survival and disease-free survival. In vivo experiment using sorafenib resistant model demonstrated that miR-486-3p could sensitize tumor to sorafenib treatment.
Conclusion: we found miR-486-3p was an important mediator regulating sorafenib resistance by targeting FGFR4 and EGFR, thus offering a potential target for HCC treatment.

SAT493

Comparative outcomes of laparoscopic and open major liver resection using benchmark article method and propensity score matching method

Hanisah Guro[1], Jai Young Cho[2], Ho Seong Han[2], Yoon Yoo Seok[2], Youngrok Choi[2], Boram Lee[3], Sook-Hyang Jeong[3], Jin-Wook Kim[3], Eun Sun Jang[3], Gwang Hyeon Choi[3]. *[1]Amai Pakpak Medical Center, Surgery, Marawi City, Philippines, [2]Seoul National University Bundang Hospital, Surgery, Seongnam, Korea, Rep. of South, [3]Seoul National University Bundang Hospital, Internal Medicine, Seongnam, Korea, Rep. of South*
Email: jychogs@gmail.com

Background and aims: To compare the outcomes of major laparoscopic liver resection (LLR) and open liver resection (OLR) for hepatocellular carcinoma (HCC) with two methods.
Method: We retrospectively reviewed a data of 177 patients who underwent major liver resection for HCC (LLR; n = 67 vs. OLR; n = 110). We performed 1:1 propensity score matching (PSM) between two groups and matched 65 patients for both groups. Another comparison was done with already published article as a benchmark after applying similar inclusion and exclusion criteria (LLR; n = 30 vs. OLR; n = 34).
Results: After PSM, there were no significant differences in blood loss (1407.2 ± 2322.7 vs 1071.5 ± 1160.6ml; $P = 0.299$), and transfusion rate (32.2% vs 32.0%; $P = 0.574$) between two groups. The mean operative time was significantly longer in LLR than in the OLR group (418.7 ± 172 vs 335.1 ± 121.6 min; $P = 0.002$). Complication rate (21.5% vs 33.8%; $P = 0.085$) was similar and the mean hospital stay was shorter in the LLR than in the OLR group (11.4 ± 8.5 vs 17.6 ± 21.4 days; $P = 0.009$). After benchmarking method, there were no significant differences in between two groups in terms of blood loss (780 ± 822 vs 947 ± 660.5 ml; $P = 0.382$), transfusion rate (30.0 vs 32.4%; $P = 0.528$), hospital stay (9 ± 3.7 vs 10.4 ± 3.59 days; $P = 0.119$), and complication rate (10.0% vs 20.6%; $P = 0.208$). Operation time (395 ± 166.6 vs 296 ± 68.3 min; $P = 0.002$) was significantly longer in the LLR than in the OLR group. Benchmarking method showed significant loss of number of patients analysed, but results were quite similar to PSM method.
Conclusion: Both methods showed that major LLR was safe compared to major OLR. Benchmarking method can be easily used to compare with data of other published article.

SAT495

Safety and efficacy of lenvatinib in Child-Pugh A and B patients with unresectable hepatocellular carcinoma in clinical practice

Katsuaki Ogushi[1], Makoto Chuma[1], Kazushi Numata[1], Haruki Uojima[2], Hisash Hidaka[2], Takashi Nakazawa[2], Shunji Hirose[3], Tatehiro Kagawa[3], Koutarou Matsunaga[4], Nobuhiro Hattori[4], Satoshi Kobayashi[5], Manabu Morimoto[5], Taito Fukushima[5], Shogo Iwabuchi[6], Tomoaki Fujikawa[6], Makoto Kako[7], Katsuaki Tanaka[8], Shin Maeda[9]. *[1]Yokohama City University Medical Center, Gastroenterology, Yokohama, Japan; [2]Kitasato University Hospital, Gastroenterology, Sagamihara, Japan; [3]Tokai University Hospital, Gastroenterology, Isehara, Japan; [4]St. Marianna University School of Medicine Hospital, Gastroenterology and Hepatology, Kawasaki, Japan; [5]Kanagawa Cancer Center, Gastroenterology, Yokohama-shi, Japan; [6]Shonan Fujisawa Tokushukai Hospital,*

Email: katsuaki.ogushi@gmail.com

Background and Aims: Lenvatinib has become available as first-line therapy in patients with unresectable hepatocellular carcinoma (u-HCC). However, factors associated with responses and outcomes to lenvatinib have not been clarified in large scale clinical practice, and the safety and efficacy of lenvatinib in Child-Pugh class B (CPB) patients with u-HCC has not been sufficiently investigated. The aim of this study was to assess the safety, efficacy and prognostic impact of clinical factors in both CPA and CPB patients with u-HCC.
Method: Patients with u-HCC who were treated with lenvatinib at multiple centers in Japan were analyzed retrospectively for treatment outcomes according to their respective CP status. Radiological objective response (OR) was assessed using modified RECIST guidelines.
Results: Baseline demographic parameters were comparable between 127 (70.2%) patients with CPA disease and 54 patients (29.8%) with CPB disease. Eighty-three (45.9%) and 98 (54.1%) cases were noted to have Barcelona clinic liver cancer (BCLC) stage B and C, respectively. Frequency of lenvatinib-related all grade adverse events, including diarrhea (P = 0.037), decreased appetite (P = 0.022), vomiting (P = 0.008) and increased blood bilirubin (P = 0.015) were higher in CPB patients than in CPA patients. Relative dose intensity (RDI) was significantly higher in CPA (0.71) than CPB patients (0.51, P < 0.001). Furthermore, OR rate was markedly higher in CPA (36.2%) than in CPB patients (16.7%, P = 0.0085). In univariate and multivariate analysis, performance status (P = 0.042), CP grade (P = 0.013), des-gamma-

carboxy prothrombin (P = 0.039), RDI (P = 0.0017) and fatigue (P = 0.008) were identified as factors associated with response to lenvatinib treatment. Overall survival (OS) at 12 months was significantly different between CPA (61.4%) and CPB patients (30.5%, P = 0.005). CP grade (P = 0.044), patients with ≥50% liver occupation (P = 0.034), BCLC stage (P = 0.040), α-fetoprotein (P = 0.007), RDI (P = 0.039), hand foot syndrome (P = 0.008) and decreased appetite (P = 0.033) were associated with OS following lenvatinib treatment.
Conclusion: Lenvatinib treatment offers significant benefit in patients with good liver function in real-world practice. The various characteristics identified in this study might be helpful as clinical-predictors of response to lenvatinib and survival in field practice.

SAT496

Analyses of intermediate-stage hepatocellular carcinoma patients receiving transarterial chemoembolization before designing clinical trials comparing transarterial chemoembolization and immune checkpoint inhibitor-based therapies

Keisuke Koroki[1], Sadahisa Ogasawara[1], Yoshihiko Ooka[1], Hiroaki Kanzaki[1], Kengo Kanayama[1], Susumu Maruta[1], Kazufumi Kobayashi[1], Soichiro Kiyono[1], Masato Nakamura[1], Naoya Kanogawa[1], Tomoko Saito[1], Takayuki Kondo[1], Eiichiro Suzuki[1], Shingo Nakamoto[1], Akinobu Tawada[1], Tetsuhiro Chiba[1], Makoto Arai[1], Tatsuo Kanda[2], Hitoshi Maruyama[3], Jun Kato[1], Satoshi Kuboki[4], Masayuki Ohtsuka[4], Naoya Kato[1]. *[1]Graduate School of Medicine, Chiba University, Chiba, Japan, Department of Gastroenterology, Chiba-city, Japan; [2]Nihon University School of Medicine, Tokyo, Japan, Division of Gastroenterology and Hepatology, Department of Internal Medicine, Tokyo, Japan; [3]Juntendo University School of Medicine, Tokyo, Japan, Department of Gastroenterology, Tokyo, Japan; [4]Graduate School of Medicine, Chiba University, Chiba, Japan, Department of General Surgery, Chiba-city, Japan*
Email: koroki-keisuke@chiba-u.jp

Background and Aims: Patients with intermediate-stage hepatocellular carcinoma (HCC) having a high tumor burden exhibit a high frequency of recurrence and progression to advanced stage HCC after transarterial chemoembolization (TACE). Novel promising results from immune checkpoint inhibitors (ICIs) and ICI-based therapies are expected to replace TACE, particularly in patients with HCC having a high tumor burden. This study aimed to evaluate the effectiveness of TACE to design clinical trials and identify limited high-burden populations that could be shifted from TACE to ICI-based therapies.
Method: We retrospectively identified patients with intermediate-stage HCC undergoing TACE from our database. Three subclassification models of intermediate-stage HCC were defined based on the diameter of the maximum tumor and the number of tumors; these models were used to verify clinical outcomes [subclassification model 1, up-to-seven criteria, high burden: largest tumor diameter (cm) + number of tumors >7; subclassification model 2, five-seven criteria, high burden: 4 lesions of size ≥5 cm or >7 lesions; and subclassification model 3, seven lesions criteria, high burden: >7 lesions]. Clinical outcomes were compared between low- and high-burden intermediate-stage HCC and between the different clinical courses reaching a high tumor burden in all subclassification models. We also assessed the ≥6-month durable response rate (DRR) [rate of continuous response (complete or partial objective response) beginning within 12 months of treatment and lasting ≥6 months] according to mRECIST.
Results: Of 1161 newly diagnosed patients with HCC, 316 were diagnosed with intermediate-stage HCC and underwent TACE. The median overall survival of the high tumor burden intermediate-stage patients was not significantly different according to the clinical course reaching a high tumor burden in all subclassification models. The prognosis of high-burden patients after initial TACE was poor compared with that of low-burden patients for two models (except for model 1). In all models, high-tumor burden patients showed a poor DRR of ≥ 6 months and a poor prognosis after TACE. Moreover, patients with confirmed durable response of ≥ 6 months showed better survival outcomes for high-tumor burden intermediate-stage HCC.
Conclusion: Our results demonstrate the basis for selecting a population that would not benefit from TACE and setting a DRR of ≥6 months as an alternative endpoint when designing clinical trials comparing TACE and ICI-based therapies.

SAT497

High rate of hepatitis B virus S-integrated human extra spindle pole bodies like 1 fusion gene is detected in hepatitis B virus-related liver cancer patients: a Chinese case-control study

Bobin Hu[1], Jianning Jiang[1], Minghua Su[1], Rongming Wang[1], Weiwei Zang[1], Xiaozhang Ling[1], Deli Deng[1], Yulong Wu[1], Lixia He[1], Zhihong Liu[1]. *[1]Department of Infectious Diseases, The First Affiliated Hospital of Guangxi Medical University, Nanning, China*
Email: jjianning@163.com

Background and Aims: It has been shown that the integration of hepatitis B virus (HBV) gene into the host genome is a high-risk factor for hepatocellular carcinoma (HCC) development. However, the relationship between HBV S-integrated human Extra Spindle Pole Bodies Like 1 (ESPL1) gene and HCC is unknown. This study was designed to detect HBV S-integrated human ESPL1 fusion gene in HCC patients for potentially developing this fusion gene as a biomarker for HCC diagnosis.
Method: Nineteen and 70 chronic hepatitis B (CHB) patients were recruited to the experimental and control groups, respectively, and both groups underwent an effective nucleoside/nucleotide analogs (NUCs) therapy and follow-up for HCC occurrence for up to 11 years. HCC tissues were obtained by surgical resection from the experimental group, while liver tissues were collected by liver biopsy in the control group prior to NUCs treatment. Alu polymerase chain reaction (PCR) was used to assess HBV S gene integration in the liver tissues from both groups. HBV S-integrated human ESPL1 fusion gene was then detected in the patients with HBV S gene integration by using the gene database.
Results: We observed that all CHB patients in the experimental group developed HCC, whereas no HCC was diagnosed in the control group. HBV S gene integration was identified in 12 out of 19 HCC tissues in the experimental group with a detectable rate of 63.2% (12/19), which was significantly greater than that of 15.7% (11/70) in the control group (P = 0.000). We further showed that HBV S-integrated human ESPL1 fusion gene was detected in 8 patients with a rate of 66.7% (8/12) among the 12 HCC patients with HBV S gene integration in the experimental group, whereas the fusion gene was not detectable in any one among the CHB patients in the control group (P = 0.001) (Fig 1).

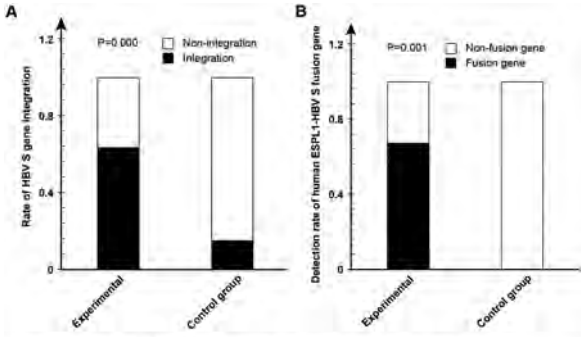

Figure 1. Detection rate of HBV S gene integration and human ESPL1-HBV fusion gene in the experimental and control groups. (A) The comparison of HBV S gene integration in both the experimental and control groups by chi-square test of four-fold table. Our data indicate that HBV S gene integration rate is significantly higher in the experimental group than that in the control group (P=0.000). (B) The comparison of the detection rate of the human ESPL1-HBV S fusion gene between the experimental and control groups by Fisher's exact probability. The data show that the detection rate of human ESPL1-HBV S fusion gene is 66.7% in the experimental group as compared with 0% in the control group (P=0.001).

Conclusion: This research demonstrates a high detectable rate of HBV S-integrated human ESPL1 fusion gene in HBV-related HCC patients and shows that this fusion gene is associated with HCC development in CHB patients. These findings suggest that HBV S-integrated human ESPL1 fusion gene may potentially serve as a biomarker for early detection of HCC in the HBV-infected populations.

SAT498

Treatment decision for hepatocellular carcinoma ?5cm: surgical resection or microwave ablation

Ping Liang[1], Jie Yu[1], Jianping Dou[1], Xiaoling Yu[1], Zhi-Gang Cheng[1], Zhi-Yu Han[1]. [1]*Chinese PLA General Hospital, Interventional Ultrasound Department, Beijing, China*
Email: liangping301@126.com

Background and Aims: Thermal ablation challenges the status of surgical resection on small hepatocellular carcinoma (HCC) treatment, while its therapeutic outcomes for larger lesions are still in debate. This study aims to compare long-term outcomes of surgical resection (SR) and microwave ablation (MWA) and give clues to treatment decision for HCC ≤5 cm.
Method: This retrospective study evaluated 639 patients with primary HCC (1 nodule <5 cm or 3 nodule <3 cm) who underwent curative SR or MWA from January 2008 to December 2015. Overall survival (OS), free intrahepatic recurrence (FIR) and disease-free survival (DFS) were compared using propensity score matching to control for potential confounders. Co-variables associated with OS and DFS were identified. The risk of death and tumor progression in HCC patients received SR versus MWA was compared.
Results: 256 Patients were well matched according to baseline characteristics. The OS rate of 1-, 3-, 5-year were estimated to be 94.9%, 81.6%, 70.6% in MWA group and 98.4%, 89.1%, 77.8% in SR group (P = 0.00). No significant differences were found in terms of DFS and FIR rate. In subgroup analysis, the OS rate of 1-, 3-, 5-year was similar in two groups for tumors smaller than 3 cm (P = 0.24), while the OS rate was higher in SR group than in MWA group for tumors between 3 cm to 5 cm(P = 0.01). Similar results were found in further subgroup analysis of MWA, anatomic and non-anatomic SR group, and anatomic SR group showed longest OS rate. Major complication rate was similar while post-treatment stay was significantly longer in SR group.
Conclusion: MWA provided non-inferior survival outcomes to SR in HCC≤3 cm. For larger tumors ≤5 cm, more techniques such as 3D visualization platform are needed to enhance the therapeutic outcomes.

Chlorogenic acid decreases malignant characteristics of hepatocellular carcinoma cells by inhibiting DNMT1 expression

Yao Liu[1], Ying Feng[1], Xianbo Wang[1]. [1]*Beijing Ditan Hospital, Capital Medical University, Center of Integrative Medicine, China*
Email: wangxb@ccmu.edu.cn

Background and Aims: Hepatocellular carcinoma (HCC) is the most common malignant tumor of the adult liver, exhibiting rapid progression and poor prognosis. DNA methylation is an essential epigenetic event in gene-expression regulation processes; it may lead to cancer. Chlorogenic acid (CGA), a polyphenol, has several biological activities, including the suppression of liver cancer cell invasion and metastasis. However, the mechanisms underlying the CGA-mediated regulation of DNA methylation are still unclear.
Method: The human HCC HepG2 cells were treated with a positive control drug 5-azacytidine (5 -AZA) or varying doses of CGA. DNA methyltransferase 1 (DNMT1) protein levels and other relevant proteins were evaluated using western blotting and immunocytochemistry. Cell-cycle analysis was performed by flow cytometry-based PI staining, and cell viability was assessed using 3-(4,5 -dimethylthiazol- 2 -yl)- 2,5 -diphenyltetrazolium bromide assay. The transwell invasion and wound healing assays were used to

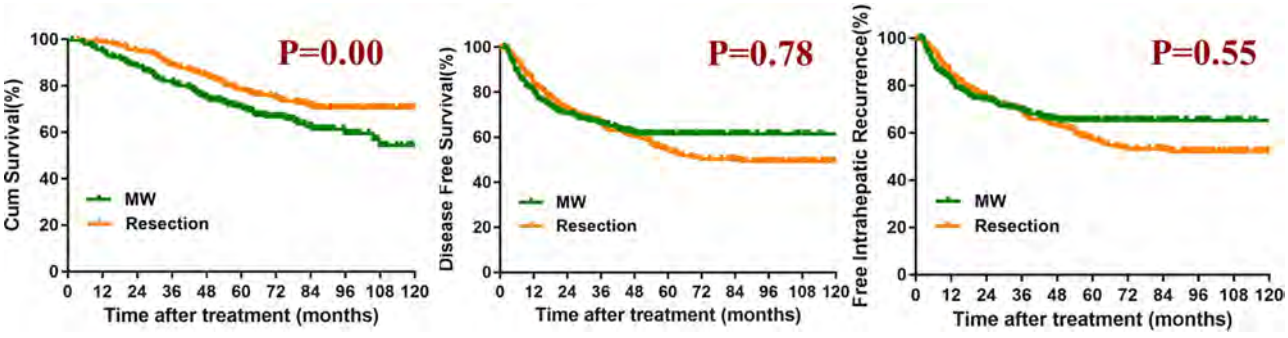

Figure 1: (abstract: SAT498): Comparison of OS(a), DFS(b) and FIR(c) between MWA group (N = 256) and surgery group (N = 256).

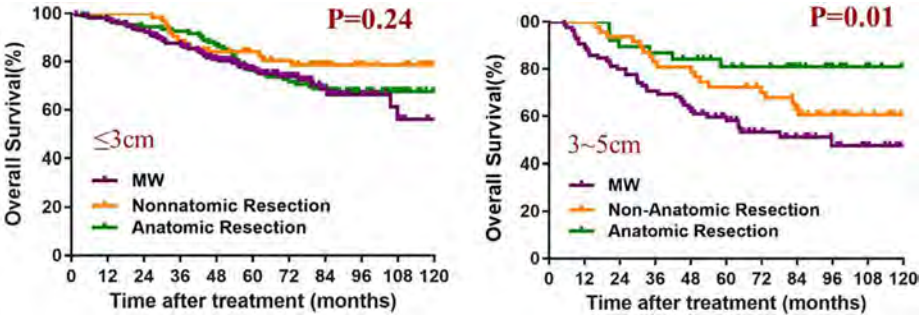

Figure 2: (abstract: SAT498): Comparison of OS(a), DFS(b) and FIR(c) in subgroup analysis.

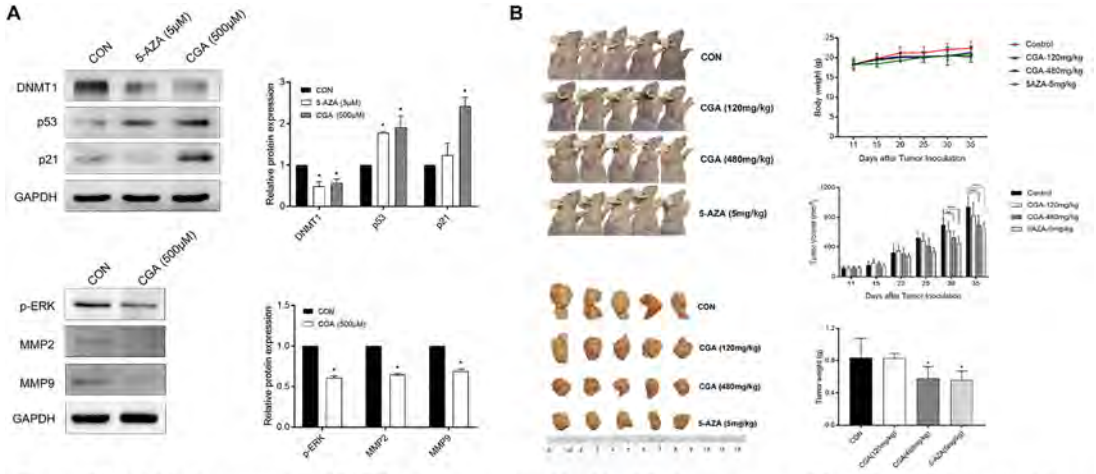

Figure. CGA inhibits the expression of DNMT1 and up-regulate p53, p21waf/Cip1, to suppress HCC cell proliferation and inhibits the expression of ERK1/2 and MMP2/9 to suppress HCC growth (A), CGA reduces HepG2 tumor xenograft's weight and volume (B). *p < 0.05, **p < 0.01, ***p < 0.001.

Figure: (abstract: SAT499)

evaluate cell migration and invasion. The in vivo anticancer effect of CGA was evaluated in immunodeficient HepG2 xenograft nude mouse models.

Results: Our results showed that CGA inhibited the proliferation, colony formation, invasion, and metastasis of HepG2 cells by down-regulating the DNMT1 protein expression, which enhanced p53 and p21 activity, resulting in significantly reduced cell proliferation and metastasis. Moreover, CGA inactivated extracellular signal-regulated kinases 1/2 and reduced matrix metalloproteinase- 2 and- 9 expression in HepG2 cells. And in vivo, CGA treatment inhibited growth of HepG2 xenograft tumors, at both 120 and 480 mg/kg of CGA causing reduction in tumor weight and tumor volume.

Conclusion: CGA can suppress liver cancer cell proliferation, invasion, and metastasis through several pathways in vivo and in vitro. CGA could serve as a candidate chemopreventive agent for HCC.

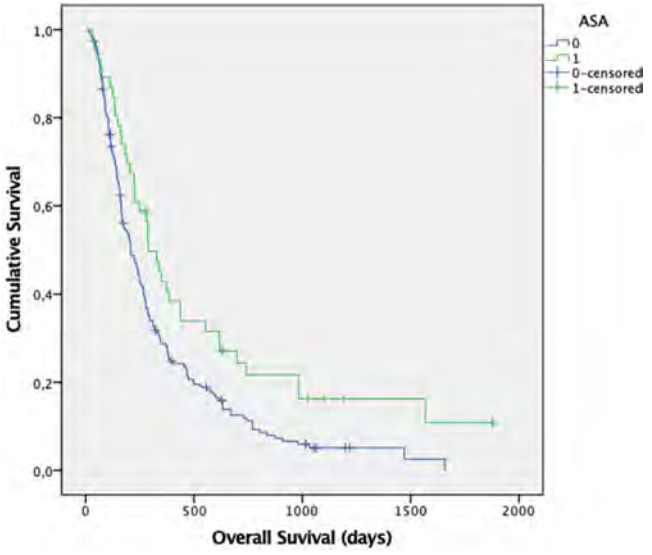
SAT500

Protective role of aspirin chronic assumption in patients treated with sorafenib for hepatocellular carcinoma

Luca Ielasi[1], Francesco Tovoli[1], Alessandro Granito[1], Matteo Tonnini[1], Fabio Piscaglia[1]. [1]*University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy*
Email: luca.ielasi.kr@gmail.com

Background and Aims: Hepatocellular carcinoma (HCC) is the most common primary liver cancer that usually develops in a microenvironment characterized by chronic liver inflammation. Several in vitro and mouse-model studies have shown the pivotal role of platelets in cancerogenesis, tumor cell migration and invasion. Platelets have also been reported to antagonize the effect of tyrosine kinase inhibitors such as sorafenib and regorafenib. The protective role of anti-platelet agents has largely been studied in different cancer types, including HCC. In particular, in vitro studies have shown the effect of aspirin in decreasing tumor cell proliferation, increasing sensitivity to chemotherapeutics and inducing apoptosis. All these findings suggest a possible synergy between the chronic inhibition of platelets activity by aspirin and sorafenib in patients with advanced HCC.

Method: We retrospectively analyzed baseline and follow-up clinical data of 232 patients who consecutively received sorafenib treatment from January 2008 and December 2017. Patients were divided in two groups according to the daily assumption of aspirin or not (46 and 186 patients, respectively). In order to evaluate the synergic activity of aspirin and sorafenib, in the OS analysis, patients who received a second-line treatment were censored when starting the new therapy.



Results: Baseline characteristics, adverse events and radiological response were consistent across groups. The OS survival of patients treated with aspirin was significantly higher (10.3 vs 7.4 months, p = 0.008). Multivariate time-dependent Cox regression analysis confirmed aspirin treatment as an independent protective factor (HR 0.658; 95%CI 0.460–0.941) when compared to other already established predictors of survival such as AFP >400 ng/ml (HR 1.341; 95%CI 0.977–1.841; p = 0.070), Performance Status 1 (HR 1.320; 95%CI 0.951–1.830; p = 0.097), neoplastic thrombosis (HR 1.422; 95%CI 1.065–1.898; p = 0.017), extrahepatic spread (HR 1.227; 95%CI 0.915–1.646; p = 0.172) and dermatological adverse events (HR 0.579; 95%CI 0.437–0.767; p < 0.001).

Conclusion: Accordingly with data from pre-clinical studies, chronic assumption of aspirin seems to have a protective role also in patients with advanced HCC. A proven synergic effect between aspirin and sorafenib needs to be confirmed with further studies.

SAT501

A lncRNA-associated ceRNA regulatory network in MVI positive hepatocellular carcinoma influences their sensitivity to sorafenib

Zhiwen Luo[1], Xinyu Bi[2]. [1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Hepatobiliary Surgery, Beijing, China;* [2]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Department of Hepatobiliary Surgery, beijing, China*
Email: beexy1971@163.com

Background and Aims: Microvascular invasion (MVI) is a histological feature of hepatocellular carcinoma (HCC) related to aggressiveness. But different sensitivity to first line targeted drug, sorafenib, in MVI$^+$ HCC has been observed. Long noncoding RNAs (lncRNAs) can act as microRNA (miRNA) sponges to regulate protein-coding gene expression; so lncRNAs are considered as a major part of competitive endogenous RNA (ceRNA) network and have attracted growing attention. We explored the regulatory mechanisms and functional roles of lncRNAs as ceRNAs in MVI$^+$ HCC, and ceRNA network's potential impact on prognosis and sensitivity to sorafenib in MVI$^+$ HCC patient.

Method: We studied the expression profiles, prognostic value of lncRNA, miRNA, and mRNA from MVI$^+$ HCC patients, established a prognosis-related network of dysregulated ceRNAs and analyzed its role in sensitivity to sorafenib and radiomics features by bioinformatics methods.

Results: A ceRNA network including 13 lncRNAs, 3 miRNAs, and 2 mRNAs specific to MVI+ HCC was established. 6 lncRNAs (ARHGEF7-AS1, ATP2B2-IT1, LINC00330, MUC2, TLR8-AS1 and ZNF385D-AS1), 2 miRNAs (has-mir-206 and has-mir-373) and two mRNAs (PAX3, SIK1) were prognostic biomarkers for MVI$^+$ HCC. PAX3 was an unfavorable prognostic gene (HR = 1.9, 95%CI 1.01 ~ 3.60), while SIK1 favored the prognosis (HR = 0.4, 95%CI 0.19 ~ 0.85). PAX3 as a stratification in recurrence predicting model was used to identify MVI$^+$ HCC with high or low recurrence risk. Datamining into the dataset of phase 3 STORM trial showed no difference in the influence of PAX3 level on the outcome between sorafenib HCC group and placebo HCC group. However, deep datamining into GDSC dataset revealed our high PAX3 group in MVI$^+$ HCC related to resistance to sorafenib (P = 0.0039). Radiomics features were extracted from CT of MVI$^+$ HCC, and texture analysis in MVI$^+$ HCCs is ongoing.

Conclusion: The proposed ceRNA network may help elucidate the regulatory mechanism by which lncRNAs function as ceRNAs and contribute to the pathogenesis of MVI in HCC. Importantly, the candidate lncRNAs, miRNAs, and mRNAs involved in the ceRNA network have shown to be potential therapeutic targets and prognostic biomarkers for MVI$^+$ HCC. PAX3 might play a vital role in the mechanism of sorafenib resistance in MVI$^+$ HCC, exclusively, this aggressive HCC subtype. The ongoing experiments on radiomics might add potent supports to identify sorafenib sensitive MVI$^+$ HCC.

SAT502

In vivo performance of PEG-coated gold nanoparticles mediated ultrasound guided radiofrequency ablation: a pilot study in swine

Tudor Mocan[1], Popa Calin[2], Pestean Cosmin[3], Al Hajjar Nadim[4], Saftoiu Adrian[5], Zeno Sparchez[6]. [1]*Institute for Gastroenterology and Hepatology, Cluj-Napoca, Romania, 3rd Medical Department, "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, Romania, Cluj-Napoca, Romania;* [2]*Institute for Gastroenterology and Hepatology, Cluj-Napoca, Romania, 3rd Surgical Department, "IuliuHatieganu" University of Medicine and Pharmacy Cluj-Napoca, Romania, Cluj-Napoca, Romania;* [3]*University of Agricultural Sciences and Veterinary Medicine, Cluj-Napoca, Romania, Cluj-Napoca, Romania;* [4]*Institute for Gastroenterology and Hepatology, Cluj-Napoca, Romania, 3rd Surgical Department, "IuliuHatieganu" University of Medicine and Pharmacy Cluj-Napoca, Romania, Cluj-Napoca, Romania;* [5]*Research Center of Gastroenterology and Hepatology Craiova, University of Medicine and Pharmacy Craiova, Craiova, Romania, Craiova, Romania;* [6]*Institute for Gastroenterology and Hepatology, Cluj-Napoca, Romania, 3rd Medical Department, "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, Romania, Cluj-Napoca, Romania*
Email: mocan_tudor@yahoo.com

Background and Aims: Radiofrequency ablation (RFA) is the first line treatment option for patients with small hepatocellular carcinoma and a recommended treatment modality for patients with hepatic metastases judged to be unfit for surgical intervention. However, RFA is still used mainly for lesions <3 cm, and despite all great advancements the ablation zone remains limited in volume. Gold nanoparticles offer the potential to heat tumour tissue selectively at the cellular level by non-invasive interaction with radiofrequency energy delivered externally. The objective of this study was to investigate the effects of polyethylene glycocol (PEG) coated gold nanoparticles intratumoral delivery on ablation zone volumes during in vivo RFA of porcine liver.

Method: This prospective study was performed following institutional animal care and use committee approval. RFA was performed in liver in ten Sus scrofa domesticus swine. PEG coated gold

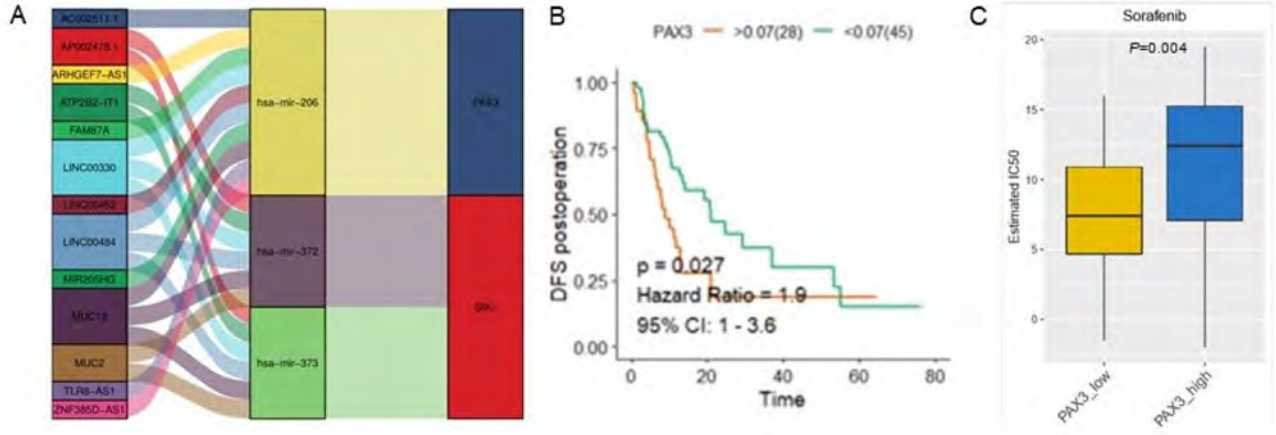


Figure: (abstract: SAT501)

nanoparticles (10 millilitres of solution for each ablation with a concentrations of 1×10^{11} and 1×10^{7} nanoparticles/ml) were injected through the radiofrequency antennae during ablation. Physiological saline (10 millilitres for each ablation) was used as control. Ten minutes after ablation contrast enhanced ultrasound (CEUS) was performed to evaluate the necrosis volume. Animals were kept under close medical observations for 5 days. On day 5 another CEUS examination was performed and animals were using a sodium pentobarbital solution. Treated tissues were explanted and the necrosis volume was measured using callipers. Haematoxylin and eosin (H&E) staining was also performed for histological analysis.

Results: A total of 30 ablations were performed in the liver. The use of PEG coated gold nanoparticles significantly increased ablation zone volumes (13.61 cm^3 versus 5.26 cm^3, $p < 0.001$). The increase of ablation zone volumes was not dose dependently (13.61 cm^3 versus 11.84 cm^3, $p = 0.17$). There was no difference between ablation zone volumes assessed by CEUS immediately after ablation compared to CEUS performed 5 days after ablation ($p = 0.34$). H&E staining showed no differences in the transition zone (the zone between coagulative necrosis and normal parenchyma) between physiological saline or nanoparticles enhanced RFA.

Conclusion: The use of PEG coated gold nanoparticles significantly increased mean ablation zone volumes following direct intratumoral RFA in a porcine model. To our knowledge this is the first study dealing with direct heating of PEG-coated nanoparticles by RF energy. However, the positive finding from our study warrants further investigations.

SAT503

The "six-and-twelve" score in a prospective cohort of patients with hepatocellular carcinoma treated with trans-arterial chemoembolization following a fixed schedule

Marco Sanduzzi Zamparelli[1], Marta Burrel[2], Anna Darnell[3], Víctor Sapena[1], Marta Barrufet[2], Patricia Bermudez[2], Alejandro Sotomayot[2], Neus Llarch[1], Gemma Iserte[1], Ernest Belmonte[3], Alejandro Forner[1], Jordi Rimola[2], Carmen Ayuso[3], Jordi Bruix[1], María Reig[1]. [1]*Hospital Clinic of Barcelona, IDIBAPS, CIBERehd, BCLC Group, Liver Unit, Barcelona, Spain;* [2]*Hospital Clinic of Barcelona, BCLC Group, Radiology Department, Barcelona, Spain;* [3]*Hospital Clinic of Barcelona, University of Barcelona, BCLC Group, Abdominal Radiology, Radiology Department, Barcelona, Spain*
Email: mreig1@clinic.cat

Background and Aims: Trans-arterial chemoembolization (TACE) is the standard of care treatment for patients with hepatocellular carcinoma (HCC) at BCLC-B stage or BCLC-0/A without other options while some BCLC-B patients receive systemic therapy as first-line treatment according to the stage migration concept. Several tools to better define the prognosis of TACE candidates have been proposed. The "Six-and-twelve" score stratifies TACE candidates into 3 strata (G1≤6; G2 >6 y≤12; G3>12) according to the sum of the biggest target lesion size and the number of lesions. It stratifies overall survival (OS) with a reported C-index of 0.67 in Asian patients (ES ASI).

To assess the performance of the "Six-and-twelve" score to predict the OS in a prospective Western cohort of patients treated with fixed-schedule TACE at 0,2 and 6 months and thereafter every 6 months until untreatable progression.

Method: All TACE candidates at Hospital Clinic of Barcelona between 01/2014 and 03/2017 were prospectively included and the OS was analyzed according to the "Six-and-twelve" score in the whole cohort and in each BCLC stage.

Results: of the 105 included patients (HCV 51.89%, Child-Pugh-A 92.45% and BCLC-A/B 46/59), 90 received at least one treatment session. The median follow-up of the whole cohort was 24.4 months and the median OS (mOS) was 35.5 moths (IC95% 28.7– 42.6).

The "Six-and-twelve" score was G1 in 60 patients and G2 in 30 but no patient had G3. The mOS of G1 patients was 42.6 months (IC95% 29.8–49.0) and of G2 de 29.0 (IC95% 21.1–36.2) with a *p*-value = 0,037 and a *C-index* of 0.54 (IC95% 0.46–0.62). Thirty-eight G1 patients were BCLC-A and 32 BCLC-B, while only 5 of the 46 BCLC-A patients were G2. When the "Six-and-twelve" score was applied in each BCLC stage, the mOS was not different [(BCLC-A ($p = 0.39$), HR = 2.07 (IC95% 0.66–6.44); BCLC-B patients ($p = 0.82$), HR = 0.85 (IC95% 0.42–1.7)]. Specifically, the mOS of G1 and G2 were 44.0 months (IC 95% 36.3 - NE) and 36.2 (17.8 - NE) in BCLC-A patients and 27.6 (IC 95% 22.3–49.0) and 28.7 (IC 95% 18.4–35.5) in BCLC-B, respectively.

Conclusion: This study confirms the ability of the score to predict OS according but with a very low performance (*C-index* = 0.54). The score is not able to stratify TACE candidates in each BCLC stage. Thus, its clinical-practice usefulness remains limited although it could be considered as a potential tool to stratify TACE candidate in clinical trials.

SAT504

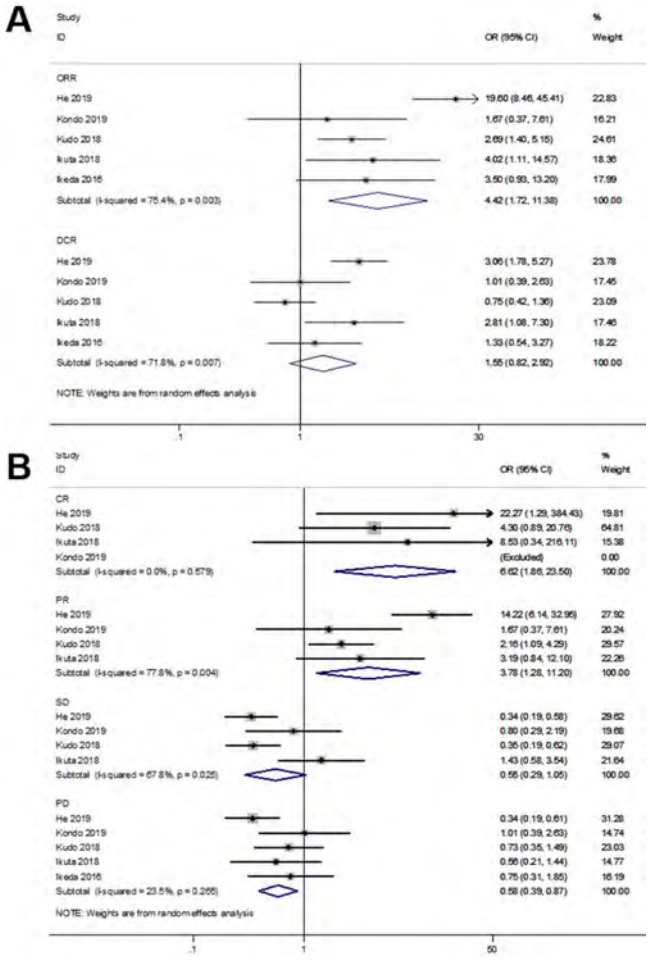
Hepatic arterial infusion chemotherapy combined with sorafenib versus sorafenib monotherapy in advanced hepatocellular carcinoma: a systemic review and meta-analysis

Zhiyuan Yao[1], Anxin Chen[1], Mingyu Chen[2]. [1]*Guangzhou Medical University, Nanshan College, Guangzhou Shi, China;* [2]*Sir Run Run Shaw Hospital, School of Medicine, Zhejiang University, General Surgery, Hangzhou, China*
Email: mychen@zju.edu.cn

Background and Aims: Recent studies demonstrated that as an alternative therapy to sorafenib, hepatic arterial infusion chemotherapy (HAIC) has promising outcomes in treatment for advanced hepatocellular carcinoma (HCC). However, it remains controversial whether the combination of HAIC and sorafenib is superior to sorafenib monotherapy. This study aimed to compare the efficacy and safety of HAIC+sorafenib versus sorafenib alone.

Method: A comprehensive search of online databases was performed from January 2009 to November 2019. All outcomes of treatment efficacy and safety were extracted and synthesized. A meta-analysis and relative subgroup analysis were conducted.

Results: A total of 724 patients (HAIC+sorafenib 353 vs sorafenib 371) from 5 studies, including 4 randomized controlled trials and 1 cohort study, were included in this meta-analysis. Compared to sorafenib monotherapy, HAIC + sorafenib has a higher objective response rate (OR:4.42, 95% CI: 1.72~11.38, P = 0.002). Similar results in higher complete response (OR: 6.62, 95%CI: 1.86~23.50, P = 0.003), partial response (OR: 3.78, 95%CI: 1.28~11.20, P = 0.016), and less progressive disease (OR: 0.58, 95%CI: 0.39~0.87, P = 0.009) were observed. However, there is no significant difference on overall survival (OS) (HR: 0.67, 95%CI 0.41~1.07, P = 0.094), except for patients with lower AFP level (HR: 0.72, 95%CI 0.52~0.99, P = 0.042). Meanwhile, HAIC +sorafenib leads to an increased tendency on adverse events including anemia, neutropenia, anorexia and nausea.



Conclusion: This meta-analysis revealed that the combination therapy of HAIC and sorafenib is superior in short-term benefits or objective response rate. However, it fails to prolong overall survival and even increased the risk of adverse events. High-quality studies should be conducted in the future to further illustrate this issue.

SAT505

Dexamethasone prophylaxis of postembolization syndrome after transcatheter arterial chemoembolization: a randomized, double-blind, placebo-controlled study

Panot Sainamthip[1], Chutcharn Kongphanich[2], Naiyarat Prasongsuk[1], Sakkarin Chirapongsathorn[3]. [1]*Phramongkutklao College of Medicine, Division of Medical Oncology, Bangkok, Thailand;* [2]*Phramongkutklao College of Medicine, Department of Radiology, Bangkok, Thailand;* [3]*Phramongkutklao College of Medicine, Division of Gastroenterology and Hepatology, Bangkok, Thailand*
Email: panotonco@outlook.com

Background and Aims: Postembolization syndrome is the most frequent adverse event of transcatheter arterial chemoembolization (TACE) in patients with hepatocellular carcinoma. We evaluated single dose of dexamethasone efficacy at preventing postembolization syndrome.

Method: This study include patients with HCC without macrovascular invasion who had a Child–Pugh score of A or B and no distant metastasis. Patients were randomly assigned to either a dexamethasone 8 mg intravenous single dose one hour prior to TACE or a placebo (saline). The primary outcome was a negative result of post-embolization syndrome (PES), which was defined as score <2 of Southwest oncology group toxicity coding(SWOG) using fever, nausea, vomiting and pain to calculated. And the secondary end point was duration of admission between two groups.

Results: From September 2017 to October 2019, 100 patients were randomly assigned 1:1. Under intention-to-treat analysis, 49 patients were randomly assigned to the dexamethasone group and 51 to the placebo. Both groups were comparable for baseline characteristics. The negative PES rate was greater with the dexamethasone group than with the placebo regimen (65.3% vs. 37.3%; P = 0.005) (Figure 1). Mean SWOG PES was 2.14 (95% CI 1.41-2.8) versus 3.71 (95% CI 2.97–4.45) between dexamethasone group and placebo group respectively. More than grade 2 fever was higher in placebo group (49.1% vs 18.4%; P < 0.001). The patients with ≥1 grade Common Terminology Criteria for Adverse Events (version 4.0) incidence of pain, nausea and vomiting were 56%, 51%, and 19% in the placebo group and 36%, 30%, and 14% in the dexamethasone regimen, respectively.The median duration of admission were 4 days (IQR 3–7 days) in patients receiving the placebo same as those receiving the dexamethasone group (IQR 3-5 days; P = 0.245). The dexamethasone regimen was generally well tolerated by HCC patients including those with well-controlled diabetes mellitus and those with hepatitis B virus infection.

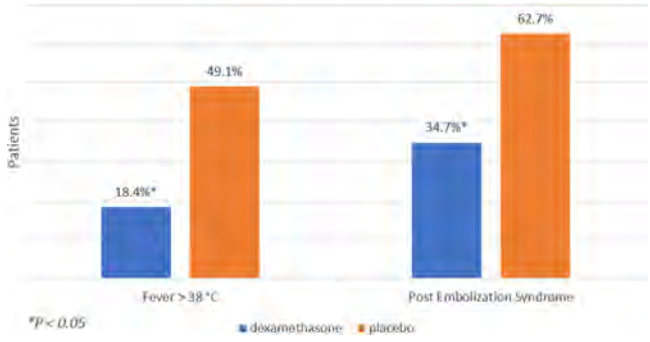


Figure: The incidences of fever and post-embolization syndrome (PES)

Conclusion: Single dose dexamethasone was more effective than the placebo at preventing post-embolization syndrome (PES) in patients with HCC and was generally well tolerated.

SAT507

Association between curative treatment after transarterial radioembolization and better survival outcomes in patients with hepatocellular carcinoma

Yoon Ah Kim[1], Han Ah Lee[2], Jae Seung Lee[1], Hye Won Lee[1], Beom Kyung Kim[1], Jun Yong Park[1], Do Young Kim[1], Sang Hoon Ahn[1], Soon Ho Um[2], Kwang-Hyub Han[1], Yeon Seok Seo[2], Seung Up Kim[1]. [1]*Yonsei University College of Medicine, Internal Medicine, Korea, Rep. of South;* [2]*Korea University College of Medicine, Internal Medicine, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and Aims: Transarterial radioembolization (TARE) is one of the therapeutic options for hepatocellular carcinoma (HCC). This study aimed to investigate the predictors and prognostic values of achieving curative treatments after TARE.

Method: Overall, 143 patients with intrahepatic HCC treated with TARE between 2011 and 2017 were recruited from two Korean tertiary institutes. Subsequent curative treatment was decided by the physician.

Results: The median age of the study population was 65.0 years. Twenty-seven (18.9%) patients received curative treatments (resection in 16, transplantation in 9, and ablation in 2) after TARE, who were likely to be younger (median 58.5 vs. 69.2 years) and less likely to have hypertension (40.7% vs. 62.9%) than those without curative treatments (all p < 0.05). In multivariate analysis, younger age (<65 years) (hazard ratio [HR] = 9.295, p < 0.001) and alpha-fetoprotein (AFP) of ≤200 ng/mL (HR = 4.246, p = 0.017) independently predicted the increased probability of achieving curative treatment after TARE. Curative treatment after TARE (HR = 0.089, p = 0.023), tumor burden

of >50% (HR = 5.690, p = 0.003), portal vein thrombosis (HR = 5.635, p = 0.002), and progressive disease based on the modified response evaluation criteria in solid tumors (mRECIST) criteria at 3 months after TARE (HR = 9.875, p < 0.001) independently predicted the risk of mortality. The cumulative survival rate of patients with curative treatment was significantly higher than that of patients without (p < 0.001 by log-rank test).

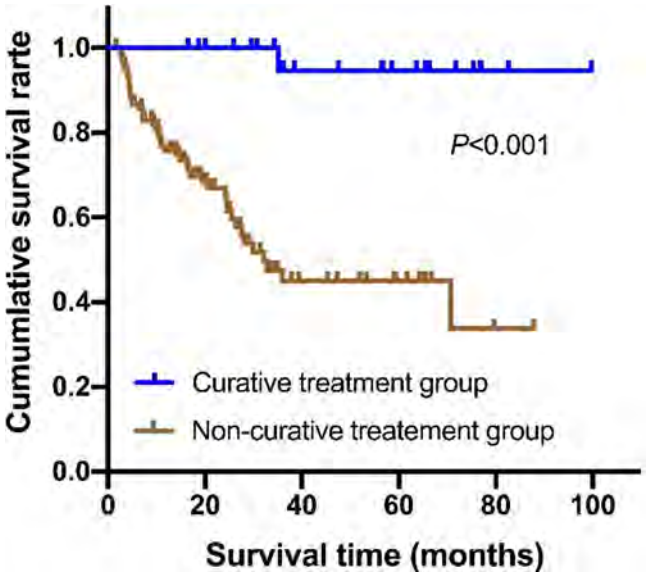

Figure: Kaplan-Meier analysis for overall survival.

Conclusion: Younger age than 65 years and AFP of ≤200 ng/mL independently predicted the increased probability of achieving curative treatment after TARE, and the curative treatment after TARE provided a survival benefit in patients with intrahepatic HCC.

SAT509

The real-world systemic sequential therapy of sorafenib and regorafenib for advanced hepatocellular carcinoma: a multicenter retrospective study in Korea

Yoonseok Lee[1], Sung Won Chang[1], Min-jin Lee[1], Ji Hoon Kim[1], Soo Min Bang[1], Sehwa Kim[1], Young-Sun Lee[1], Sung Bum Cho[2], Yeon Seok Seo[1], Hyung Joon Yim[1], Sang Youn Hwang[3], Hyun Woong Lee[4], Young Chang[5], Jae Young Jang[5]. *[1]Korea University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [2]Chonnam National University Medical School, Department of Internal Medicine, Hwasun, Korea, Rep. of South; [3]Dongnam Institute of Radiological & Medical Sciences, Department of Internal Medicine and Gastrointestinal Cancer Center, Busan, Korea, Rep. of South; [4]Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; [5]Soonchunhyang University College of Medicine Seoul Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of South*
Email: kjhhepar@naver.com

Background and Aims: Regorafenib has been proved as 2nd line systemic therapy for hepatocellular carcinoma (HCC) patients through phase III trial. We analyzed the real-world data to assess clinical efficacy and safety.
Method: This study was a multicenter, non-comparative, retrospective cohort study. Between July 2017 and May 2019, 133 patients with HCC who received regorafenib after sorafenib therapy were eligible for inclusion in this study. Tumor response was assessed according to modified RECIST criteria. We evaluated time to progression (TTP), progression-free survival (PFS) and overall survival (OS) of regorafenib therapy including prediction factors for prognosis.
Results: Their median age was 60 years, and most patients (82%) were male. Hepatitis B virus infection (68.4%) was the most common etiology of HCC. Most of patients (98.5%) were classified as Child-Pugh A except 2. Eighty-four percent of patients had extrahepatic metastasis and Vascular invasion was presented in 45.1%. Three patients (2.7%) achieved complete response and 11 (9.8%) patients had a partial response resulting in objective response rate 12.5% in 112 available patients for response assessment. The disease control rate (DCR) was 34.8%. Median treatment duration of regorafenib was 2.6 months (1.5–4.7 months). During follow up, 38 patients died. On regorafenib, the median OS was 10.0 months (95% CI, 8.4–11.6), the median PFS survival was 2.7 months (95% CI, 2.5–2.9 months), and the median TTP was 2.6 months (95% CI, 2.4–2.8). The OS rate from the start of regorafenib at 6 months and 1 year were 71.2%, and 38.7%. In multivariate analysis, Child-Pugh score >5 (HR 3.037 95% CI 1.46–6.314; p = 0.003), AFP >400 ng/ml (HR 5.9; 95% CI 2.608–13.349; p < 0.001), and TTP on sorafenib ≥ median (HR 0.441; 95% CI 0.310–0.629; p < 0.001) were independently associated with OS. In exploratory analysis from the time of sorafenib administration, the median OS from sorafenib administration was 25.8 (95% CI 8.7–42.9 months). The 1 year and 2years survival rate were 79.5% and 53.1%.
Conclusion: Regorafenib was effective in patients with advanced HCC who failed first-line sorafenib in real-life setting, consistent with previous clinical trial. Regorafenib may improve the prognosis of patients who had longer TTP on previous sorafenib therapy.

SAT510

Multicenter, real-world experience with lenvatinib for patients with advanced hepatocellular carcinoma in Japan

Takuya Sho[1], Goki Suda[1], Koji Ogawa[1], Masato Nakai[1], Kenichi Morikawa[1], Naoya Sakamoto[1]. *[1]Hokkaido University, Department of Gastroenterology and Hepatology, Graduate School of Medicine, Sapporo, Japan*
Email: shotaku0128@yahoo.co.jp

Background and Aims: Lenvatinib has been recently approved as a first-line systematic therapy for patients with advanced hepatocellular carcinoma (HCC) based on the results of the phase 3 clinical trial REFLECT. However, this trial did not enroll patients with a history of systemic chemotherapy including sorafenib and regorafenib, bile duct invasion, and main portal vein invasion (Vp4). This real world multicenter study aimed to investigate the efficacy and safety of lenvatinib for these patients.
Method: Patients who were administered lenvatinib for advanced HCC between April 2018 and July 2019 were enrolled. In principle, the treatment response and safety were evaluated via dynamic CT or MRI every 2 months until radiological disease progression. We evaluated treatment response in accordance with mRECIST. Further analysis by stratifying patients according to compliance and non-compliance with the REFLECT inclusion criteria was conducted.
Results: A total of 105 patients were included. More than 60% (64/105) did not meet the REFLECT inclusion criteria. In total, 11 (10.5%), 42 (40.0%), 38 (36.2%), and 8 (7.6%) showed complete response, partial response, stable disease, and progressive disease, respectively. The overall objective response rate was 50.5%. The objective response rate (p = 0.1853) was similar between patients who did and did not meet the REFLECT inclusion criteria. Moreover, the progression free survival was 10.3 months and 9.8 months, respectively (Hazard Ratio:1.087, 95% CI:0.593–1.686, p = 0.7831). The safety profile was also similar between the patients.
Conclusion: Lenvatinib showed high response rate and tolerability for patients with advanced HCC. Favorable outcomes were similarly observed even in patients who did not meet the REFLECT inclusion criteria.

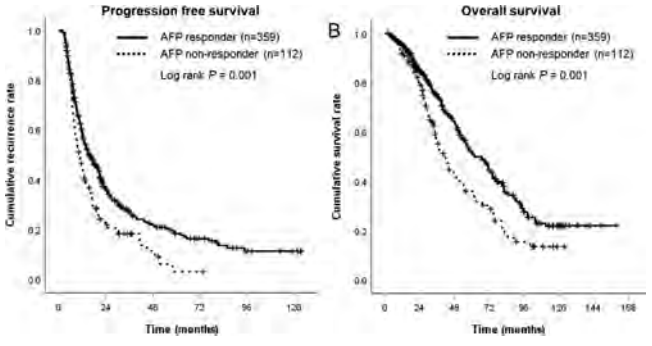
SAT511

Prognostic value of alpha-fetoprotein in patients achieving complete response to transarterial chemoembolisation for hepatocellular carcinoma

Jae Seung Lee[1,2], Wonseok Kang[3], Dong Hyun Sinn[3], Moon Seok Choi[3], Geum-Yon Gwak[3], Yong Han Paik[3], Joon Hyeok Lee[3], Kwang Cheol Koh[3], Seung Woon Paik[3], Hwi Young Kim[4], Tae Hun Kim[4], Kwon Yoo[4], Yeonjung Ha[5], Young Eun Chon[5], Mi Na Kim[5], Jooho Lee[5], Seong Gyu Hwang[5], Soon Sun Kim[6], Hyo Jung Cho[6], Jae Youn Cheong[6], Sung Won Cho[6], Seung Ha Park[7], Nae-Yun Heo[7], Young Mi Hong[8], Ki Tae Yoon[8], Mong Cho[8], Jung Gil Park[9], Min Kyu Kang[9], Soo Young Park[10], Young Oh Kweon[10], Won Young Tak[10], Se Young Jang[10], Beom Kyung Kim[1,2], Jun Yong Park[1,2], Do Young Kim[1,2], Sang Hoon Ahn[1,2], Kwang-Hyub Han[1,2], Seung Up Kim[1,2]. *[1]Yonsei University College of Medicine, Department of Internal Medicine, Korea, Rep. of South; [2]Severance Hospital, Yonsei Liver Center, Korea, Rep. of South; [3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Medicine, Korea, Rep. of South; [4]Ewha Womans University College of Medicine, Department of Internal Medicine, Korea, Rep. of South; [5]CHA Bundang Medical Center, CHA University, Department of Internal Medicine, Korea, Rep. of South; [6]Ajou University School of Medicine, Department of Gastroenterology, Korea, Rep. of South; [7]Inje University Haeundae Paik Hospital, Department of Internal Medicine, Korea, Rep. of South; [8]Pusan National University Yangsan Hospital, Liver Center, Korea, Rep. of South; [9]Yeungnam University Medical Centre, Department of Internal Medicine, Korea, Rep. of South; [10]Kyungpook National University School of Medicine, Department of Internal Medicine, Korea, Rep. of South*
Email: ksukorea@yuhs.ac

Background and Aims: Alpha-fetoprotein has been used as a diagnostic and prognostic marker in patients with hepatocellular carcinoma (HCC). We investigated the prognostic value of AFP in patients with HCC who achieved complete response (CR) after transarterial chemoembolisation (TACE).

Method: Between 2005 and 2018, 890 patients with HCC who achieved CR according to the mRECIST criteria after TACE as the first-line anticancer treatment were recruited from eight Korean tertiary, academic institutes for this retrospective, multicentre, cohort study. An AFP responder was defined as a patient with an elevated AFP level showing >50% reduction in AFP level after TACE (>10 ng/mL).



Results: During follow-up after CR, 473 (53.1%) patients showed HCC recurrence and 417 (46.9%) died. Before TACE, 305 (34.3%) patients had multiple tumours, 219 (24.6%) patients had a maximal tumour size >3 cm and 22 (2.5%) patients had portal vein tumour thrombosis. On achievement of CR after TACE, the median AFP level was 6.36 ng/mL. The median progression-free survival (PFS) and overall survival (OS) were 16.3 (interquartile range [IQR] 7.9–41.6) and 62.8 (IQR 34.9–103.6) months, respectively. In multivariate analysis, AFP at CR >20 ng/mL was associated with a shorter PFS (hazard ratio [HR] = 1.403, 95% confidence interval [CI] 1.167–1.686) and OS (HR = 1.310, 95% CI 1.050–1.636), together with multiple tumours (HR = 1.518 [95% CI 1.262–1.827] and 1.614 [95% CI 1.307–1.993], respectively). Of 471 patients with AFP >10 ng/mL before TACE, 359 (76.2%) were AFP responders, showing higher median PFS (15.5 [IQR 12.2–18.8] vs. 10.5 [IQR 8.1–12.9] months, respectively) and OS (61.8 [IQR 52.3–71.3] vs. 41.4 [IQR 33.6–49.2] months, respectively) compared to non-responders (both p = 0.001, log rank test). In multivariate analysis, AFP non-response was independently associated with shorter PFS (HR = 1.375, 95% CI 1.077–1.756), together with Barcelona-Clinic-Liver-Cancer Stage B and C (vs. A) (HR 1.377, 95% CI 1.027–1.847) and multiple tumours (HR 1.317, 95% CI 1.022–1.697), and also with shorter OS (HR = 1.406, 95% CI 1.056–1.872), together with a higher bilirubin level at CR (HR 1.439, 95% CI 1.263–1.640).

Conclusion: Low AFP and AFP response were still good predictors of recurrence and OS after achievement of CR by TACE. Therefore, AFP and its response should be used for more detailed risk stratification even after achieving CR following TACE.

Email: t.meyer@ucl.ac.uk

Background and Aims: Genetically engineered affinity-enhanced autologous SPEAR T-cells (AFPc332T-cells) directed towards the HLA-A*02 are being tested in an ongoing Phase 1 trial to evaluate safety and antitumor activity in patients with hepatocellular carcinoma (HCC; NCT03132792).

Method: In this first-in-human study in HCC, patients must be HLA-A*02:01$^+$ or 02:642$^+$ and have AFP expression by immunohistochemistry (IHC) at ≥1+ in ≥20% HCC cells or serum AFP ≥400 ng/ml, and ≤5% IHC AFP in non-cancerous liver tissue. Up to 24 patients will be enrolled using a modified 3+3 design. In Cohorts 1 and 2, lymphodepletion consists of fludarabine (FLU) 20 mg/m^2 and cyclophosphamide (CY) 500 mg/m^2 QD for 3 days. For Cohort 3, lymphodepletion consists of FLU 30 mg/m^2 per day for 4 days and CY 600 mg/m^2 QD for 3 days. Following lymphodepletion with FLU and CY, the target transduced cell doses for Cohorts 1–3 are 0.1×10^9, 1×10^9, and 5×10^9 cells, respectively. Cohort expansion will occur at maximum tolerated dose and may allow doses up to 10×10^9 transduced cells.

Results: As of 14 October 2019, 2 patients were treated in Cohort 1 (previously reported), and 3 in Cohort 2. Following lymphodepletion, Cohort 2 patients were treated with 1.17, 1.14, and 1.15×10^9 transduced T-cells. Patients across cohorts have experienced cytopenias (up to Grade 4 neutropenia and thrombocytopenia) related to lymphodepleting chemotherapy followed by recovery. There were no reports of hepatic toxicity, cytokine release syndrome or DLTs in these

cohorts with minimum follow-up of 4 weeks. Although there were no RECIST-defined responses, 1 patient in Cohort 2 had a reduction in the size of 2 target lesions (1 mediastinal lymph node metastasis decreased by 42% at Week 24). Transient decreases in serum AFP levels post-ADP-A2AFP therapy were also observed. A digital PCR-based assay specifically targeting the packaging signal element of the lentiviral vector detected the presence of SPEAR T-cells in post-treatment tumor tissue from a patient in Cohort 1.
Conclusion: ADP-A2AFP T-cells have shown no evidence of on target or off target toxicity in the first 5 patients with transduced cell doses up to 1.17×10^9 cells. No protocol-defined DLTs were reported. Current data support continued investigation of ADP-A2AFP in Cohort 3 with target transduced cell doses 5×10^9 cells (range 1.2 to 6.0×10^9).

A nationwide multicenter study of Japanese patients with unresectable hepatocellular carcinoma treated with regorafenib in real-world practice

Kaoru Tsuchiya[1], Masayuki Kurosaki[1], Azusa Sakamoto[2], Hiroyuki Matusawa[2], Chitomi Hasebe[3], Takehiko Abe[4], Kouji Joko[5], Chikara Ogawa[6], Koichiro Furuta[7], Atsunori Kusakabe[8], Haruhiko Kobashi[9], Hiroyuki Kimura[8], Tomomichi Matsushita[10], Yasushi Uchida[11], Namiki Izumi[1]. *[1]Musashino Red Cross Hospital, Department of Gastroenteorlogy and Hepatology, Tokyo, Japan; [2]Japanese Red Cross Osaka Hospital, Department of Gastroenterology and Hepatology, Osaka, Japan; [3]Japanese Red Cross Asahikawa Hospital, Department of Gastroenterology and Hepatology, Asahikawa, Japan; [4]Japanese Red Cross Maebashi Hospital, Department of Gastroenterology and Hepatology, Japan; [5]Japanese Red Cross Matsuyama Hospital, Department of Gastroenterology and Hepatology, Japan; [6]Japanese Red Cross Takamatsu Hospital, Department of Gastroenterology and Hepatology, Japan; [7]Japanese Red Cross Masuda Hospital, Department of Gastroenterology and Hepatology, Japan; [8]Japanese Red Cross Kyoto Daiichi Hospital, Department of Gastroenterology and Hepatology, Japan; [9]Japanese Red Cross Okayama Hospital, Department of Gastroenterology and Hepatology, Japan; [10]Japanese Red Cross Gifu Hospital, Department of Gastroenterology and Hepatology, Japan; [11]Japanese Red Cross Matsue Hospital, Department of Gastroenterology and Hepatology, Japan*
Email: tsuchiyakaoru5@gmail.com

Background and Aims: Regorafenib was approved in Japanese patients with unresectable HCC (u-HCC) in Jun 2017. We performed a nationwide multicenter study of regorafenib therapy and investigated the factors associated with overall survival (OS).
Method: A total of 81 u-HCC patients received regorafenib from Jun 2017 at 12 sites in Japan were registered. Tumour assessments in accordance with modified RECIST was done using dynamic CT or MRI within 4–8 weeks and every 6–8 weeks thereafter. Adverse events (AEs) were graded according to the CTCAE ver4.0.
Results: Median age and body weight were 70 years and 59 kg. The baseline liver function was Child-Pugh class A in 70 (86%) patients and 50 (62%) patients were BCLC stage C. Median overall survival (OS) and follow-up duration were 14.1 and 8.5 months. Median overall time under treatment was 3.1 months. Median progression free survival (PFS) was 4.2 months. Based on mRECIST, CR was shown in 0 (0%), PR in 8 (13%), SD in 34 (53%), and PD in 21 (33%) patients. Overall response rate (ORR) and disease control rate (DCR) were 13% and 67%. Fifteen patients started regorafenib at the standard initial dose (160 mg/day) and 66 patients started at reduced doses. There were no significant differences in median OS and PFS between the standard and reduced group. The patients who experienced hand-foot skin reaction (HFSR) during regorafenib significantly showed better OS and PFS (<0.0001) than the patients without HFSR. The independent factors associated with OS in regorafenib therapy were pretreatment performance status (HR 3.5, 95%CI 1.42–8.64, p = 0.007), pretreatment Alb level (HR4.4 , 95%CI 1.82–11.8, p = 0.001), Major portal invasion (HR 10.4, 95%CI 2.94–37.2, p = 0.0003), and HFSR during regorafenib (HR 0.13, 95%CI 0.05–0.33, p < 0.0001). In the geriatric patients (≥75 years, n = 31), median OS and PFS were 8.4 and 3.1 months. In the geriatric patients with ALBI grade 1 or 2a (n = 10), the median OS was 12.7 months and no grade 3 adverse event associated with regorafenib therapy was reported.
Conclusion: Clinical outcome of regorafenib therapy for Japanese patients with u-HCC in real world practice was similar to the phase 3 clinical trial, even though the Japanese patients were older and had lower bodyweight. The geriatric patients with well-preserved liver function could tolerate regorafenib therapy and showed excellent survival.

SAT515

Antiplatelet therapy improves the prognosis of patients with hepatocellular carcinoma

Tsuguru Hayashi[1], Michihiko Shibata[1], Yuichi Honma[1], Masaru Harada[1]. *[1]University of Occupational and Environmental Health, Third Department of Internal Medicine, Kitakyushu, Japan*
Email: tsuguru033185@gmail.com

Background and Aims: Aspirin is demonstrated reducing the risk of colorectal cancer. In contrast, study of antiplatelet therapy for liver disease is limited. Antiplatelet therapy decreases the progression of hepatic fibrosis and prevents the development of hepatocellular carcinoma (HCC). However, effect of antiplatelet therapy after hepatocarcinogenesis remains unclear. This study aimed to clarify the effect of antiplatelet therapy for HCC patients.
Method: 697 consecutive naïve HCC patients, treated from January 2005 to May 2018, participated in this retrospective study. 104 patients used antiplatelet agents, aspirin or clopidogrel. We analyzed liver related death and periods to HCC progression, decompensated cirrhosis and bleeding with or without antiplatelet therapy. Kaplan-Meier method with log rank test was used to analyze the occurrence of events and the Cox proportional hazard model was used for multivariate analysis.
Results: Patients with antiplatelet therapy were older, and they had significant better liver function at the first treatment. Stage, tumor size and number, tumor markers were not different between patients with and without antiplatelet therapy. Patients with antiplatelet therapy had better prognosis than non-users (62.8% vs 37.4% / 5years, P < 0.005), and antiplatelet therapy was an independent factor to predict the prognosis by multivariate analysis (HR:0.5, 95%CI:0.4–0.7, P < 0.001). Recurrence after curative therapy (liver resection or radiofrequency ablation) was not different. However, time to HCC recurrence of patients received transcatheter chemoembolization as the first treatment was longer in patients with antiplatelet therapy (P < 0.05). Time to progress to decompensated cirrhosis was longer in patients with antiplatelet therapy (P < 0.01). Bleeding rate was not significantly different between the two groups.
Conclusion: Antiplatelet therapy reduced the risk of liver related death by anti-tumor effect and preservation of good hepatic reserve.

SAT516

No risk of hepatitis B reactivation in hepatocellular carcinoma patients with HBV-DNA >100 iu/ml undergoing immune checkpoint inhibitor immunotherapy by pre-emptive strategy

Pei-Chang Lee[1], Yee Chao[2], ChiehJu Lee[1], Ming-Chih Hou[1], Yi-Hsiang Huang[1]. *[1]Taipei Veterans General Hospital, Gastroenterology and Hepatology, Taipei, Taiwan; [2]Taipei Veterans General Hospital, Oncology, Taipei, Taiwan*
Email: yhhuang@vghtpe.gov.tw

Background and Aims: Immunotherapy with checkpoint inhibitor (ICI) is a promising and FDA-approved treatment for unresectable hepatocellular carcinoma (HCC). According to the clinical trials (CheckMate-040 and Keynote-224), effective anti-viral treatment and lower HBV viral load (<100 IU/mL) was required in patients with chronic hepatitis B before entering to ICI treatment. However, the rationale was still unclear.

Method: From May 2017, 66 patients had received treatment of ICI (nivolumab or pembrolizumab) for unresectable HBV related HCC in Taipei Veterans General Hospital. Among them, 62 patients with documented baseline serum HBV-DNA level were enrolled for clinical assessment. HBV reactivation is defined as a 10-fold increase in HBV viral load.
Results: At the date of data cut on November 15, 2019, the objective response rate was 27.8%, including 2 (3.7%) complete responses and 13 (24.1%) partial responses. The median time to response was 61 days (IQR 46–75 days), and the median duration of response was 5.8 months (IQR 2.9–10.0) for responders. Patients received nucleos(t)ide analogues (NUCs) (n = 55) had similar objective response rate (ORR) to those without NUCs treatment (n = 7) (ORR: 27.1% vs. 33.3%, p = 1.000). HBV reactivation developed in one patient (14.3%) who did not receive NUCs treatment during immunotherapy; whereas, no such event developed in patients with NUCs treatment. Among 23 patients with HBV viral load ≥100 IU/mL at the time of immunotherapy, 19 patients received pre-emptive NUCs treatment and 4 patients did not have NUCs treatment. All patients administrated with NUCs were safe from viral reactivation; whereas, one patient (25.0%) without NUCs treatment experienced HBV reactivation. The other patients with HBV viral load less than 100 IU/mL at the time of immunotherapy were free from HBV reactivation during immunotherapy regardless of NUCs treatment or not.
Conclusion: ICI treatment is not contraindicated for HCC patients with HBV viral load higher than 100 IU/mL once pre-emptive NUCs could be provided.

SAT517
Effect of antibiotics, proton pump inhibitors and steroids on survival and response to immune-checkpoint inhibitors in patients with hepatocellular carcinoma

Pei-Chang Lee[1], Yee Chao[2], ChiehJu Lee[1], Ming-Chih Hou[1], Yi-Hsiang Huang[1]. *[1]Taipei Veterans General Hospital, Gastroenterology and Hepatology, Taipei, Taiwan; [2]Taipei Veterans General Hospital, Oncology, Taipei, Taiwan*
Email: yhhuang@vghtpe.gov.tw

Background and Aims: Immune-checkpoint inhibitors (ICIs) are promising therapeutic agents for unresectable hepatocellular carcinoma (HCC). Prior exposures to antibiotics or other drugs were reported to have influences on the treatment response and survival in ICI-treated patients across malignancies. However, such probable effects were still unclear in HCC.
Method: From May 2017, 105 patients had received ICI treatment for unresectable HCC in Taipei Veterans General Hospital. Among them, 94 patients with evaluable radiographic images following treatment before November 15, 2019 were enrolled for clinical assessment. The effects of various drug exposures on treatment outcome were investigated.
Results: At the date of data cut, the objective response rate (ORR) was 25.5% including 6 (6.4%) complete responses and 18 (19.1%) partial responses. The median time to response was 63 days (IQR 50–75 days), and the median duration of response was 6.5 months (IQR 3.8–13.8) for responders. The median overall survival (OS) was 11.9 months (95% C.I. 5.3–18.5). Within 30 days prior to ICI treatment, 19 (20.2%), 30 (31.9%), and 3 (3.2%) patients had been administrated with antibiotics, proton pump inhibitors (PPIs), and steroid, respectively. Patients who were exposed to antibiotics before immunotherapy had similar ORR (21.1% vs. 26.7%, $p = 0.772$) but shorter overall survival (OS: 13.5 vs. 6.9 months, $p = 0.147$) than the others without antibiotic exposure. Besides, there was no significant differences about ORR (23.3% vs. 26.6%, $p = 0.738$) and OS (13.5 vs. 11.9 months, p = 0.948) according to the prior administration of PPIs. On the other hand, prior steroid treatment was associated with less ORR (0% vs. 26.4%, $p = 0.568$) and significantly shorter OS (2.6 vs. 12.5 months, $p = 0.004$) compared to the others without steroid treatment.
Conclusion: Prior administration with antibiotics, proton pump inhibitors and steroids before ICI therapy did not contribute to significant adverse effects on the treatment outcomes of unresectable HCC. However, poorer survival were observed in patients who had received steroids prior to ICI treatment.

SAT518
Nucleos(t)ide analogs reduces hepatocellular carcinoma mortality in patients with low HBV-DNA levels

Xinhui Wang[1], Xiaoli Liu[1], Lihua Yu[1], Peng Wang[1], Yuyong Jiang[1], Xian-bo Wang[1], ZhiYun Yang[1]. *[1]Beijing Ditan Hospital Capital Medical University, Center of Integrative Medicine, Beijing, China*
Email: yangzhiyun2016@163.com

Background and Aims: Despite antiviral treatment has been shown to reduce hepatocellular carcinoma (HCC) mortality for hepatitis B virus (HBV)-related HCC in patients with high HBV-DNA levels, it is still unclear whether antiviral therapy is useful in reducing mortality in patients with low HBV-DNA levels.
Method: A retrospective analysis was performed of 853 patients diagnosed with HBV-related HCC with HBV-DNA <500 IU/mL between January 2008 and June 2017 at the Beijing Ditan Hospital. Patients were divided into antiviral group and non-antiviral group according to whether they were treated with Nucleos(t)ide Analogs (NA) in the first diagnosis of primary liver cancer in our hospital. We used 1:4 frequency matching by tumor size and Barcelona Clinic Liver Cancer staging to compare the antiviral group (n = 444) and non-antiviral group (n = 111). A Cox multivariate regression analysis was employed to evaluate the effects of NA therapy on the HR value and Kaplan-Meier survival curve for mortality risk in HCC patients. A log-

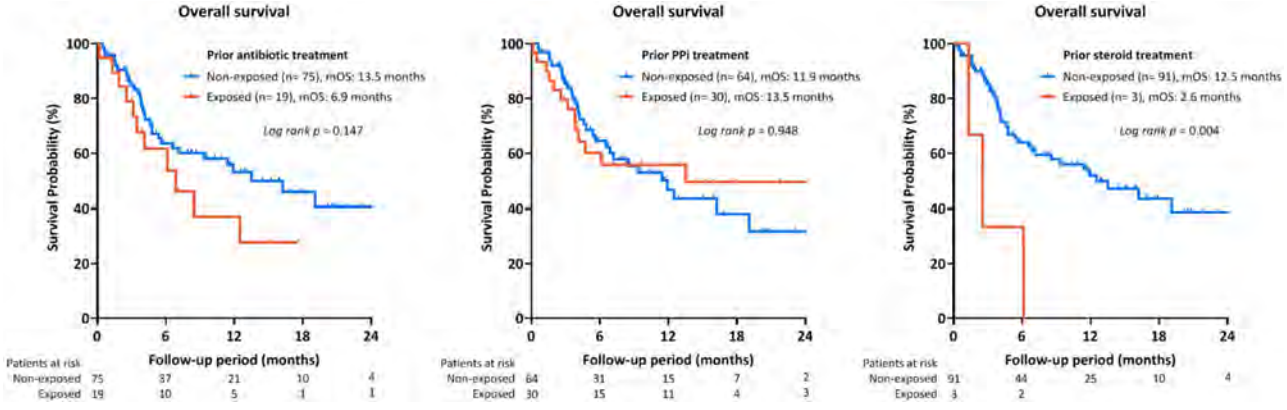

Figure: (abstract: SAT517)

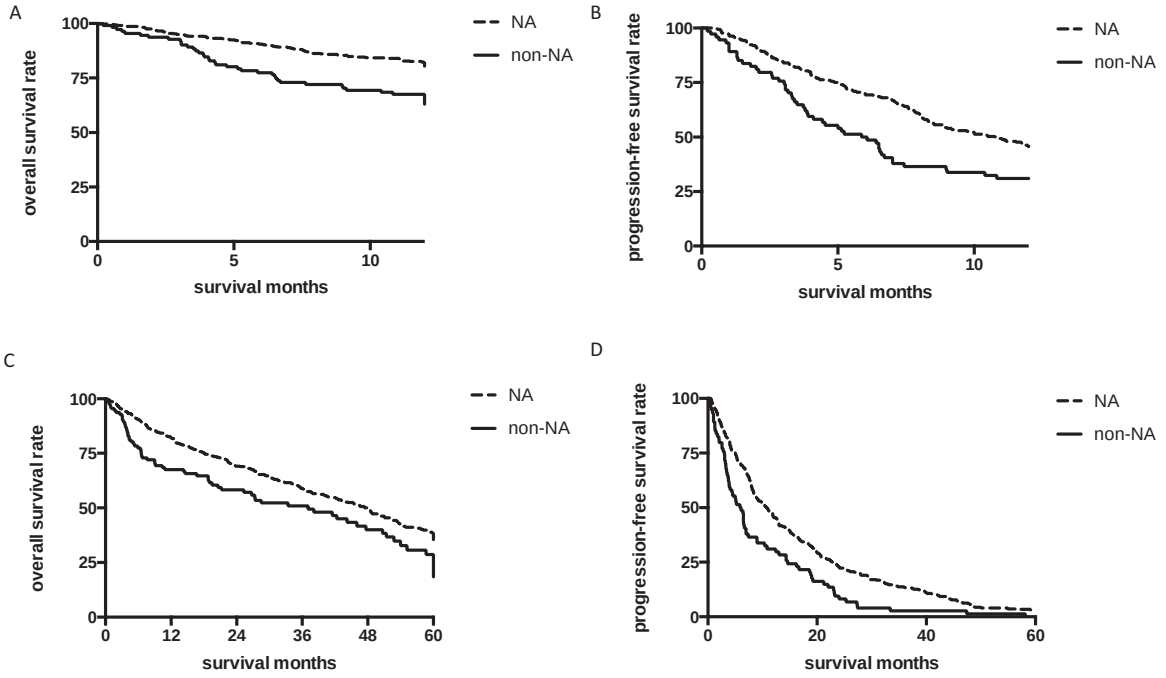

Fig. 1: (abstract: SAT518): Kaplan–Meier curves of overall survival (OS) and progression-free survival (PFS) for total 853 of propensity-score- matched patients. (A) OS and (B) PFS for 1 year; (C) OS and (D) PFS for 5 years.

rank test was performed to analyze the effect of NA therapy on the survival time of HCC patients.

Results: After propensity score matching, the 1-, 3-, and 5-year overall survival rates for the antiviral group and the control group were 78.8%, 61.9%, 26.2%, and 63.1%, 49.5%, and 12.9%, respectively. The l year progress free survival rates for the 2 groups were 63.3% and 54.1%, respectively. The overall survival for the antiviral group were significantly better than the control group (P = 0.001, P = 0.023, P = 0.018, respectively). There was no difference between the 1-year progression-free survival of the antiviral group and the non-antiviral group (P = 0.081). After adjusting for confounding prognostic factors in a Cox model, the relative risks of death for antiviral treatment was 0.651 [95% confidence interval (CI), 0.496– 0.856; P = 0.005]. Antiviral therapy was an independent protective factor of mortality.

Table 1: Univariate and multivariate Cox analysis for 5 year OS of Hepatocellular Carcinoma in PS matched patients

		Univariate analysis			Multivariate analysis	
	P	HR	95%CI	P	AdjustHR	95%CI
Gender	0.993	1.001	[0.770 1.302]			
Age	0.036*	1.357	[1.020 1.807]			
HBeAg	0.362	0.925	[0.783 1.093]

Comparative effectiveness of nivolumab versus regorafenib for hepatocellular carcinoma patients who experienced sorafenib failure

Yun Bin Lee[1], Cheol-Hyung Lee[1], Minseok Albert Kim[1], Heejoon Jang[1], Hyunwoo Oh[1], Sun Woong Kim[1], Eun Ju Cho[1], Kyung-Hun Lee[2,3], Jeonghoon Lee[1], Su Jong Yu[1], Jung-Hwan Yoon[1], Tae-You Kim[2,3], Yoon Jun Kim[1]. *[1]Seoul National University College of Medicine, Department of Internal Medicine and Liver Research Institute, Seoul, Korea, Rep. of South; [2]Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of South; [3]Seoul National University, Cancer Research Institute, Seoul, Korea, Rep. of South*
Email: yoonjun@snu.ac.kr

Background and Aims: Several treatment options are now available for patients with hepatocellular carcinoma (HCC) who fail sorafenib treatment. We aimed to compare the effectiveness of regorafenib and nivolumab in those patients.

Method: Consecutive HCC patients who received regorafenib or nivolumab after sorafenib failure were included. Primary endpoint was overall survival (OS) and secondary endpoints were time to progression, tumor response rate, and adverse events. Inverse probability of treatment weighting (IPTW) using the propensity score was conducted to reduce treatment selection bias.

Results: Among 150 study patients, 102 patients received regorafenib and 48 patients received nivolumab. Median OS was 6.9 (95% confidence interval [CI], 3.0–10.8) months for regorafenib and 5.9 (95% CI, 3.7–8.1) months for nivolumab (p = 0.77 by log-rank test) (panel A). In the multivariable analysis, nivolumab was associated with prolonged OS (vs regorafenib: adjusted hazard ratio [aHR], 0.54; 95% CI, 0.30–0.96; p = 0.04). After IPTW, although there was no statistically significant difference between the groups, nivolumab

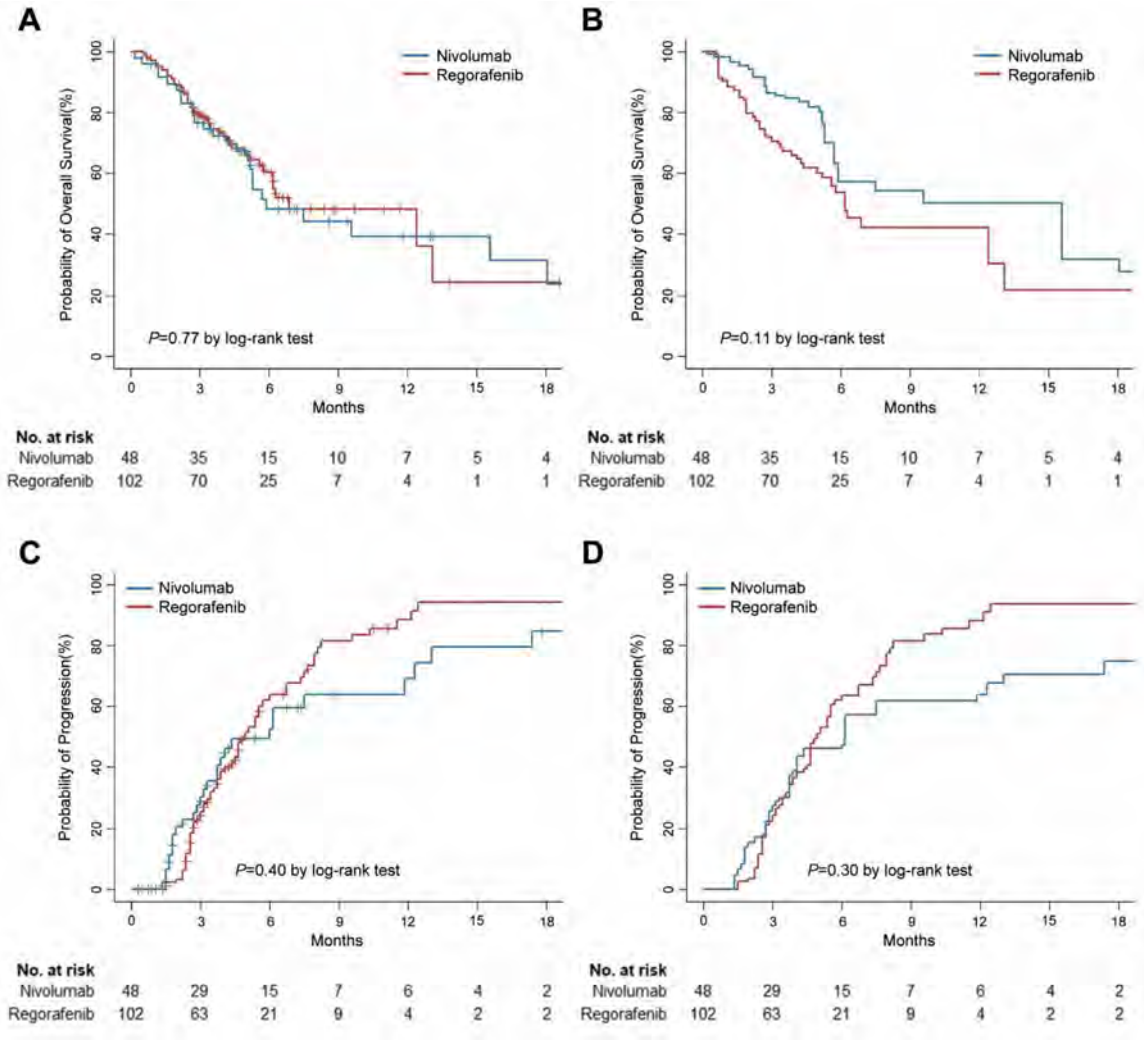

Figure: (abstract: SAT519)

was associated with better OS than regorafenib (p = 0.11 by log-rank test) (panel B). Weighted Cox proportional hazards model also revealed that the nivolumab treatment was associated with improved OS (vs regorafenib: aHR, 0.34; 95% CI, 0.18–0.65; p = 0.001). Time to progression was not significantly different between the groups (nivolumab vs regorafenib: aHR, 0.82; 95% CI, 0.51–1.30; p = 0.48) (panel C). Similar results were found after IPTW in the analysis for time to progression (panel D). Objective response rates were 5.9% and 16.7% in patients treated with regorafenib and nivolumab, respectively (p = 0.04).

Conclusion: After sorafenib failure, nivolumab was associated with improved OS and better objective response rate compared with regorafenib.

SAT520

Zinc phthalocyanine/sorafenib-conjugated bovine serum albumin nanoparticles provide effective synergistic therapy against hepatocellular carcinoma

Xiang-Nan Yu[1], Jia-Lei Sun[1], Guang-Cong Zhang[1], Ji-Min Zhu[1].
[1]*Zhongshan Hospital, Department of Gastroenterology*
Email: zhu.jimin@zs-hospital.sh.cn

Background and Aims: Sorafenib, a multi-targeted kinase inhibitor, has been reported to exert a systemic benefit against advanced hepatocellular carcinoma (HCC). However, various side effects, such as hand-foot syndrome and perforating folliculitis, has been reported. Therefore, new approaches are urgently needed to improve the therapeutic effectiveness of sorafenib and to reduce its side effect. To overcome this limitation, we developed a Zinc phthalocyanine (ZnPc) and sorafenib (SFB) conjugated bovine serum albumin (BSA) to trigger photodynamic therapy (PDT), photothermal therapy (PTT), and chemotherapy, and investigated its effects in mice with HCC.

Method: For in vitro study, cell phenotype was determined with flow cytometry, cell counting kit 8, live and dead viability staining, colony formation, wound healing and Transwell assays. Apoptosis- and proliferation-related protein expression was analyzed using immunoblot. Reactive oxygen species (ROS) were detected using a luminescent assay. For in vivo study, human HCC cells were inoculated to form subcutaneous tumors, and were then implanted into the liver to establish orthotopic tumor models of HCC in nude mice. After tumors formed, mice were given an injection of ZnPc plus laser treatment, ZnPc-SFB@BSA plus laser treatment, BSA, sorafenib or vehicle via tail vein every other day for 2 weeks. Tumor growth and volume were monitored. Apoptosis- and proliferation-related protein expression was also analyzed using immunohistochemistry and immunoblot.

Results: After irradiation by a 730 nm laser, ZnPc-SFB@BSA nanoparticles significantly suppressed proliferation and metastasis, and

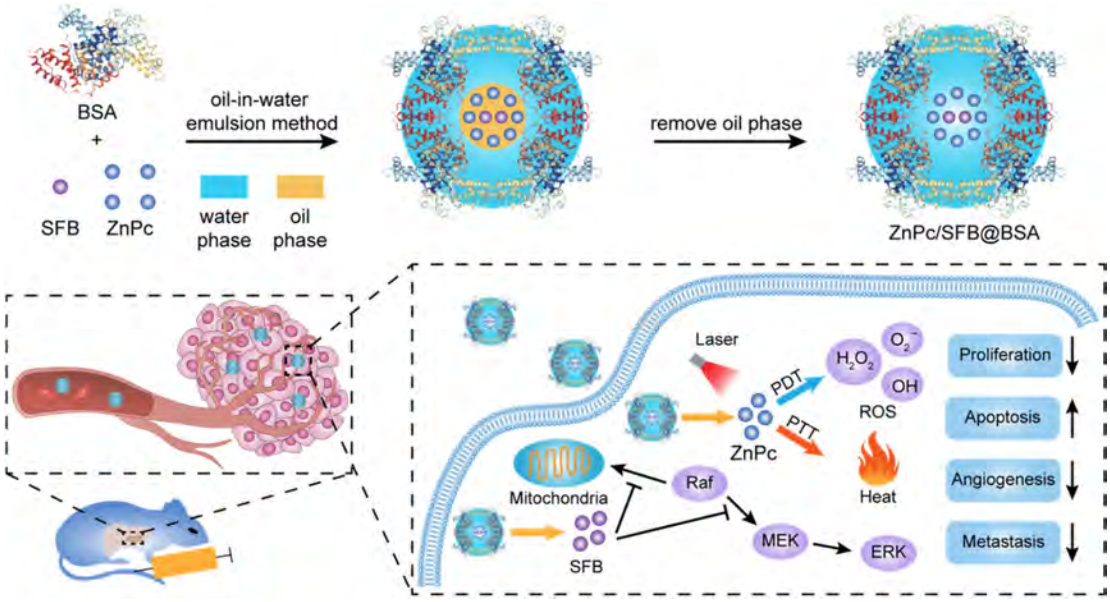

Figure: (abstract: SAT520)

promoted apoptosis *in vitro*. For in vivo study, combination therapy of Injection of ZnPc-SFB@BSA plus laser treatment slowed tumor growth by reducing tumor cell proliferation and the expression of MCL-1, Bcl-xl and Bcl-2, and by increasing tumor cell apoptosis, compared with other groups. More importantly, ZnPc-SFB@BSA nanoparticles presented low toxicity and excellent blood compatibility.

Conclusion: a multimodal therapy using combination of ZnPc with sorafenib via BSA nanoparticles can markedly suppress HCC growth and metastasis, representing a promising strategy for HCC patients.

Project duration
6 ¼ years

Start
1 January 2019

www.microb-predict.eu
@MicrobPredict

Grant amount
15 million €

10 Countries
22 Partners

MICROB-PREDICT

will investigate the human microbiome to identify predictors and mechanisms associated with the development of decompensation of cirrhosis and progression to **acute-on-chronic liver failure (ACLF) and death.**

- → New microbiome-based tests for better stratification of cirrhosis patients
- → Personalized prediction and prevention of decompensation and ACLF
- → Clinical trial to predict response to treatment
- → Modern, effective nanobiosensors as clinical tools with improved specificity
- → More personalized treatment
- → Increased survival times
- → Decreased costs for the health systems

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 825694.
